Breakout of the Box: Innovative Education Using an Escape Room

Julie Bianco, MS, RN, CPEN, Courtney Elliott, BSN, RN, CPEN and Figaro Loresto Jr, PhD, RN
Children’s Hospital Colorado, Anschutz Emergency Department, Division of Nursing

Background

- Emergency Department (ED) nurses must possess the complex knowledge and skills necessary to competently care for critically injured patients.
- Providing meaningful educational opportunities to assist with maintenance of trauma competencies is challenging (Stephenson, 2015).
- Passive education doesn’t meet the needs of most adult learners (Brull et al. 2017).
- An escape room was designed and implemented as an educational tool with the objective of engaging staff in an interactive learning environment to increase knowledge and skills requisite when caring for trauma patients.

Methods: Escape Room

- An in-situ trauma room was set up by the facilitator in the ED, nurses were assigned to teams of 4-6, and each participant was assigned a trauma team role (such as medication nurse or procedure nurse).
- The moderator read the rules of the escape room and the patient scenario aloud and then followed a step-by-step guide formatted to reflect the Trauma Nursing Process as teams proceeded to gather information and solve clues.
- The moderator observed team performance and utilization of equipment. Teams could ask for up to 2 “free clues” and could not progress to the next step in the scenario until the skill was completed accurately.
- All teams were able to complete the learning experience by successfully accomplishing all tasks/skills to break out of the escape room.
- A 5-point Likert scale post-survey with 21 responses was used to quantify participants’ perceptions of how the experience affected knowledge and comfort level with skills applicable in the care of trauma patients.

Methods

- A Learning Needs Assessment was conducted for ED nurses to categorize trauma-related education gaps.
- Four objectives were identified including overall comfort level when caring for trauma patients, massive transfusion protocol (MTP), locating supplies rapidly, and familiarity with resources available in the trauma room.
- The escape room was conducted during an attendance-optional trauma-focused educational event offered to all ED staff.
- A total of 35 nurses and EMTs attended the event, all of whom participated in the escape room.

Results

- Overall, the experience was rated positively with 86% of participants agreeing or strongly agreeing that the escape room was fun, engaging, and realistic.
- 91% agreed or strongly agreed that the experience increased their knowledge of trauma care, while 73% agreed or strongly agreed that it improved their comfort level when caring for trauma patients.

Implications

- Development of a trauma focused escape room learning activity promotes learner participation and engagement, provides an opportunity for immediate feedback, and brings excitement to the classroom.
- Results suggest this approach positively impacts nurses’ knowledge and comfort with skills necessary to care effectively for trauma patients.
- Nurse educators utilizing this education modality should consider implementation of program evaluation via pre, post, and periodic surveys at 3, 6, and 12 months post-event.
