Glossary

A **plenary session** is a session in which an invited speaker, usually with a significant subject matter, presents their work or viewpoint. All attendees attend these general sessions as they usually begin and end a program of events. Plenary sessions vary in length from one (1) hour to one and a half (1½) hours and can be accompanied by PowerPoint presentations, audio and/or video files and other visual aids.

An **oral presentation** is a brief 15-20 minute individual presentation time moderated by a volunteer. An effective oral presentation should have an introduction, main body and conclusion like a short paper and should utilize visual aids such as a PowerPoint presentation. Oral presentations are divided into different categories based on the program presented. Categories can include: clinical, leadership, scientific, evidence-based practice, or research.

A **poster presentation** is the presentation of research information by an individual or representatives of research teams at a conference with an academic or professional focus. The work is peer-reviewed and presented on a large, usually printed placard, bill or announcement, often illustrated, that is posted to publicize. Exceptions to peer-reviewed posters include Rising Stars student posters and Sigma Theta Tau International's Leadership Institute participant posters.

A **symposium** is a presentation coordinated by an organizer similar to a panel discussion and contains at least three (3) presentations concerning a common topic of interest. Each symposium session is scheduled for 45-75 minutes and allows for questions at the end of the session. Symposia provide an opportunity to present research on one topic, often from multiple perspectives, providing a coherent set of papers for discussion.

A **peer-reviewed paper** is simply an individual abstract that has been reviewed by at least three (3) peer-reviewers to determine the eligibility of the submission to be presented during a program. The determination is made by the peer-reviewer answering a series of regarding the substance of the abstract and the materials submitted. Scores from each reviewer are compiled. The average score must be 3.00 on a 5-point Likert scale in order to qualify for presentation. Sigma Theta Tau International enforces a blind peer-review process, which means that the reviewers do not see the name or institution of the authors submitting the work. All submissions, with the exception of special sessions and invited posters are peer-reviewed.

An **invited** or **special session** is similar to a symposium in the length of time allotted for presentation, but is not peer-reviewed. These sessions focus on a specific area, but are conducted by individuals invited to present the work.

Introduction

The Honor Society of Nursing, Sigma Theta Tau International (STTI) conducted its 28th International Nursing Research Congress in Dublin, Ireland, 27-31 July 2017. Nearly 1400 nurses from around the world gathered at the congress, which had as its theme “Influencing Global Health Through the Advancement of Nursing Scholarship.”

Program objectives of the 28th International Nursing Research Congress include:

- Promote the transformation of knowledge and practice to advance global health and nursing.
- Exchange ideas and solutions that promote the integration of technology into evidence-based nursing practice.
- Discuss research strategies to promote evidence-based teaching and learning that influences interprofessional environments.

These conference proceedings are a collection of abstracts submitted by the authors and presented at the research congress. To promptly disseminate the information and ideas, participants submitted descriptive information and abstracts of between 300 and 1500 words. Each oral and poster presentation abstract was peer-reviewed in a double-blind process in which three scholars used specific scoring criteria to judge the abstracts in accordance with the requirements of STTI’s Guidelines for Electronic Abstract Submission.

The opinions, advice, and information contained in this publication do not necessarily reflect the views or policies of STTI or its members. The enhanced abstracts provided in these proceedings were taken directly from authors’ submissions, without alteration. While all due care was taken in the compilation of these proceedings, STTI does not warrant that the information is free from errors or omission, or accept any liability in relation to the quality, accuracy, and currency of the information.

Format for Citing Papers

Author. (Year). Title of paper. In *Title of conference proceedings* (page numbers). Place of publication: Publisher.

Special Sessions

G 01 - SPECIAL SESSION: The STTI Chapter Development Process: How to Start a Chapter

Jenny Hoffman, BS, USA

Abstract

Chapter establishment is a six-phase process. To establish a new chapter, groups must first form a local honor society at their institution of higher education. This developing honor society shall complete the tasks outlined within each phase of development to learn, grow, apply, and transition into a successful and sustainable chapter. Chapter development staff are available to guide groups through the process.

In phase 1, Inquiry, Institutions of higher education that are interested in starting a chapter shall contact STTI staff to inquire about the requirements, process, and timeline. Most groups complete phase 1 in approximately 1-3 months.

After a school of nursing receives information and pre-approval to proceed with the STTI honor society and chapter development process, the school of nursing shall form an independent, local nursing honor society. In phase 2, Formation of a Developing Honor Society, the honor society agrees to follow STTI's recommended honor society procedures and policies while forming and operating the honor society with intent to apply for official chapter status. During phase 2, groups will complete tasks such as strategic planning, program planning, communications, and budgeting to establish the foundation or groundwork of the prospective chapter. Most groups complete phase 2 in 3-6 months.

In phase 3, Operation as a Developing Honor Society, the newly formed nursing honor society shall induct members and operate according to STTI developing honor society bylaws for one year or more. One year is marked from the day of the developing honor society's first induction ceremony (which is the first task in phase 3). Developing honor societies are asked to operate for more than one year so they become familiar with STTI bylaws, guidelines, and recommended operations and so they may demonstrate sustainability to become an official chapter. Developing honor societies must operate for a minimum of 12-18 months before they are eligible to submit the chapter charter application.

Application submission marks the beginning of phase 4, Application Submission & Review. After operating as an honor society for one year or more (one year begins at the first induction ceremony) and meeting specific milestones such as acquiring more than 50 active members, conducting a renewal cycle, and building the treasury to one-year's worth of operating expenses, the honor society may be eligible to apply for chapter status. By phase 4, reviewers expect applicants to consistently meet or exceed all bylaws requirements and guidelines while also demonstrating sustainability in the areas of membership, leadership, and finances. Applications for chapter charters are accepted twice annually. Application review takes approximately 4 months. Applications are reviewed by staff, 2 reviewers of the Charter Review Task Force, the entire Charter Review Task Force, the STTI Governance Committee, and the STTI Board of Directors.

A chapter designate is an honor society that has received final approval to become a chapter and is awaiting and planning the chartering ceremony. In phase 5, the Chapter Designate phase, staff work with approved groups to begin the transition from a developing honor society to an official chapter, including preparing for and planning the official chartering ceremony.

After the STTI chartering ceremony, the chapter designate is now considered an official STTI chapter. All chartering members and future inducted members will become members of STTI and the chapter. In addition to the benefits that the chapter will provide, active members are eligible for valuable STTI resources throughout their entire nursing career. In phase 6, the New Chapter phase, staff continue to transition the developing honor society to an official chapter and provide structured training, consultation, and support to the new chapter for a period of 2 years.

G 02 - SPECIAL SESSION: The United Nations and the Sustainable Development Goals

Cynthia Vlasich, MBA, BSN, RN, USA

Abstract

Sigma Theta Tau International provides a solid nursing presence at the United Nations and continues to conduct outreach around the world to help our nurse members better understand the work and aims of the United Nations, including the 17 Sustainable Development Goals.

In July 2012, the United Nations Economic and Social Council granted Special consultative status to Sigma Theta Tau International, which refers to expertise in the field of nursing and global health. This move helps Sigma Theta Tau International demonstrate its commitment to achieving international cooperation toward solving humanitarian related issues while at the same time providing a blueprint for how the organization can support its mission and goals.

Special consultative status grants Sigma Theta Tau International greater privileges and access to nearly all intergovernmental processes at the United Nations dealing with economic and social development. This designation allows Sigma Theta Tau International to participate on United Nations committees through which it has a voice. As part of this affiliation, Sigma Theta Tau International commits to disseminate information and raise public awareness about the purposes and activities of the United Nations and related issues of global concern. The United Nations Sustainable Development Goals is one way chapters can achieve the mission of Sigma Theta Tau International.

To help fulfill our mission, STTI has three volunteers – one United Nations liaison, two United Nations youth representatives - who are the ‘eyes and ears’ at various United Nations activities and events. Their purpose is to represent STTI to the United Nations by attending briefings, presentations and as appropriate, participating in United Nations committees, working groups, activities, and events.

The United Nations also provides a forum for its members to express their views in the General Assembly, the Security Council, the Economic and Social Council, and other bodies and committees. By enabling dialogue between its members, and by hosting negotiations, the United Nations has become a mechanism for governments to find areas of agreement and solve problems together.

G 04 - SPECIAL SESSION: Domestic Violence and Abuse: Preparation of Preregistration Nursing and Midwifery Students

Parveen Ali, PhD, MScN, RN, SFHEA, FRSA, United Kingdom

Abstract

Intimate partner violence (IPV), which is also referred to as domestic violence and abuse (DVA). It is a major social and public health concern affecting millions of individuals globally (World Health Organisation, 2015). DVA impacts significantly on the physical and mental health and wellbeing of those who experience abuse. Nurses and midwives working in any health care settings can play a crucial role in identification, prevention and management of DV (NICE, 2014) as they may regularly encounter DVA victims, who visit health care settings frequently (Houry et al., 2008). However, effective identification and the provision of support for those who have experienced DVA is essential but is dependent on the provision of the appropriate training, preparation and on-going professional development for nurses as well as other care professionals.

On the other hand, DVA victims report feeling blamed for the abuse they experience. They feel that health care professionals (HCPs) do not show a concern, and do not address the abuse even when DVA is disclosed to them or is obvious. Evidence also suggests that nurses and other HCPs are often unprepared to deal with DVA victims (Sundborg, Saleh-Stattin, Wandell, & Tornkvist, 2012). To be able to effectively identify and respond to DV victims, nurses, midwives as well as pre-registration nursing and midwifery students need to understand DV and associated complexities. However, not much emphasis is placed on preparing nursing and midwifery students and registered nurses and midwives to deal with DV issues in clinical practice. There is a need to explore DV related knowledge, attitude and skills of registered nurses, midwives and nursing and midwifery students. Such knowledge will help in identifying the training and education needs of nurses, midwives and nursing and midwifery students. The aim of this session to share findings of my DVA related work and specifically findings of a cross sectional national survey conducted to measure registered nurses, midwives, pre-registration nursing and midwifery students' level of knowledge, attitude and skills related to DV and its management. Responses collected from more than 900 nurses, midwives and pre-registration nursing and midwifery students from England and Wales provide useful information about the training needs of the future workforce.

G 06 - SPECIAL SESSION: Mobile Health Technologies and Precision Health

Ryan Jeffrey Shaw, PhD, RN, USA

Abstract

Current care delivery models often revolve around a series of episodes, rather than functioning as a continuum. These single data points are collected where patients spend little lift time, and are compared with the patient's history and analyzed to make presumptive diagnoses and care recommendations. This neglects significant amounts of potentially meaningful data from patients' daily lives and results in less-informed treatment and scheduling of follow-up visits. This prevents clinicians from delivering precision healthcare that can predict changes in health status in real-time and prevent future illness before it occurs (1).

Advances in information technology are enabling the development and delivery of affordable health interventions beyond the traditional office visit and across populations. Over one billion users have mobile broadband and connect with mobile application marketplaces, and an estimated 75% of the world population has access to mobile communications (2)(3). Healthcare providers have an opportunity to use these interactive capabilities to connect with patients and enable personalized health interventions in real-time. By using technologies from cell phones to wearable sensors, providers can monitor patients and families outside of the traditional office visit and across inpatient and outpatient settings. The ability to objectively see a patient's biological, behavioral, environmental, and social environment in real-time can allow for high level of analytics such as predictive modeling to occur. This continuous stream of data has the potential to yield new insight into disease processes and can enhance our understanding of the longitudinal effect of care delivery, medications, and health behaviors – known as precision health.

Creating the ability to obtain continuous streams of data and to intervene in near real-time with patients and populations requires new software tools to developed, data science techniques that can analyze multiple streams of data, integration into electronic health record systems, and new of models of care delivery. Across several clinical research trials, our team developed a web-based software platform that assembles data from patients and their devices into a single aggregate secure database. This aggregation of data allows for real-time data analysis and in an automated feedback loop sends a response to patients, their social network, and to clinicians. This response can take a variety of forms including but not limited to the following: text and voice messaging feedback; physical prompts using wearables or sensors in a patient's environment; alerts to a smartphone or an electronic health record; and visualization of data to clinicians and patients that allow for a longitudinal view of data and predictive factors.

We demonstrate how this system is used to intervene with patients to self-manage diabetes, manage weight loss, promote smoking cessation, and monitor patients in a variety ways as a follow-up tool (4)(5)(6). We describe how these tools and their data can be integrated into health systems in a resourceful way. The aggregation of data in software and then analysis allow for the majority of feedback to patients and the health system. This automated system is resourceful and help patients manage during their everyday lives with limited need for clinician intervention and resources. The first level of intervention involves the software guiding patients to collect correct data and within specific parameters to take health-related actions. A second level of intervention occurs when the software alerts the health system to trends and changes in patients' conditions. Similar to a model in an inpatient telemetry floor, a technician intervenes as needed as the first step. If further clinical intervention is needed then a registered nurse is alerted to intervene (7). As care needs escalate, other providers are involved to adjust medications, change treatment, and to recommend in-person follow-up.

Challenges with integrating such a system into care delivery are not without its challenges. These include data quality, technical issues, data science challenges, integration into electronic health records, privacy, security, and regulations, among others. Finally, we discuss future directions and the next generation of mobile health tools for precision health. These tools include point-of-care diagnostics, environmental

sensors, biomechanics, wearable tattoos, ingestibles, implantables, and the merging of genomics with mobile health.

As mobile technologies and access to the Internet become universal, healthcare systems will leverage capabilities that allow the transfer of data on a daily and hourly basis, analysis of this data, and near real-time intervention. More important, this will reflect the unique environment patients reside in, taking into account the different exposures, stressors, and influences on their disease state (1) – known as precision health.

G 07 - SPECIAL SESSION: Nurse Entrepreneurship: Where Nursing Research Meets Opportunity

Kenneth W. Dion, PhD, MBA, RN, USA

Abstract

Nurses are the source of many revolutionary innovations. All too often, non-nurses reap the profits from nursing innovation. The session is for nurses and nurse researchers interested in exploring of commercializing their efforts. Many of the topics covered in this session are transferable to the research grant application process. This session is applicable for nurse entrepreneurs, aspiring nurse entrepreneurs, nurse researchers and treasurers, given the strong financial component of the session.

Entrepreneurs will face a gamut of both personal and professional challenges during the lifecycle of the business endeavor undertaken. The least of which may be the failure of the business. The challenges of entrepreneurship will be discussed so that the attending will be able to complete a self-assessment of readiness to embark on the entrepreneurial journey.

Entrepreneurs often have great ideas. Successful entrepreneurs identify a customer need. Clearly identifying a single customer for the product or service and determining their purchasing motivation is the cornerstone on which all successful enterprises are formed. Techniques for customer segmentation and uncovering customer motivations will be explored as the precursor to business plan development.

The business planning process closely parallels the research grant development process. The plan guides the effort so it remains on track during all of the challenges it will face as it progresses through its lifecycle. Sections of the business plan will be identified. An exploration of each section will identify questions that will need to be answered in order to produce a marketable plan. Specific attention will be given to the relationship between the financial projections and each section of the plan itself.

"What makes a rocket go up? Funding!" Funding is the life blood of the business enterprise. There is a broad spectrum of funding sources. Each source may fit with a specific type of business or a specific stage in the business lifecycle. Each source definitely comes with its own risk which may outweigh the rewards. Funding requirements, sources, benefits and risks will be explored.

H 03 - SPECIAL SESSION: How to Amend Your STTI Chapter to Add a College of Nursing or Practice Setting

Jenny Hoffman, BS, USA

Abstract

When an existing chapter adds a school of nursing or practice setting to its existing charter, the process is called charter amendment. There is an application and review process for amending a charter. The process is somewhat faster than chartering a brand new chapter because the STTI Board of Directors gives final approval for amending a chapter's charter. Groups wishing to pursue a chapter charter amendment shall follow the charter amendment process.

MINIMUM REQUIREMENTS TO ADD AN INSTITUTE OF HIGHER EDUCATION TO A CHAPTER

The minimum requirements for a school of nursing to begin the process of joining a STTI chapter include:

- School of nursing grants a minimum of a baccalaureate or equivalent degree in nursing
- School of nursing's programs are accredited by an appropriate accrediting agency recognized by STTI Governance Committee
- University administration and school of nursing officials agree to support an STTI chapter at the university

MINIMUM REQUIREMENTS TO ADD A PRACTICE SETTING TO A CHAPTER

The minimum requirements for a practice setting to begin the process of joining a STTI chapter include:

- A practice setting is an entity where professional (registered) nursing is practiced.
- Practice setting must be accredited by an appropriate accrediting agency recognized by the STTI Governance Committee (such as the Joint Commission or equivalent).
- Practice setting administration and chief nursing officer officials must agree to support a STTI chapter at the university.

PROCESS:

Contact STTI Headquarters chapter development staff to inquire about charter amendment process and requirements.

The STTI chapter and the joining school(s) or practice setting(s) shall conduct an

- Why the joining group wants to join the established chapter
- How the collaboration will benefit the chapter and the joining group
- What contributions can the joining group add to the established chapter (resources, leadership, perspective, financial or in-kind donations)
- Ways the joining group could engage potential student and professional nurse candidates
- Potential barriers
- Leadership Inclusion-- Representatives from the joining groups will need to be included and take an active role within the prospective at-Large chapter to ensure collaboration among all schools and practice settings involved
- Per STTI bylaws and guidelines, at-Large chapters are required to have a counselor at each school and practice setting.
- A vice president is highly recommended at each school or practice setting to assist with program planning and development
- How physical distance between the schools and/or practice settings will affect operations
- Where, when, and how events, programs, and inductions will take place
- How finances will be handled for each location
- How future elections and chapter leadership will be structured to ensure equal representation and workload
- How will members perceive the collaboration? Will they realistically attend events at the school(s) or practice setting(s)? Will leader candidates be put off at having to attend meetings/events at the various locations?

- How to best serve clinical nurse members who work 2nd shift, or weekend schedules

Chapter Board Vote — If all parties agree to pursue a chapter charter amendment, the board of directors of the established chapter must vote to approve this action. Be sure to document this vote in the meeting minutes, including:

- Date the chapter board of directors voted to amend chapter
- Number of board members present
- Number of votes to approve charter amendment
- Number of votes to not approve charter amendment
- Number of voters who abstained
- Chapter leaders and school or practice setting representatives should talk to the following groups to for having an at-large chapter of STTI. Letters of support for the collaboration will need to be submitted from each of the following as part of the chapter charter amendment application.
 - Each university or college already affiliated with chapter
 - Administrator
 - Dean or head of the school of nursing
 - Each practice setting interested in joining chapter
 - Chief nursing officer or head nurse
 - Hospital administrator

Continue to consult with STTI Headquarters staff

The chapter's board of directors and representatives from the new school(s) or practice setting(s) to be added to the chapter should meet to discuss and agree upon how chapter

- There should be an equal partnership among all parties involved in the new at-large chapter.
- All groups should demonstrate an ability to work together and document efforts as evidence of this collaboration (on average this will take a minimum of six months or more).
- Documentation may include:
 - Copies of meeting minutes
 - Copies of policies and procedures
 - Statements and appendices requested on application
 - Reviewers will expect high levels of inclusion and collaboration in the areas of leadership, programming and events, inductions, communications, board planning, and finances. Supporting documentation submitted with the application should reflect this.

Draft proposed at-large chapter bylaws

- If your chapter is already an at-large chapter and it is just adding the new practice setting(s), submit a revised copy of the chapter's current at-large bylaws (including each new school or practice setting name to be added within the heading and Article 1, as the proposed at-large bylaws).
- You may also add revisions in the allowable, sections of the chapter bylaws. (Consult Chapter Bylaws Guidelines — areas you are allowed to revise are highlighted in yellow. Additional changes must be approved by the STTI Governance Committee.)

Membership Vote — The membership must vote to add a school(s) or clinical setting(s) to the chapter's charter and

- The vote can be electronic, by mail, or at a chapter meeting (check local laws in your area).
- Notice of the vote must be sent to all members at least 30 days prior (60-90 days' notice is recommended).
- If the vote is conducted electronically or by mail, $\frac{3}{4}$ of the ballots must be favorable.
- If the vote is at a chapter meeting, the opportunity to vote should be announced with the notice of the meeting. $\frac{3}{4}$ of those present and voting must vote in favor of the charter amendment.
 - If you do not give 30 days' notice of the vote, 100 percent of the ballots returned or completed must be favorable.(If no notice is given, unanimous approval is required.)

Chapter should send

- Hold informational meetings and orientations.
- Promote chapter collaboration with school(s) or practice setting(s) and all chapter events via flyers, newsletters, etc., at the practice setting(s).
- Ask chapter members that are employed by this practice setting to invite colleagues to next chapter event.

After above tasks are completed, please utilize the Charter Amendment Application Readiness Checklist with staff to determine readiness to submit and official application.

APPLICATION SUBMISSION AND REVIEW

Please contact staff to request an application. Submitted applications will be reviewed by staff, the Charter Review Task Force, the STTI Governance Committee, and the STTI Board of Directors. Final approval of the application is given by the STTI Board of Directors.

Application Submission Date	Final Approval Date	Potential Chartering Date
15 June 2016	September 2016	After 1 February 2017
15 February 2017	June 2017	After 1 October 2017
15 June 2017	October 2017	After 1 February 2018

Approval and the Charter Amendment Ceremony

If approved by the Board of Directors, a charter amendment ceremony will be arranged with headquarters and the new at-large chapter. The amendment ceremony is required and consists of two parts:

- Official chartering of the new practice setting(s) to be included in the chapter
AND
- A chapter induction

STTI will identify and pay travel expenses for the STTI leader who will officiate at the chartering ceremony.

Ceremonies will be scheduled:

- For U.S. chapters — no earlier than 12 weeks after final board approval.
- For international chapters — no earlier than 16-20 weeks after final board approval (extra time needed for packages shipped to clear customs).

Newly chartered amendments will be recognized during the biennial convention House of Delegates session(s):

- 2017 Biennial Convention in Indianapolis, Indiana, USA
- 2019 Biennial Convention (location to be announced)

H 04 - SPECIAL SESSION: Secrets of the Most Successful Nurse Educators

Suzanne Prevost, PhD, RN, FAAN, USA

Abstract

Successful nurse educators make a profound impact on their students, their workplaces, their communities, and the profession. The wisdom they impart can prevent complications, save money, and save lives, both today and for years to come. What does it take to become the best of the best in nursing education? Is it the powerful presentations, the clinical expertise, the publications and research funding? Are all of these skills required to be successful as a nurse educator? How do these expectations vary across the global regions of Sigma Theta Tau? What is the role of collaboration, partnerships, and networks?

In this session, sponsored by the Center for Excellence in Nursing Education, we will share our observations and unwrap the strategies and secrets used by highly successful nurse educators around the globe. Join in the discussion to share your insights regarding - what makes an educator successful? Is one type of educational preparation better than others? Are successful educators a product of successful academic environments? What role does mentorship play? What techniques and interpersonal skills are most important? How should we measure the impact and outcomes of successful nurse educators?

We will explore the attributes of the most successful nurse educators and strategies for developing those attributes. The session will include a description of the programs and resources available through Sigma Theta Tau and the Center for Excellence in Nursing Education. These programs include: The Faculty Knowledge Skills Development Program, The Faculty Professional Role Development Program, The Nurse Faculty Leadership Academy, The Experienced Nurse Faculty Leadership Academy, and The Emerging Educational Administrator Institute. Finally, we will share recommendations for finding your niche, targeting the right audience, expanding your influence, and making an impact that will last beyond your years. The best nurse educators leave a legacy for their students and their profession. This session will challenge participants to take the next step in developing a legacy of their own.

H 07 - SPECIAL SESSION: Sigma Theta Tau International Global Initiatives

Cynthia Vlasich, MBA, BSN, RN, USA

Abstract

The history of Sigma Theta Tau International (STTI) is varied and rich. It includes a deliberate decision to become international, including global expansion, which was formalized at the 1985 Biennial Convention in Indianapolis, when the House of Delegates voted to add "International" to Sigma Theta Tau's name. The international work of STTI undertaken since that time has led to the current Global Initiatives department.

Focusing on the past five years, STTI has made great strides in its global advancement. For example, STTI has its first president, elected by the full House of Delegates, from outside of North America. STTI launched its first formal presence outside of America, contracting with a nursing organization in South Africa to specifically conduct work to advance the organization, under the auspices of STTI. STTI launched its first International Leadership Institute based outside of North America, with the Maternal-Child Health Nurse Leadership Academy in Africa. Global regions were identified and Regional Coordinators elected from around the world. More than 735 institutions are now engaged with STTI, through 529 chapters, located in 30 countries. Currently, over 135,000 members can be found in 92 countries across the globe.

The International Nursing Research Congress annually hosted by STTI is held in rotating global regions around the world. Over the past five years, this event has been held in Brisbane, Australia; Prague, The Czech Republic; Hong Kong, SAR, the People's Republic of China; San Juan, Puerto Rico; and Cape Town, South Africa. And our Biennial Convention, held in the United States every other year, brings in STTI members and nurse leaders from dozens of countries around the world.

The Global Initiatives department focuses on five key strategies: Global Expansion; the Global Advisory Panel on the Future of Nursing; Relationship Building; Member Engagement and Member Growth. This session will include discussion on STTI's global initiatives, and invite dialogue on efforts to enhance member growth and engagement.

H 17 and I 17- SPECIAL SESSION: Nurse Faculty Leadership Academy Sustainable Advancements in Nursing Education

Deborah Cleeter Bailey, EdD, MSN, RN, USA
Larry Z. Slater, PhD, RN-BC, CNE, USA
Barbara J. Patterson, PhD, RN, ANEF, USA
Jackie L. Michael, PhD, APRN, WHNP-BC, USA
Jodie C. Gary, PhD, RN, USA
Carolyn Hart, PhD, RN, CNE, USA

Abstract

The Nurse Faculty Leadership Academy (NFLA) is an international leadership development experience designed for doctorally prepared nurse educators with under seven years of full-time teaching experience. Administered by Sigma Theta Tau International and funded by the Elsevier Foundation, the NFLA is currently conducting its third cohort. The purpose of the NFLA is to: facilitate personal leadership development; foster academic career success; promote nurse faculty retention and satisfaction; and cultivate high performing supportive work environments in academe.

The NFLA curriculum is constructed upon three learning domains: individual leadership development, advancing nursing education through leadership of a team project, and the Scholar's expanded scope of influence. A mentoring triad serves as the Academy relationship foundation as each Scholar and Leadership Mentor dyad is connected with a Faculty Advisor for the entire NFLA experience to accomplish the Academy goals. Kouzes and Posner's "Leadership Challenge" model of five exemplary leadership practices provides the theoretical foundation of the curriculum. The leadership practices include: model the way, inspire a shared vision, challenge the process, enable others to act, and encourage the heart.

Successful individual leadership development in the Nurse Faculty Leadership Academy (NFLA) is initiated through in-depth targeted assessments and ongoing re-assessments of leadership behaviors. Scholars design an individualized leadership development plan that seeds the development of strategic leadership behaviors with life-long results.

Leadership development in the NFLA is actively realized through a team project that advances nursing education. Scholars learn to identify and engage stakeholders, build a collaborative team, and gather institutional and evidence-based data, all of which are essential for project planning, development, implementation, and sustainability. Completion of the project not only assists the Scholar in achieving personal leadership and career development goals set during the Academy, but also provides measurable benefit to the Scholar's organization in terms of educational programming and evaluation.

Through the triad relationships and dynamic mentorship, Scholars are guided to cultivate high performing, supportive work environments in academe. Leadership Mentors are essential to the success of the Academy. Their role of behaviorally oriented mentorship is distinctly different from traditional content expertise mentoring.

Through guided leadership development, nurse faculty Scholars expand their scope of influence within institutions, communities, and on a national or international level as part of the nursing profession. The NFLA process offers opportunity to intentionally impact broader networks and lead significant change through expanded influence.

The future of nursing education exists outside the silos of schools of nursing; thus, it is crucial for developing academic nurse leaders to be cognizant of what is happening in higher education broadly examining the educational landscape as a whole, not just through a local scope of influence within the nursing community. Leaders need to be knowledgeable and have the evidence readily available or know how to retrieve it. External drivers impacting nursing education include funding and regulatory issues, resource allocations, and shifts in healthcare delivery such as the increase push for primary care at the

BSN level. While overlapping, drivers within the profession focus on nursing roles and role preparation, maintaining a nursing identity in a time of transdisciplinary education and care, as well as being prepared to take risks for faculty, students, and ultimately the society we serve.

Abstract

Purpose: The purpose of this project was to use technology to provide an avenue for nurses from different geographical backgrounds to stay connected and provide support in a way that has not been done before. A new web-based technology has allowed experienced nurses to connect and mentor or coach new nurses to support their transition into their current practice.

Relevance/ Significance: Globally, the populations of the world are experiencing poor access to care, insufficient resources, and nursing shortages of overwhelming proportion. The integration of best available evidence is associated with improved patient outcomes, reduced treatment costs and need for clinical interventions. Lack of professional support and a dissatisfying work environment are associated with high levels of job-related burnout and nurses' intent to leave their job. A distance-mediated formal mentoring program has been shown to provide the support new nurses need to grow in the profession.

Strategy and Implementation: A task force was convened of nurse researchers, academicians, and clinicians from around the world to develop a distance-mediated nurse mentoring program. Over the span of five months, the task force met via web-based technologies to develop a comprehensive, formal mentoring program designed to advance and encourage nurses to pursue lifelong learning opportunities, demonstrate new competencies in systems thinking, quality improvement, and care management that will better prepare them to improve health care outcomes in academic and/or clinical settings around the world.

The task force developed criteria to match nurse mentors with nurse mentees from around the world based on the needs, or perceived needs, of the nurse mentee and the experience and expertise of the nurse mentor. An online educational course is completed to ensure that program expectations are known and agreed to prior to enrolling in the program. Utilizing new technologies, nurses are matched based on their provided mentoring topics, nursing specialty, career stage, global region, spoken language(s) and time commitment. Software then allows nurse mentors and mentees to agree to be matched. Once a match has been confirmed, both parties then agree to which venue or form their communication will take place.

Evaluation: Once a match has been confirmed, mentors and mentees are expected to complete periodic program evaluations. Data is measured via online evaluations performed four times during the first year and each year after that based on the initial match date. Along with demographic data, an adapted version of the Johns Hopkins University School of Nursing Mentorship Effectiveness Scale (2002) is used throughout the evaluation period.

Implications for Practice: To address the nursing shortage issue, it is critical to create supportive and positive environments to promote the well-being and professional development of nurses. This distance-

mediated formal mentoring program, located at <http://bit.ly/SigmaMentoring>, will provide one avenue of support and encouragement nurses so desperately need.

J 15a - SPECIAL SESSION: "Finding a Balance Point": A Concept Central to Family Caregiving for Older Persons in Taiwan

Yea-Ing Lotus Shyu, PhD, RN, Taiwan

Abstract

Using a grounded theory approach, a conceptual framework was developed to explain the caregiving process in Taiwanese families that taking care of older persons. "Finding a balance point" was the basic process used by Taiwanese caregivers to achieve or preserve interactive equilibrium in caregiving while facing competing needs. This process can be explained using the analogy of the concept of *tiao biaoan dan*. *Biaoan dan* is a flat carrying pole, usually made of bamboo, which laborers or farmers in Taiwan use to transport objects in balance. The carrier must adjust the weights of the two loads while continuously adjusting the position of his or her shouldering in order to maintain balance and continue to walk forward. Similarly, family caregivers need to adjust their daily priorities and efforts among competing needs while moving forward with everyday life. For example, a caregiver needs to find a balance point in facing the competing needs of doing housework and fulfilling the needs of the care receiver. Caregivers who did better in finding a balance point between competing needs often can plan ahead for upcoming competing needs, simulate their choices and flexibly use a wide variety of different balancing strategies, and were shown to have more positive caregiving consequences, including better quality of care for disabled elders, better caregiver outcome and less negative impact on the family as a whole. The Finding a Balance scale was then developed to measure the degree to which a caregiver is able to handle competing caregiving demands simultaneously based on the prior study. Adequate reliabilities and appropriate validities of the Finding a Balance scale was established and an optimal cutoff was also determined. The validated Finding a Balance scale can provide an assessment tool to explore the competing responsibilities, conditions and difficulties for family caregivers of elders with dementia in Taiwan. Model testing of the developed conceptual framework was also conducted in a different study. We found that the associations of caregiving demand with role strain and depressive symptoms were mediated by balancing the competing needs of the care receiver and other responsibilities. Another study found that providing discharge consultation to family caregivers on balancing possible competing needs was effective in preventing institutionalization of the patients with stroke 6 to 12 months following hospital discharge. This model may also be applicable for explaining family caregiving process for older persons in areas with Chinese context. A series of studies from theory development to theory testing and its application in family caregiving process for vulnerable older persons will be presented.

