The FADE Model serves as a framework to support this Quality Improvement project. The FADE Model focuses on four main phases which include Focus, Analyze, Develop, and Execute. Within the Focus phase, the basis for what will be set among the other three steps will be identified. Through initial research with regards to adolescent military population, one substantial issue will be discussed and verified in order to further define a PICO question and guide focus for the rest of the model’s phases. During the Analyze phase data, patterns and protocols will be collected and reviewed to determine influential factors, key stakeholders, and to identify what needs to be known regarding this population specifically. Key stakeholders will be identified and communication will be initiated. Within this phase, efforts are made to identify root causes of screening problems for which a solution is being sought. Present screening depression protocols will also be reviewed to identify gaps current within the system. The next phase known as the Development phase, will encompass development of implementation plans for a selected solution for screening depression. This step is critical and must be clearly defined so that proposed actions may take place without disruption or uncertainty. Final actions within the FADE Model revolve around project Execution. For purposes of this academic project, within this phase dissemination plans and action will be discussed. Key stakeholders previously identified will be contacted to discuss proposed execution plans as well as compelling evidence consistent for consideration of a pilot change for further investigation as well as provide a proposed Clinical Practice Guideline.