J 15b - SPECIAL SESSION: Computer-Tailored Interventions to Increase Cancer Screening: Building a Program of Research

Susan M. Rawl, PhD, RN, FAAHB, FAN, USA

Abstract

Susan M. Rawl, PhD, RN, FAAHB, FAAN, is a Professor of Nursing at Indiana University and Co-leader of the Cancer Prevention and Control Program at the Indiana University Simon Cancer Center. For the past 20 years, Rawl has conducted patient-centered research testing interventions to increase cancer screening among people at increased risk, including those with limited resources, low literacy levels, and minority populations. Rawl's research has been funded by the National Cancer Institute, the National Institute for Nursing Research, the American Cancer Society, and the Walther Cancer Foundation. She has developed and tested tailored print, telephone, and computer-based interventions to promote screening. Currently, she is conducting a comparative effectiveness trial, funded by the Patient Centered Outcomes Research Institute (PCORI) to increase colorectal cancer screening among low-income and minority patients who have cancelled or did not attend their colonoscopy appointment. She is also collaborating on a multi-behavior intervention trial to increase colon, breast, and cervical cancer screening among rural women in Indiana and Ohio. During this presentation, she will provide an overview of the global impact of colorectal cancer – a preventable cancer that remains the third leading cancer killer in the United States. She will describe the theoretical rationale for tailoring, evidence of the effectiveness of computer-tailored interventions to help people change a variety of health behaviors, and future directions for research in this area. Rawl will describe the development of her program of research beginning with descriptive studies, instrument development work, the process of developing computer-tailored interventions, as well as the results of randomized clinical trials testing their effects. Lessons learned along the way will be shared with the goal of providing guidance for young nurse scientists who are early in their careers. As the daughter of Irish immigrants, Dr. Rawl is deeply honored to be named to the International Nurse Researcher Hall of Fame this year in Dublin.

J 16a - SPECIAL SESSION: Advancing Research and Researcher Training by International Research Collaboration

Katri Vehviläinen-Julkunen, PhD, Lic HC, MSc, RN, RM, Finland

Abstract

This presentation will discuss background and current experiences of international and multidisciplinary research collaboration between European and USA partners in advancing care of cancer patients and their family caregivers. This session will highlight the importance of a clear, longstanding program of research for knowledge and innovation development as well as impact on health policy and practice.

International research collaboration has been a high priority in national research strategies in major research economies (European Science Foundation 2010, Adams & Kurney 2016). Research is driven by international collaboration between research groups. Research problems are complex and that is why multidisciplinary and international approaches are imperative. Collaboration contributes to impact and relevance of research results on several levels. Research intensive universities usually have active international research collaboration with joint projects, publications and systematic researcher career support. As such the demand of nursing to be global is evident (Callister et al. 2006, O'Keefe et al. 2016). International nurse organizations such as Sigma Theta Tau International (STTI) Honor Society of Nursing (<http://www.nursingsociety.org>) and International Council of Nurses (ICN) (<http://www.icn.cd>) emphasize the international research collaboration.

During the presentation the background of European Union funded INEXCA project (www.uef.fi/inexca) for four years 2015-2019 will be described as well as challenges faced so far in international research collaboration. Inexca –project was built on two main activities: exchange of researchers in different career phases as well as actual research and data collection on cancer patients, their family caregivers and health professionals. The countries involved are Belgium, Denmark, Finland, Italy, Finland, United Kingdom and USA as well as a business partner and hospital from Finland. The project aims to provide multi-scientific research data to promote evidence-based health care across borders. The project outcomes will strengthen the roles played by patients, employees, employers and researchers in modern health care service sectors and research institutions.

J 16b - SPECIAL SESSION: Developing the Evidence for Airway Management of Critically Ill Ventilated Patients

Mary Lou Sole, PhD, RN, CCNS, FAAN, FCCM, USA

Abstract

Background. Many practices in critical care lack evidence to support the best patient outcomes. Additionally, it is challenging to conduct clinical studies in the environment of a fast-paced critical care unit. This session will describe a program of research focused on airway management of critically-ill patients who require mechanical ventilation. Mechanically-ventilated patients are at risk for infection and other complications associated with the artificial airway, such as aspiration and ventilator-associated conditions. Strategies for conducting successful studies in the critical-care setting will also be addressed.

Objectives. To detail a successful research trajectory for studying airway management practices in the critically-ill ventilated patient, and discuss strategies that facilitated conduct of research in the critical-care setting.

Methods. After established a broad research focus on use of technology to assess oxygenation and circulation, the research focus was narrowed to emphasize airway management strategies. Both nurses and respiratory therapists (in the U.S.) manage the patient with an artificial airway. Management strategies include oral care, oral suctioning, endotracheal suctioning, and care of the endotracheal tube. Equipment to facilitate airway management is also required. Airway management is important to prevent aspiration of oral and gastric secretions, and ventilator-associated pneumonia and conditions. The researcher has conducted many descriptive, pilot, and interventional studies addressing airway management strategies. The most recent is a large clinical trial investigating the impact of enhanced oral suctioning on prevention of aspiration and ventilator-associated events. Each study has laid the groundwork for future studies.

Results. Study findings have identified the importance of strategies to reduce complications associated with mechanical ventilation. Nurses and respiratory therapists often differ in their airway management practices, which may affect patient outcomes. Additional and ongoing research is needed to establish the best practices for oral suctioning, endotracheal suctioning, and management of the endotracheal tube cuff to prevent complications such as aspiration and infection. Strategies for success have included a spirit of inquiry along with self-motivation and determination to make a difference in nursing practice. Collaboration and partnerships provide support needed for success. Team-building is one of the most important parts of a successful trajectory and includes personnel from many disciplines. Each has a unique and synergistic role in the success of the study.

Conclusions. A successful program of research will impact nursing care and patient outcomes. Tenacity, time, and teams are essential!

J 17 - SPECIAL SESSION: Publishing: A Career Road for You?

Susan Gennaro, PhD, RN, FAAN, USA

Bernadette Mazurek Melnyk, PhD, RN, CPNP/PMHNP, FAANP, FNAP, FAAN, USA

Abstract

Career opportunities for nurses interested in publication will be presented. Specific and detailed advice on how to become a manuscript reviewer, editorial board member, associate editor and journal editor will be provided. Each role will be examined and a discussion will be held about the benefits of becoming involved in each of these very distinct publication opportunities. A conversation about an overall career trajectory in publishing will be held by two editors of top rated nursing journals. Often before one strives to become an editor or an associate editor other roles, such as manuscript reviewer or editorial board member are appropriate. Participants will have the opportunity to discuss their experiences and their interest in publication. In nursing we particularly need peer reviewers so the role of the manuscript reviewer will be discussed in depth. This session is designed for all nurses (academics, administrators or those involved in clinical practice) who are interested in becoming involved in publication. Each role will be carefully discussed and advice on how to move from one role to the next will be provided. This is an interactive session for those interested in how nurses can help in dissemination of quality work through roles other than authorship. Authors appreciate the work, mostly voluntary, of peer reviewers and editorial board members and so this is an opportunity to learn how these roles work and how people move into these very important roles. There are many, many opportunities for nurses who are interested in publications so the presenters will spend some time thinking about fit between an individual's interests and publication opportunities. Additionally, there will be a discussion of how much time each of these activities take so that participants can think about whether or not they wish to become involved in publication activities. Becoming involved in publication activities can be a very rewarding part of a scholarly nurses' career.

K 01 - SPECIAL SESSION: From Cherry Ame's Nursing Dreams to Sigma Theta Tau International Hall of Fame

Jane M. Armer, PhD, RN, CLT, FAAN, USA

Abstract

"Before you can make a dream come true, you must first have one."

Ronald E. McNair, PhD, was a mission specialist on the 1986 *Challenger* space shuttle, and the first African-American astronaut for the United States' mission in space. His legacy was memorialized by establishment of the Ronald E. McNair Post-Baccalaureate Achievement Program and the McNair Scholars Program in 1986. This quote is the motto for the McNair Scholars Program.

This session focuses on the value of dreams in setting and achieving our goals. Dreams are the first steps in intrinsic motivation and setting goals, even when they may seem out of reach.

In this session, the life story of a successful nurse researcher will be shared. The narrative will begin with childhood perceptions and aspirations of becoming a nurse based on the images portrayed in the popular 1960s-era book series *Cherry Ames*. The story will continue through the educational journey (training and certification as a nurse's aide, a medication aide, a diploma nurse, a bachelor's prepared nurse, a clinical nurse specialist in gerontology, a PhD-prepared nurse faculty, a post-doctoral fellow, a specialist in lymphedema management, and an NIH fellow in genetics) to becoming a nurse clinician, educator, mentor, and researcher. Establishment of programs of research in community-based gerontology; multi-generational and multi-cultural health beliefs and behaviors and chronic disease; and breast cancer survivorship will be shared. Professional service includes membership on the Board of Directors of the Lymphology Association of North America, on the Medical Advisory Committee and editorial committee of the National Lymphedema Network, and as founding director of the American Lymphedema Framework Project which aims to increase awareness of lymphedema and improve care for persons with lymphedema in the US and around the world. Outcomes contributing to a research legacy will be summarized. Recognition of career accomplishments have come in the form of a three-time National Lymphedema Network 'Making a Difference Day' award; the International Lymphoedema Framework's Outstanding Contribution to Research award; induction as a Fellow of the American Academy of Nursing; being named 'Extraordinary Faculty' at University of Western Cape, Republic of South Africa; and now the 2017 Sigma Theta Tau International Nurse Researcher Hall of Fame. Opportunities, diversions, and decision points will be noted. Motivational strategies and accumulated wisdom will be summarized. Opportunities for questions and answers will conclude the session.

K 02 - SPECIAL SESSION: The Nurse Scientist in a Practice Organization

Diane L. Carroll, PhD, RN, FAAN, USA

Abstract

The advancement of nursing research outside of the academic environment continues to grow. In a practice organization, the demands of patient care often challenge the ability of the nurse to generate nursing knowledge. Strategies to promote a culture of inquiry, to support the implementation of research projects, and to disseminate the findings that impact patient outcomes are required. The organization that welcomes and rewards those who develop and implement a nursing research agenda have the support from the Chief Nurse and nursing leadership. And the presence of a nurse scientist demonstrates this commitment to advancing a nursing research agenda within this setting.

The nurse scientist advances a culture of clinical inquiry by focusing the nurse on their practice. Connecting research to clinical practice makes every nurse a potential investigator, and patients who receive research-based care have better outcome. Clinical triggers from the bedside can be constant reminders of opportunities for nurses to examine their practice. These triggers are gathered from the patient/family healthcare experience, current practices that improve illness management, quality and safety goals, and designing or implementing innovative technology to improve care. These triggers can create a nursing research agenda that develops nursing science.

Nurses are charged with using the research process to generate and disseminate new knowledge that may lead to innovations in nursing practice. Key to the development of nursing research in a practice organization is to reduce perceived barriers to undertaking a research project, development of the skills and confidence in the nurse, and passion to ask and answer the research question. The nurse scientist, in her/his unique role, can support research activities by educating and mentoring the nurse in the conduct of research.

The nurse scientist uses various strategies, as a part of a clinical research model, to capture clinical research questions, to evaluate the questions in relation to organizational priorities, assist in the identification of a research workgroup that can include members of the multidisciplinary healthcare team, and verify that the project has measurable patient outcomes. Acting as a mentor, the nurse scientist can create the spirit of inquiry, reduce system barriers, create capacity and guide the research workgroup through the process. The workgroup members must be willing to attend meetings, review the literature gathered by the librarians, write and edit the research proposal, participate in the implementation of the research project, and work on the final research report. This model is practice driven using a team approach, and utilizes a research mentor, the nurse scientist.

One example of a practice-driven research projects that used this model is the project: 'Improving Venous Thromboembolism Prophylaxis with mechanical modalities in a Surgical Intensive Care Unit'. Paula Restrepo, a staff nurse, was the principal investigator with a research librarian and a nurse scientist. This project was published in 2015 in *Journal of Nursing Care Quality*.

Venous thromboembolism (VTE) remains a significant source of morbidity and mortality in the surgical population. Surveillance for signs/symptoms of VTE is a part of nursing care. Non-invasive mechanical devices, graduated compression stockings (GCS) and intermittent pneumatic compression (IPC) devices, are widely used as the sole or adjunct method of VTE prophylaxis in the Surgical ICU (SICU). The success of the GCS and IPC devices relies on actual use and compliance with these mechanical devices. The purpose of this study is to measure the compliance rate of VTE prophylaxis with GCS and IPC devices pre/post the development of a VTE prophylaxis guideline in a SICU. This pre/post observational study used a VTE prophylaxis guideline development as the intervention. During each observation period (3 weeks), data were collected, twice a day, on the presence of a physician order for VTE prophylaxis mechanical devices, and correct application of these devices on all patients in SICU. Following the pre-observation period an intervention of a written guideline was completed and approved, and initial

implementation occurred. A follow-up post-observational period (3 weeks) occurred 3 months after guideline implementation. A compliance score was calculated by dividing the number of compliant evaluations by the total number of evaluations of mechanical device use. There were 610 pre and 602 post observations made during these 2 three-week periods. There were 95 pre and 92 post subjects, mean age 61.4- 60.9 years respectively, with a total of 123 males and 64 females. The majority (58%) were trauma/general surgical patients. Using observation data, the compliance rate pre was 80% and post was 78% of all mechanical device evaluations ($p > .79$). These results are comparable to other compliance studies. In the surgical patient, VTE prophylaxis is limited to mechanical devices, monitoring of compliance with VTE mechanical devices is essential.

With a comprehensive review of the literature completed as a part of this project and the SICU guideline, the investigators discussed results with the interdisciplinary surgical quality team. They supported a change in practice that the IPC device is the mechanical device of choice. With this decision, the GCS were removed from the surgical order template and there was a cost saving of about \$45 000 per year on reductions in GCS use. With support from the American Academy of Nursing's Expert Acute and Critical Care Panel, a Choosing Widely campaign was initiated to share the knowledge of IPC devices as the mechanical method of choice. Nurses play an important role in risk assessment, application of correctly sized IPC devices, and evaluation of signs and symptoms of VTE. They also can impact practice to provide safe quality patient care.

Nurses are an integral component to the advancement of patient care, the enhancement of the practice environment, and the culture of care. The role of the nurse scientist is to explore and engage nurses in the pursuit of knowledge through inquiry. Knowledge-based care is safe, efficient, and promotes high quality patient outcomes that can be leveraged to improve the health care delivery system globally.

K 03 - SPECIAL SESSION: The International Nurse Researcher Hall of Fame: One Nurse's Journey

Trisha Lynette Dunning, PhD, MEd, AM, RN, CDE, ACN-DLF, Australia

Abstract

The aim of my presentation is to outline my journey from trainee nurse to induction into the STTI International Researcher Hall of Fame.

I will share my journey through pictures and story vignettes that exemplify my key transitions and learnings as I developed into a nurse researcher and that led me to the honour of being inducted into the STTI Researcher Hall of Fame. I will trace my journey from trainee nurse in an Australian country hospital to one of the top 40 Universities in the world.

I will share some significant outputs and impacts from my research. My philosophy of nursing and research will emerge from the story. I will share some of the things I learned such the difficulty separating the academic researcher and clinician from the person: they enhance and balance each other. Research is a collaborative endeavor: there are strength in partnerships that enhance individual contributions. The research field is very competitive. It values 'track.' Researchers must learn how to market themselves and their research. They must be creative and recognise and make opportunities, which often means selecting 'the path less travelled', which can make all the difference to a research career. At least it did for me.

Along the way I learned that:

- All types of research are valuable..
- It is important for nurses to engage in research at the level of their knowledge and competence research.
- It is important to seek, recognise and make opportunities for research activities.
- It is useful to be able to 'think outside the square.'
- Researchers must encourage, support and acknowledge the contribution of relevant others.
- Researchers have an obligation to inform research participants, colleagues, service providers and others about their research findings and how they could apply them.
- It is vital to care for oneself throughout the research journey.

K 04 - SPECIAL SESSION: Getting the Most Out of Existing Data Sources for Nursing Research Questions

Veronica D. Feeg, PhD, RN, FAAN, USA

Abstract

Some researchers' program of study follows a single line of inquiry that delves deeper and deeper, peeling back the layers to get at underlying phenomena. Other researchers take a more circuitous route, using the research process and analytics, combined with opportunity, to answer questions that arise from a more practical than theoretical origin. This special session will provide a summary of the winding road that this researcher's career has taken in the evolution of a body of work that spans three seemingly disparate paths: (1) the information technology revolution that provided a vehicle for process and products of research; (2) the clinical pediatrics and decision-making areas of inquiry that incorporated technological strategies to answer questions; and (3) the methodologic and analytical skill sets that developed along the way and prompted organizations to fund requests for technical assistance and secondary analysis of existing data.

In this session, participants will be taken on a journey from the early days of electronic health records and personal computers to the presenter's recent research efforts that have incorporated technology and methods. In the middle of these two bookends, the presenter focused her professional work on children with special health needs – including children facing life-limiting illnesses – and served as editor of a pediatric clinical journal. Over 25 years, child health, illness, and palliative care were frequent editorials among a variety of policy focused research and papers. These publications helped to foster international collaborators with shared interests and clinical areas of inquiry in child and family centered care. Several important results from this role derived from her work on the scientific advisory board of Children's Hospice International, and several studies – including the earliest versions of “standards of pediatric palliative care” – were the products of collaborative research.

At the same time, her early research on computer use and building clinical trials around a personal computer version of an electronic nursing documentation system, were part of this researcher's informatics trajectory before electronic health records (EHRs) were commonplace. Several funded pilot studies resulted in the development of computerized support of decision-making (used in clinical areas of inquiry) and educational studies that prepared students to work in an electronic world. Advanced mathematical modeling for decision-support using the Analytical Hierarchy Process (AHP) was tested and published in *Nursing Research*.

Over the same years, the opportunities to mentor dozens of PhD doctoral students were central to this presenter's research productivity. With well-developed methodology and analytical skills, her research path included additional directions to explore secondary analysis of large data sets leading to several important publications that have informed nursing educators. Simultaneously, these opportunities were cultivated numerous entry-points for doctoral students to be mentored in these research techniques toward their own dissertation successes. In recent years, several articles have been published on nursing workforce issues and student loan debt.

Today, with over 30 active students in the PhD program and over 25 successfully mentored dissertations, this presenter will describe a research career that wandered on three disparate trails connected with numerous intersecting points where opportunity and access to data sources paved the way for research. In the informatics world, pediatrics world, and nursing education, this presenter has had the good fortune to be able to collaborate internationally, to leverage technology and to foster opportunities that contributed toward a successful academic research career.

K 05 - SPECIAL SESSION: Lymphedema Symptom Science: Precision Phenotyping, Genotyping, and Intervention

Mei R. Fu, PhD, RN, FAAN, USA

Abstract

The purpose of the presentation is to share the experience of establishing a program of research on lymphedema symptom science.

Each year, 1.38 million women worldwide are diagnosed with breast cancer and more than 40% of the women suffer lymphedema, a chronic condition of more than 20 distressful symptoms and currently no surgical or medical approach can provide a cure. Starting with qualitative inquiry to understand patients' daily symptom experience and self-care of lymphedema and symptoms, the researcher has developed and tested instruments to effectively assess symptoms, pushing the boundaries of using cutting-edge technology for quantifying lymphedema, accomplished much-needed prospective investigation to discover the biological pathway of lymphedema symptomology using genomic and biomarker approach, and let prospective randomized intervention trails to test interactive and personalized interventions which are technology-driven and cost-effective. From her early career of scientific inquiry, the researcher has purposefully built her program of research in two synergetic lines of inquiry: (1) lymphedema symptom science to discover the biological pathways and significant relationships between symptoms and objective measures of lymphedema; and (2) technology-driven intervention to develop pragmatic symptom assessment and self-care mHealth (mobile health) intervention to reduce the risk of lymphedema and optimize lymphedema management through symptom assessment and management.

This presentation focuses on the methods for precision phenotyping and investigation of biological mechanisms of symptoms to develop an innovative and pragmatic assessment and precision interventions for lymphedema. Discussions will be focused on definition and process of precision phenotyping for lymphedema, including limb volume measurement, level of fluid level and symptoms. Descriptions of research methods will be discussed to explore to the relationships between lymphedema symptoms and limb volume and fluid level as well as genomic research to discover the biological underpinning of symptoms related lymphedema. Finally, discussions will be on the process of developing pragmatic patient-center risk assessment and intervention based on phenotyping characteristics and biological mechanism of symptoms for risk reduction and symptoms symptom management.

K 06 - SPECIAL SESSION: Using the Decisional Involvement Scale (DIS) to Gauge Staff Nurse Unit Decisional Involvement

Donna S. Havens, PhD, RN, FAAN, USA

Abstract

Introduction- It has long been recognized that involving the front line workforce in decisions about the work that they are performing is associated with positive outcomes. This is particularly true of professionals working in organizations such as professional nurses delivering care to patients. Staff nurse decisional involvement -- defined as the pattern of distribution of authority for decisions and activities that govern nursing practice policy and the practice environment. For decades, enhancing staff nurse decisional involvement in matters of nursing practice and patient care has been identified as a long-term strategy to improve the quality of the nursing practice environment and the safety and quality of patient care (Begun, 1985; Heydebrand, 1983; Scott, 1982, Aydelotte, 1981, 1983; Maas & Jacox, 1977; and McClure, Poulin, Sovie, & Wandelt, 1983). Central to any initiative to enhance nurse involvement in decision making is the ability to measure staff nurse decisional involvement. Thus, the Decisional Involvement Scale (DIS) was developed for this purpose (Havens, 1990; Havens & Vasey, 2003, 2005). The purpose of this study was to describe staff nurse reports of actual and desired decisional involvement, decisional dissonance and dissonance between staff nurse and unit manager perceptions of staff involvement.

Methods – IRB approval was granted for the parent study – a five year project focused on improving the nursing practice environment. A secondary analysis was conducted for the study reported here to explore staff nurse reports of actual and desired decisional involvement at the unit level. The DIS (Havens, 1990; Havens & Vasey 2003, 2005) was used to measure staff nurse reports of actual and preferred decisional involvement and decisional dissonance (the gap between actual and desired). The DIS is a 21 item psychometrically valid and reliable scale developed from the sociology literature on professionals working in organizations and the literature on professional nursing practice (Havens, 1990). The DIS consists of six empirically derived subscales: decisions about unit staffing, quality of professional practice, governance and leadership, quality of support staff, and collaboration/liaison activities (Havens & Vasey, 2005). Response choices are as follows: administration/management only = 1; primarily administration/management with some staff nurse input = 2; equally shared by administration/ management and staff nurses = 3; primarily staff nurses with some administration/management input = 4; and staff nurses only = 5. Results can be considered by individual items, by subscale, or as an overall scale. The sample consisted of 1,066 clinical staff nurses working in six acute care community hospitals in Pennsylvania in the U.S. For the most part, sample demographics matched those of the state and the U.S. The DIS was administered to staff RNs as part of an anonymous questionnaire that participants completed and deposited into a sealed box on their work unit. Questionnaires were sent to the study coordinator in the sealed envelopes and then were then scanned into a data base. Descriptive statistics were used to evaluate staff nurse reports of actual and desired levels of involvement in unit decision making, the dissonance between staff nurses and their unit managers perceptions as well as to identify staff nurse decisional dissonance – decisional involvement either above or below the actual or desired level.

Findings- Overall, staff RNs reported that they were not at the point where they were sharing decision making with unit managers, they perceived that in general most decisions were made entirely by managers or in a few cases, with some staff nurse input. They reported that they preferred to share decision making with managers for five of the six subscales and in no area, did staff report wanting to be entirely responsible for decision making with no manager input. Decisional dissonance was reported as well as dissonance between perceptions of staff nurses and managers on the same unit.

Implications -- Enhanced staff nurse decisional involvement may not be a simple case of “one size fits all”, because control may not be equally desired by all staff nurses. Decisional dissonance is an important decisional state that must be considered in efforts to improve the nursing practice environment. Assessing nurse perceptions of actual and desired levels of decisional involvement as well as nurse

manager perceptions may provide rich opportunities for “important” unit conversations about the work environment and shared governance.

K 07 - SPECIAL SESSION: The Tale of Two Tengu: A Program of Research in a Child's World

Christine Kennedy, PhD, RN, PPCNP-BC, FAAN, USA

Abstract

Highlights from a career program of research focused on the influence of illness, media and culture on children's health will be shared. From children's TV habits and behavior in working class neighborhoods to influencing health policy engagement this brief précis will demonstrate the tenet that 'research is all about relationships.' Using an analogy from the retelling of a Japanese folktale - concepts such as serving two masters, undefined expectations and how cooperation can underpin a research career path will be shared.

Dr. Kennedy's research has spanned the globe; with a particular focus on Pacific Rim countries and populations whose historical presence in California is critical to appreciate in primary care. Her research team is currently funded to study various aspects of health literacy and its role in clinical care and outcomes to reduce health disparities among underserved populations. Her research broadly addresses the impact of daily life activities on children's development, specifically on the behavioral underpinnings to health in early childhood (3-8 years of age).

Collaborative work with colleagues in pediatric oncology with an emphasis on symptom science has been a secondary line of enquiry. Her work over the past twenty-five years has built on relationships with colleagues and students around the world. Findings from early work on risk taking and injuries lead to examining how media, especially how television was influential in young children's perception of the "real world" and was grounded in her dual role in clinical practice as a PNP and graduate academic teaching in pediatric behavior and development. Interventions to change sedentary behaviors and increase healthy lifestyles in families use of mobile phone visual pictorial apps to facilitate physical activity in low health literacy populations and other relevant findings from this body of work will be reviewed.

Research for knowledge generation alone is at times insufficient and translation of evidence to practice with a measurable impact on policy can bring nursing science full circle. Policy activity has had a direct relationship to this program of research. Examples from legislation in the late 1990's from tobacco product taxes and the eventual Universal health care program for children in California; and more recently with Dr. Malpass and her examination of aspects of the Affordable Care Act and the needs of special health care children will be shared to illustrate this perspective.

K 08 - SPECIAL SESSION: A Program of Research: Cancer Symptom Management

Susan C. McMillan, PhD, MS, ARNP, FAAN, USA

Abstract

The purpose of this presentation is to describe the program of cancer symptom research conducted over a 30 year academic career and how that research fit into teaching and service efforts of this oncology nursing faculty member. Dr. Susan McMillan from the University of South Florida in Tampa, Florida, begins by describing her early unfunded exploratory and descriptive studies conducted at the beginning of her research career, as she served on committees and boards in local cancer centers, general hospitals, veterans administration hospitals and hospices, and founded and implemented the only oncology nurse practitioner program in the state of Florida. She will then demonstrate how this program of research built to include large funded clinical trials that brought in more than \$12 million dollars in research funding to her university. Her research has been funded by the American Cancer Society, the U.S. Veterans Administration, the National Cancer Institute, the National Institute for Nursing Research, and the Patient Centered Outcomes Research Institute. She has studied pain and side effects in patients in surgical units, intensive care units, cancer center in-patient units, and several local hospices. Results of her early descriptive studies changed practice outcomes in some local settings where cancer patients receive care.

Results generally reveal that 1). pain is poorly assessed and poorly managed with nurses giving patients a fraction of what is ordered for pain each day while they report significant pain; 2). hospice family caregivers are able to give more effective care resulting in better outcomes for both hospice patients with cancer and the caregivers themselves when they are taught a systematic approach to symptom management such as COPE; 3). Nurses do not know enough about pain management and have attitudes that interfere with their success in pain management for persons with cancer; 4). Opioid-induced constipation is under-recognized and under treated in persons with cancer; 5). COPE as a symptom management approach is more effectively taught to family caregivers than to the patients themselves. Research in these important areas needs to continue.

K 09 - SPECIAL SESSION: Nurse-Initiated Protocols Save Lives: The QASC Trial

Sandy Middleton, PhD, RN, Australia

Abstract

The Quality in Acute Stroke Care (QASC) Trial was a cluster randomised controlled trial conducted in 19 stroke units in New South Wales (NSW), Australia's most populous state and involved 1696 patients. We used proven implementation strategies consisting of: examination of barriers and enablers, provision of education; reminders and clinical champion support to introduce three nurse-initiated clinical protocols to manage fever, hyperglycaemia and swallowing following acute stroke. Results demonstrated decreased death and dependency by 16% ($p=0.002$); reduced temperatures ($p=0.001$); reduce glucose levels ($p=0.02$); and improved swallowing management ($p<0.001$).¹

A subsequent follow-up study was conducted to determine long-term all-cause mortality. Data were obtained from the National Death Index. Cox proportional hazards regression was conducted. Median time for follow-up was 4.1 years (minimum 0.3- maximum 70 months). Of the 1076 participants, 264 (24.5%) died during study follow-up (intervention $n = 134$ (22.3%); control $n = 130$ (27.3%)). After adjusting for age, sex, marital status, education, stroke severity and correlation within stroke units, patients cared for in intervention stroke units had improved long-term survival (>20%) (adjusted HR:0.77, 95% CI 0.59-0.99, $p=0.045$).²

We then conducted a large-scale, 12-month translational study promoting upscale and spread of this proven intervention into all 36 NSW stroke services. Collaborations with government agencies, academics, clinicians and the Stroke Foundation were formed. We mirrored the QASC trial implementation process. Medical record audits measured protocol adherence using a pre-test/ post-test study design. All 36 NSW (100%) stroke services participated with 2144 patients (pre-implementation: $n=1062$; post-implementation: $n=1082$). Significantly increased proportions of patients received care according to the fever (pre: 69%; post: 78%; $P=0.003$), hyperglycaemia (pre: 23%; post: 34%; $P=0.0085$), and swallowing (pre: 42%; post: 51%; $P=0.033$) protocols post intervention.³

We showcase three inter-related studies that provide evidence for: i) the effectiveness of nurse-initiated care protocols for management of fever, hyperglycaemia, and swallowing dysfunction post-stroke in reducing death and dependency; ii) the potential long-term and sustained benefit of these protocols; iii) state-wide translation of evidence into routine clinical practice on a limited budget, in a short timeframe with applicability beyond acute stroke care. These protocols should be a routine part of acute stroke care internationally and now are being implemented in up to 300 stroke units across Europe as part of a continent-wide translational project.

K 10 - SPECIAL SESSION: Physical Restraint and Falls in Older Hospitalized Adults: Where Do We Go From Here?

Lorraine Mion, PhD, RN, FAAN, USA

Abstract

Since the 1980s, physical restraint practices and hospital falls have been major care issues in hospitalized older adults in the United States and the two have remained inexorably linked. Despite over two decades of research and legal and economic sanctions against hospital falls, fall rates have remained basically unchanged. Similarly, national accrediting organizations and federal regulations have placed restrictions on physical restraint practices. Unlike fall rates that have remained relatively unchanged, rates of physical restraint use have decreased on general adult units but remain a common practice in the intensive care units.

A number of qualitative and quantitative studies have been conducted to examine factors predictive of physical restraint or hospital falls. One major organizational variable has been staffing levels and staffing mix. The National Quality Forum has designated both physical restraint and hospital falls as a nurse-sensitive indicator. However, the number and skill mix of nursing personnel have remained inconclusive for either indicator. Similarly, numerous guidelines exist that purport to reduce fall rates. Yet few clinical trials exist demonstrate the evidence of these 'evidence based' guidelines. The mounting pressure from external forces, such as the Centers for Medicare and Medicaid, as well as internal forces of administration and leadership, have influenced nurses' practices to revert. Evidence is emerging that nurses' fear of reprisals have led to enhancing bedrest and immobility at the very least, and increasing physical restraint use at the very worst.

There are a number of gaps related to fall prevention strategies. For example, patient education and patient reminders are universal strategies for hospital fall prevention. However, few studies have addressed this in the acute hospital setting. There is a dearth of knowledge on the most effective ways to provide education and reminders to patients, and to do so in a cost-effective manner. Similarly, 'leadership support' is also promoted in most fall prevention guidelines. There is a dearth of knowledge on the level of leadership needed, the intensity or frequency of leadership involvement, and what does staff consider as supportive versus repressive. The next generation research is needed to elucidating the best strategies targeted to amenable variables at the levels of the organization, the nursing staff and the patient.

K 11 - SPECIAL SESSION: Self-Management of Insomnia Among Patients With Stable Heart Failure: Evolution of a Research Program

Nancy S. Redeker, PhD, MSN, RN, FAHA, FAAN, USA

Abstract

Chronic heart failure (HF) afflicts as many as 26 million people world-wide and is associated with high levels of morbidity, mortality, poor quality of life, decrements in functional performance, and excessive health care costs. Sleep disturbance is common among people with HF occurs in as many as 75%, and there is increasing evidence that it contributes to important HF outcomes. The purpose of this presentation is to describe the evolution of a program of research focused on improving this problem and developing and testing an efficacious self-management intervention focused on improving sleep disturbance and sleep-related outcomes among this vulnerable population.

We conducted a series of funded studies focused on characterizing the nature of sleep and sleep disturbance among HF patients; understanding correlates and consequences of sleep and sleep disturbance; and designing and testing a self-management intervention for sleep disturbance among patients with stable HF. This ongoing program contribute to significant advances in knowledge regarding this important problem. Following is a summary of key findings:

- 75% of patients with stable HF reported sleep disturbance.
- Actigraphic and self-report indicators of sleep indicated more sleep disturbance among HF patients than a group of matched healthy controls.
- Half of HF patients reported insomnia symptoms that were not explained by sleep disordered breathing, another common and prevalent sleep disorder in these patients.
- Insomnia, but not sleep disordered breathing, was associated with fatigue, daytime sleepiness, depressive symptoms, and both self-reported and objectively measured functional performance (Six Minute Walk Test).
- The association between insomnia and fatigue was higher in younger patients, in contrast to older adults.
- Daytime symptoms, including fatigue, depression, and excessive daytime sleepiness mediated the relationship between insomnia and functional performance.
- Participants in a qualitative study indicated that insomnia was important to them and rarely addressed by health care providers, and they disliked taking hypnotic medications.
- Our pilot randomized clinical trial of a self-management intervention (cognitive behavioral therapy for insomnia - CBTI) was feasible, acceptable, and had large effects on insomnia and fatigue, compared with an attention control condition that included HF self-management education. There were trends that suggested that the patients who received CBTI were less likely to be rehospitalized.
- We are now conducting a randomized clinical trial to evaluate the sustained effects of CBTI on sleep; sleep-related symptoms and symptom clusters; functional performance; and health care resource utilization. We are also exploring the effects of CBTI on event-free survival.

Based on our research to date, it is evident that sleep disturbance, including insomnia symptoms is an important problem for HF patients. Self-management focused on insomnia has high potential to improve significant outcomes, including symptoms, function, and health care resource utilization, for this large and growing group of HF patients.

K 12 - SPECIAL SESSION: Research Passages in Cancer Symptom Management and Lymphedema

Sheila Hedden Ridner, PhD, RN, FAAN, USA

Abstract

Dr. Ridner began her research career in 2006. She quickly became recognized internationally as nurse scientist because of her expertise in cancer symptom management, and more specifically, her research related to lymphedema. Dr. Ridner's research has included clinical descriptive studies that established the first known lymphedema symptom cluster and identified social marginalization of patients with lymphedema as a significant problem. Her longitudinal descriptive study of patients with head and neck cancer found a high rate of lymphedema in survivors of head and neck cancer (about 90%), bringing this previously unknown problem to the forefront. She has been a team member on two studies that addressed economic issues related to lymphedema that established: 1) increased cost to patients and the healthcare system when breast cancer patients develop lymphedema subsequent to their cancer treatment; and, 2) the health and economic benefit of using pneumatic compression pumps as a component of lymphedema self-care.

Dr. Ridner has been actively involved in the development of both self-report and physiological patient assessment tools for use in the cancer and lymphedema populations. With a team of Vanderbilt scientists, Dr. Ridner assisted in the development and testing of the Vanderbilt Head and Neck Symptom Survey (VHNSS) Versions 1 and 2, and in the initial testing of a self-report symptom assessment tool for patients with recurrent cancer of the head and neck. The VHNSS is the most used symptom assessment tool for patients with head and neck cancer in the USA. She is leading the development and testing of a battery of self-report symptom assessment tools for patients with lymphedema. The Lymphedema Symptom Intensity and Distress Survey-Arm has been published and leg, truncal, and head and neck tools are in final testing. The LSIDS-A has been translated to Turkish and is being used in international clinical and research settings in both English speaking (Australia) and non-English speaking (Turkey) countries. Her physiological measurement studies served as some of the foundational work that lead to the development of recommendations for lymphedema measurement standards for Accredited Breast Centers in the United States. Another of her studies established that breast cancer survivors with lymphedema can and will use bioelectrical impedance to self-monitor their arm swelling and that such use improves self-care. In Sept. 2016 Dr. Ridner's team successfully conducted the first human factors study for a new lymphedema self-measurement bioelectrical impedance device.

Interventional studies have also been a focus of Dr. Ridner's program of research.

One study demonstrated the effectiveness of advanced pneumatic compression devices on arm and truncal swelling; another demonstrated the effectiveness of low-level lasers on arm swelling and skin condition in breast cancer survivors with lymphedema. A third found that tailored Yoga improved the symptom burden of head and neck cancer survivors, while a fourth study found that a web-based multi-media intervention improved mood in breast cancer survivors with chronic lymphedema.

Currently, Dr. Ridner is the PI for a large, international, multi-site lymphedema prevention study. The study will enroll over 1,000 patients world-wide, approximately 800 have been enrolled to-date.

Dr. Ridner's work has been impactful. One area of major impact to science has been in developing assessment and measurement tools that filled gaps for both patient self-report instruments and physiological monitoring of lymphedema. This improves the quality of patient assessment in clinical environments and adds value to the clinical service provided. A second area of impact has been in conducting and disseminating information from studies regarding the psychosocial and physical impact of cancer related lymphedema on patients. These studies provided information regarding previously unidentified and poorly understood symptoms experienced by patients with cancer and cancer survivors. Dr. Ridner has been sought out by industry to assist in the development and testing of medical devices that will affect not only cancer patients and those with lymphedema, but also obese patients and those

with congestive heart failure. This demonstrates that nurses can assume leadership in non-traditional research environments.

Dr. Ridner's program of research will leave a lasting legacy for nursing science, as she has mentored multiple new nurse scientists to successful independent careers and is currently an active mentor to multiple other future nurse scientists.

K 13 - SPECIAL SESSION: Improving Health and Wellness for Persons With Chronic and Disabling Conditions: Evidence for Practice

Alexa Stuijbergen, PhD, RN, FAAN, USA

Abstract

Purpose: One of the most significant and intriguing questions for both researchers and clinicians interested in developing interventions to prevent disability and promote quality of life among persons with chronic conditions is: What factors (other than biological impairment and disease process) influence the development of functional limitations and explain the progression of functional limitations to disability? For more than 25 years we have explored this question with persons experiencing a variety of chronic disabling conditions through descriptive and intervention research using both qualitative and quantitative methods. The extensive data underlying this program of research comes from persons with a variety of disabilities and diagnoses including those with multiple sclerosis (MS), post-polio syndrome, fibromyalgia, diabetes, mobility impairments, HIV and cancer survivors.

Methods: Initially we explored whether persons with chronic and disabling conditions considered the philosophical perspective of health promotion as relevant to their lives. Descriptive and longitudinal data were used to design and test wellness interventions with persons with a variety of chronic disabling conditions.

Results: Our early work revealed that these individuals had strong interest in this perspective and that they were challenged by a lack of information about how to practice health promotion within the context of their specific condition. The majority of participants viewed their health as good or excellent despite the fact that they were living with an often serious and limiting chronic condition or disability (Stuijbergen, Becker, Inglasbe & Sands, 1990). Participants had strong interest in improving the skills and knowledge needed to improve health behaviors and address barriers. They identified the positive impact of health behaviors as enhancing their overall well-being, managing difficult symptoms (e.g. fatigue, weakness), and enhancing the social connectedness in their lives (Stuijbergen & Rogers, 1997). A large descriptive study with more than 800 persons with MS as exemplars of those with chronic conditions was used to develop and test a model of health promotion and quality of life for persons with chronic disabling conditions. Findings indicated that health promoting behaviors mediated the impact of functional limitations on quality of life (Stuijbergen, Seraphine & Roberts, 2000). The model was subsequently cross-validated in a sample of 1,600 persons with post-polio syndrome (Stuijbergen, Seraphine, Harrison, & Adachi, 2005).

The initial large descriptive study with persons with MS continued as a longitudinal study, *"Health Promotion and Quality of Life in Chronic Illness"* and is now in its 21st year of data collection. The data from this study allow detailed exploration of how selected self-directed psychosocial and behavioral factors may influence the trajectory of functional limitations, disability, and quality of life in persons with MS. Most recently we have documented that the practice of health behaviors – specifically exercise – over an eleven-year period improves the trajectory of functional limitations for those with MS (Stuijbergen, Blozis, Becker, Harrison & Kullberg, 2016).

Building on the findings from descriptive and longitudinal research, our team developed a theoretically and empirically-based lifestyle intervention for women with MS (Stuijbergen, Becker, Rogers, Timmerman & Kullberg, 1999). In a randomized-controlled trial, the women in the intervention group had significant improvements in self-efficacy for health behaviors, the frequency of health behaviors and mental health and pain scores compared to those in the control group (Stuijbergen, Becker, Blozis, Timmerman & Kullberg, 2003). Next, the team developed a process for adapting interventions for persons with other chronic conditions (Stuijbergen, Harrison, Becker & Carter, 2004) and the lifestyle based intervention was subsequently adapted and tested for persons with fibromyalgia syndrome, cancer survivors, women with HIV, men with MS, and cancer survivors with functional limitations (Becker, Henneghan, Volker & Mikan, 2017; Meraviglia, Stuijbergen, Parsons, & Morgan, 2013; Stuijbergen et al, 2010).

Conclusion: Low cost health promotion interventions may hold substantial promise as a complementary strategy for decreasing the burden of functional limitations among persons with chronic disabling conditions. Persons with chronic conditions generally have positive perceptions of their health and a strong interest in health promotion activities. An emerging body of evidence supports the positive impact of health promotion/wellness interventions on quality of life outcomes for persons with chronic disabling conditions (Stuifbergen, Morris, Jung, Pierini, & Morgan, 2010).

K 14 - SPECIAL SESSION: The Evolving World of Qualitative Methodology as a Tool for Nursing Knowledge Development

Sally Thorne, PhD, RN, FAAN, FCAHS, Canada

Abstract

Since the early 1980s, when nurses began to take up the qualitative research methods of the social sciences as a way of engaging with certain forms of knowledge relevant to their practice knowledge development, there has been considerable tension between those who advocate conventional as opposed to the more applied forms of qualitative inquiry (Thorne, 2014b). Over time, the qualitative methodology conversation has become increasingly intertwined with the more philosophical debates within nursing thought, including the relationship between knowledge of the general and that which pertains to the particular, the standardizing forces of an evidence-based care agenda, the nature of nursing's distinctive epistemological position on matters of health and health care, and the moral implications of a social justice mandate (Thorne, 2014a, 2016b; Thorne & Sawatzky, 2014). Nurses have long wrestled with how to appease the extant methodological rules structures while simultaneously producing knowledge forms that have demonstrable relevance for the work of the discipline. And over recent decades, the communities of scholars oriented toward formal theorizing (such as conventional social science) and application (including nursing and the applied practice disciplines) are becoming increasingly differentiated (Thorne, 2016a).

It is exhilarating to stand witness to an era in which we are reaping the benefits of nursing's longstanding passion for philosophizing about the discipline as it is now being played out in the arena of applied qualitative methods development. Increasingly, we have access to new qualitative research design options that offer the "look and feel" of a legitimate nursing inquiry process rather than merely conforming to a set of rules and conventions developed for the purposes of other disciplinary knowledge projects. These newer applied approaches allow us to integrate our disciplinary intelligence and insight into the kinds of research questions we generate, guide us to determine study samples and data construction approaches that reflect the nature and diversity of the phenomena we wish to study, allow for critical, cross comparative, and deep interpretive analysis at a level reflective of a solid grounding in the body of knowledge available to the discipline, and steer us toward articulating findings of a nature that can "speak" to the intended audience with disciplinary relevance and epistemological authority (Thorne, Stephens & Truant, 2016). In keeping with the nursing discipline's deep commitment to knowledge that is "of use" to the profession, knowledge translation is therefore integrated into study design from the outset, such that the user community becomes an inherent stakeholder in the interpretive engagement of ideas throughout the entire process.

Qualitative research designed to align with the logic of the nursing discipline lends itself to a wide range of study forms, from the largescale formal inquiries that can enter such dimensions as patient perspective and human subjectivity into the evidence dialogue within a field to the smaller practice based kinds of studies in which teams of nurses build sensitivity, understanding and insight around the complexities of the clinical phenomena they encounter. As we continue to build our disciplinary sophistication around how we can know good qualitative research when we see it, and gain confidence in designing the kinds of qualitative studies that will be best suited to answering the questions our profession most urgently needs to ask, we are increasingly well positioned to play a leadership role in the evolving evidence-based practice discourse, thereby ensuring that patient voices and the capacity to individualize care remain -- long into the future -- a hallmark of what our nursing profession stands for.

K 15 - SPECIAL SESSION: The Postpartum Transition: A Critical Life Course Juncture for Women's Behavioral and Psychosocial Health

Lorraine O. Walker, EdD, MPH, RN, USA

Abstract

The session describes a program of research related to psychosocial and behavioral health among women during the year after giving birth. In summary, the postpartum period is often seen as a brief stage of transient importance in the life course. This session will present a re-vision of the postpartum period as one of consequence for both maternal and infant health and well-being. Often care after childbirth involves a brief hospitalization and then, in the United States, it may involve no more than one or two health care visits up to 6 weeks postpartum. Development of the maternal role and breastfeeding are central concerns during this period in order to promote the health and development of the infant. The shift of the health care focus from the mother during pregnancy to the infant after birth often overshadows domains of maternal health that are of importance to immediate and long term health of women. Many of these areas also have implications for infant growth, development, and health. Of these domains, postpartum depressive mood has recently been given widespread attention, with some recent recommendations supporting universal screening of new mothers as well as pregnant women, for depression. However, other areas of psychosocial and behavioral health that have been well documented in studies of postpartum women include: body image dissatisfaction, shifts to less healthy diet after pregnancy, sedentary lifestyle, smoking relapse, and immoderate alcohol use. Despite these potential adverse changes after pregnancy, multiple studies indicate that only about 1 in 2 women report depression was discussed in any of their postpartum healthcare; 1 in 3 indicate physical activity or alcohol use discussed; and only 1 in 4 report smoking or diet discussed. Depression, or high depressive symptoms that do not rise to the level for a diagnosis of depression, may have an impact on maternal quality of life and their care of infants, and consequently an impact on the development of infants and young children. Body image dissatisfaction is of import not only for maternal well-being, but also because it is associated with increased postpartum smoking and depression among mothers. Unhealthy behaviors related to tobacco and alcohol use, as well as diet and physical activity, have been shown to provide an unhealthy context for infant health and development and, of course, also immediate and long-term maternal health. For example, smoking, high alcohol use, unhealthy diet and sedentary lifestyle are each related to development of chronic diseases, such as ischemic heart disease as well as certain cancers. Examples of strategies to increase attention to maternal psychosocial and behavioral health will be presented. Nurses are in an ideal position to foster such strategies because of their expertise in health education, community resources for health, and health communication.

K 16 - SPECIAL SESSION: Feeding and Dementia: Bridging the Gap

Roger Watson, PhD, BSc, RN, FRCN, FEANS, FFMRCSE, FAAN, United Kingdom

Abstract

In the commonest forms of dementia, especially Alzheimer's disease, there is a decline across the whole spectrum of activities of daily living and this includes the ability to self-feed. Patients inevitably lose weight, with the sequelae that involves and relatives and carers find the situation very distressing. Assistance is required by caring staff but there is little research to guide practice and to indicate what best practice is in this area. In addition, the area is fraught with ethical and legal issues. The missing link between the problem and interventions is assessment and the Edinburgh Feeding Evaluation in Dementia (EdFED) scale remains the only validated instrument internationally (Alzheimer's Disease International 2014).

The EdFED was developed by the author following clinical practice where the number of older people with dementia was rising and the problems associated with helping older people with dementia to feed were a major aspect of nurses' work. The scale was developed based on the best literature available in the early 1990s and the pattern of feeding difficulty was demonstrated to be cumulative using Guttman scaling. Later, a form of item response theory: Mokken scaling, was applied and the cumulative pattern was demonstrated again (Watson 1996) and - with only minor changes in item order - has been shown to be replicable across several studies.

The psychometric properties of the EdFED scale have been shown to be robust and its use has extended from assessment to measurement of change in the first rigorously conducted randomised controlled trials into an intervention aimed at alleviating feeding difficulty in older people with dementia. These interventions are based on Montessori and Spaced Retrieval techniques (Lin et al 2010) and rely on the fact that procedural memory remains intact in dementia. The interventions are successful at alleviating feeding difficulty in dementia in mild to moderate dementia as shown by a declining score on the EdFED scale. Other aspects of feeding difficulty in dementia such as nutritional status, however, have not been demonstrated to improve within the timescale of these trials. Work is currently underway to develop a short intervention based on Spaced Retrieval techniques.

K 17 - SPECIAL SESSION: Can't Sleep at Night, Can't Function During the Day: Effect of Sleepiness on Daily Behaviors

Terri E. Weaver, PhD, RN, FAAN, USA

Abstract

Over 70 million individuals suffer from sleep problems. This session will share a program of research that explored the impact of these problems, centered on excessive daytime sleepiness, on daily behaviors and neurocognitive functioning. The development of a measure to assess the impact of daytime sleepiness on functional outcomes, the Functional Outcomes of Sleep Questionnaire, enabled the description of the impact of sleep disorders and the efficacy of treatment. Using this measure, it was determined that the affect is pervasive influencing general productivity, social interactions, activity, vigilance, and intimate and sexual relationships. The most common sleep disorder is obstructive sleep apnea (OSA) where the primary treatment is continuous positive airway pressure (CPAP). Twenty-eight percent of women and 26% of men suffer from obstructive sleep apnea. Untreated sleep apnea has been linked to diabetes, hypertension, cardiovascular disease, stroke, cancer and premature death, as well as impaired work performance and increased risk of work and driving-related accidents. CPAP had been previously established as the standard of care for severe obstructive sleep apnea, but because there was no such standard for milder cases, its application in this population was questionable. The first and largest controlled clinical trial in those with milder OSA (CATNAP study) demonstrated that CPAP treatment produced positive outcomes with improved quality of life, enhanced mood, better neurobehavioral functioning, and decreased daytime diastolic blood pressure. This program of research revealed the pattern of adherence to CPAP treatment. It was determined that the pattern was bimodal with half of patients treated with CPAP adherent using the device at least 6 hours per night and the other was not adherent using it on average three hours per night and skipping nights of treatment. This pattern of adherence is established early on in the first week of treatment. There are differences in self-efficacy between those who are and are not adherent as measured by the Sleep Apnea Self Efficacy Measure. This program of research documented a linear relationship between nightly CPAP use decreased objective and subjectively measured daytime sleepiness as well as improved functioning. This work established the nightly dose of CPAP to achieve optimal outcomes. However, the magnitude of the change was dependent on which concept was measured suggesting that recommendations for level of adherence are dependent on the goal, i.e., improved symptom of daytime sleepiness, physiologic daytime sleepiness or better daytime functioning. An unexpected finding of this study was that a segment of CPAP users continued to experience residual daytime sleepiness despite high hourly use. This formed the basis of a separate study that explored potential mechanisms for this phenomena where diffusion tensor MRI imaging showed brain white matter changes in the sleepy group compared to high users who were not sleepy.

L 06 - SPECIAL SESSION: Gerontological Nursing Leadership Academy (GNLA): Leading Advancements in Interprofessional Care for Older Adults

Deborah Cleeter Bailey, EdD, MSN, RN, USA
Karen Reynolds, DNP, CNS-BC, FGnLA, USA
Deborah Ann D'Avolio, PhD, BC-ACNP, ANP, USA
Patricia Ann Kappas-Larson, DNP, APRN-BC, FAAN, USA

Abstract

As the world's population changes and we intentionally center more attention on caring for older adults in every practice setting, we must prepare and position nurse leaders to influence the advancements in interprofessional delivery of gerontological healthcare. This requires strong and effective leadership to address the growing need that exists for large scale improvements and directed change resulting in better health outcomes for older adults. Advancements in delivery of care and policy development must achieve measurable impact on health, cost and quality.

Currently conducting the fifth cohort, the international Gerontological Nursing Leadership Academy (GNLA) provides a deeply personal and guided professional development experience for mid-career nurse Fellows. The selected Fellows engage in eighteen months of rigorous leadership development through formal mentoring and faculty relationships. This triad serves as the foundation for an integrated experiential and intellectual curriculum, development of goal directed interprofessional leadership behaviors, and key partnerships with senior executives of healthcare organizations. Through extensive personal assessment and commitment, Fellows emerge as gerontological leaders and change agents demonstrated through learned behaviors and actualizing their potential. The GNLA Fellowship provides the foundation for ongoing and sustainable influence and impact in leading practice advancements and advocacy in caring for older adults ranging from frontline to policy and global forums.

Mentoring for leadership development of the GNLA Fellows is accomplished through intense relationship building, mentoring, and guidance of the Fellow's academy experience. The design, development, and implementation of the Fellow's interprofessional team project is the experiential vehicle that provides a dynamic environment for strategically guided leadership development. The "Triad" relationship between Faculty Advisor, Fellow, and Leadership Mentor is integral in providing support, feedback, and guidance throughout the Fellow's leadership journey.

The GNLA Fellows have achieved significant outcomes within the three curricular domains: individual leadership development; advancement of practice through leadership of interprofessional team projects; and expanded scope of influence at the organizational, community, and professional levels. Through this behaviorally focused leadership development experience, the GNLA Fellowship provides the foundation for ongoing and sustainable influence at the organizational, community, and professional levels.

As healthcare systems around the globe face many complex and interconnected challenges in providing high quality, innovation and cost-effective care; interprofessional leadership must be the cornerstone to the design, delivery, and implementation of new models of care. Nursing leaders can strategically respond to these change drivers by actively engaging care model design and policy development.

L 17 - SPECIAL SESSION: Getting Published

Susan Gennaro, PhD, RN, FAAN, USA

Bernadette Mazurek Melnyk, PhD, RN, CPNP/PMHNP, FAANP, FNAP, FAAN, USA

Abstract

The Editor of the Journal of Nursing Scholarship and the Editor of Worldviews on Evidence Based Nursing, both well-published nurse researchers will present this session on getting published. The presentation will start with defining what is a publishable manuscript? The presentation will then cover tips for planning and writing manuscripts for authors of all levels of experience, including deciding on the kind of manuscript, following author guidelines, formatting, and thinking about target audience. A typical outline of a databased paper will be reviewed. The presenters will discuss problems and common pitfalls often encountered by authors and how to avoid or address them effectively when writing a manuscript. This will include titles that don't match, structured abstracts, literature reviews, standards for reporting, validity and reliability, tables and figures, discussions that don't relate to the findings, and incomplete, old, or incorrectly formatted reference lists. Some tips for writing in teams will be covered, including how to set expectations and what constitutes being an author on a manuscript. Novice writers will be encouraged to find a writing mentor. The peer review process will be discussed. Presenters will summarize the three potential outcomes of submitting a manuscript (accept, revise and resubmit, and reject). Typical reasons for rejections will be discussed, as well as common emotions experienced by authors when they receive this news. Next the presenters will cover typical reasons for revising, and the importance of paying attention to the reviewers concerns. The presenters will cover strategies for resubmitting, including writing a cover letter, highlighting changes made, and meeting the resubmission deadline requested. The presenters will also speak about ethical issues related to writing and publishing manuscripts including authorship, duplicate publication, and conflicts of interest. Persistence will be encouraged as the key to success in getting published. A few helpful resources will be provided to the participants.

A 02 - Promoting Maternal-Child Health

Use of the Pediatric Infant Parent Exam: Screening Maternal-Infant Interactional Synchrony During Well-Infant Visits

Kathryn Sridaromont, PhD, RN, USA

Abstract

Maternal-infant interactional synchrony is a dyadic interaction between mother and infant that provides an observable mutually regulated pattern of contingent reciprocal rhythm as each member makes behavioral adjustments to maintain a balance in the system (Leclere et al., 2014). Reciprocal synchronous interaction results in greater maternal sensitivity and more secure infant attachment. A major anticipatory need has been identified to screen for altered maternal-infant interaction early in life to identify at risk dyads and guide appropriate interventions to ameliorate maladaptive patterns. Nurses are well suited to screen early maternal-infant interactional synchrony as a component of well-baby visits via direct observation of the dyad. A psychometrically sound instrument for use during clinic visits would satisfy such a need. One instrument that was found to be desirable for use in an outpatient clinic setting is the Pediatric Infant Parent Exam (Fiese, Poehlmann, Irwin, Gordon, Curry-Bleggi, 2001).

The purpose of the dissertation study was to determine the interrater reliability, overall impression, and scoring of typicality of the interaction and time required for nurses' use of the Pediatric Infant Parent Exam (PIPE) to screen the interaction of a convenience sample of 50 mother-infant dyads during a well-baby visit in a clinic setting. After IRB consent was obtained, the PI and three pediatric clinical nurses completed training based on the PIPE manual. The research assistant identified English speaking mother-infant dyads using the pediatric clinic as a medical home. Infants were between six and nine months of age. Exclusion criteria were infants with congenital anomalies, fever or illness. On reporting for the scheduled well-baby visits, Mothers who expressed an interest received further information about the study. Once they expressed an interest in participation, informed consent was obtained and the one time brief observations were carried out in the private exam room by the PI and pediatric clinical nurse. A book was presented to each dyad who participated. Raw scores were transformed with SAS, version 9.3 and analyzed using Cohen's *kappa*. The *kappa* was 0.809 and the weighted *kappa* was 0.840 for cumulative paired ratings of the various stages of the PIPE while the "overall synchrony" ratings did not meet the assumption of symmetric distribution making any *kappa* analysis questionable at best. As to the "judgement of typicality", *kappa* was 0.666. Two of the pediatric clinical nurses rated use of the Pediatric Infant Parent Exam as "somewhat easy" while one nurse rated the instrument as "easy to use". The time for scoring the observation ranged from 60 to 202 seconds with a mean of 90.57 seconds, a median of 67.5 seconds, and a standard deviation of 44.13 seconds.

Early identification of dyads at risk can expedite early treatment thereby creating a more favorable developmental trajectory for the maternal-infant dyad. The use of the PIPE offers one instrument to assist in this process. Nurses in an outpatient clinic used the instrument in screening maternal-infant interactional synchrony with outcomes to suggest the additional use by others who attend to infants early in life.

A 02 - Promoting Maternal-Child Health

Abnormal Thermal Patterns in Very Preterm Infants Associated With Infection and Maternal Smoking

Robin B. Dail, PhD, RN, FAAN, USA

Abstract

Introduction: More than 63,000 very preterm infants (<32 weeks gestational age (GA)) are born annually in the United States¹ and survival free from major morbidity is a significant problem for them.² Up to 30%³ of these infants experience a neonatal infection and 5-15% of these infants acquire an infection or inflammation of the gastrointestinal (GI) track called necrotizing enterocolitis (NEC);^{4,5} NEC has a mortality rate as high as 50%.⁶

Hypothermia is related to increased morbidity and mortality in preterm infants⁷⁻¹¹ and continues to be a problem in very preterm infants.¹² Hypothermia is associated with an increased incidence of NEC in preterm infants.¹³ Abnormal postnatal circulation can lead to problems with feeding intolerance and intestinal motility, both associated with NEC.¹⁴ Continuous temperature monitoring is crucial to preventing hypothermia in very preterm infants due to their inability to self-regulate their body temperature.¹⁵ Abdominal temperature (AT) is measured with a covered thermistor on the skin surface, which reflects core temperature in preterm infants, and foot temperature (FT) is measured on the sole of a foot.¹⁶ When a preterm infant has central hypothermia, peripheral vasoconstriction should decrease blood flow to the feet to limit heat loss, but this mechanism is not operative in most very preterm infants in the first hours after birth.^{17,18} Inability to effectively dilate and constrict blood vessels affects thermoregulation negatively. Previously, we examined AT and FT in 10 very premature infants every minute over their first 12 hours of life. Only one infant exhibited peripheral vasoconstriction briefly and 7 of 10 infants kept their FT greater than AT for most of their first 12 hours, indicating altered vasomotor tone.¹⁷ Because of this finding, we wanted to examine thermal patterns longitudinally.

Purpose: The purpose of this study was to examine AT and FT in 30 very preterm infants over their first 2 weeks of life in relationship to morbidity and mortality using an exploratory case study approach.

Methods: After IRB approval, parents of infants expected to be born less than 29 weeks GA were consented for study participation, prior to their infants' birth. Infants were eligible for enrollment by 6 hours of age if their birth weight was between 500 and 1200 grams and if there were no visible anomalies or medical complications initially after birth. AT and FT was measured every minute using a thermistor secured to the skin, which stored temperatures into a data logger. Once the infant reached 2 weeks of age, temperatures were downloaded to a secure server, then imported into a SAS (Cary, NC) data set for analysis. Each physiological variable had 20,000 measures. The research nurse entered clinical data from the infants' medical record into a data form.

Results: We obtained study consent from 107 parents prior to their infants' births. Of those, 76 infants were not eligible for data collection because they did not meet birthweight or GA inclusion requirements. The remaining 31 infants were eligible for data collection; 22 of these infants had complete AT and FT data for a 14-day period for analysis. The remaining 9 infants were excluded for incomplete data. The mean GA of the 22 infants was 26 (SD =1.2) weeks with a mean birthweight of 860 (SD=135) grams with 32% males, 27% white, 68% African American, and 5% Hispanic infants. Infants were housed in heated, humidified incubators and on servo control at 36.5°C. However, the charted servo temperatures ranged between 36.0°C to 37.0°C between infants. Over all infants, the mean AT was 36.53°C ± 0.19° (36.09°C-36.81°C) and the mean FT was 35.91°C ± 0.28° (35.10°C-36.40°C). Each infant was evaluated for the percentage of minutes each day having a warmer FT than AT. The range for all days and all infants was 0 to 70.7%, with a 2 week mean of 7.32% to 38.51%. We used a Wilcoxon signed rank test to compare groups of infants with and without morbidity.

Three infants of the 22 were diagnosed with NEC by an abdominal radiograph between 33-60 days of age. NEC occurrence was too low for hypothesis testing; however, the 3 infants who acquired NEC prior

to discharge had a higher mean percentage of minutes (26.88%, SD 10.56%) in their first 2 weeks of life with warmer FT than AT compared to infants that did not acquire NEC (17.88%, SD 6.28%), $p < .11$. Four infants had infections during their hospital course. The infants who acquired an infection or UTI had a higher mean percentage of minutes (27.78%, SD 9.52%) over their first 2 weeks of life with warmer FT than AT compared to the 17 infants who did not acquire infection (16.44%, SD 5.34%), $p < 0.05$.

We also compared infants born to mothers who smoked during pregnancy to infants born to mothers who did not smoke during their pregnancies by self-report of smoking. Infants of mothers with a smoking history tended to have an increased mean percentage of minutes with warmer FT than AT over their first 2 weeks of life (26.6%, SD 25.75, $n=4$) than non-smokers (16.7%, SD 16.99, $n=18$), $p < 0.06$.

We examined the percentage of minutes with FT greater than AT and clinical events thought to be stressful on a day by day basis with all infants using mixed modeling with repeated measures evaluating the effect of intervening events. Over all infants, days when infants received blood transfusions had more mean percentage of minutes with FT greater than AT than on days without blood transfusions (22.42% vs 18.14%, $p < 0.26$). Infants also had a higher mean percentage of minutes with FT greater than AT while on CPAP than infants had on days without CPAP (20.19% vs 15.91%, $p < 0.06$) in contrast to infants who were intubated and on a ventilator had less mean percentage of minutes with FT greater than AT than non-intubated infants (14.60% vs 20.36%, $p < .03$).

The infants with the highest mean percentage of minutes with FT greater than AT over their first 2 weeks of life had more "risk" factors than infants with lower mean minutes. The infant with the highest mean minute percentage was an 880 gram, 27 weeks GA African American female infant who was born to a mother who smoked and used drugs during pregnancy by self-report. She acquired an infection in the neonatal period and NEC at 33 days of age. The infant had two blood transfusions, two PICC line attempts, and was fed days 4-11 and 14. The infant was also on dopamine and epinephrine for the first 4 days of life. This infant had 38.51% of her minutes over the first 2 weeks of life with a warmer FT than AT.

The only other infant with more than 30% of minutes with FT warmer than AT over their first two weeks of life was an 890 gram, 23 week GA African American female infant with 32.66% minutes. This infant was born to a mother who had chorioamnionitis and admitted to drug use during her pregnancy. The infant had presumed sepsis at birth. This infant also received two blood transfusions and three PICC line attempts in her first 2 weeks of life and was noted to have three episodes of abdominal distention. She was fed from 4-14 days of age.

Conclusion: Very premature infants with colder central temperatures (AT) and discordant warmer peripheral temperatures (FT) have an increased risk for infection. We also found infants who were diagnosed with NEC had more time in their first 2 weeks with warmer FT than AT compared to infants that did not acquire NEC; however, our sample was small and we did not have enough NEC cases for statistical comparison. The infants in our study were more likely to have colder AT than FT if they received a blood transfusion or were on CPAP. However, intubated infants had more time spent with warmer AT than FT. Infants in our study who were born to a mother who smoked during pregnancy were more likely to have warmer FT than AT over their first 2 weeks of life compared to those that did not have in utero exposure to tobacco. Approximately 12% of pregnant women smoke in the United States during pregnancy.¹⁹ Smoking during pregnancy is related to fetal growth restriction, preterm delivery and infant death with 23-34% of infant deaths from Sudden Infant Death Syndrome (SIDS) associated with maternal smoking. Maternal smoking also increases the risk for postnatal infections.²⁰ A larger study is needed to examine central and peripheral temperature in very preterm infants over their neonatal period in relationship to infection, NEC and maternal smoking. Continuous monitoring of AT and FT may guide acute clinical care in the future to decrease acute morbidity and identify infants who are high risk.

A 03 - Nursing Education: Substance Abuse Interventions

Addressing Substance Abuse Using Evidence-Based Practice: Screening, Brief Intervention, and Referral to Treatment (SBIRT)

Marie N. Bremner, PhD, RN, USA

Barbara J. Blake, PhD, RN, ACRN, FAAN, USA

Mary Beth Maguire, DNS, MSN, BSN, RN, CNE, USA

Abstract

Significance: Nurses can have an important role in addressing substance use disorders among healthcare consumers. Approximately 20.8 million people (7.8 percent of the population) met the diagnostic criteria for a substance use disorder in 2015. Unfortunately, only 2.2 million individuals (10.4 percent) received any type of treatment (Center for Behavioral Health Statistics and Quality, 2016). The latest US Surgeon General report calls for a cultural shift in thinking about addiction as a disease rather than a personal weakness (U.S. Department of Health and Human Services, 2016). Nurses work in a variety of healthcare settings and are apt to encounter individuals at risk for substance abuse. Thus, they are in an ideal situation to make a meaningful contribution in addressing this crisis.

Evidenced Based Practice: Screening, Brief Intervention, and Referral to Treatment (SBIRT) is an evidence-based public health approach for providing early intervention and treatment for individuals at risk for developing substance use disorders. SBIRT incorporates motivational interviewing skills. Motivational Interviewing is a clinical approach that helps individuals make positive behavioral changes to support better health.

It respects patients' autonomy, is patient centered, and minimizes resistance to change. This interview style is collaborative, non-judgmental and recognizes patient responsibility.

In 2015, faculty teaching in an undergraduate nursing program located in the southeastern US, implemented a SBIRT training program. One hundred twenty students enrolled in a community health-nursing course completed the self-directed six-week training. The training consisted of five on-line modules, virtual training, and a 2 ½ hour face-to-face interactive workshop. This workshop required students to interview live standardized patients (SPs). Recordings of the SPs interviews were used to enhance reflection and learning during the debriefing session held immediately after the workshop. Funds from the Substance Abuse and Mental Health Services Administration, Center for Substance Abuse Treatment (SAMHSA CSAT) were used to implement the SBIRT training.

Evaluation Methodology: The Survey of Attitudes and Perceptions (SAP) instrument was used to evaluate changes in core knowledge, attitudes, and perceptions in nursing students. This survey was developed based on questions from the Alcohol and Alcohol Problem Perceptions Questionnaire (AAPPQ) and the Drug and Drug Problem Perceptions Questionnaire (DDPPQ) (Terhorst et al., 2013; Watson, Maclaren, Kerr, 2007). The SAP was administered to students prior to beginning the training and upon completion. In addition, a Training Satisfaction Survey was administered to the participants who completed the SBIRT training. The survey was given at the end of the training and again 30 days post training.

Process evaluation activities were performed upon conclusion of training and include key informant interviews with faculty and focus group discussions with students from the training. The goal of these process evaluation activities was to gather feedback on the training and solicit ideas and recommendations for improvement.

Key Findings and Recommendations: The majority of students found the SBIRT training to be very useful or useful because it provided them with the skill set to address sensitive topics such as substance use with patients. Results from the SAP indicated an increase in core knowledge and perceived competency among the students. The face to face interactive workshop was well-received, particularly the live standardized patients. Students verbalized that the workshop was valuable and simulated nursing

practice in the real world. Students recommended that on-line training could be enhanced by embedding audio into the Power Point presentations and requested more detailed patient history prior to the live interview.

Conclusion: Nurses' engage patients through guidance and negotiation rather than directing, which fits in well with the SBIRT approach. SBIRT is a technique nurses can use to provide effective risk reduction and intervention prior to a patient's need for more extensive treatment.

A 03 - Nursing Education: Substance Abuse Interventions

Integrating Substance Abuse Screening Brief Intervention and Referral to Treatment Into Nursing Curriculum

Julie A. Fitzgerald, PhD, RN, CNE, USA

Abstract

It is estimated that about 30 percent of US adults experience a mental health or substance abuse disorder in a year, and many struggle with both. There is also wide geographical variation in the proportion of alcohol-attributable deaths and disability adjusted life years (DALYs), with the highest alcohol-attributable fractions reported in the WHO European Region (WHO, 2014). It is estimated that 15.3 million persons worldwide suffer from a substance use disorder (WHO, 2014). Globally, excess alcohol intake is responsible for approximately 6% of deaths. Culture, gender and religious norms impact alcohol consumption throughout the world. Substance abuse disorders are associated with high rates of disability and earlier mortality worldwide (Whiteford, Degenhart & Rehm, 2013). In the United States, 88,000 deaths are related to alcohol, making it the fourth leading cause of preventable deaths (Stahre, Roeber, Kanny, et.al., 2014). In spite of these grim statistics, universal screening for substance disorders is lacking.

Motivational interviewing is a person centered counselling style that can be utilized to promote a number of lifestyle changes (Ostlund, Wadensten, Kristofferzon & Haagstrom, 2015). Motivational interviewing has been used as an effective strategy in a variety of settings. Motivational interviewing has had a positive impact on medication adherence in bipolar disorder, (McKenzie & Chang, 2013), weight loss and increased physical activity (Hardcastle, Taylor, Bailey, Harley, & Hagger, 2013) and smoking cessation (Lindson-Hawley, Thompson, & Begh, 2015).

In spite of the prevalence of substance abuse, few nurses are taught to screen for substance abuse or use motivational interviewing to discuss change. To bridge this gap, a state college introduced Substance Abuse Screening, Brief Intervention and Referral for Treatment (SBIRT) into its undergraduate and graduate nursing curriculum. SBIRT is an evidence based practice that has been an effective strategy for risk reduction in persons with substance use disorders (Tanner-Smith & Lipsey, 2015). Studies have noted that SBIRT can take five to thirty minutes, depending on the patient's reported use and is appropriate for many settings. Nurse led integration of SBIRT into practice can identify patients at risk of substance abuse and allow intervention early in the addiction process.

To educate our undergraduate and graduate students in the use of SBIRT, we introduced the topic of substance abuse through required readings and an online education program on substance abuse. After completion of the introductory information students completed an online tutorial in motivational interviewing and "change talk". The nursing students then signed up to participate in role play using motivational interviewing techniques with their peers. Students were given case studies that described their substance use and willingness to change. They took turns playing the client and nurse and used motivational interviewing to discuss change. Instructor and peer feedback was provided after the role play.

Pre and post surveys assessing knowledge and skills in discussing use of substances showed increased knowledge, skills and attitude towards persons with substance abuse disorders after completion of the education. It is believed that early intervention in persons using substances can prevent long term dependence (Lacey, 2012). Nurse led integration of SBIRT into practice can identify patients at risk of substance abuse and allow intervention early in the addiction process. Widespread integration of SBIRT into the curriculum will allow for SBIRT to become a routine part of nursing care.

A 04 - Advanced Practice Fellowships

The Lived Experience of New Graduate Nurse Practitioners Who Participated in an Academic-Based Fellowship Program

Michelle L. Edmonds, PhD, FNP-BC, CNE, USA

Hilary S. Morgan, PhD, MSN, BSN, ARNP, CNM, USA

Abstract

Purpose: The significance of this study helps to close the gap between theory and practice of NP transitions. Little is known about NP-specific “transition to practice” programs that originate from academia. Some employers offer NP residencies or “transition to practice” orientations, but they have very limited, competitive enrollment and only open to those employed with the organization. It is important to determine the benefits of offering an academic-based solution for a greater number of NP graduates prior to or concurrent with their first NP employment. This study sought and has begun to fill this need. The primary purpose of this qualitative descriptive study was to identify facilitators and barriers of the successful transition to FNP clinical practice. A secondary purpose was to evaluate the effectiveness of this unique academic-based NP Fellowship designed and implemented by the researchers to ease the transition to practice for their former FNP students.

The research question for this study was: What is the lived experience of family nurse practitioners' transition into clinical practice?

Methods: To evaluate the overall success of the academic-based NP Fellowship, the faculty researchers conducted a qualitative descriptive study to evaluate transitional experiences of FNPs during their first year in practice. Institutional Review Board approval was obtained from the university where the researchers are currently employed and where the NPs previously attended.

After obtaining their informed consent, a focus group of five participants from the academic-based NP fellowship were interviewed to share their transition experiences. Of those five participants, three remain in their first NP position and the remaining two have either changed positions or were planning to over the next few weeks. The focus group was conducted on the university campus for approximately two hours and was not recorded. The faculty researchers took notes during the focus group which were later reviewed first independently and then, jointly for common themes.

Interview questions were:

Describe your first year in practice.

What parts of your transition were successful? What plants were challenging? Why?

Why did you think you were successful? Was there something specific that prepare you?

How did you overcome the challenges? What resources if any would have helped you achieve an easier transition in that experience?

What would you do differently over this past year in regards to your transition?

Describe the support you received from your organization.

What recommendations would you make to a new NP graduate?

What benefits if any did you gain from participation in the NP fellowship?

Results: From the focus group of participants who completed an academic-based NP Fellowship program, three essential themes became evident in the data analysis: *role preparation, role initiation, role acquisition*. These themes described the essence of the NPs transition to their first year in practice.

1. **Role preparation:** Role preparation was the theme that described the participants' active engagement in securing the resources they needed to have a successful transition to practice.
2. **Role initiation:** The theme of role initiation was encompassed the myriad of feelings that new NP graduates experience in their first year of practice.
3. **Role acquisition:** The final theme, role acquisition, communicated a sense of achievement – a successful transition to NP.

Conclusion: Given that the topic of academic-based NP fellowships is scarce within the current literature, the implications from the findings in this study are promising. Immediate implications for nursing education are evident. Nurse educators can be empowered to offer similar opportunities for their NP graduates. There are growing residency experiences for RN graduates that have been extremely successful but limited offerings for NPs who also have a challenging transition to practice. The implications for nursing education include strengthening nursing curricula to include topics that help in the transition during the first year as well as providing support to NP graduates to ensure success on the certification exams and employment, both important measures for accreditation of NP programs.

The academic-based NP fellowship described in this study is unique to any other offerings noted within the current literature. Findings from a focus group of participants noted that the residency was an effective tool in helping to ease their transition to practice from RN to NP. Participants moved through phases as described by three themes: *role preparation*, *role initiation*, and *role acquisition*. The first two themes (*role preparation* and *role initiation*) received their foundation within the academic-based NP fellowship with the third theme (*role acquisition*) occurring after the fellowship ended. Topics presented in the fellowship were timely and relevant to the needs of the graduate NP and set the stage for a successful transition. Based on the findings of this study, it is recommended that future academic-based NP fellowships be offered, expanded, and studied to determine their impact on nursing practice.

A 04 - Advanced Practice Fellowships

Advancing the Practice of Nursing Through Specialty Fellowship Development

Kelly Keefe Marcoux, MSN, APN, CPNP-AC, PPCNP-BC, CCRN, USA

Shayleigh K. Dickson, MSN, BA, APN, CPNP-AC, CPN, USA

Cathleen A. Cahill, MSN, APN, CPNP, USA

Christopher Haines, DO, MBA, FAAP, FACEP, USA

Abstract

In the United States, Advanced Practice Nurses (APNs) include nurse practitioners, clinical nurse specialists, nurse midwives and nurse anesthetists. This presentation will focus primarily on nurse practitioner APNs. Upon graduation from a master's or doctoral program in nursing, APNs are eligible for national certification and state licensure in one of six population foci. APNs are fully prepared to practice in a variety of inpatient and ambulatory settings upon graduation; however, for APNs who choose to further specialize their practice within one of these population foci, options for post-graduate training are limited. Historically, fellowship training has been utilized by physicians to further develop clinical acumen and skills as well as promote research within a specialized population. Previous research on APN "transition to practice" indicates that formal orientation programs are desired by APNs (Hart & Bowen, 2016) and positively correlated with successful role transition (Barnes, 2015). Additionally, mentorship by APNs and physicians within the context of an inter-professional fellowship increases provider confidence and development of clinical skills (Zapatka et al, 2014). This presentation describes the design, development, implementation, and outcomes of the first year of an APN Fellowship in Developmental-Behavior Pediatrics (DBP).

The APN Fellowship in DBP was designed to provide advanced didactic education, focused clinical experience, and professional mentoring to prepare APNs to provide optimal care to children with developmental needs. This particular specialty was selected for a fellowship to meet the growing national need for providers trained in this specialty. In the United States, the field of DBP currently has the second highest shortage of pediatric providers and wait-times for appointments that are seven times the national benchmark (Children's Hospital Association, 2012). The host organization is a national leader in the care of children with developmental disorders, particularly Autism Spectrum Disorder (ASD), and this data was integral in establishing need and financial feasibility of an APN fellowship program. In this organization, APNs are highly valued as evidenced by their status as members of the medical staff, ability to practice in a collaborative yet autonomous environment, and senior leadership support for innovative approaches to improving APN transition into practice and quality of care.

The APN Fellowship in DBP was implemented as an intensive 12-month program integrated with curriculum from the Accreditation Council for Graduate Medical Education (ACGME) Fellowship program in DBP. The APN fellow received comparable training and experience as the physician fellow in DBP in the first year. Didactic education included weekly lectures, completion of an online mental health fellowship (KYSS, Ohio State University), and attendance at an annual DBP conference. Clinical experience included hands on training under the supervision of experienced DBP physicians and APNs, formal training on the use of standardized DBP screening and diagnostic tools, and observation of other specialties and disciplines. APN role development including advocacy, research, professional growth and development was promoted by yearlong mentorship by an experienced APN. Finally, a research component included participation in an interdisciplinary research project related to the health care transition of adolescents & young adults with ASD.

Evaluation of the APN fellow occurred throughout the year on an ongoing basis. The fellow was expected to be deemed competent in all core competencies required for APN practice in the US based on the National Organization of Nurse Practitioner Faculties (NONPF, 2014), which included competencies in Scientific Inquiry, Practice & Policy, Leadership, Autonomous Practice, Ethics, Healthcare Delivery Systems, Quality, Practice Inquiry, and Technology & Information Literacy. Furthermore, the fellow was given DBP-specific competencies that required completion prior to the culmination of the fellowship. The

fellow had the opportunity to self-assess as well as be evaluated by each preceptor at least three times throughout the year.

The first year of the APN Fellowship in DBP will conclude in January 2017 and the outcomes of the first year of the APN Fellowship in DBP will be reported. The anticipated outcomes include successful completion of all core and specialty competencies, review of pre and post capstone assignment as developed by Ohio State KYSS fellowship, survey feedback from fellow and preceptors, timely transition into full time role and retention of fellow as full time medical staff member. Future outcomes to be assessed include time to transition to full time practice compared to non-fellow prepared new graduate APNs, time to meeting productivity measures, retention, customer satisfaction and APN satisfaction. The anticipated success of this program has led to continuation of the fellowship for a second year as well as development of an APN Fellowship in Physiatry.

A 06 - Interprofessional Collaboration in Education

Application of Interprofessional Simulation-Based Clinical Examination in Extended Nursing Experimental Teaching Practice

Hangjian Chen, MSN, RN, China

Abstract

Purpose: To explore the feasibility of inter-professional simulation-based clinical examination for nursing students in China. This study attempts to apply the simulation technology of evaluation on expanding experimental teaching to improve the ability of nursing students, to provide reference for more comprehensive evaluation of comprehensive ability of nursing students. At the same time, we would like to provide scientific basis for formation of medical cooperation education mode, which can help nursing educators and nursing students adapt to the change of the health care system, improve the medical and nursing quality, meet people's growing health needs of the diversification.

Methods: Ninety seniors in school of nursing and school of medicine were included in the study. Inter-professional cooperation, high-fidelity simulated patients and other simulation technology were used to evaluate students' clinical abilities. The teaching activity was consisted by three steps. The first step was construction of the collaborative team. The team members included students from nursing school and clinical school, teachers were also participants as the advisor of the team. The second step was to design the simulation cases which should be combined the clinical materials and theoretical knowledge. The last step was the procedure of evaluation. The performance of students was evaluated by five groups of examiners and the two examiners in each group conduct the evaluation simultaneously. Students' suggestions about the evaluation were collected after the test and correlation analysis was used to show the relationship between comprehensive ability evaluation scores and the total scores.

Results: The consistency coefficient of two examiners was 0.976; the score ranged from 7.21 ± 1.44 to 8.32 ± 2.13 ; There was significant correlation between the ability evaluation of cooperation and other ability evaluation.

Conclusion: Inter-professional simulation-based clinical examination can be used as an assessment tool for students' academic competition. Expanding nursing experimental teaching is considered as an important platform for students' practical ability and innovation quality, through the design of teaching contents, organization and evaluation, closely integrated experimental teaching and clinical practice. The ability of collaboration is very important for students as team members of health care unit and educators are suggested to apply the method of expanding experimental teaching to inter-professional training.

A 06 - Interprofessional Collaboration in Education

Developing a Creative Collaboration to Promote Interprofessional Education for Baccalaureate Nursing Students

Tauna Fleming Gulley, PhD, RN, FNP-BC, USA

Abstract

In November 2012, the School of Nursing and the XXX College of Osteopathic Medicine at XXXX created a workgroup aimed at structuring interprofessional learning activities for students. Since that time, the interprofessional education (IPE) initiative has expanded to include the disciplines of optometry and social work at the University of XXX, the XX College of Pharmacy in XXX and the school of nursing from XXX .

The aim of this presentation is to describe how a small university in the central Appalachian region of the United States developed a creative collaboration among various disciplines to promote interprofessional educational experiences for their students. The collaboration was named the XXX.

The Baccalaureate Essentials for Nursing Education (2008) state interprofessional education provides opportunities for the baccalaureate prepared nurse to acquire knowledge of various practice disciplines, to develop confident communication skills, and to create effective collaboration techniques. Proficiency in each of these areas will result in optimal patient outcomes for the baccalaureate prepared nurse.

This interprofessional education project provides opportunities for nursing students to participate in IPE activities. For example, nursing students participate on an IPE team consisting of other student nurses, student physicians, student pharmacists, and student social workers. The IPE teams meet face to face in the fall and spring of each year. At that time, teams are presented with a case study. Teams are responsible for providing a final plan of care for the patient described in the case. Specific goals for the collaborative learning activity include the following: 1) Students will be able to work with individuals from other professions to maintain a climate of mutual respect and shared values, 2) Students will use knowledge of their role and those of other professions to develop a plan of care for a hypothetical patient, 3) Students will communicate effectively and 4) Students will learn and apply the principles of team dynamics.

Collaborative actions are demonstrated throughout the process. Case studies are created collaboratively among faculty members from each discipline. Faculty members from each discipline also serve as facilitators during the case study activity. Facilitators are provided a training luncheon prior to each activity. Training is focused on reviewing the goals of the activity and the facilitator's role in guiding the students through the case study.

Participants, students and faculty, complete surveys before the case study activity and immediately after the activity. Results indicate there are improvements of the knowledge base of each other's professional expertise and capabilities. In addition, there is a consistent awareness of the participants recognizing the need to work as a team in collaboration with each other in the healthcare arena. A positive interaction between each professional group was noted. Students from all disciplines reported higher levels of teamwork than the facilitators' assessment of the group experience. Following the case study activity, student physicians and student pharmacists rated student nurses higher in these categories: academic ability, professional competence, interpersonal skills, ability to make decisions, leadership ability, practical skills and competence.

Student testimonies included the following:

*Experience is the best teacher. I believe this should be done again during rotations for all students again to see how much true knowledge they acquire.

*This was a great learning opportunity. It was good to work with other professions to solve a problem.

*Great experience enjoyed communicating and solving the case!

*We had a great team! Thank you for the opportunity.

Future Endeavors: The XXX has been a successful way for nursing, medical, pharmacy and social work students to learn collaboration skills with, and from each other in order to provide optimal care and improve patient outcomes. Future endeavors include participation with the XXX College of Optometry and the XXX School of Law. Including optometry students and law students in this collaboration will provide valuable considerations when developing a plan of care for clients.

Results have been positive. Students learn the roles of disciplines other than their own and they practice essential communication skills. In addition, faculty members from the various disciplines create and share curriculum pearls for teaching interprofessional collaboration skills.

A goal of the XXX is to provide virtual experiences for participants who are unable to meet face to face. Virtual IPE experiences could include global collaborations among students with various cultural backgrounds living in different parts of the world.

A 17 - Advancing Global Health Through Education

Influencing Global Health: Creating an Interprofessional Global and Rural Health Certificate Program

Wendy Renee Thal, DNP, APRN, FNP-C, APHN-BC, USA

Emily S. Merrill, PhD, RN, FNP, BC, USA

Rosalinda Jimenez, EdD, MSN, APRN, FNP-C, USA

Abstract

This presentation details the development process and implementation of a graduate level, inter-professional global health certificate program in a graduate level nursing program. The on-line program was developed in direct response to an identified need from the student body within the HSC. The certificate program, a set of three core courses, a total of 12 credit hours, is designed to prepare professionals with in-depth knowledge to enhance the care of populations in underserved global and rural communities both at home and abroad. Healthy People 2020 (ODPHP, N.D.) and the United Nations Sustainable Development Goals (UN, N.D.) guided the development of the program content.

Course content is taught by expert health professionals from diverse backgrounds through various technological modalities. Foundational course content includes social determinants of health, application of theory, research, and current evidence related to access to care, culture, ethics, and health policy. Health care systems are explored, with community engagement a key concept threaded throughout the three course program. Current trends and issues in global health are explored including epidemiology, infectious and non-infectious disease processes. Health information technology, including telehealth and the application of informatics in a global health setting is explored through the use of technology with experts from around the world. The use of community health workers as part of the health care system is described through case studies and interactive activities via our online platform. The final course practicum is application of concepts as a Capstone project in a global community of the students choosing.

Completion of the program by the first pilot cohort was in summer 2016. Students reported a high overall satisfaction with the program and student reflections described personal satisfaction in working with medically underserved populations in diverse environments. Discussion will include challenges encountered in implementing the programs, lessons learned, and strategies for success.

A 17 - Advancing Global Health Through Education Providing Future Nurses With Experiential Learning Opportunities in Global Nursing: The Belize Experience

*Joann Marie Sands, DNP, RN, ANP-BC, USA
Jennifer M. Guay, DNP, CNM, USA*

Abstract

Nursing is becoming more global every day; from the patients we care for, the patients families that we provide support, to the medical providers we work with, and the types of diseases and diagnoses we are treating. As nurses we must understand the impact that these global influences have on the healthcare of individuals and populations which ultimately impact healthcare delivery.

Due to the intense, rigorous workload of nursing students, and their demanding, structured school schedule, it is often very difficult to incorporate a global health experience into the nursing curriculum. At the University at Buffalo, we were able to utilize the three week winter intercession between fall and spring semester to develop and implement a 2-credit, faculty led global study abroad course. The destination for this global study abroad course has been Belize in 2014 and 2015. This global study abroad course provides students an opportunity to integrate academic study with community engagement. The course fosters the development of cultural sensitivity, civic engagement, advocacy, collaborative practice, ethical decision making, and social responsibility. In 2016, while Belize was still the global study abroad course destination, we collaborated with the University at Buffalo School of Pharmacy, to create an interdisciplinary approach to the study abroad course. Students from both nursing and pharmacy traveled and worked together providing care to the Belizean villagers.

Initially seven students participated in the global study abroad course in 2014, with an increase in student engagement with twelve students participating in 2015. Students included pre-nursing majors, junior and senior nursing students, as well as nursing students from another university. Students were required to complete pre-departure orientation including review of common tropical diseases, their presentation and treatment. To facilitate effective communication with the villagers, students were required to learn some common Spanish words and phrases. To provide a detailed log of their trip experiences, students completed daily journals documenting their daily activities, village home visits, and medical clinics. Upon return to the United States, students completed a written reflection and evaluation, as well as a video compilation of their experience.

Students had a wide range of experiences and knowledge prior to embarking on this journey. They were able to build upon each other's strengths to increase their own knowledge and skill set. Further, they were responsible for initial triage of the patient, followed by completing a history and physical, reporting their assessments to the physician, and most importantly, providing education to the patient addressing health promotion, medication management, and safety practices in the home. At both villages, students had an opportunity to visit with the school children to provide education on topics such as skin care, oral hygiene, and personal hygiene.

Students were truly immersed in the culture of Belize. Student lodging was at a small missionary camp in one of the local villages where traditional Belizean meals were prepared. Students visited two villages for a total of four days, while completing home visits. Students were encouraged to communicate with the villagers in the villager's preferred language. They were able to witness the living conditions the villagers experienced on a daily basis.

Students participants also had an opportunity to participate in a few recreational activities where they were able to gain an appreciation for both the history of Belize and its vast tourism which provides the country with an immense amount of economic support. Students had the experience of visiting the University of Belize nursing school where they had the opportunity to speak with a director of the nursing program. Ultimately, students came to appreciate the similarities in their own home nursing program and

the University of Belize nursing program. Students were truly immersed in an experiential learning opportunity and gained a true appreciation of the people and culture of Belize.

Analysis of student journals and reflections revealed an overwhelmingly positive response to the global nursing experience. Only one student had any previous study abroad experience, so the remaining eleven students were embarking on this journey for the first time. 100% of the students felt the cross-cultural experience was the best aspect of this global nursing course. As there were very few diagnostic tests available for the residents of Belize, students had to rely solely on their ability to obtain a complete history as well as their astute assessment skills and completion of a thorough physical exam. There were no automated blood pressure cuffs, x-ray machines, or CT scanners to support the delivery of nursing care.

The majority of students had completed only one semester of nursing school, which included their health assessment course, but very limited, if any, time in the hospital clinical setting. After completing this global health course, students felt much more confident in their ability to perform a thorough and accurate history and physical assessment; report pertinent findings to the physician, and provide education to their patients. Students also reported that this course made them feel more comfortable communicating with their patients and physicians. Several students stated they felt less intimidated when having to work with a physician or asking the physician a question. They felt this confidence would carry over when they return to the clinical setting in the United States. In terms of cultural competence, one of the student's statements "says it all, *"There are many cultural differences. I will never learn them all. There are cultural differences within one culture. I don't have to understand them all, what's most important is that I respect them."*

B 01 - Strategies to Assist Patients Exposed to Violence

Knowledge Mobilization of Methods and Findings of Intimate Partner Violence Research in Canada's North

Pertice M. Moffitt, PhD, RN, Canada

Heather Fikowski, MSW, RSW, Canada

Abstract

Intimate partner violence (IPV) in Canada's Northwest Territories (NWT) is a grave social and public health issue with rates of IPV nine times the national average (Statistics Canada, 2016). The social, contextual and cultural context including colonization (Kubik, Bourassa & Hampton, 2009), the intergenerational impact of Indian residential school (Bombay, Matheson & Anison, 2014; Elias et al., Mohatt et al., 2014), alcohol and substance use, and social determinants (poverty, housing, unemployment, gender) all factor into the high rates of IPV (Moffitt et al., 2013; Weurch et al., 2016).

From 2011 to 2016, researchers conducted an investigation into "the Rural and Northern Community Response to Intimate Partner Violence", funded by a Social Sciences and Humanities Research Council of Canada (SSHRC) and Community/University Research Alliance grant. The research questions are: What are the needs of women experiencing intimate partner violence? What are the gaps in services to meet these needs? How can we create and sustain nonviolent communities? Frontline service providers (n=56) were interviewed through individual interviews (n=44) and two focus groups (n=12). A grounded theory was generated through constant comparative methods identifying the central problem as "*our hands are tied*." The social processes that create this community response are three: putting up with violence; shutting up about violence; and, getting on with life. An action plan was created to address the problem of "*our hands are tied*." One of the tenets of the action plan expressed by frontline service providers was the salience of education and awareness to overcome the culture of violence and silence that is present in the territory.

The purpose of this presentation is to highlight knowledge mobilization (a way of taking the knowledge generated by a study and putting it into action to afford change in a culturally and contextually congruent way) in relation to the research findings of this study and to specific strategies of knowledge mobilization used for our northern culture. Knowledge mobilization was conducted from the beginning of the research through to completion of the project and will extend beyond the completion date with dissemination of the findings. The process of knowledge mobilization occurred through a variety of different activities, some of which were related to the research methods and some activities were conducted in collaboration with a territorial activists' group, the Coalition Against Family Violence, of which the researchers were active members.

One of the unique methods that was used in year one of the study was geographical information system (GIS) maps to plot the incidents of IPV in the territory. At the same time as we gathered statistics from the federal policing agency, we conducted an environmental scan to illuminate the resources available for women in the territory (emergency shelters, victim services, police services, hospitals and health centers). Both data sets were accessed by geographers on our team to create a GIS map of "IPV Incidences and Resources". The map provides a visual of the high number of IPV incidents in all communities of the NWT and in the gaps in services. This map was a tool for knowledge mobilization for the research team and also for public consumption when we were asked to speak during "family violence awareness week". As well, as themes that emerged through data analyses, more ideas were generated to map (a comparison of seasonal distances to shelters; homicides in the territory and emergency protective orders). During this presentation, the GIS maps will be shared and their contribution to knowledge mobilization will be highlighted.

In addition, examples of specific strategies that were used within our context included: Community Fairs in remote communities, Community Presentations and Dialogue with Frontline Service Providers and Safety School with Undergraduate Nursing and Social Work Students. Community fairs were sponsored by the territorial government as a way of bringing government and nongovernment agencies together to

provide knowledge of resources available and health promotion of a variety of issues. During a community fair, we used a flyer written in plain language to translate our research findings to the community and response cards where community members had the opportunity to answer the question, "what can you and your community do to end violence?" The responses were both drawings by children and words by adults covering a variety of topics. Formal community presentations about the findings of the research and the action plan have been delivered to five communities targeting frontline service providers. Following the presentations, a facilitated conversation was conducted with the participants to encourage their feedback about what the findings and suggested actions. Safety school is a half-day class spent with undergraduate students to address violence in the territory and provide access to resources available for women. The safety school promotes sharing local resources and initiatives to enable knowledge translation with future frontline workers.

It is no secret that there are higher rates of intimate partner violence throughout the North and in the Northwest Territories particularly. Working with service providers to mobilize the limits and challenges they face in alleviating suffering and eliminating violence in their communities is critical to developing collaborative and effective systems and programs. Education and awareness through informative presentations and campaigns and providing opportunities to reflect and create space for dialogue will assist in the transformation towards nonviolent communities.

B 01 - Strategies to Assist Patients Exposed to Violence

Transforming Research to a Global Application for Assessment of Women and Children Exposed to Violence

Judith M. McFarlane, DrPH, RN, FAAN, USA

Fuqin Liu, PhD, RN, USA

Nina Fredland, PhD, RN, USA

Anne Koci, PhD, RN, FNP-BC, WHNP, USA

Lene Symes, PhD, RN, USA

Abstract

Among women in the United States (U.S.) and worldwide, an estimated 30% have experienced intimate partner violence (WHO 2013). Consequences of violence include acute trauma, poor physical health, and compromised functioning (Ellsberg, Jansen, Heise, Watts Garcia-Moreno, 2008) and is most commonly associated with mental health problems of depression and posttraumatic stress disorder (PTSD) (Symes, McFarlane, Nava, Gilroy, Maddoux, 2013). Recent research indicates the pass through of poor mental health of the mother to behavioral problems of the children (McFarlane, Symes, Binder, Maddoux, Paulson, 2014). To better understand the risk predictors of sustained poor mental health, specifically PTSD, for women reporting intimate partner violence, a multi-year study is underway in Houston, Texas, USA.

Methods of the study include recruitment of 300 mothers reporting intimate partner violence to justice or shelter services for the first time. The women are followed for 7-years to determine the temporal sequencing of how violence impacts women's mental health and the impact on poor maternal mental health, specifically PTSD, on her children's functioning. To learn the determinants that mitigate or intensify the impact of violence on mental health, specifically PTSD, measures of mental health are completed every 4-months using validated tools. (One child of each mother is being followed and the child's behavioral functioning and school performance is measured every four months also).

At year 5 of the study, 94% of the mothers and children are retained. A portfolio of 40 peer-reviewed articles are published, including predictor tools to determine mothers at highest risk to sustained mental health problems, especially PTSD. To transform the research to a smart device, such as a phone and tablet, predictor models were derived and validated for sustained maternal PTSD and sustained child dysfunction and the information programmed to a predictor application. The predictor applications are available in English and Spanish, designed for use on a hand-held device, and disseminated through the World Wide Web at no charge. The predictor tools enable first responders and front line providers to quickly assess and triage women and children exposed to domestic violence to needed services.

The predictor applications, termed FAST (First Assessment Screening Tools) Apps, translate 5-years of research into strategies for practitioners worldwide to optimize health of women and children experiencing domestic violence, by taking into account determinants of health measured through nursing research. The presentation will discuss the continued validation of the First Assessment Screening Tools and uptake internationally of the application. Connection of the FAST application to addressing Sustainable Development Goals 2013 (Transforming Our World, 2016) will be discussed. Additionally, the audience will have the opportunity to download the FAST application and comment on usefulness for best practices during the presentation.

B 02 - Advancing Nursing Education

Advancing Nursing Education: BSN Completion Messaging Materials for Associate Degree Nursing (ADN) Faculty

Linda E. Moody, DNP, MBA, RNC-OB, USA

Abstract

Problem: The IOM's Future of Nursing report calls for increasing the proportion of baccalaureate-prepared nurses to 80% by 2020. There is supports for nurses' to pursue education beyond an associate's degree. Many initiatives have been implemented to encourage academic progression toward BSN. To increase the proportion of BSN-prepared RNs, additional options need to be considered. The support and message that ADN faculty provide to ADN students is crucial for students to recognize and understand the benefits, opportunities, and importance of continuing their nursing education.

Project Aim: To develop resources that ADN faculty can use to advise and encourage ADN students in advancing their nursing education through pursuit of a baccalaureate degree.

Project Method: Using a strategic communication framework, BSN completion messaging materials were developed for ADN faculty to use with students. Evaluation sessions of the messaging materials occurred with faculty from two Kansas ADN programs to elicit feedback and recommendations for the materials.

Findings and Conclusion: Overall, participants supported the messaging materials. The responses from both ADN faculty groups were similar. Faculty responses included the appreciation of having current resources available to share with students in group and individuals sessions, a variety of documents and messaging material mediums, and a plan to share information with other nursing programs. The ADN administrators and faculty responded that the materials were ready for use.

The comprehensive set of BSN completion messaging materials provides options for approaching and supporting students in the completion of their BSN degree. Considerations need to be given with whom and how to share the information among a wider group of nursing leaders in practice settings. Additional work needs to be done so that all RNs have the opportunity to complete their BSN degree to obtain the knowledge, skills, and attitudes required in healthcare and to achieve their professional goals.

B 02 - Advancing Nursing Education

Integrated Application Process for Nursing Student Clinical Practicum

Nancy S. Goldstein, DNP, MS, RNC-OB, ANP-BC, USA

Diana Lyn Baptiste, DNP, MSN, RN, USA

Sibyl Snow, MA, BA, USA

Abstract

The nursing students' decision where to complete their education can be difficult with multiple clinical options. A process to improve communication and quality of selection through an integrated application was the aim. A strategy was developed with functionality and technical capabilities to support wide-ranging needs of all clinical practicum options.

Supporting learning for pre-licensure nursing students in the clinical arena for their final clinical practicum continues to challenge nurse educators. Finding the right clinical setting and mentor in that setting continues to test nursing educators. The nursing students' decision for completion of their education can be difficult when there are so many practice settings and clinical options. The method to support placement of individual students on a particular clinical site for their final practicum course was our focus.

We developed a web-based application using Qualtrics® survey software. Students were provided a link to complete the application within a two-week time frame. The application process includes an algorithm to assist students with selecting locations, clinical sites, clinical areas of focus, and a narrative describing the rationale for their selection. We divided options into the categories based on various clinical areas. Students were provided a text box to type a 250-word narrative about why they are interested in the clinical areas.

The process to improve student selection quality for an integrated application was the goal. By analyzing and reorganizing the process a strategy was developed. This process focused on developing functionality and technical capabilities to support the wide ranging needs of all clinical practicum options including local area, distant, specialty and international. Each option had some degree of requirements in which there may have been need for added supplemental forms. Communicating the goals, process and outcomes was important in the development and implementation process to achieve change in the workflow for students and educators. Benefits, limitations, and barriers related to the development, maintenance, and application of the program will be addressed.

Developing a process to improve selection quality for an integrated application became a challenging goal. Limitations identified included incomplete applications, discrepancies between narrative and drop-down menu selections, and the narrative word-length was limiting. Students had difficulty selecting clinical placements as a result of novice skillsets, modest patient exposure, and limited experiences in a variety of clinical areas. Using technology to support the application has enabled educators to successfully assign students to the practicum site of their choice. All applications are retrieved from Qualtrics® and transcribed to an Excel® spreadsheets. The electronic application enables faculty to review student selections via spreadsheets that combined all data onto one file. Students were able to quickly and easily select choices and add pertinent information related to each selection, giving the educator a clear understanding of their post-graduation goals.

B 03 - Promoting Mental Health in Vulnerable Populations

Perceptions of Stigma by Parental Caregivers With Mentally Ill Family Members

Linda Carman Copel, PhD, MSN, MSMFT, BSN, RN, PMHCNS, BC, CNE, ANEF, NCC, FAPA, USA

Abstract

Purpose: The experience of stigma is recognized as a widespread, universal phenomenon which is a major cause of personal suffering and a deterrent to obtaining health care. Vulnerable populations, such as people with mental illness or psychiatric disabilities are at risk for various forms of stigma. Caretakers can frequently identify the types of stigma experienced by their family members. Yet, often there are no services or support groups where the caregivers may verbalize their concerns and frustrations. There is a strong need for caregivers to becoming educated about strategies to advocate for their family members, and reduce or eliminate the stigma associated with mental illness. Since health care providers and social scientists believe that stigma has a negative influence on people's lives by contributing to high levels of stress and social disadvantage, it is the responsibility of providers in the mental health care communities to work with individuals and families to reduce the stigma of mental illness. The main purposes of this study are to describe the parental perceptions of stigma experienced by their adult children with mental illness, and to determine the educational and advocacy strategies that caregivers perceived as useful. An additional secondary purpose was to evaluate an outpatient, community mental health, educational and support program for parent caregivers.

Methods: This retrospective, descriptive qualitative research study examined issues raised by the parental caregivers of adult children diagnosed with mental illness and the effectiveness of two educational programs delivered in a support group format. After obtaining informed consent from all registered participants, the caregiver group meetings held at the community mental health center were video-recorded. Data from each of the ten sessions were analyzed using Elo and Kyngas' content analysis method. Descriptive statistics were used to compile the demographic and evaluation data. Eighteen participants were referred to the program through one of the county family service programs or the outpatient community mental health centers located in two counties in the mid-Atlantic region of the United States.

Results: The findings revealed the specific concerns about stigma experienced by the participants' family members. The information related to the identification of stigma, and the communication and the strategies to address stigma were valued by the participants. Participant comments focused on program content they viewed as making a difference in reducing the experience of stigma. They proposed recommendations to streamline the program and identified the difficult-to-master topics. Six themes that emerged from the data were: Caregiver feelings of frustration, anger and discrimination when their family members experience stigma; Experience of stigma by association; Stigma contributing to health problems of people with mental illness; Concerns about advocacy actions being successful; Desire to establish mental health advocacy groups for education, employment and vocational training; and Need for consumer centers.

Conclusions: Participants appreciated having the educational information and a safe place to discuss stigma experiences and their personal concerns. Customized segments of the program addressing individual concerns were valued. The new knowledge related to strategies to address how to cope, communicate and handle the discrimination associated with stigma facilitated participant learning. Concerns and hesitations were voiced by caregivers about the success of advocacy actions and the ongoing establishment of community-based services for persons with mental illness. The creating and sustaining of Consumer Centers within communities for socialization, peer support, relaxation and fun activities were viewed as important to the well-being of people with mental illness and their family members. Revision of the educational programs based on participant feedback is warranted. Further research is necessary on topics concentrating on the stigma of mental illness, caregiver perceptions of addressing stigma, advocacy strategies, the provision of appropriate community services, and the efficiency and cost-savings of consumer-run centers. Research on the steps to improve mental health

policy, funding, research and legislation can eventually contribute to overall quality of life for people with mental illness and their family caregivers.

B 03 - Promoting Mental Health in Vulnerable Populations

Whole Person Wellness: Integrating Care to Improve Physical Health of Persons With Serious Mental Illness

Kathleen McDermott, DNP, RN, APRN, PMHNP-BC, USA

Abstract

Historically, treatment for serious mental illness has been separated from the rest of medicine resulting in gaps in medical care, redundant care, and increased costs. To address the healthcare needs of those with serious mental illness, primary care services are now being embedded in and connected to community mental health centers. However, numerous barriers exist including cost, program design, sustainability, and the adaptability of electronic health records. The purpose of this project was to describe and analyze the system changes that occurred in a nationally recognized community mental health center resulting from the implementation of grant-funded initiatives to promote the importance of whole health and wellness by integrating primary and behavioral healthcare into its repertoire of services for persons with serious mental illness. Grant outcomes included increasing the number of persons with serious mental illness who were connected with a primary care provider in the local community and those who have active insurance. These outcomes were successful, as nearly three-quarters of the previously uninsured members became connected with public insurance, and greater than 70% of the members were connected with a community primary care provider. Other deliverables designed to increase the level of integration at the community mental health center encountered barriers, such as staff resistance, electronic health record challenges, philosophical differences, and the need for program re-design and highlighted the lack of coordination between agencies. Recommendations have been made for other community mental health centers who are pursuing efforts to increase the level of integrated care they provide, including relevant lessons learned, effective practical approaches, strategies to overcome common barriers, areas of expansion, and methods for sustainability. This case study suggests that efforts to provide integrated care in a community mental health center may necessitate an organizational culture shift that includes the active, cohesive, and clear support of leadership. In addition, strong theoretical underpinnings are necessary to support the change. Prochaska and DiClemente's stages of change (1982) and Roger's Diffusion of Innovations (1962) are examples of theories that can help organizations to successfully adapt to a fully integrated care system.

B 04 - Promoting Health Through Immunizations

Improve Competency With Evidence-Based Immunization Practice Education

Pamela K. Strohfus, DNP, MA, RN, CNE, USA

Abstract

Aim: To improve competency of health care personnel and increase vaccine effectiveness and medical office immunization rates, an evidence-based immunization educational program was implemented and analyzed. The goals of the program were to develop fiscal responsibility of resources, improve internal processes, enhance learning and education, and increase patient safety through effective vaccination.

Background: Vaccines may be compromised partly due to educational deficits of inter professional healthcare personnel in vaccine administration and storage (Nikula, Nohynek, Puukka, & Leino-Kilpi, 2011; Yeung, Goodman, & Fedorak, 2012). These knowledge deficits could further compromise vaccine efficacy decreasing immunization rates among populations (McCollister & Valbona, 2011). Disease outbreaks could occur when herd immunity is not achieved (Centers for Disease Control and Prevention (CDC) 2016).

Evidence based resources are available to ensure quality immunization practices through the use of standing orders, documentation into immunization registries, utilization of data and thermoregulation guidelines (Darden, et al., 2011; LeClaire-Smith, 2016). Yet several studies reveal errors in administration and storage of vaccines which affect the vaccine efficacy (Lang, et al., 2014; Merhekar, et al., 2013).

Methods: Twenty-seven medical offices participated in an educational program in a rural/urban area in the United States. Knowledge-based testing of immunization practices was conducted pre-education, post-education, and 12-months post-education of medical assistants, licensed practical nurses, registered nurses, nurse practitioners, and physicians. Immunization rates were assessed before-education and 18-months post-education.

Results: There were several significant findings when education was provided including: 1. Immunization rates increased by 10.3%, 2. Knowledge overall increased by 7.8%, 3. Under-educated personnel did not pass the test before or after education, 4. Registered nurses and pediatric medical offices passed the test before and after education, 5. Use of standing orders increased by 84%, and 6. Knowledge did not improve overall in 'storage' category.

Conclusion: Managing immunization practices is very complex. Registered nurses are well suited to manage, administer, and handle vaccines. Unlicensed personnel are less able to appropriately manage, administer, and handle vaccines without formal and continuous education and administrative support. Storage and handling education must be reviewed intermittently to assure compliance. Education saves resources, decreases errors, & increases immunization rates.

B 17 - Advancing the Nurse Practitioner

The Nurse Practitioner Clinical Ladder Program: A Journey to Professional Nursing Excellence

Lisa M. Paplanus, DNP, ACNP-BC, ANP-BC, CCRN, RN-C, USA

Patricia Bartley-Daniele, PhD, FNP-BC, CCRN, CNRN, CPAN, CAPA, USA

Patricia D. Chibbaro, MSN, CPNP, USA

Abstract

Quality Nurse Practitioner (NP) care delivery is associated with teambuilding, leadership, communication, clinical knowledge and skills, evidence-based practice, and quality outcome achievement (Cronenwett, 2012; Elliot, 2016). Yet, organizational structures and processes fostering continuous NP practice development have been infrequent (Elliot, Begley, Sheaf, & Higgins, 2016; Porter-O'Grady, 2011). In response to an organizational NP job satisfaction survey, the Nurse Practitioner Clinical Ladder (NPCL) program was developed to enhance professional excellence at a university affiliated medical center in the United States (Misener & Cox, 2001). Senior nursing leadership and administrative support were critical to the NPCL program development. The purpose is to describe professional practice journey and governance needed for the NPCL program development, implementation, and evaluation.

Registered Professional Nurse (RN) clinical ladder program research has been associated with increased RN role development, job satisfaction, and decreased turnover (Adeniran, Bhattacharya, & Adeniran, 2012; Warman, Williams, Herrero, Fazelli, White-Williams, 2016). There was a dearth of knowledge concerning NPCL program development and outcomes. Benner's (2000) five levels of nursing practice provided a blueprint for behaviors and competencies associated with beginning, competent, proficient, and expert RNs. Benner's nursing practice levels were viewed within an advanced practice nursing lens and incorporated into the NPCL program.

Critical literature review, deliberation, and reflection by the NPCL committee members provided consensus for the NPCL program development. The organizational professional nursing practice model building blocks of caring, practice, collaboration, communication, professional development, and evidence-based practice were incorporated into the NPCL program. Three levels of NPCL practice were developed as a blueprint to foster NP role development, professional growth, evaluation, promotion, and rewards. The NPCL is reflective of the American Nurses Credentialing Center (ANCC) Magnet Model (2016), and the National Organization of Nurse Practitioner Faculties NP Core Competencies (NONPF, 2012). The NPCL practice domains and competencies included clinical practice and outcomes, academics and advanced nursing expertise, leadership and administrative support, professionalism, and community service.

Donabedian's Model of Quality Health Care (1988) guided the NPCL structure and process standards. The NPCL Structure Standard defined the program goals, NP practice levels, advancement opportunities, an incentive and reward system, and annual NP level performance appraisal components. The NPCL Process Standard described the NP promotional application requirements, professional portfolio elements, the NPCL review committee roles and responsibilities, the promotional decision-making, and the appeal process (Hespenheide, Cottingham, & Mueller, 2011). The NPCL outcome measures included the NP job satisfaction survey, job retention, and NP level promotional statistics. The need for an ongoing NP mentorship program and formalized orientation to the NP role were NPCL outgrowths. Ultimately, the NPCL can serve as a foundation for other nursing specialties to develop, implement, and evaluate their clinical practice. The NPCL program supports advanced practice nursing roles and competency development that can be translated at organizational, national, and global levels.

B 17 - Advancing the Nurse Practitioner

The Nurse Practitioner (NP) Mentorship Program: Supporting Role Transition Into Practice

Patricia Bartley-Daniele, PhD, FNP-BC, CCRN, CNRN, CPAN, CAPA, USA

Tracy Lynne McTiernan, MA, CPNP, USA

Camille LaPera, MA, ACNP-BC, USA

Abstract

Political, social, and governmental influences have increased the nurse practitioner (NP) demand in the United States (Institute of Medicine, 2010; McMullen & Philipsen, 2012). Graduate NP programs have developed practice competencies and support the Doctorate of Nursing Practice preparation to enhance NP roles (National Organization of Nurse Practitioner Faculties, 2012). Although there have been efforts to increase the NP workforce, there remains a current gap in the health care provider supply (Sargen, Hooker & Cooper, 2011). Therefore, it is critically important to support novice NP role development (Poghosyan, Liu, Shang, & D'Anno, 2015). Although novice NPs have varying amounts of registered professional nursing experience, they are becoming new health care providers with significant new advanced role responsibilities. The NP graduates must be socialized to a new professional role and navigate complex regulatory and reimbursement requirements (Barnes, 2014; Fitzpatrick & Grishover, 2016; Simone, 2014). A university affiliated medical center analyzed NP job satisfaction results and the need for a mentoring program was identified (Harrington, 2011; Simone, 2014). The purpose is to describe a NP mentorship program that is supportive of newly hired NP role transition into practice.

Mentoring has been explored as a strategy to foster NP transition into practice (Gerhardt, 2012; Pop, 2016; Rafferty, 2015). Mentoring, through a nursing lens, has been a teaching-learning process. Conceptually, mentorship is a relationship in which a more experienced professional provides support and guidance for the novice (Harrington, 2011). Mentorships encompass formal and informal relationships. Formal mentorships are structured workplace agreements that foster mentee success through mentor-mentee matching and are time limited. In contrast, informal mentorships develop as the result of mutual interests and are not confined to time, structure, or third party expectations (Grossman, 2014). Successful mentoring relationships require the participants' time, commitment, communication, availability, and compatibility (Fitzpatrick & Grishover, 2016; Grossman, 2014; Simone, 2014). High quality mentoring relationships have been characterized as being meaningful, mutually beneficial, and fostering professional and personal growth (Allen & Eby, 2003). Mentorship has been identified as a need for successful novice NP transition into practice (Gerhardt, 2012; Pop, 2016; Rafferty, 2015).

Benner's (2000) Novice to Expert Model and Donabedian's (2005) structure and process framework provided the foundation for the NP Mentorship Program development. The novice NPs were newly hired into their first NP position; the NP mentors were identified as experienced NPs who accepted a mentoring assignment (Benner, 2000). The NP Mentorship Program Structure Standard defined the NP practice levels, competencies, onboarding process, orientation, mentor and mentee responsibilities, and NP preceptor roles. The NP mentorships were formal relationships with mentor and mentee matching. During the yearlong mentoring relationship, NP mentors and mentees participated in quarterly invitational meetings. The invitational meetings included mentoring circles and opportunities for professional development, problem solving, and psychosocial support (Maynard, Scandura, & Bishop, 2013).

The NP Mentorship Process Standard described the Mentorship Committee members' role responsibilities. The NP Mentorship Program coordinator role was developed to maintain the mentor directory, communicate with the mentees, match the mentor and mentee, and assist with program implementation and evaluation. Formative evaluation components have been incorporated. Ongoing feedback during the mentoring invitational meetings was welcomed and influenced the future invitational meeting themes. Summative NP Mentorship Program measures included NP job satisfaction, job retention, mentoring relationship quality (Scandura, 2015), and career and psychosocial functions development (Allen, Eby & Lenz, 2006).

The NP Mentorship Program has challenged traditional concepts and ideas (Huizing, 2012); Maynard, Scandura, & Bishop, 2013). Implications for future nursing knowledge development include multiple mentoring strategies exploration, mentor perspectives evaluation, and the long term impact of NP mentoring relationships (Allen & Eby, 2003). Currently, international NP residency, orientation, and fellowship programs support NP competency development (American Nurses Credentialing Center, 2016; Brown, Poop, Kaminetzky, Wipf & Woods, 2015; Furfari, Rosenthal, Tady, Wolfe, & Glasheen, 2014; Sciacca & Reville, 2016). Mentoring can enhance NP competency through role development within a nurturing advanced practice nursing culture. A NP mentorship program has the potential to support transition into practice and enhance NP orientation, residency, and fellowship program development.

C 01 - Student Nurse Communication Skills

A Global Measure of Nursing Student Communication: The Interpersonal Communication Assessment Scale (ICAS)

Marilyn Klakovich, DNSc, RN, NEA-BC, USA

Abstract

The purpose of this presentation is to describe the Interpersonal Communication Assessment Scale, its usefulness in nursing schools in the USA, and efforts to increase the global usefulness of the scale through translation and adaptation for use in other languages and cultures.

In the late 1990's, despite the centrality of interpersonal communication in nursing, there were few psychometrically sound instruments to measure the communication competencies of undergraduate and graduate nursing students. A colleague and I set out to develop and test the Interpersonal Communication Assessment Scale (ICAS), which was designed to assess the communication competencies of students in undergraduate and graduate nursing programs.

We used responses from undergraduate and graduate clinical faculty from 246 American Association of Colleges of Nursing member schools for the psychometric testing of the ICAS. The three subscales of the ICAS represent important dimensions of interpersonal communication and include advocacy, therapeutic use of self, and validation. Advocacy is clearly conveying diagnostic and other relevant information in a way that supports patient/family wishes and decisions. Therapeutic use of self is defined as demonstrating interpersonal behaviors that assist clients in achieving healthy emotional and behavioral outcomes by being genuine, empathetic, and respectful to the client). Validation consists of listening carefully and verifying that the intent of messages is accurately interpreted (Klakovich & dela Cruz, 2006). In a systematic review of objective measures used to assess pre-registration students' clinical competence, the ICAS was one of 6 instruments out of 16 judged as having high quality with low risk of bias (Cant, McKenna, & Cooper, 2013). It is listed by the Health Foundation (2014) in their "Helping measure person-centred care" publication as a professional measure of a behavior that supports person-centered care. And Oermann (2013) lists the ICAS as a level 2 affective measure as part of the Kirkpatrick model.

The ICAS has been used to track the communication development of nursing students in both undergraduate and graduate programs in the United States. It has also been adapted for work with Alzheimer's patients and their caregivers. Since all of the initial testing was completed with United States students and faculty, careful translation, adaptation, and further testing were needed before use in other countries. To date, it has been translated into Chinese, Italian, Portuguese (Lopes, Azeredo, & Rodrigues, 2013), Tagalog, and Viet Nameese.

Educators and researchers seeking permission to translate and adapt the ICAS are guided to use the process described by dela Cruz, Padilla, and Agustin. This process includes translation and back-translation. The original authors of the ICAS served as consultants to ensure the interpretation of each item was preserved. Items were adapted as needed to be sensitive to cultural issues. Judges of the translation of the ICAS into Portuguese concluded that it is suitable for use with Portuguese nursing students (Lopes, Azeredo, & Rodrigues, 2013).

As global boundaries continue to blur, it is important that nurse educators and researchers identify instruments that can be used in a variety of countries as teaching tools and evaluation measures to ensure we are preparing a global nursing workforce for the future.

C 01 - Student Nurse Communication Skills

How Baccalaureate Student Nurses Use Art Therapy to Facilitate Therapeutic Communication

Robyn Rice, PhD, MSN, RN, CNE, USA
Joyce Mary Hunter, MSN, RN, USA

Abstract

Background: Developing communication skills and therapeutic relationships are key components in baccalaureate nursing education. These skills and techniques are emphasized within mental health courses as student nurse interactions are seen as key interventions to foster patient coping, stabilization, and recovery. However, patients with mental illness are not an easy population to communicate with as related to their stress levels and disease processes. This situation is magnified for student nurses who are still learning ways to dialogue. In fact, establishing one to one interactions with mental health patients and experiencing moments of silence with them, both embedded in therapeutic relationships, may be very challenging for student nurses. This can possibly be related to inadequate or under-developed student nurse communication skills as well as a fear of saying the wrong thing. Communication and verbalizing healthcare concerns may play a major part in assisting mental health patients to develop positive coping skills for recovery and community independence. Difficulties in communicating with mental health patients may be further compounded by the nature of involuntary settings where the mental health nurse must negotiate relationships and set boundaries regarding angry or otherwise unacceptable patient behaviors. A significant issue here is that patients with mental health disorders often experience varying degrees of inactivity, boredom, perceptual disturbances, angry and isolative behavior making communication difficult for them. When working with this group, student nurses may lack self-confidence and be fearful of saying the wrong thing to the patient. Moreover, and of importance to this study, student nurses may find it very difficult to form therapeutic relationships with mental health patients related to a lack of targeted communication skills and techniques which they do not necessarily get in school for this special patient group. Art therapy is a recognized method of promoting mental health. Moreover, art therapy can re-direct patients' mental suffering into positive forms of self-expression(s) that may improve their overall quality of life. To date, no research has been done to investigate how student nurses develop a therapeutic relationship with mental health patients using art therapy to facilitate communication. Of consequence, art therapy may be very helpful in assisting student nurses within clinical experiences in the mental health setting.

Purpose: The purpose of this study was to explore how undergraduate student nurses use art therapy to promote therapeutic communication with mental health patients. This was a qualitative study using principles of thematic analysis. The following research question was asked:

What is the effect of art therapy on the therapeutic relationship and communication between student nurses and mental health patients?

Participants: Participants in the study were undergraduate nursing students from a mid-western university. Two of the researchers not affiliated with the university went to the students' class to describe the study and ask for volunteers. Participants were offered a 25 dollar gift certificate for participating in the study. Thirty-two student nurses agreed to participate in the study. Participants in the study consisted of both male and female student nurses from diverse social and ethnic backgrounds.

Design and Methods: This was a qualitative study using principles of thematic analysis. Art therapy was rendered in each clinical setting in the form of crayons and paper or coloring books, whereby student nurses and mental health patients actively participated in coloring together on a one to one basis in an open, observed area such as in the dining room or in a group setting under the direction of a certified art therapist. A semi-structured interview was administered to undergraduate student nurses. Three primary interview questions with probes were asked of the students during all interviews in order to answer the research question:

1. What is it like to communicate with mental health patients?
2. Have you used art therapy when communicating with mental health patients? What was it like?
3. How does art therapy assist you to communicate with your patient during your mental health experience?

All student nurses took turns answering the interview questions; when responding to the questions they were assigned numbers rather than using their names. In some exchanges student comments supported those of others. In other exchanges student comments stimulated new insights among the group.

Data were collected via audiotape and then analyzed and summarized into themes for reporting according to principles of thematic analysis. The interviews were professionally transcribed verbatim and accuracy of the transcriptions verified by the primary investigator. The transcripts were read multiple times to identify commonly occurring words and ideas. These formed the basis for the analysis. Data were processed and analyzed using a software program. Discrete themes were initially identified by in vivo coding of the student nurse's open-ended interview responses. Later, these codes were refined to reflect common elements and were named to capture the essential meaning of each theme. Subthemes were identified during this process. In addition, the investigator's memos, hand written notes, and diagrams of the data were used in the data analysis. All themes were reviewed to ensure that they emerged from the data thus avoiding *a priori* assumptions. Transcripts were read multiple times by all researchers. The in vivo codes and emerging themes were reviewed by the researchers and discrepancies were resolved by examining the transcripts to ascertain the meaning of the thoughts of the student nurses. The participants' words in the transcripts provided final support of the results derived. Findings were compared with the original transcripts as well as the researchers' memos and diagrams. To promote credibility of the findings a confirmatory analysis was done by a colleague expert independent of the study having a mental health clinical background and experienced in qualitative research methods.

Results: Art therapy facilitated student nurse and mental health patient communication. Art therapy also enabled a comfortable silence between student nurses and mental health patients where both could just *bewith* each other in a safe and non-judgmental relationship. Students overcame their fears of saying or doing the wrong thing. Patients began to share feelings and tell their stories; student nurses began to understand what was going on with them and grew professionally in learning more effective ways of gathering information. Silently being with the mental health patients and communicating non-verbally built on the student nurse's professional experiences of presence, reflection, and intuition.

Conclusions: In conclusion, this study supports art therapy as a valuable tool in facilitating therapeutic communication between student nurses and mental health patients. Art therapy promotes patient self-revelation of thoughts and feelings as well as comfortable silences between student nurses and their patients where trust is established and positive relationships with the patient occurs. It allows for professional growth of student nurses in their communication skills. Most importantly, this study supports the incorporation of art therapy as a deliberate communication strategy in baccalaureate nursing education to enhance the professional growth and development of student nurses as practicing nurses today and tomorrow.

Implications: Research should be conducted with mental health patients and staff nurses regarding the efficacy of art therapy. This study also supports the intentional use of art therapy with mental health patients to enhance communication and suggests it be integrated into baccalaureate nursing education both in the classroom and clinical setting as well as in online curriculum design.

C 02 - Domestic Violence and the Promotion of Mental Health

The Relationship Between Marginalization and Mental Health Symptoms in Abused Women

Anne Koci, PhD, RN, FNP-BC, WHNP, USA
Judith M. McFarlane, DrPH, RN, FAAN, USA
John A. Maddoux, PhD, MA, USA

Abstract

Background: Globally intimate partner violence (IPV) affects 1 in 3 women (WHO, 2013). One important factor that may be associated with the increased vulnerability to abuse is marginality which brings about social isolation as well as psychological isolation of individuals. This isolation has negative consequences for emotional health (Koci, 2012; Symes, McFarlane, Nava, Gilroy, Maddoux, 2013) Anxiety, depression and PTSD are adverse mental health symptoms that increase the risk for suicide. The World Health Organization's Sustainable Development Goal 3 is to ensure healthy lives and promote well-being for all at all ages and to reduce premature mortality from suicide.

Purpose: The purpose of this study was to examine the link between marginalization and mental health symptoms among women with known histories of intimate partner violence.

Methods: Data utilized in this study included five-year data from a prospective seven-year study examining the clinical outcomes of women seeking support through either a safe shelter or the DA's office for the first time following a violent relationship (n=279). Women were surveyed every four months for five years. Key measures utilized for this sub-analysis included the Koci Marginalization Index, Brief Symptom Inventory, and a PTSD screening measure.

Results: A series of multiple linear regressions were conducted to predict mental health outcomes (depression, somatization, anxiety, PTSD) from current levels of marginalization, controlling for entry levels of marginalization. Results indicated that marginalization was significantly associated with higher levels of Global Distress ($Beta = .319$), Depression ($Beta = .349$), Anxiety ($Beta = .294$), Somatization ($Beta = .197$), and PTSD symptoms ($Beta = .366$). Results consistently demonstrated that higher levels of marginalization were associated with higher levels of mental health symptoms.

Conclusions: Our findings revealed a positive relationship between marginality and adverse mental health outcomes of depression, anxiety, somatization, and PTSD symptoms indicating that the more marginalized woman suffers more deeply with mental health symptoms which may put her at higher risk for suicide. These findings concur with previous research (Koci, 2004) that marginality of women contributes to social isolation and deterioration of mental health. This longitudinal study in the 5th year serves as an alert to healthcare providers to the possibility of long-term abuse-related sequelae in their practice. This research contributes to the knowledge of marginality, a social determinant of health. Understanding marginality and its impact on mental health may aid in reducing mortality from suicide. Policymakers need to be cognizant of the role of marginality in females and its potential adverse impact on their mental health which may aid in the development of healthcare agendas at all levels of government.

C 02 - Domestic Violence and the Promotion of Mental Health

A Cognitive-Behavioral Therapy Program for Youth Who Engage in Domestic Violence Against Their Parents

Anthony J. Roberson, PhD, RN, PMHNP-BC, USA

Abstract

Purpose: The purpose of this oral presentation is to present the specifics and the results of an evidence-based, Cognitive-Behavioral Therapy intervention program developed for youth who engage in domestic violence against family members, and their parents.

Problem: Domestic violence by youth against family members, particularly their parents, is on the rise in the USA and in other countries (Imbusch, P., Misse, M., & Carrion, F., 2011; Martinez-Lanz, P., Gonzalez, A., & Ocampo, D.B., 2014; Zeoli, A.M., Rivera, E.A., Sullivan, C.M., Kubiak, S., 2013). Specifically, in Miami-Dade County (Miami, Florida, USA), the number of youth who engage in abusive behaviors (physical and verbal) against their family members has led to an increase of juvenile arrests and encounters with the juvenile justice system (JJS) (Jouriles, E.N., Rosenfield, D., McDonald, R., Mueller, V., 2013; Miami-Dade, 2016). Unfortunately, these arrests have led to incarceration of youth who otherwise had no previous encounters with the JJS. Further, data indicates that initial arrests among youth have resulted in a noticeable increase in subsequent arrests (for various reasons) upon release of the youth from the JJS back into the community (Miami-Dade, 2016). Because of the increase in domestic violence of youth against their parents and family members, and the unmanageable increase of youth who were being incarcerated for domestic violence, a judge within the Miami-Dade JJS sought the assistance of a research/advanced practice nurse, therapists, lawyers, probation officers, and social workers, to address this growing and seemingly uncontrollable epidemic. In collaboration with a representation of disciplines, this author (research/advanced practice nurse) led the development of a program that was implemented to divert youth who engaged in domestic violence from encountering the JJS, thereby avoiding incarceration when unnecessary and otherwise avoidable.

Intervention: The four week, four module program, solidly grounded in the tenets of Cognitive Behavioral Therapy (Clark, P., 2010; Townsend, E., Walker, D., Sargeant, S., Vostanis, P., Hawton, K., Stocker, O., & Sithole, J., 2010) was a collaboration between a School of Nursing, Coordinated Victims Assistance Center (CVAC), Miami, Florida, and the Miami-Dade County Juvenile Justice System (JJS). The target population was youth, male and female, age 13-17, who engaged in domestic violence against their parents and/or a family member, had a history of psychiatric mental health treatment, and who had limited previous encounters with the JJS. The latter criteria proved important, as research indicates that youth who are not fully involved in the JJS are more likely to change their behaviors and avoid further involvement in the system if interventions are implemented in the early stage(s) of their offenses (Jouriles, E.N., Rosenfield, D., McDonald, R., Mueller, V., 2013). In addition, because of the limited involvement of these youth in the JJS, the intervention program served as a diversion for the youth, as agreed upon by the judge; meaning that if youth successfully completed the program, s/he could avoid further incarceration, probation, and/or record of involvement in the JJS. Parents of the youth were also involved in the intervention program (Aos, S. & Drake, E., 2013).

Cognitive Behavioral Therapy (CBT) is the psychiatric mental health therapy approach that has proven exceptionally and consistently successful among various incarcerated populations, including offenders of drug paraphernalia, driving while intoxicated, and those who commit what are considered minor offenses, such as petty theft, vandalism, and battery/assault (Clark, P., 2010; Townsend, E., Walker, D., Sargeant, S., Vostanis, P., Hawton, K., Stocker, O., & Sithole, J., 2010). Further, CBT is a short-term, focused, and concise therapy approach, which is ideal for the youth population. Lastly, CBT approaches can easily be implemented in a group setting, thereby reducing costs associated with individual therapy approaches and casting a larger net in terms of treatment (WSIPP, 2015). Since domestic violence is defined for the most part as a minor offense (especially among youth), and a short-term, brief therapy approach was desired, a program with a strong CBT approach was created. The overall goal was to improve the lives of

the youth who were enrolled in the program. Therefore, Transforming Our Youth (TOY) became the name of the program.

The content of the TOY program modules included anger assessment (identified through the administration of the GAIN-I and GAIN-SS), reviewing domestic violence concepts, understanding the profile of the batterer, and describing the cycle of violence. In addition, roles (present and desired) within the family were explored, which included a discussion related to the strong cultural component of domestic violence (especially relevant considering the strong Hispanic representation of youth in the program), and the communication between youth and their parents were evaluated (Macias, R.L., Rosales, A., Morales, A., Serrate, J., Perilla, J., 2013; Perilla, J., 2013). The program also included a component of self-evaluation which involved the youth considering the consequences of their abusive behaviors. Lastly, the program incorporated activities (homework) for the youth to begin adopting and implementing more effective and healthy communication and interactions with those in their family. The parent component of the program was similar in content to that of what was presented to the youth. However, parents were also encouraged to process their concerns with specific parenting issues, along with ways to better manage their youth in terms of setting limits in productive, healthy, and effective ways. The youth and parent groups, although facilitated in separate rooms at the JJS, were held at the same times, mainly for convenience, but most importantly so the youth and parents received the same information and worked on the same assignments between sessions. Each cohort of youth and parents completed the program over a consecutive four week period, completing one module of the program each week.

Results: Considering the nature and cycle of domestic violence, we defined initial success of the program as a youth who avoided encountering the juvenile justice system at least six (6) months after the initial domestic violence offense. The program continues to date, and is now being facilitated by youth and parents who completed the program. Nevertheless, for this presentation, the data from the first four cohorts of youth (n=45) and their parents (n=53) are included. Among the four cohorts, all have reached the six (6) month post-intervention date, and no youth have re-encountered the JJS since completing the TOY program. Based on the pre-intervention data provided by the Miami-Dade JJS youth domestic violence arrest record, the fact that no youth was arrested within the six month post-intervention period was a significant and promising finding.

Summary: A Cognitive Behavioral Therapy approach to address youth domestic violence against their parents and other family members was implemented as a component of a diversion program. Success in the program was measured if the youth never engaged in domestic violence six months post intervention. The first four cohorts of youth were included in the initial evaluation of the program. The results include no re-arrest of youth, which is significant considering the number of youth who were being arrested after their initial arrest for domestic violence.

Implications for Nursing Practice and Future Projects: As a researcher and advanced practice nurse with over 20 years of experience of service in the JJS, I recognize that the TOY intervention program can be implemented in a variety of juvenile justice settings, including the USA and other countries. As part of a global initiative, my goal is to introduce this program not only in other counties across Florida and the USA, but also in countries where domestic violence among youth is increasing (i.e. Latin American countries) (Martinez-Lanz, P., Gonzalez, A., & Ocampo, D.B., 2014). Further, the evaluation of the TOY program includes only the first four cohorts that completed the six-month evaluation period, which was the intent when the program was originally implemented. However, since that time, our interests have expanded to include evaluation of the long-lasting, and perhaps lifetime, effect(s) of the program. Therefore, longitudinal data collection and analysis, including arrest activity of youth who completed the TOY program, will be conducted and eventually presented in subsequent scholarly publications.

C 03 - Nursing Student Support Strategies

Those Entitled Millennials: Comparative Analyses of Nursing Faculty and Student Narcissism and Organizational Support Measurements

Kate Rocklein Kemplin, DNP, MSN, BNSc, RN, CCEMTP, USA
Peyton Marie O'Kain, BSN, SN, USA

Abstract

Purpose: Internationally, attrition of nurses and nursing faculty is well-documented (Aiken, Sloane, Bruyneel, Van den Heede, Sermeus, & RN4CAST Consortium, 2013; Van den Heede, Florquin, Bruyneel, Aiken, Diya, Lesaffre, & Sermeus, 2013). Intergenerational antagonism between the millennial generation of nursing students who are entering practice and older generations of nurses and nursing faculty may lead to high professional attrition and therefore, poor patient outcomes due to the lack of dedicated, young nurses who feel supported by those who should be mentoring them for the future. Vast generational differences exist between the upcoming cohorts of nurses, i.e. "Millennials" entering practice and those who educate, supervise, and design these millennials' education and career pathways. Older generations of nurses and nursing faculty often view students and younger nurses as entitled and unprofessional, yet the evidence supporting these assumptions and perceptions is virtually nonexistent.

The scope and purpose is to globally disseminate the results of this innovative nursing research that generated new knowledge of entitlement and narcissism plus organizational support as perceived by intergenerational nursing faculty and student participants. Investigating generational divides between faculty and students is imperative, as such divisions exist in nursing academia, research, and practice. This study demonstrated that students, particularly undergraduate, feel less supported than what faculty believe they provide in supportiveness. Millennial nursing students likely have vastly different expectations of support than previous generations (Goldman & Martin, 2016); anecdotally, such expectations are often perceived by nursing faculty as unbridled entitlement. This generational disconnect between nursing students and faculty can cause tension, miscommunication, and possibly obstruct learning and effective teaching. Exhaustive review of extant literature revealed little-to-no investigation of the relationships between perceived support and measures of entitlement and narcissism in nursing students.

Methods: After institutional review board (IRB) approval, 329 participants were recruited via email and social media; total participants were 110: 56 undergraduate students, 29 graduate students, and 25 faculty. Using psychometrically superb instruments such as the perceived organizational support scale (POSS) (Kottke & Sharafinski, 1988) and the Narcissistic Personality Inventory (NPI) (Ackerman, Donnellan, & Robins, 2012), participants responded anonymously after granting informed consent. The POSS has high internal consistency with a Cronbach's alpha of .97; the NPI has a high Cronbach's alpha of .84.

Results: Multivariate analyses revealed significant differences and predictions of generational perceptions between nursing faculty, undergraduate, and graduate students. We also ran nonparametric analyses (Kruskal-Wallis) to confirm results among the three groups of median scores. Perceptions of support, plus measures of narcissism and entitlement, differed significantly between groups and categories ($p < .05$; .01; .005; .0005). Despite nursing practice experience and presumed maturity, perceived support, entitlement, and narcissism differed significantly between nursing student groups and nursing faculty. Generational assignment does not appear to influence entitlement as heavily as hypothesized. Faculty feel they are supportive beyond what students reported. There were also strong disparities between participant beliefs regarding what elements of student performance should be factored into grades.

Conclusions: Despite pervasive cultural stereotypes of millennials, all participants plus categorical designations scored differently than hypothesized on measures of entitlement and narcissism. These new results from this innovative research are supported by previous investigation indicating that millennial learners have different expectations of faculty than older or previous generations (Johanson, 2012).

Faculty must begin to consistently examine their own generational characteristics and understand how that influences teaching and students (Roberts, Newman, & Schwartzstein, 2012). Students feel more supported by faculty when interpersonal initiatives bridge generational gaps (Roberts et. al, 2012), such as incorporated technology (Montenery, Walker, Sorensen, Thompson, Kirklin, White, & Ross, 2013). This research should be presented internationally to educate nurse scientists and educators to improve intergenerational relationships in nursing education and throughout the workforce.

C 03 - Nursing Student Support Strategies

Embedding a Clinical Therapist as Staff Into a Faculty/School of Nursing

Linda J. Patrick, PhD, MSc, MA, BScN, RN, Canada

Laurie M. Carty, PhD, BA, BScN, RN, Canada

Sheema J. Inayatulla, MBA, BSc, Canada

Katelyn J. Verkoeyen, Canada

Abstract

The mental health of post-secondary students on college and university campuses has received considerable media attention especially when harm to self or others is the outcome. Nursing students are not immune to psychological distress and mental illness (Stallman & Shochet, 2009). Compared to the majority of post-secondary students, nursing students reportedly have a higher risk of mental health difficulties including excessive stress, anxiety and depression that can lead to poor health outcomes (Chernomas & Shapiro, 2013; Fitzgerald, 2015). There are many campus wide resources for students to access at their respective institutions, but they are often unwilling to voluntarily seek counselling during periods of escalating stress and anxiety. According to Galbraith et al., they prefer instead to confide in friends and family (2014). This avoidance behavior was described by Goff (2011) as possibly due to the perception that accessing services is a sign of weakness or inability to cope with the requirements of being a nurse. Our experience has included students revealing ineffective coping skills and mental health related issues to clinical and theory teachers when unsuccessful in a course. Instructors struggle with separating academic advising from emotional support during a student crisis. In severe cases, intervention includes walking a distraught student to counseling services across campus for fear that they would harm themselves. Additionally, faculty voice frustration with delays in assessment and interventions by external therapists to allow students to have a timely return to their studies. The inability to provide a smooth transition back to clinical in particular resulted in higher attrition rates and delayed completion of the nursing program. In 2012, a part-time clinical therapist was hired as a permanent staff position in our Faculty of Nursing. Students self-refer to the therapist or are referred by our academic advisor or faculty. The addition of a clinical therapist to our team has led to our students receiving timely and often pre-emptive counseling for issues related to both personal and academic stress. Outcomes include decreased attrition rates across all four years of the baccalaureate program and an enhanced student experience.

D 13 - Clinical Care Practices

Clinical Practice Characteristics of Nurse Practitioners Managing the Care of Older Adults

Laurie Kennedy-Malone, PhD, GNP-BC, FAANP, FGSA, USA
Marianne Shaughnessy, PhD, RN, AGPCNP-BC, USA

Abstract

Purpose: A national survey of nurse practitioners (NP) who manage the care of older adults in the United States was conducted to determine the practice characteristics in terms of engagement in professional activities and clinical skills in relationship to years of experience as a nurse practitioner, practice setting, and population foci nurse practitioner preparation (adult, gerontological, adult-gerontology, family, or other).

Methods: The Advanced Practice Nurses Managing the Care of Older Adults Practice Profile (APNMCOA), a 153 item survey designed to ascertain practice characteristics of nurse practitioners managing the care of older adults was developed to be administered in an on-line survey format. Using a variety of electronic communication to invite nurse practitioners to participate in the study, the survey was made available for two months for nurse practitioners to voluntarily complete and submit. The APNMCOA is divided into five sections. The first section pertains to demographic information, followed by a section on type of national certification, educational preparation and prescriptive privileges. The nurse practitioners are then asked to rate the frequency and importance of 61 professional activities. Given next a list of 41 clinical procedures, the nurse practitioners were asked to indicate where they learned how to perform the procedure and how often they performed the procedure. The final section of the survey pertained to prescribing patterns of specific classes of medications.

Results: Over 1200 nurse practitioners responded to the survey during the two month time period that the survey was available on-line. With an average age of 51, the majority of respondents were master's prepared Caucasian females with prescribing privileges, DEA number billing under their National Provider Identifier Standard number. The average number of years practicing as a nurse practitioner was 11. Only a small percentage of the NPs (12%) responded that they were billing "incident-to" the work of a physician in their practice. Many of the respondents indicated that they held more than one national certification as a nurse practitioner and multiple subspecialty certifications. The educational preparation of nurse practitioners responding was almost divided evenly amongst adult, gerontological, and family nurse practitioners with a small remaining percentage indicating preparation as an adult-gerontology acute or adult-gerontology primary care nurse practitioner. The majority reported having prescription privileges their own DEA number and billing using the NP special national provider number. When examining the responses to the 61 professional activities which were indicative of engaging in gerontological specific practice, the respondents more often responded that they valued the activity more than they actually engaged in the activity. Procedures that nurse practitioners responded that they regularly perform included clinical skills performed by primarily by registered nurses as well as procedures often deemed medical acts in state nurse practice regulations.

Conclusion: The results of this study indicate that nurse practitioners manage complex care of older adults across multiple practice settings. Findings of this study need to be disseminated to nurse educators, policy makers and consumers alike.

D 13 - Clinical Care Practices

The Value of Fracture Liaison Services: A Focus Group Study

Sharon Kan-Ha Chow, DNP(c), RN, ANP-BC, PPCNP-BC, CCD, USA

Abstract

Purpose: Economic analysts have predicted that worldwide aged 65 years and older will increase to more than 1.3 billion by 2040. The growing aging population carries a high prevalence of osteoporosis and a high incidence of morbidity and mortality. In the United States, only 5% of patients with osteoporosis are properly diagnosed. The International Osteoporosis Foundation advocates Fracture Liaison Services (FLS) as best practice that ensures appropriate osteoporosis testing, diagnosis, treatment and ongoing support for fracture patients. Highly collaborative Kaiser Permanente Southern California Healthy Bones Program is recognized as best FLS practice to proactively identify, screen, and treat adults who may have or be at risk for osteoporosis. The purpose of this qualitative study is to explore the value of the Healthy Bones Program as perceived by Kaiser Permanente members aged 65 years and older, specifically relating to patient care experiences and health outcomes. A secondary purpose is to elicit information about members' knowledge and value for the collaborative efforts that are implemented to improve patient care experiences and health outcomes.

Methods: Two focus group interviews were conducted with 6 participants per group, for a total of 12 participants at Fontana Kaiser Permanente Medical Center. The interviews were conducted by the primary investigator and co-investigator using semi-structured, open-ended and prompting questions to gain participants' detailed insights. All recorded interviews were professionally transcribed verbatim. Qualitative content analysis and interpretive processes were utilized to facilitate better understanding of participants' experiences and perceptions. The use of Nvivo software assisted in coding, as well as generating reports of coded text for analysis. A word cloud was developed to enhance a visual representation of overlapping themes within the study.

Results: This focus group study successfully explored participants' understanding and experience of the value of Healthy Bones Program, and investigated participants' views on how they would like to be involved in care experiences and health improvement. Five cluster themes and their subthemes were identified, such as Healthy Bones Program knowledge, perceived collaborative care, osteoporosis self-care management, Healthy Bones Program care experiences, and healthy lifestyle and living longer. Participants' positive and negative comments of their care experiences were carefully summarized. Health education of bone health and osteoporosis management were highly appreciated as beneficial and informative intervention, to enrich and empower osteoporosis self-care management. Participants felt well informed and motivated, to get more involved in their osteoporosis care. Participants experienced that electronic health records facilitated collaborative care in osteoporosis screening, treatment and follow up. Preventive care was valued as the key measure for general health and bone health promotion. Participants commented that bone health promotion and osteoporosis prevention should be started at an earlier age, around 30-40 years of age. In order to live longer, participants all seek for health education, and maintain healthy eating and healthy lifestyle.

Conclusion: In today's ever-changing, complex healthcare systems, patient care experience is purposefully built on an organization's collaborative efforts to shape a positive care experience. When patients can have a voice, quality patient-centered care will be expected throughout health continuum. In order to meet the preventive care commitment, FLS strategies will interprofessionally help decrease the burden of osteoporosis. The focus group study findings can influentially impact in measuring program success, and triggering necessary program improvement. The results will be disseminated at the local, national and international levels to transform collaborative, evidence-based osteoporosis care management, to improve patient care experiences and health outcomes.

The Effect on Inter-Rater Consistency Using a Standardized Assessment Tool/Framework in Musculoskeletal Examinations

Debra Lynn Brewer, DNP, RN, FNP-BC, USA

Abstract

This quality improvement (QI) project was conducted to determine if a standardized assessment framework/tool for clinician use when conducting musculoskeletal examinations for disability claims would increase inter-rater consistency. The problem of inconsistent musculoskeletal examination outcomes was identified when clinicians performing disability examinations at a large healthcare organization reported a lack of criteria on which to base the determination of "functional loss." The finding of "functional loss" was being made independently by each clinician without any specific criteria and the examination outcomes lacked inter-rater consistency. A survey of the clinicians revealed that several examiners concluded that an examinee experienced "functional loss" in a large percentage of the examinations they completed, while other clinicians rarely indicated a "functional loss" existed, despite similar findings in examination metrics, such as range of motion and/or pain. This resulted in unfair compensation for the disability claimants. Standardized assessment tools have been used widely in a variety of settings in various disciplines and have proved to be beneficial in identifying and quantifying body function and structure limitations; this improves inter-rater consistency and clinical practice. A thorough evaluation of available tools and frameworks for use in musculoskeletal examinations was conducted and an appropriate framework was selected for use in this QI project by the clinicians performing the disability examinations. Rhetorical education, lunch-time discussions, slide presentations, and case studies were carried out to convey all educational information necessary regarding the purpose, function, and use of the selected framework. Clinicians were required to achieve an 80% pass rate on a post-education examination to assure appropriate use of the selected framework. A three-month period of post-education shoulder examination data was collected for comparison with the previously collected data. A Pearson's Chi-Square test performed to analyze the data and revealed a statistically significant association ($\alpha=0.05$ level) between post vs. pre-intervention for "functional loss" findings by clinicians, along with a seven-fold increase in overall positive findings for "functional loss" by clinicians using the standardized framework to perform the musculoskeletal examinations.

D 16 - Developing Faculty Globally

Using the Lived Experience to Increase the Cadre of Nursing Faculty Who Teach Online

Elizabeth A. Gazza, PhD, RN, FACCE, LCCE, USA

Abstract

Purpose: The use of online delivery modalities continues to increase across higher education (Allen & Seaman, 2016) and in nursing education. The integration of technology into nursing education has improved access for students, influenced the delivery of nursing education, and expanded the need for evidence-based teaching specific to online teaching. Additionally, as more students enroll in online courses and programs, so does the need for nursing faculty who are qualified to teach online, and interested in doing so. While data about the number of nursing faculty who teach online is not readily available, only 32% of faculty from public, private, and for-profit institutions in higher education have taught online (Straumsehlm, Jaschik, & Lederman, 2015). This leaves two-thirds of full faculty who have not engaged in online teaching. Lack of familiarity with online teaching and perceived time associated with the instructional approach can deter faculty leaders from teaching and supporting online instruction (Chiabocchi, Ginsberg, & Picciano, 2016). Nursing faculty who can effectively use technology to deliver online education are essential in order to deliver online courses and programs. However, the shortage of nursing faculty in the US and the difficulties associated with attracting qualified applicants to available nursing faculty positions (AACN, 2015) can limit online offerings. Increasing the number of online faculty requires development and support systems that can assist them in this expanding role. This can be challenging because little is known about what it is like to teach online. The purpose of this presentation is to share research-based strategies that can increase the cadre of nursing faculty who integrate technology into nursing education and teach online.

Methods: A hermeneutic phenomenological study that uncovered the experience of teaching online in nursing education provides a description and interpretation of the online teaching experience serves as the basis for this presentation. Full-time nursing faculty who taught in a Bachelor of Science in Nursing (BSN), RN-BSN, Master of Science in Nursing (MSN), PhD in nursing, and/or doctor of nursing (DNP) programs in the United States and who completed at least 50% of their teaching workload assignment in the previous year in fully online courses were eligible to participate in the Institutional Review Board-approved study. Fourteen informants from ten different institutions of higher education located in nine different states in the US including four Northeastern, two Northern, and three Southern states volunteered to share their experience. Data were collected over an 8-month period through personal interviews and a demographic questionnaire. Interviews were recorded, transcribed, and analyzed using a 5-step process.

Results: Four themes emerged from the data including 1.) Looking at a lot of moving parts, 2.) Always learning new things, 3.) Going back and forth, and 4.) Time is a blessing and a curse. Findings indicate that online teaching differs from traditional classroom teaching and as a result, faculty in nursing education require development and support in order to attract them to online teaching and to retain them in the role.

Conclusion: Meeting the educational needs of the nursing workforce can be achieved in part through the use of technology to delivery online programs that can reach larger populations around the world. Comprehensive development and support programs, including mentoring specific for online teaching faculty, are needed to build the cadre of nursing faculty who teach online. This session offers strategies for creating such programs. It behooves nursing to lead the way in developing and supporting online faculty in nursing education.

Developing Nurse Educators and Leaders: A Collaborative Effort By National and International Faculty in Rwanda

Olivia Bahemuka, DNP, MSN, RN-BC, CTN-B, Rwanda

Oluyinka Adejumo, DittetPhil, RN, RPN, RNE, Rwanda

Sheila Shaibu, PhD, MNS, BEd, RN, Rwanda

Gilbert Banamwana, MSc, RN, Rwanda

Abstract

Introduction: The need for continued growth of the health sector across Africa is well known and well documented. Rwanda is one African country that is harnessing collaborative resources in building a competent and knowledgeable healthcare workforce to improve the healthcare and wellness of its population (Ansoms & Rostagno, 2012). Following the wake of post-genocide in 1994, Rwanda has tackled head on, some of the health sector challenges succeeding to making such milestones as reducing maternal mortality ratios from 750/100,000 in 2005 to 210/100, 000 live birth in 2014 (Rwanda Annual Health Statistics, 2014). As part of the effort to build the healthcare workforce, the Human Resource for Health (HRH) program for Rwanda was birthed out of the government's strategic plan intended to combat HIV back in 2002 (Binagwaho et al., 2013). The Rwanda ministry of health (MoH), working with its partner - the Clinton Access Initiative, established a unique seven year partnership with thirteen universities in the United States (US), six of which were schools of nursing (Mukamana, Uwizeye, & Sliney, 2015). The expectations for nursing were very clear and overall was aimed at restructuring nursing programs to equal accepted international level through curriculum development; and increasing the number of nursing and midwifery practitioners for both education and clinical practice areas. Further, the MoH identified a need to develop nursing leaders and educators at an advanced level that would carry on the growth and development of nursing achieved thus for purposes of sustainability chose to establish the first master's program in nursing. This paper reports on the specific aspect of the need to develop nurse leaders and nurse educators that are expected to take the development of nursing workforce to a higher level in terms of quality and quantity required for future and optimum health of the population of Rwanda.

Purpose: The purpose of this presentation is to describe the development, and the extent of collaboration involved in the preparation, of the next generation of nurse educators and nurse leaders in Rwanda, highlight the challenges faced during the process and share experiences on how some of the challenges have been managed in Rwanda.

Methods: The Rwanda Ministry of Health (MoH) working with its partner the Clinton Health Access Initiative established a unique 7 year partnership with thirteen universities in the United States (US). The US institutions (USI) included Duke, Howard, New York, Chicago, Maryland and Texas Health Science center Universities. The USI recruited a pool of needed nursing experts and nurse academics from the US and other countries who would work directly with the Rwandan nursing faculty at the University of Rwanda (UR) through a 'pairing' or "twining" mentorship model to achieve the consortium goals of development, skills transfer and sustainability.

There were 18 nurse academics recruited by the USI for the first Master's in Nursing degree program based at UR. The USI initiated a joint development of the Masters in Nursing curriculum with the UR faculty for the eight (8) new specialty tracks in the Master's program. The curriculum went through a rigorous approval process of the University and the country education system regulation. This culminated in the program starting late in October 2015, a month behind the UR normal academic calendar, with 120 students in the 8 specialty tracks.

The Education, Leadership, and Management (ELM) track is composed of 3 fulltime HRH foreign faculty (USI employed), 3 UR faculty and fourteen (14) students. The collaboration and twining relationship requires both faculty (HRH/Rwanda faculty) to work closely together so that the transfer of necessary skills takes place. Opportunities for transfer of skills prevailed at varied times including: the reviewing and development of undergraduate and graduate curriculums; development of modules and assessment of

units; team teaching, sharing of information, text books, articles and all necessary resource; research initiation and research supervision, as well as advising toward professional development. The University of Rwanda (UR) structure requires a minimum of 240 credits (2400 notional hours) for a professional master's degree such as nursing; with at least 100 credits for the dissertation. These would be distributed over four semesters or two years.

Output: It was expected that through a 'pairing' or "twining" mentorship model the program would achieve the consortium goals of development, skills transfer and sustainability (Binagwaho et al., 2013). The team teaching model approach was mandated to maximize opportunities for skill transfer from foreign faculties to the Rwandan faculties. Supervision for research is shared so that both students and the national faculty have a sort of one to one supervision mentorship, with the student benefiting richly from both local and visiting faculty. The 14 students that enrolled for the ELM track are continuing in the program with no attrition. The students in the Master's program are on campus three full days each week – Monday through Wednesday returning to serve in their pre-program jobs prior to the program from Thursday through the weekend. Students presented their theses proposals in October 2016 and have submitted these for review to the UR Institutional Review Board which meets quarterly. The University of Rwanda School of Nursing is set to be graduating its first cohort of the Masters of Nursing students in August of 2017.

Lessons learnt: A number of factors are impacting on the progress of the HRH development and particularly the ELM track. Among the challenges faced include the timing of the program, the program structure, the full time-part time nature of the program, the cultural context of Rwanda, grossly limited resources, the novelty of the program and the consolidation of the sustainability for the program. How the challenges were handled and further recommendations for the sustainability are given.

Conclusion: The Human Resource for Health work is ongoing in Rwanda and the fruits of capacity building for health professions are tangible. The opportunities for growth from this HRH endeavor should enable, and have already informed, other North and South global health collaborative initiatives for purposes of effectiveness and efficiency.

Significance to Nursing: The need for nurse leaders and nurse educators has been well documented and hailed by leading organizations such as World Health Organization (WHO) Collaborating Center for International Nursing Education as far back as 2004 (Woodring, 2004). The gap in the nursing workforce is not only highlighted by the pronounced shortage in nursing around the world, but also by the increased demand for population health nursing services that are required to meet the human right for health and wellness for all (Ugochukwu, Uys, Karani, Okoronkwo & Diop, 2013). For African countries which have the lion's share of the burden of disease, a competent, sufficient and capable nursing workforce is essential to participate in leading the achievement of the sustainable development goals. Nursing leaders and educators are necessary in Rwanda to guide healthcare provision for the Rwandan population by contributing to nursing research to guide evidence based care. In addition, nurse leaders and educators are essential for continued recruitment and retention of the much needed nursing workforce globally (Littlejohn, Campbell, Collins-McNeil & Khanyile, 2012).

D 16 - Developing Faculty Globally

Developing a Framework for Faculty Global Scholarship

Inez Tuck, PhD, MBA, MDiv, RN, USA

Abstract

Global health is a strategic initiative for the nursing program and the institute where I serve as Dean. Faculty are actively engaged in a number of global projects including participating in mission trips, providing professional services and direct patient care, leading student immersions and studies abroad, and consulting and training nurses in nursing programs or practice sites. Faculty activities occur in diverse sites including locations in the Caribbean, Africa, South and Central America, the former Soviet Union and Asian-Pacific countries.

As a nursing dean supporting faculty members with great interest in international work and a strategic goal to enhance the global awareness of our students and faculty, it was critical that we develop a framework to guide the global activities, provide coherence to the disparate work, and measure our outcomes. Many of these activities become part of the faculty's work life and are reported annually as teaching and service activities and/or scholarship. My institution uses the Boyer's model of scholarship (1990) and faculty conduct global projects in discovery, teaching and application. Our promotion criteria are built on Boyer's model and we continue to explore ways to make the model relevant for our faculty by reviewing current literature. A recent article by Moser, Ream and Braxton (2016) provides additional perspective.

The World Health Organization (WHO) has the global strategy to deliver its global mandate and implement its programs in a timely and cost effective manner with six major goals:

providing leadership on matters critical to health and engaging in partnerships where joint action is needed; shaping the research agenda and stimulating the generation, translation and dissemination of valuable knowledge; setting norms and standards and promoting and monitoring their implementation; articulating ethical and evidence-based policy options; providing technical support, catalysing change, and building sustainable institutional capacity; and monitoring the health situation and assessing health trends (Retrieved from <http://www.who.int/about/what-we-do/en/>).

While our work does not equal the scope of that done by WHO, we have created our version of the six goals and they are reflected in our global work.

The strategies used to develop a framework and a process for global nursing occurred over a period of one year in an effort to unify and strengthen the School's global health initiative with minimal resources. Our process was comprehensive in scope and included many dimensions. The global health faculty met every two months to discuss projects and to share perspectives. We developed shared values and agreed upon a common ground rules to guide our work. Faculty integrated global competencies into the curricula and competed for internal grants to support interprofessional and uniprofessional student experiences. We are addressing the need for domestic and global partnerships to increase our access to resources. We have offered a global health certificate at the graduate level for several years. Finally, faculty have published articles and textbooks on global health and disseminated project findings in oral and poster presentations.

Our framework is designed to provide coherence to our work. Ways to enhance global scholarship among faculty, develop partnerships with global organizations and develop an approach to educate our students have become the foci of this important work. The presentation will highlight the opportunities and challenges of our focus on global health in a nursing program.

E 01 - Health Promotion for Adolescents

Implementation of a Mentor-Led Physical Activity Program for Inner-City High School Students

Huey-Shys Chen, PhD, RN, MCHES, FAAN, USA
Karen M. Martin, DNP, PNP, USA

Abstract

Introduction: Physical activity is an integral part of the war on pediatric obesity. Pediatric obesity is a worldwide epidemic affecting children of all races, classes, and gender. According to the Ohio Youth Risk Behavior Survey of 2013 over one third of Ohio children in grades nine through twelve were considered overweight or obese and engage in more than three hours of screen time, television, computers or video games daily.

Purpose: The purpose of this project was to introduce an evidence-based physical activity program (*Let's Move Active Schools*) led by physical activity leaders (PALs) to improved BMI, increase GPA, and increase physical activity (PACE score) for disadvantage high school students in health class.

Strength of Evidence: An appraisal form from Larrabee was utilized to assess strength and quality of evidences. Level of evidences for selected articles ranged from 1a to 2a and quality of evidences was rated from acceptable to high. A synthesis of evidence supports the benefits of increased physical activity including better BMI and improved academic performance.

Practice Change: Let's Move Active Schools streamlines the selection of programs including PAL learning system and delivers a customized action plan. The 7 hour PAL trainings are skill building leadership workshops and support individuals who will champion an effort in their local schools/school district to ensure 60 minutes a day of physical activity for all school-aged youth through Let's Move Active Schools. The proposed change was presented to the targeted school Wellness Committee including the superintendent, the high school principal, the school nurse, and the physical activity coordinator.

Implementation: The Larrabee's Model for Evidence Based Practice Change was used to guide the implementation of this project. The intervention was delivered to an inner city high school in West Central Ohio. Two health teachers and the project coordinator were enrolled and trained in *Let's Move Active Schools* curriculum and served as PALs. The PALs designed physical activities and introduced physical actives in the classroom in the form of physical activity breaks for ten minutes.

Evaluation Methods: The outcome indicators, BMI, PACE score, and GPA were measured at before and after Let's Move Active Schools program. Data was coded and analyzed using the SPSS. Paired T tests were used to compare the outcome measures before and after the proposed practice change within the participant group.

Results: Thirty eight freshman in health class completed program. Results showed that there were significant differences in GPA and PACE; however, there was no significant difference in body weight status due to short time frame of project. Project results were disseminated to school Wellness Committee and school administration with anticipation of inclusion of physical activity breaks for every classroom for the future.

Conclusions: The Larrabee's model for change to evidenced based practice successfully provided a step-wise approach for planning, implementing, and evaluating this evidence based project. Small changes in the form of teacher and staff education, becoming PALs, can result in major impact in the war on pediatric obesity and a lifetime of wellness.

E 01 - Health Promotion for Adolescents

Adolescents Using the Internet for General and Sexual Health Information: An Evidence Review

Jean M. O'Neil, DNP, RN, FNP-BC, USA

Abstract

Problem: While adolescent pregnancy numbers may be decreasing, there are millions of new cases of sexually transmitted diseases that are diagnosed each year in the young adult population. Adolescents often express feelings of invincibility and egocentric behavior (Wickman, M. et al., 2008). This, combined with peer pressure and misinformation, can lead to high risk behaviors that can compromise their health. While most providers routinely address general health concerns, some are not as comfortable speaking with the adolescent about their issues regarding sexual health, family planning needs or sexual orientation. Also, access to healthcare can be a problem for this population because adolescents often have to rely on adults to get them to clinics and hospitals. Therefore, the adolescent worries about the lack of confidentiality regarding the information they share with the provider. Adolescents have been known to access health education via the Internet (Alison, S. et al., 2012) Recently, more teens are expressing their need to access healthcare information in this way. This may be in part due to easy access of information, as well as a more private way to explore sites regarding confusion related to their sexuality. There is an abundance of general and sexual health information online (Whiteley, L., 2012). However, there are concerns by both the medical community, as well as the adolescents themselves, as to whether these sites are presenting accurate and reliable health information (Jones, R. et al., 2011)

Objective: An integrative literature and evidence based informational review was conducted regarding the following factors: the ethnicity, age, gender, socioeconomic status and sexual orientation of these adolescents, the type of health information they are seeking, how these teens are using this information, the reliability of these health education sites and how the healthcare provider is incorporating this information into their practice.

Method: A comprehensive search strategy was used to identify English language evidence published between 2010-2016 via PubMed, CINAHL, Science Direct, PsychNet and Cochrane Library. A total of 3615 hits yielded 23 articles that met criteria in addition to 5 contextual articles; therefore 28 articles were included for the final review.

Results: Results indicate that there are a growing number of adolescents that are getting their health information from the Internet. However, many of them have expressed that they weren't sure if the information was appropriate, accurate or useful. Adolescents were confused by some of the sexual health information they found and expressed interest in speaking with family, friends, teachers or a trusted health provider but were concerned about the possible breach in confidentiality. The community of LGBTQ and transgender teens were also identified as users of the Internet for health information especially, if they were still hesitant about talking about their sexual orientation with their healthcare providers.

Implications: The medical community needs to be aware of what types of online health and sexual health education are available for adolescents. Providers can use this knowledge to their advantage by reviewing these sites and recommending those they feel are appropriate. These sites could work to serve as an adjunct to the adolescent visit and open up avenues for conversation on general, and especially on sexual health topics, between the provider and the patient.

E 02 - Care Initiatives for Chronic Conditions

Improving Self-Management Practices Among Patients With Chronic Conditions: “We’ve Got an App for That!”

Shannon Cronin Patel, DNP, BSN, RN, AGPCNP-BC, PCCN, CCRN-CMC, USA
Pamela Walch, MSN, BSW, ANPD, USA

Abstract

Purpose: The Nurse Developed Manage ME model was created to address the gaps that existed within patient education delivery models for patients living with chronic conditions. This self-management education deliver model has been foundational to creation of the innovative Manage ME toolkits and Mobile ME smart device applications. These self- management focused patient education “toolkits” have enabled all patient educators, including busy clinical nurses, to provide successful, standardized, patient-centric, self management education in an effective and efficient manner that crosses all transitions in care. The use of these Manage ME toolkits and Mobile ME smart device apps. have improved self-management related behaviors of patients with chronic conditions, resulting in improved patient outcomes.

Relevance/Significance: According to data collected through the Centers for Medicare & Medicaid (CMS), one of the leading causes of “avoidable” hospital readmissions for patients with chronic conditions have had a causal relationship to ineffective self management practices commonly demonstrated by this patient population. Multiple gaps have existed within the current self management education delivery models. The "Manage ME" toolkits have enabled clinical nurses to provide focused self management education to this patient population in an efficient and effective manner leading to improved patient outcomes and decreased readmission rates.

Strategy and Implementation: The Manage ME education delivery model has been used to create a suite of 5 self- management toolkits and smart device applications for the following conditions: heart failure, diabetes, COPD, as well as tobacco cessation management and wellness support. The pioneer toolkit that was created for heart failure self-management education and this toolkit and smart device app. will serve as example for this abstract.

After a successful pilot study, the WOW ME 2000 the WOW ME 2000 (**W**eigh, **O**utput & intake monitoring, **W**alk and be active, **M**edication adherence, **E**valuation of symptoms, **2000** mg or less of sodium and fluids daily) was implemented throughout a multisite health care system. This innovative toolkit was created based in accordance with current guideline recommendations and regulatory standards of care. This toolkit enabled nurses of all experience levels to provide self management education in a standardized, systematic, progressive, manner that incorporated the 'Teach Back' method after each information segment to ensure that frequent knowledge assessments dictate the progression of education at the appropriate speed for each individual patient. The WOW ME 2000 self-management tool is patient centric and devised to span the continuum so that nurses/patient educators are not pressured to complete all education during a brief hospital stay.

Evaluation: A 6 month pilot program that utilized the WOW ME 2000 Self Management Toolkit to educate all inpatient heart failure patients prior to their discharge from the acute care setting was conducted during the creation/developmental phase of this innovative practice intervention. This pilot program resulted in decreased heart failure readmissions from 26% to 17% this use of the heart failure self-management education toolkit continued to yield similar results across the health care continuum. There are several studies in progress that officially and unofficially include this self-management toolkit. The results from these studies prompted the creation of the WOW ME 2000 smart phone app. Since 2010 several organizations have successfully implemented the WOW ME 2000 toolkit and/or app. into their standard of care with similar successes.

Based upon the success of the heart failure toolkit, a smart device app. was developed. This self-management focused, interactive smart device app. was created to compliment the toolkit to provide

ongoing guidance, support, communication and of heart failure patient. This smart phone application was accepted by Apple and released as a free app. in the Apple App. store in 2012. The app was also created for androids and was released on Google Play in 2011. Since its release, the app has been updated and the new version was released in 2015.

There has been one study of the WOW ME 2000 smart device app. and the data was published in the November 2014 issue of the Remington Report. A current study being conducted is studying heart failure patients while they utilize the WOW ME 2000 app for 30 days. This practice improvement, capstone project will refute or support the hypothesis that daily use of the WOW ME 2000 app. can increase knowledge of and adherence to successful self management practices.

The positive outcomes that our patients have experienced throughout our healthcare system has been successfully replicated at number of healthcare organizations including: acute care organizations, provider offices, rehab centers, heart failure and diabetes management clinics. Since their release, the WOW ME 2000 heart failure app. and the MEET ME @ 7 diabetes self- management app. have both been downloaded in over 16 different countries around the world.

Implications for Practice: This nurse led innovation has significantly improved upon the provision of self management education for patients with heart failure and/or Diabetes. Through the provision of focused, standardized, patient centered education, nurses have been able to facilitate improved outcomes and decreased acute care admissions for patients with these chronic conditions.

Based upon the overwhelming success of our heart failure and diabetes self management educational toolkits and smart device apps. the nursing leadership team at our organization has approved the creation and implementation of additional toolkits for COPD, smoking cessation and wellness promotion. These toolkits and smart device apps. are currently in development. The additional toolkits will be initiated throughout our healthcare organization as soon as they are completed and vetted throughout the organization's leadership team.

E 03 - Use of Technology in Nursing Education

Nursing Education in a Virtual World

Cynthia Foronda, PhD, CNE, ANEF, USA

Abstract

Studies have indicated that virtual simulation is an effective pedagogy associated with positive student learning outcomes. Nurse faculty members are challenged with translating this evidence into the practice of nursing education. As a global shortage exists in doctoral-prepared nurse faculty members, many faculty carry heavy workloads and lack the time and resources to successfully implement novel technology. The purpose of this presentation is to 1) provide a synthesized review of the evidence in virtual simulation, 2) display technologies including augmented reality and virtual simulation, and 3) provide strategies for successful implementation with students.

Virtual simulation has been used in nursing education to improve teamwork (Caylor et al., 2015; Kalisch et al., 2015), leadership (Foronda, Budhathoki, & Salani, 2014), communication (Foronda, Gattamorta, Snowden, & Bauman, 2014), and decision-making (Hudson, Taylor, Kozachik, Shaefer, & Wilson, 2015). Additional contexts include the art of instruction (Foronda, Lippincott, & Gattamorta, 2014) and disaster triage (Farra, Miller, Timm, & Shafer, 2013; Farra, Smith, Gillespie, Nicely, Ulrich & Hodgson, 2015; Foronda et al., 2016a; Jose & Dufrene, 2014). Students have expressed learning skills of assessment, prioritization, and emergency management through virtual simulation (Foronda, Swoboda, Sullivan, Kamau, & Hudson, unpublished manuscript). Research has supported the use of virtual simulation to impact students' cognitive and affective knowledge of evidence-based practice (Foronda, Hudson, & Budhathoki, In Press).

After amassing evidence that consistently supports use of this pedagogy, nurse faculty members are challenged to apply the evidence and implement educational technologies. To assist faculty members to develop a better understanding of the existing technologies and how they fit into a nursing curriculum, cutting edge augmented reality and virtual simulation technologies will be displayed and described. Technologies include but are not limited to BodyExplorer™, Microsoft Hololens™, CliniSpace™, Digital Clinical Experience™, and vSim for Nursing™.

The process of testing and implementing new technology demands a culmination of various factors. The faculty member must possess motivation, administrative support, time, resources, and technological assistance. Strategies for facilitating new technology include designating a champion, obtaining funding for purchase or obtaining complimentary use, pilot testing, and faculty development. Faculty should examine the curriculum for existing gaps or areas that can be enhanced or supplemented with virtual simulation. Further, learning objectives, teaching methods, and an evaluation plan warrant consideration. Proper student orientation is critical for student buy-in and implementation success.

E 03 - Use of Technology in Nursing Education

Replacing Hard Copies of Textbooks With e-Books in Bahrain: Effects on Nursing Student Learning

Seamus Cowman, PhD, MSc, RGN, RPN, RNT, DipN, FFNMRCIS, FAAN, Bahrain
Eman Ebrahim Fateel, MSc, BSc, RN, Bahrain

Abstract

Background: Within one month of launching iPads, Apple announced that 1.5 million eBooks were downloaded and with the accelerating educational technology, sophistication has given rise to specific tools for education and student learning⁽¹⁾.

Since the foundation of the School of Nursing & Midwifery at RCSI Bahrain in 2006, undergraduate nursing students' have been provided with hard copies of textbooks and a laptop at the commencement of the programme. Educationally, the provision of a MacBook Air and hard copies of text books, was somewhat contradictory. Given the high level of smart phone ownership, social media usage, and the provision of a MacBook Air to all students, it was believed that a move away from hard copies of text books, to eBooks, could enhance nursing student learning approaches. A strategic and policy decision was taken to provide all students entering nursing from 2014 with eBooks, as an alternative to hard copies of textbooks. The provision of eBooks was consistent with the schools educational emphasis on blended learning, the use of a VLE and the encouragement of independent and flexible learning approaches. To evaluate the impact of eBooks, a research study was developed to evaluate and understand student nurse learning approaches.

Methods: A longitudinal, descriptive, mixed methods research approach was agreed with data collection through surveys, focus-group interviews and documentary data on student use. The eBook vendor held extensive records of student eBook engagement through the technology platform, which served as an important data source. The study was approved through the research ethics committee of the university. The study participants included: yr 1 students provided with eBook only; yr 2 students provided with a combination of eBooks and hard copies of text books and yr 4 students who in former years had been provided with hard copies of text books only. Structured training on the use of eBooks was provided to students with eBooks and staff, separately, by the vendor. An established questionnaire, Approaches and Student Skills Inventory for Students (ASSIST instrument, which was previously validated for use with nursing students⁽²⁾) was selected to examine student nurses learning approaches. The instrument consists of three sections; (a) describing learning; (b) approaches to studying; (c) preference for different types of teaching.

Findings: The findings reflected no differences in examination results between study participants with eBooks and examination results for the previous corresponding year cohort, without eBooks. Overall students with eBooks, only, stated a greater preference for eBooks when compared to students with eBooks and hard copies of books. Students reported that eBooks facilitated the accessibility of wide ranging learning materials through the different platforms at any time and any place in formal and informal locations; stimulated peer-to-peer interactions and supportive learning. In particular the potential to access text books on a phone introduced flexibility to student learning. Some difficulties reported related to the artifact of the digital technology and system unfamiliarity which highlighted the need for continuous technology support and guidance for students whilst using eBooks. The majority of students reported that they had not used an eBook prior to entering nursing school. The results show that the most common method of accessing the eBook was the PC however 16% of students reported using a smart phone most often. The most common place to use the eBook was the home, followed by the classroom, and out socially. Some the more negative reporting included: a minority of respondents suggested that eBooks caused problems such as headache, eye strain and backache due to continually using a machine to read the eBooks. User interface improved the usability of eBooks especially when the layout is organized and included supportive learning features such as: creating highlights; adding notes; sharing highlights and notes; definitions, translation; ability to copy and paste information, and cite and reference material for assignments. Participants also stated that the ability to perform split view allowed them to multitask and

leads to better time utilization. Other important patterns of approaches to learning will be reported in the presentation.

Conclusion: Educational technologies have been slow to impact on medical and nursing education. Internationally there is a paucity of published work on the use of eBooks in nursing and there are no reported studies Bahrain. This study provides important educational insights into nursing students' learning behaviours and studying approaches with the use of assisted technology. Training in the use of eBooks and technology support is essential in not only providing the necessary confidence to users, but also ensures that students embrace the full potential of eBooks in their learning. The outcomes of this study indicates that the use of eBooks adds a new dimension to nursing education.

E 04 - Perspectives on Pediatric Health

Personalized Pediatric Pain Management: Myth or Reality?

Cheryl Mele, DNP, PNP, AC/PC-BC, NNP-BC, USA

Abstract

For a child undergoing a surgical procedure or issues with chronic pain, an essential goal is to obtain optimal pain management without significant adverse effects. Regretfully, safe and operative analgesia is an indefinable medical objective. Pain management within the pediatric realm reports that 50% pediatric perioperative pain experience will be efficient and acquire minimal side effects from opioids (Sadhasivam et al., 2014). It is well known that poor pain control can harvest physical difficulties, prolonged post-op recovery, and long-term behavioral complications. Still there is an extensive range of reactions to opioids secondary to variability in patient's gender, ethnicity, development, co-morbidities and genetic factors. Research demonstrates that up to two-thirds of the unpredictability in pain perception and differences in the effectiveness of analgesic drugs are partly genetically predetermined (Cregg, et al., 2013).

Since the completion of the Human Genome and Hap Map Project the era of personalized medicine is upon us. Sequencing of the entire human genome has brought about a progression of knowledge regarding drug therapies, genetic predisposition and environmental impact such as epigenetics. Every individual has a distinctive genetic code. Pharmacogenomics is the study of how disparities in the human genome ultimately affect the response to medications and offer different views into the variability observed within individuals prescribed opioids for pain management (Jannetto & Bratanow, 2011). Pharmacogenomics seeks to link differences in gene structure or genotype (polymorphisms) with pharmacologic differences in drug action (phenotype) (Galinkin, et al, 2010). Pharmacogenomics primarily is split into two parts describing genetic variants involving pharmacokinetics (absorption, distribution, metabolism and elimination of a drug) and pharmacodynamics (an activity of the drug at the target site/receptor of a drug (Janicki, 2013; Jannetto & Bratanow, 2011).

Opioids are standard treatments for chronic and post-operative pain. Reports of prescription opiate misuse in adolescence and adult population is predominant in the media. The concern in healthcare providers and families is fear of exposure to prescribed opioid prescription drugs may be a catalyst for addiction. Hence, pain pharmacogenomics has held promise to provide information on one's genome, identify patients at risk for complications or inadequate response to pain pharmacotherapy. The purpose of this presentation is to explore the genetic science involved with drug and individual variability which can aid nurses to support patient/families in developing guidelines towards a personalized pain management plan based upon one's genome.

E 04 - Perspectives on Pediatric Health

Perspectives From Europe and the United States on Perinatal Palliative Care and Current Ethical Dilemmas

Charlotte Wool, PhD, RN, USA

Joana Catarina da Cruz Mendes, PhD, BSN, MS, Portugal

Jesse Wool, BSN, RN, USA

Abstract

The purpose of this presentation is to review current international scientific findings and perspectives about perinatal palliative care (PPC) from Europe and the United States. Further, two recent clinical challenges in the area of PPC, neonatal organ donation (NOD) and post-mortem cooling, will be examined through a principle-based ethical lens.

Perinatal palliative care refers to comprehensive, holistic and interdisciplinary services for parents who receive a diagnosis of a life-limiting fetal condition and choose to continue the pregnancy (Limbo & Wool, 2016). Provision of services begins at diagnosis, extends through birth and the postpartum period and includes care for the neonate who is expected to have a shortened life span (Wool, 2013). Nurses are instrumental in providing PPC for parents and often provide leadership through coordinating services, collaborating with providers and creating plans of care for the pregnancy and birth, and plans of care for the infant following the birth. Treatment plans for the infant may include curative interventions, palliative support, or a combination of both depending on the infant's condition at birth. An international body of literature has grown from the evidence in pediatric and neonatal palliative care and guidelines from the adult palliative care sector. Several standards of care have emerged in the European sector, and in the United States (US) a survey of PPC programs was recently published (Wool, Côté-Arsenault, Black, Denney-Koelsch, Kim & Kavanaugh, 2016). Recommendations have emerged as international organizations formally recognize the need for PPC services (ACOG, 2016).

The growing acceptance of PPC in the mainstream has resulted in parents requesting interventions that may be unfamiliar to, or uncomfortable for, clinicians (Mendes, Wool & Wool, 2016). Neonatal organ donation is the practice of retrieving organs and tissues from infants who die during birth or shortly thereafter. The Internet has increased parental awareness of NOD as an option despite the fact that in the United States and Europe organ procurement organizations are not currently promoting such options or logistically prepared to engage in such activities. An additional ethical challenge includes the physiologic component of the maternal-fetal dyad in which the fetus is stable, followed by a low probability of survival post birth. When a parent learns of a life-limiting fetal condition (LLFC) it is not unreasonable they look for meaning through such a tragedy. This altruistic approach may help families cope with loss and give them a sense that "good" may result from their heart-wrenching situation (Sarnaik, 2015). Benefits of NOD center on beneficence toward others [the recipient population] and the real possibility of securing an increased number of tissues or organs for pediatric patients.

Several potential and real challenges of NOD exist. As parents make decisions for their fetus or infant, it is important to recognize that this population is considered vulnerable because of their lack of autonomy. The donating infant may be exposed to life-supporting interventions for the sole purpose of extending life long enough to procure organs. These measures introduce avoidable harm to the infant, thus raising concerns about their ethical appropriateness.

An important aspect of PPC is the opportunity for parents and family members to meet, hold and create memories with their infant. Nurse experts encourage parental participation at the end of life through final acts of caregiving such as bathing, dressing or including spiritual and cultural rituals (Limbo & Lathrop, 2014). Usurping bereavement interventions for the sake of attending to time-sensitive procurement procedures is unstudied in the PPC population. Should the donation be "unsuccessful," parents' loss of time with their infant could be especially distressing. Corr and associates (2011) have highlighted similar experiences with families, describing them as secondary losses which feel like a "second death" to family members.

Nurses have played a lead role in perinatal bereavement care for decades. Nurses educated in bereavement practices have implemented best-practice standards for the perinatal population. New medical equipment is currently available and in use in some US hospitals. The equipment includes a cooling pad, insulated hose and small cooling unit which can be used after an infant dies for the entirety of the hospital stay so use of a mortuary is not needed. Use of the equipment provides extended opportunities for parents and family members to spend time with their infant in order to create memories or conduct special rituals. Parents, often suffering from profound grief or shock, or recovering from a difficult labor and birth, have increased autonomy to assimilate to their circumstances and prepare to say goodbye to their infant. Nursing staff has additional time to collect mementos for the family.

One aspect of palliative care is that it neither hastens or prolongs death and it is respectful of the time of death (WHO, 2014). Use of cooling equipment interferes with natural postmortem physical changes. Clinicians, responsible for assessment and well-being of their patients at the end of life, may be unsure about how, or if, to assess an infant who has died. Family members and clinicians may be uncomfortable with the psychological implications of using such equipment. Should such equipment become the norm in health care systems, nurses will need appropriate education to supplement their expertise in bereavement services. Research regarding parental outcomes related to equipment usage is necessary to guide practice initiatives.

An understanding of the current literature in PPC enables clinicians to provide optimal, compassionate care to families who experience a life-altering event. The Nursing Code of Ethics (2015) lays a foundation for nursing care, especially when firm evidence is unavailable or unexplored. Provision Two in the Code of Ethics explicitly states that the nurse's primary commitment is to the patient. When patients request interventions for which outcomes are unstudied, clinical experts, nurse leaders and nurse scientists have an opportunity to carefully collaborate, study and evaluate practices that have not yet entered the mainstream. This presentation evaluates the international state of the science on perinatal palliative care. The exchange of ideas that considers ethical challenges during the integration of technology into nursing practice raises awareness and spurs future research.

E 05 - Promoting Health in the Older Adult

Assessment and Management of Alcohol Use Disorder in Older Adults: A Review of the Evidence

Mary DiBartolo, PhD, RN-BC, CNE, USA

Judith M. Jarosinski, PhD, RN, CNE, USA

Abstract

Purpose: The aim of this presentation is to summarize and critically evaluate the recent literature on methods to better identify AUD in older adults, including instruments specifically developed or modified for this age group, as well as, delineate targeted treatment strategies which may be more effective in achieving and maintaining sobriety in this population.

Background: Alcohol Use Disorder (AUD) has been identified as a significant, under-recognized, underreported and hidden epidemic in the U.S. (Alpert, 2014). The prevalence is expected to rise dramatically as the number of adults aged 65 and older increases to one in five by 2030. Worldwide, older adults aged 60 and older are currently at 800 million and this figure is expected to climb to over two billion in 2050 (World Health Organization [WHO], 2012). With this escalation in the number of older adults comes a concomitant increase in those struggling with AUD, where the health consequences can be significant. According to WHO (2016), 5.9% of all global deaths are attributable to alcohol consumption.

Challenges in assessment include acknowledging differences in drinking patterns, onset (early vs. late onset), symptom presentation, difficulties in differentiating symptoms of AUD from other health complaints associated with aging, as well as the denial, shame, and stigma which can present major barriers to prompt identification. In the care setting, busy practitioners with limited resources and time often confine screening to persons with a known history. However, complex comorbidities that usually present in older adults can delay assessment and subsequent treatment. A latent missed diagnosis fails to capture individuals who may have AUD and may preclude or delay appropriate interventions, and ultimately, the goal of sustained sobriety. The inconsistent use of evidence-based screening instruments to identify those at risk is an obstacle to successful diagnosis and treatment.

With regard to management, older adults do achieve equivalent or better results than younger counterparts when they enter treatment (Bakhshi & While, 2014; Yasamy, Dua, Harper, & Saxena, 2013), especially when interventions are focused on the needs of this specific age group. Furthermore, a substantial “treatment gap” exists brought about by the inability to access and/or afford care. The literature also highlights treatment modalities as part of the alcohol screening and brief interventions (ASBI) model, such as cognitive-behavioral therapy (CBT) and mutual help (aid) groups (MHGs). There is emerging evidence that interventions must be both engaging and tailored to this specific age group to enhance compliance and optimize probability of ongoing recovery.

The issues surrounding the assessment and management of older adults with AUD are complex and poorly understood. Furthermore, both the literature and research on older adults with AUD has been minimal given the growing prevalence of this population. Nurses have the potential to enhance awareness, initiate screening with appropriate instruments, participate in treatment plans that are individualized to achieve treatment success and play a key role in advocacy for this underserved and vulnerable group.

Methods: An in-depth review of the literature was conducted to ascertain the state-of-the science related to instruments used in screening older adults for AUD, as well as, age-appropriate interventions. Key words included: alcohol use disorder (AUD), alcoholism, older adults, elderly and substance abuse. Articles on substance use disorder (SUD) were excluded unless there was a significant or updated component related to AUD. In addition to integrative reviews, an emphasis was on primary sources incorporated from the last decade to identify more recent trends and obtain the most pertinent and comprehensive information.

Results: A total of 36 articles were found within the past decade, with four of those being integrative reviews. As far as AUD assessment instruments, the CAGE is considered a primary screening instrument because of its ease of use; its drawbacks include failure to identify binge drinking and separating a drinking history from current use. The MAST-G scale is specifically formulated for geriatric patients and has been gaining substantial support in the literature. Treatment approaches include inpatient detoxification followed by targeted interventions to maintain sobriety. Detoxification can be more problematic in the older adult population, with confusion rather than tremors being the predominant sign. The subsequent phase of implementing Alcohol Screening and Brief Interventions (ASBIs) is increasingly recognized in the literature as both a screening strategy and supportive treatment. ASBIs can include mutual help groups, cognitive behavioral therapy, motivational interviewing, the FRAMES model, and other related approaches (Blow & Barry, 2012). The literature specifically highlights mutual health groups, such as Alcoholics Anonymous (AA), as most beneficial when comprised primarily of older adults who have similar issues of retirement, loss, physical co-morbidities, diminished self-esteem, shame and stigma. The literature strongly supports that for the older adult, ASBIs should be both engaging and tailored to enhance compliance and optimize treatment success and sustained recovery.

H 01 - Service Learning in Nursing Education

Using Service Learning to Increase Depression Awareness on College Campuses

Linda Mays, DNP, ARNP, PMHNP-BC, USA

Abstract

There are an increasing number of college students experiencing depression. Approximately 41% of the students seen in college counseling centers self-report depression while almost 33% of college students reported having suicidal thoughts (Reitz et al., 2015). Though these statistics are alarming, depression awareness is not routinely addressed on college campuses. Service learning projects for nursing students may help meet this growing need.

In their professional role, nurses commonly discuss depression with patients and communities yet student nurses' teaching skills are limited. Service learning brings real world learning to students, enhances student engagement and can also add an invaluable benefit to the college community. Peer teaching has been found useful in undergraduate nursing education to develop skills and self-confidence (McKenna & French, 2011). Student nurses, who possess limited skills teaching a variety of populations, can help educate patients and college communities about depression.

Purpose: The purpose of this presentation is to discuss the benefits and challenges of using service learning as a teaching project to increase depression awareness on a college campus.

Methods: Over six weeks, traditional students enrolled in an undergraduate psychiatric nursing course participated in a service learning project as part of their course curriculum. National Depression Screening Day, a national initiative, was used to bring education and awareness to student depression. Prior to the project, students wrote a reflection describing their unique perspective of service learning, depression and civic duty to their college community. Students explored the details of implementing the project and identified target specific audiences that may experience depression: freshman, minorities, transfer and LGBTQ students. To enhance their knowledge base as "consultants" for depression, psychiatric nursing students attended lectures conducted by both the experts as well as those who live with severe depression. The day of the service learning project, students provided handouts, posters and personal dialogued to college students to engage them in doing the screening. The screening was completed online anonymously through the school's counseling center. Students were given the opportunity to have the results sent to their email or make an appointment for further treatment.

Results: The counseling center reported a substantial increase in completion of the online depression screening as a result of the service learning activity. End of course evaluations and reflection journaling indicated the service learning activity had a positive impact on the nursing students: it increased their empathy towards mental illness; helped improve their psychiatric assessment skills; and fostered a positive civic attitude.

Conclusions: Nursing students are in the unique position to make a significant impact on the mental health of their peers and increase their professional growth through service learning activities.

H 01 - Service Learning in Nursing Education

How to Embrace (and Love?) Community Engagement

Melissa A. Wholeben, PhD, RN, USA

Carla J. Ellis, MSN, RN, USA

Abstract

Identify the teaching challenge: As healthcare moves into the 21st century, it is vital that educators create learning environments that give students the opportunity to practice what they have learned in didactic. However, with the major influx of students in clinical sites, it has become necessary to think outside the box for potential community opportunities. In addition there is content overload to contend with and the pressure from outside stakeholders and accreditation bodies to create service learning education opportunities. Trying to incorporate these educational goals creates some challenges in creating projects that incorporate these demands. Health Fairs and other community engagement projects are time consuming and demanding but there is a great deal of literature on how to attack this endeavor with great success in all your goals.

What have you learned from conferences, online sources about your challenge?

Research has shown us that it is important to incorporate classroom learning with an opportunity to practice. In addition, it is important to present an environment that not only promotes 'learning in the form of practice' but also gives the students a feeling of pride and accomplishment in their ability to help others. Health fairs are one way in which the community is engaged and can promote excellent communication skills in nursing students. Planning health fairs seems daunting but is well used and researched on how to create a successful one. Putting the health fair into a project format is a active learning tool to promote concepts in almost any course/clinical objective.

Describe the intervention

By partnering with local TV stations, and interdisciplinary teams, our senior students have had the opportunity to provide healthcare in the form of prevention teachings and screenings to the El Paso community. The students determine the leading health concerns for the El Paso region; research best practice measures by means of Evidence Based Practice; and present the material using the domains of learning (cognitive, affective and psychomotor), using primary, secondary and tertiary prevention strategies. We hope to present the ways in which this can be produced in any course to meet your objectives as well as all stakeholders.

Qualitative and/or Quantitative feedback

The students have provided overwhelmingly positive comments of "I was able to teach the participant about diabetes and strategies to stay healthy" and "It was amazing to see how many people came to the health fair to get screened for Blood Pressure and Height/Weight/BMI". "I felt I made a difference" As a personal observation, it is rewarding to see the students become excited about community health and present their knowledge to the community in a form of wellness project. Addressing the possibility of burn out in this endeavor due to the work of developing this sort of project will also be discussed.

Future Plans

Next steps would be to create even more "real world" application by partnering with local hospitals and disciplines within the UTEP community to assist in producing a Community Needs Assessments on a local Colonia to assist in getting health care assistance there. Also a possibility is for student participation in research, partnering with graduate programs to produce real world information. The literature is rich in the possibilities of where these can go after you dip your feet in the process.

H 02 - Interprofessional Practice to Promote Health

A Pilot Interprofessional Education and Practice Project With Migrant Farm Workers

Lora R. Shelton, DNP, RN, FNP-BC, CNE, COI, USA
Cynthia G. Cortes, DrPH, MSN, RN, CPNP-PC, COI, USA
Andrea W. Collins, DNP, RN, NP-C, CNE, COI, USA

Abstract

Purpose: Annually, hundreds of migrant farm workers and their families migrate to the United States to harvest crops on family-owned farms. This population is plagued with recurring health conditions and chronic diseases (Nicholas, Stein, & Wold, 2014). Since few receive regular care, treatable conditions can become acute; resulting in costly emergency room visits or hospital stays. The Migrant Farm Worker Project was developed by nurse practitioners at a College of Health Sciences in the Southeastern United States. The project provided opportunities for faculty and students from nursing, communication sciences and disorders, and nutrition to provide medical screenings and education for Hispanic migrant farm workers.

ROL: The hardships of life of the migrant farm worker result in unique challenges to the physical and mental health of these individuals, and create significant barriers to quality health care (Walsh & Schub, 2013). Most do not earn enough to afford health care and are ineligible for existing community programs (Galameau, 2013). Many suffer from the same chronic health problems so prevalent in the Hispanic population such as diabetes, skin, respiratory, musculoskeletal and numerous eye and vision problems (Bauer & Kantayya, 2010).

Summary of the Innovation: After the faculty met with stakeholders to determine the needs of the community, a variety of opportunities were provided for the migrant farm worker population over an intensive three day period including: physical exams, hearing screening, body mass index, blood pressure screening, and nutrition education for K-8th grade students at a local migrant school; medical care provided at convenient locations for farm workers at the end of the work day; women's health services and HIV testing provided via a mobile clinic van; physical exams performed at the local East Coast Migrant Head Start Center for children 6 weeks to 5 years; health promotion and education provided and printed material distributed. Literacy education was provided to Head Start teachers and literacy materials were provided for parents.

Results: Through this pilot project data were gathered on number of screenings, screening results, referrals, and unmet community needs. At the migrant school, 88 children (K-8th grade) were provided hearing screenings, nutrition education, physical exams, and health screenings. Physical exams were performed on 32 children (6 weeks-5years) at the East Coast Migrant Head Start Center. Physical exams, health screenings, and women's healthcare services were provided to 43 adults via mobile medical clinics offered in convenient locations for the migrant farm worker.

Implications for Practice: Interprofessional teams are qualified to provide healthcare services to underserved and vulnerable populations such as migrant farm workers. Nurse practitioners can be leaders in innovative methods of healthcare which can lead to greater access to care and healthier populations. Implementing interprofessional education activities allows students to learn to work together across disciplines, leading to improved patient outcomes in future clinical practice (Luque & Castañeda, 2013).

H 02 - Interprofessional Practice to Promote Health

An Interprofessional Collaborative Practice Model (IPCP) for Enhancing Population Health and Care Transitions

Maria R. Shirey, PhD, MBA, RN, NEA-BC, ANEF, FACHE, FAAN, USA
Connie White-Williams, PhD, RN, NE-BC, FAAN, USA

Abstract

Background: Changing requirements shifting the focus of care from an emphasis on value over volume demand delivery models that cultivate teamwork and collaboration across the healthcare continuum. Academic-practice partnerships represent a desirable vehicle to test innovative interprofessional collaborative practice (IPCP) models to enhance population health outcomes and care transitions.

Purpose: This purpose of this presentation is to discuss early findings following implementation of an IPCP model used as part of an academic-practice partnership to enhance health outcomes and care transitions in a complex and underserved heart failure patient population. Leadership and partnership strategies used to facilitate IPCP and care coordination will also be identified.

Methods: An innovative IPCP model was implemented in a nurse managed heart failure clinic impacting health outcomes for an underserved patient population in an academic health center in the southeastern United States. Professionals from various disciplines including nursing, medicine, social work, health services administration, and health informatics worked together as a unified team to enhance the patient experience, health outcomes, and cost of care. Leveraging resources of a grant-funded opportunity and longstanding academic-practice partnership, the IPCP model incorporated transitional care coordination approaches to affect population health outcomes and care transitions across the healthcare continuum.

Findings: Two years of project data reflect positive outcomes. Patients reported enhanced access to care, availability of life-sustaining medications, superior experience ratings, and improved physical and mental health outcomes. Care transitions improved with a reduction in hospital readmissions for this complex patient population. Use of an IPCP model also demonstrated enhanced teamwork and collaboration amongst healthcare team members from multiple disciplines. The IPCP model also provided clinical placement opportunities for students from the various disciplines represented to learn about teamwork and build their competencies for IPCP, population health, and care coordination across transitions.

Conclusions/Implications: An IPCP model of care is an effective approach to improve health outcomes and care transitions in underserved patients with chronic diseases such as heart failure. Members of various health professions working together in a collaborative model can enhance teamwork that ultimately benefits patient outcomes. Working together, academic-practice partners can achieve impactful outcomes that one partner alone might not be able to achieve.

H 11 - Promoting Health Policy

Using Twitter to Engage Nurses in Policy Debate to Inform Health Strategy

Siobhan O'Connor, BSc, CIMA, CBA, RN, FHEA, United Kingdom

Abstract

Purpose: Health policy can often be designed with little input from frontline nursing or managerial staff, whose clinical and organisational expertise could add value to the development of national health strategies (Gebbie et al, 2000). The Chief Nursing Officer (CNO) for Scotland used social media as part of a communications plan, to help identify areas of practice that need investment and ensure all nurses can contribute to health policy discussion. This study aims to explore the views of those who participated in a Twitter chat and examine the usefulness of social media to engage nurses in policy debate and future health strategy development.

Methods: The Twitter chat was advertised using email and social media to recruit participants. It was promoted through health boards, higher education institutes, voluntary organisations and other agencies related to nursing and healthcare and run by the CNO and her team in May 2016 under the hashtag #CNOScot. A series of questions were posed throughout the online chat to generate discussion, which lasted one hour. This study adopted a mixed approach as the views of those who participated in the virtual focus group were explored using the framework approach to produce a thematic analysis of nursing priority areas identified. Descriptive statistics from an analytics platform were also examined to see how useful social media was in reaching and engaging nurses and others in a health policy discussion. No ethical approval was necessary for this study as Twitter is an open public platform. To protect participant privacy identifying information in tweets was anonymised following best practice (Chretien & Kind, 2013; Eysenbach & Till, 2001).

Results: Sixty-five people took part in the Twitter chat from a range of nursing and other nursing backgrounds. The debate centred around areas of nursing that need investment in particular technology, nursing research and education were identified as vital to developing in the future. *"Agree re IT skills - we need to be intentional around development rather than assume"; "It is in pre reg & then not used post reg. The culture is about audit & not research"*. Expanding primary care services were also seen as critical to supporting older adults with complex health and social care needs and people suggested successful pilots of innovative practice currently underway that could be scaled up. *"currently working with DN colleagues telehealth project & supporting them with their new clinical skills #CNOScot"*. Finally, advanced practice and leadership roles in specialist areas such as mental health and palliative care were discussed as being necessary to address frailty, cognitive decline and other conditions associated with ageing. *"#CNOScot I think further development in MH might be a priority and specialist dementia care too?"*.

Conclusion: Social media was used to gather a diversity of perspectives on how nursing in Scotland needs to develop and was helpful in informing future health policy developments in this area. However, only a small proportion of practising nurses participated and certain groups such as students and those working in the private sector were missing. A multifaceted communications strategy is needed to reach and engage nurses and other key stakeholder groups such as patients and carers to inform future health policy.

The Challenges of Online Education With Respect to Accessing Health Policy Expertise

Patricia A. Brennan, PhD, RN, DFNAP, USA

Abstract

Purpose: This project was undertaken to evaluate the utilization of available technology within the context of several on-line distance learning formats to access appropriate health policy expertise. This access was intended to provide the student an opportunity to critically appraise health policy relevant to clinical practice and learn skills to engage in policy development at the intersection of practice and research, as outlined in the Essentials of Doctoral Education for Advanced Nursing Practice

Session Objectives: At the completion of this presentation the participant will be able to

1. Articulate the challenges of health policy education with respect to asynchronous, synchronous and hybrid course delivery formats
2. Compare the effectiveness of various pedagogical approaches to delivering health policy content.
3. Illustrate strategies to access health policy expertise in an effort to provide authentic exposure to the clinical relevance of health policy.
4. Articulate the value of “social presence” in the on-line environment and how synchronous, asynchronous and hybrid course content delivery contribute to its development among geographically distant participants.
5. Explore inter-professional and international opportunities to collaborate on health policy education across local and geographically distant graduate programs.

Implementation: Through the collaborative efforts of an inter-professional team, four on-line synchronous sessions were delivered during a semester-long Advanced Health Policy Course within a nursing doctoral program. One session included engagement with an NIH researcher and clinician from the National Cancer Institute/National Institutes of Health. Similar content was delivered in an asynchronous and hybrid graduate health policy course.

Outcomes: Through the utilization of a distance-learning platform, “synchronous” exposure to an NIH researcher and health policy expert created “social presence” among a cohort of geographically distant doctoral students. This delivery methodology was compared to both a hybrid and asynchronous module with the same content. The pedagogy of synchronous on-line content delivery was compared to asynchronous and hybrid delivery of similar content. Insights for the faculty member will be shared with respect to the value and “cost” of providing “access” to “quality” experts in health policy development.

Implications for Policy Education: Moving beyond the “webinar” model of asynchronous on-line education, the ability to create social presence through the integration of real time dialogue will provide opportunities for richer understanding of health policy and a more active engagement in health policy education. In addition, this model creates inter-professional opportunities to collaborate across geographically distant doctoral programs, while sharing both resources and expertise

I 01 - Promoting Health in Obese Patients

A College and a University Collaborating on “Moving On” Project: Reducing Hispanic Childhood Obesity

Patricia R. Messmer, PhD, MSN, MA, BSN, RN-BC, FAAN, USA

Nora Hernandez-Pupo, MSN, RN, USA

Yolanda Nitti, MSN, RN, USA

Giannina Santos, DNP, MSN, ARNP, USA

Guillermo Valdes, DNP, RN-BC, USA

Kathleen Muniz, MSN, RN, USA

Yamina Alvarez, DNP, RN, USA

Abstract

Introduction: Childhood obesity is known to increase risk of obesity in adulthood and can lead to type 2 Diabetes & Cardiovascular Disease (Chen et al, 2016, Evans et al, 2016; Bauer, 2015; Brown, Kuk & Lee, 2015) Treating obesity-related illness in Florida (25%) costs \$6,675,940. Latino children are at a greater risk of obesity with prevalence increasing over time. National Association of Hispanic Nurses (NAHN) Miami Chapter was a site for Muevete USA™ Project (2012-2015) reducing Hispanic childhood obesity (Milan, 2011). The 2016 project partnered with U.S. 1st Lady Michelle Obama Let’s Move (www.letsmove.gov). The collegiate ASN/RN-BSN students was at a summer camp while the University BSN students conducted their program in a elementary school.

Purpose: To determine if an education program can increase the level of knowledge preventing childhood obesity focusing on 1) awareness/understanding of food labels; 2) daily portions of fruits, vegetables, grains, dairy, protein;and 3) incorporating daily physical activity and exercises.

Methodology: A descriptive exploratory research design was conducted with children completing five pre/post tests of 15 questions - “My Plate”; “Food Label”; “Physical Activity and Exercise” “Healthy Snacks” and “Goal Setting”. Content validity was established. Community Health ASN & RN-BSN students participated in Muevete projects at South campus (1st-3rd) and Homestead (2nd - 4th years) . Students, received 10 community hours; orientation, designing posters and attending events. Children were divided into 12 groups (2 students/group) taking food cutouts, making plates with appropriate portions, nutritional requirements and reading labels. In the 4th year, President-elect NAHN, Miami Chapter had 7 University BSN students teach "Moving -On" for two 4th grade classes.

Results: In 2016, 56 children did "Moving-On" at a summer camp in Homestead; 58% males 42% females ages 9-12 Hispanic 75%, White 20%; Black 5%; with 34% change while 42 children did Moving-On during school; ages 10-11, 55% females-45% males 95% Hispanic 3% Caucasian and 1% Asian with 23% change. In 2015, 128 children participated ages ranged 4-15 mean=8.51 years; males- 59% females 41%. Hispanic 74%, Black 36%, White 22%, Asian-1% pretest-posttest scores increasing 9.77-11.81, a 21% change. at the 2nd site, 109 children participated ages ranged 5-12 mean= 8.51 years, males- 65%, females 41%; Hispanic 74%, White 20%; Black 5% Asian 1%; pretest-posttest scores increased 9.77--11.81, 42% change. In 2014, 125 children participated-ages ranged 4-15 mean=8 years, kg-8th grade males-62%, females 38%; Hispanic 55%, White 30%; Black 9% Asian 6%; pretest-posttest scores increased 9.40--10.68, 13.62% change. At the 2nd site 102 children participating ages ranged 4-15 mean= 9 years; males- 54% females 46%. Hispanic 41%, Black 38%, White 13%, Asian-8% pretest-posttest scores increasing 8.33-9.45, a 13% change. In 2013, 130 children participated; ages 5-12; males 50%, females 50%; mostly Hispanics. All mean scores increased pre-to posttest 1st test 3.13-4.67; 2nd test 2.94-3.72 3rd test 3.50-4.55 4th test 3.50- 4.13; 5th test 2.96-3.52

Discussion: Over the past four years over 692 Children drew plates with food portions (www.choosemyplate.gov), ate healthy snacks, exercised to Zumba or exercised to a youtube video, did hand washing techniques, wearing “Moving-On” t-shirts. Parents received nutrition classes. Most missed question -“How much Sodium is in entire food product?” on a food label. Sodium is 440 mg but for 4 servings = 1760mg.

Conclusion: Children learned healthy food habits to overcome childhood obesity. This program increases knowledge of obesity for Hispanic/non-Hispanic children while decreasing associated healthcare costs.

I 01 - Promoting Health in Obese Patients Using Motivational Interviewing to Address Obesity: A Global Perspective

Juanita L. Wilson, DNP, NP-C, COHN-S, USA

Abstract

Obesity is a growing global public health epidemic affecting all ages and socioeconomic groups. Commercial truck drivers (CTDs) have a greater obesity rate and decreased life expectancy compared to the general population. The nature of the commercial truck driving occupation places the truck driver at an increased risk for obesity. CTDs work sedentary jobs with long hours that pose barriers to eating healthy, regular exercise, and regular sleep patterns. The outcomes of a four-week evidenced-based practice (EBP) change project that utilized a motivational interviewing (MI) intervention and included diet and exercise education was found to have a positive impact on outcomes. MI has enabled individuals to evaluate personal ambivalence about healthy lifestyle choices thus, increasing self-efficacy to induce healthy diet and exercise behavior changes to promote weight loss. MI has been found to encourage behavior change by helping people understand the need to change in terms of lifestyle choices. MI has been supported in the literature as an intervention to increase one's self-efficacy promoting weight loss.

There were two outcomes this evidence-based practice (EBP) change project measured and evaluated. The first outcome was an increase in weight loss measured by a reduction in body mass index (BMI). The second intended outcome was an increase in self-efficacy for healthy behavior change and weight loss as a result of a MI intervention. Data revealed an increase in group aggregate self-efficacy for weight loss by 14.8%, exceeding the benchmark of an 11%. An analysis of aggregate group BMI revealed CTDs lost a mean of 0.65 kg/m², exceeding the benchmark of 0.5 kg/m² to two pounds per week. The outcomes of this EBP change project suggests that MI was successful as a group, in helping CTDs increase their confidence for weight loss and for decreasing BMI (group aggregate benchmarks were met for both outcomes). The results suggest a short term MI intervention can be a cost-effective and easy to implement solution to mitigate obesity when implemented as a clinical standard for CTDs, as well as other populations.

I 02 - Education Strategies in Academia

Self-Leadership in Male Learner Nurses during Their Training at a College in South Africa

Shahnaaz Mia, MCur, RN, RM, South Africa

Abstract

Male learners in the nursing profession have been found to face self-leadership challenges. Self-leadership is an enabling process whereby a people learn to know themselves better and through this improved self-awareness, are better able to steer their work life. Self-leadership includes both personal and professional growth. It requires certain attributes such as maturity and endurance. This leads to the empowerment of the individual and to the fulfillment of goals and desires. The purpose of this study was to describe guidelines for male learner nurses on self-leadership during a four-year nursing programme at a nursing college in the Western Cape.

The objectives of this study were to explore and describe the best experiences of self-leadership in male learner nurses during their four-year training programme at a nursing college in the Western Cape Province of the Republic of South Africa.

A qualitative research design incorporating the philosophy of the Appreciative Inquiry paradigm was used. The research design was exploratory, descriptive and contextual to match the research questions.

The research questions were framed from an AI perspective:

'What are the best experiences of male learner nurses on their self-leadership during their four-year programme?'

'How can male learner nurses lead themselves during their four-year programme?'

The target population consisted of all the male student nurses from 1st to 4th year (n=151) following the R425 undergraduate diploma programme at a nursing college in the Western Cape. Data was collected by means of individual, semi-structured interviews with 12 male learner nurses until saturation occurred. The interviews were audio-taped and transcribed verbatim. Data analysis consisted of thematic analysis using Tesch's eight-step method to generate themes, categories and sub-categories. The findings consisted of five themes:

Theme 1 – The peak experiences of the male student nurses relating to self-leadership occurred on multiple levels – academic, interpersonal, personally associated and practice-linked.

Theme 2 – Self-leadership was a process (at times difficult) of growth, adaptation and developing attitudes that culminated in building character.

Theme 3 – Future aspirations included professional and educational aspects and interpersonal leadership.

Theme 4 – This revealed the qualities needed for attainment of future aspirations.

Theme 5 – The value of the programme was enhanced through educational, fellow student and practice support.

The conclusion of this study was that male learner nurses have the capacity to lead themselves as they displayed those characteristics identified for their self-leadership. Characteristics such as maturity, responsibility, advocacy, strong resolve, hard work, endurance and a willingness to sacrifice were identified by the participants. They employed the use of self-talk and they were able to make firm decisions, but they required guidance and active support from significant others such as family, friends, nurse supervisors, nurse educators and faculty.

The value of their training programme was enhanced by educational support from lecturers and mentors, fellow students and practice support in the wards and simulation laboratory. Guidelines for self-leadership for male learner nurses were described from the findings of this study.

Ethical considerations included obtaining informed consent from the participants, while ensuring confidentiality and anonymity. Ethical clearance to conduct this study was obtained from the Ethics Committee at the University of the Western Cape, Western Cape College of Nursing (WCCN) and Cape Peninsula University of Technology (CPUT). Trustworthiness was ensured throughout the research process through credibility, transferability, confirmability and dependability.

I 14 - Promoting Safety and Clinical Outcomes

Adopting a High Performance Management System Utilizing a Lean Visual Management Tool to Sustain Improvements

Louise C. Rudden, MScN, RN, BScN, NP (Paed), Canada

Melody Hicks, BScN, Canada

Stephanie Lappan-Gracon, MN, BScN, Canada

Yogini Walli, MN, BScN, RN, Canada

Irene Koo, MHA, BSc, BScPT, Canada

Rose Rivard, CPA, CA, BA (Hons), Canada

Abstract

After the implementation of a LEAN Daily Continuous Improvement Program (DCIP) in a Large Pediatric ambulatory portfolio the momentum for process improvement accelerated and great successes were achieved. However, after a period of time ideas for improvement began to decrease. Managers resorted to look for solutions to sustain and maintain the improvement. As healthcare evolves so do the increasing demands on manager responsibilities limiting their ability to not only find solutions but act on them.

In an effort to support managers and leaders in sustaining improvement, a High Performance Management System (HPMS) was adopted using a LEAN visual management tool called an Obeya, translates as “big room” in Japanese. A HPMS is an organizational framework that defines standard work for each tier of management and the integrated hierarchy that reinforces, supports, and improves work at all levels. Its theory is grounded in the Juran Trilogy (Quality Planning, Quality Control, and Quality Improvement). A HPMS enables a culture of transparency that encourages and sustains improvement.

The Obeya aids in visualizing priority projects within the portfolio and a visual map of how each project is directly aligned with the organizational strategy and goals to achieve key performance metric targets.

Using a visual management tool has allowed managers and leaders to quickly visualize their progress on many important initiatives and move projects along at a more efficient pace. Some of the early outcomes experienced by managers who have piloted this framework include increased focus, collaboration, and efficiency. The Obeya allows managers to “see together, learn together, act together”.

Defining management standard work enables managers to reduce variation and achieve outcomes more efficiently. This framework will aid in eliminating non value added/non managerial work in a manager’s schedule supporting them to find and implement solutions that sustain improvement both at a departmental and organizational level. As a framework its adaptability to all tiers of management in an organization will really drive the strategic agenda for organizations.

I 14 - Promoting Safety and Clinical Outcomes

Improving Clinical Outcomes: A Study of the Impact of Audit and Feedback on Nurse Performance

Rebecca Clark, PhD, MSN, BSN, RN, USA

Kimberly Ferren Carter, PhD, RN, USA

Abstract

Purpose: The purpose of this project was to explore the impact of timely, individualized audit and feedback on clinical outcomes and nursing behaviors. The specific focus of the study was to improve the pneumococcal immunization rate for at-risk adults in ambulatory settings. The objective of the study was to increase immunization rates to 50% for eligible patients.

Background: While vaccines are noted to be among the most successful health advances in recent history, adult immunization rates in the United States are well below the recommended levels. The economic and personal costs far outweigh the cost of effective immunizations but studies continue to indicate the need for effective strategies to immunize our at-risk groups. Centers for Disease Control and Prevention estimates that only 20% of the at-risk population ages 19 to 64 has been immunized, contrasted with 61% of those greater than age 65.

While adults are often hesitant to obtain vaccines, the literature indicates that providers may avoid administering the vaccines per immunization schedule. Studies have demonstrated that interventions targeted toward provider behavior on a variety of patient care issues can have a major impact on improving implementation of practice guidelines.

Studies have shown that individualized assessment (audit) and feedback (A & F) can be effective in improving outcomes in numerous settings. Effective A&F interventions includes key components of timeliness, individualization, and nonpunitiveness. This study explored the impact of audit and feedback on individual performance and the clinical outcome of pneumococcal immunizations.

Study: This study was deemed a quality improvement study by the Institutional Review Board, and consent was not required. The study was conducted from October 2014 to August 2015.

Setting: This study was conducted in a presurgical testing center (PST) that is a department of a large healthcare system in southwestern Virginia. This center is a referral site for the region and has over 12,000 patient visits annually. The PST is staffed by RNs who conduct risk assessment on patients prior to surgeries. The departmental goal for immunizations was set at 50% of eligible patients and each staff member had this as an individual goal.

All patients seen in the PST were screened for eligibility for the pneumococcal vaccine per Centers for Disease Control criteria: 18 years of age or older, history of chronic disease, and/or smoker. At the time of the study only the Pneumovax 23 immunization was recommended by the CDC. The staff were educated regarding the importance of the vaccine and how to use the electronic medical record (EMR) to determine patient eligibility for the vaccine.

This study consisted of 2 phases: Phase 1) feedback to staff regarding personal performance for the previous year and Phase 2) individual audit and feedback that reflected the individual performance for the previous month.

Results and Analysis: Data were collected for nine months, and analyzed for Phase 1, Phase 2 and the total study using chi square. The mean immunization rate from the preceding fiscal year (November 2013 through October 2014) served as the control and was 41.68%.

Phase 1: The nurse manager provided staff members with data about individual performance for the previous 12 months (November 1, 2013 to October 31, 2014). For the three months following this

feedback (November 2014 through January 2015) the mean departmental immunization rate was 32% (range: 27% to 32%). This was not statistically significant $X^2 (1, N=614) = 1.74, p=1.86$ when compared with the control.

Phase 2: Phase 2: From February through August 2015, the manager provided each staff member with a monthly email that detailed the personal rate of administration of vaccines to eligible patients. Data for these emails were generated through reports based on the EMR.

During this six-month period, the mean departmental immunization rate rose to 56.8% (range 45% to 67%). This individual, timely feedback was significant $X^2 (1, N=1379) = 4.50, p=0.033$.

The impact of the intervention for both phases of the study was 49%. The result was not significant $X^2 (1, N=1993) = 0.98, p=.32$.

Discussion: The purpose of this project was to improve the immunization rates for adults to 50% using audit and feedback on nurses' performance. This goal was achieved in the second phase of the study where the clinical outcomes (immunization rates) for the department were significantly higher.

These findings support the hypothesis that timely, individualized audit and feedback that is not punitive can have a positive impact on the departmental outcome of immunizations. Generalized feedback that does not provide information that is actionable did not have the same impact. Staff commented to the nurse manager that the 12-month data point was not something they could impact. However, they noted that the monthly emails provided them with data about current performance that they could change.

It was not possible to assess the impact on individual performance due to variations in staffing. For example, within the six-month time frame of the study, several nurses rotated to clinical leadership positions and did not administer vaccines, while others were on extended leave. This resulted in a small sample size of nurses who worked in a consistent role over the period of the study.

Limitations: Generalizability is limited due to the time frame for this study. More study is needed to understand the sustainability and impact of these findings. The trend in this study supports that timely, actionable feedback, provided by a manager, has a positive impact on individual behavior related to immunizations of eligible patients. Further study regarding the impact of individualized audit and feedback will yield a deeper understanding.

Conclusion: Individual variations in practice account for variations in clinical outcomes. In efforts to improve patient care and clinical outcomes, it is important to influence individual provider efforts to encourage compliance with guidelines. It is essential for providers to have actionable information about their behavior if they are to improve.

J 14 - Promoting Interprofessional Teams

Interprofessional Collaboration: Nurses and Physicians Continue to View Collaboration Differently

Tanna Thomason, PhD, RN-BC, CNS, PCCN, USA
Belinda M. Toole, PhD, RN, CCRN, CCNS, USA

Abstract

Purpose: Interprofessional collaboration fosters quality and safety clinical outcomes and is a requisite element in our complex healthcare delivery environment. Yet, as noted by The Joint Commission (2009), the relationship between nurses and physicians has been a major determinate of the quality of healthcare. Hierarchical power relationships between nurses and physicians were first described by Stein in 1967. Power dynamics, whether real or perceived, impede teamwork, collegiality, and patient advocacy. Although significant progress has been since Stein's seminal article, conflict and discord persists leading to errors and increased healthcare costs (Crawford, Omery, & Seago, 2012; Nair, Fitzpatrick, McNulty, Click, & Glembocki, 2012).

Frontline nurses at a southwestern United States community acute care hospital identified collaboration as a topic of research interest. Seven frontline nurses developed a research study to explore interprofessional collaboration. The team was sponsored by medical and nursing leadership and mentored by two PhD prepared clinical nurse specialists.

The purpose of the research study was to investigate the current state of collaboration between nurses and physicians at a non-profit acute care hospital in the southwestern United States.

Methods: Following Institutional Review Board approval, the frontline nurses conducted a non-experimental, concurrent mixed methods study. Quantitative data included the use of two instruments. The Positive Professional Practice Environment Assessment Scale (PPEAS) consists of 13 items on a 1-10 point Likert Scale. Eight items are scored from disagree (1) to agree (10); three items are scored from insignificant (1) to significant (10), and two items are scored from poor (1) to excellent (10). The scale produces an overall score and four subscale scores (presence of positive physician characteristics, presence of positive nurse characteristics, presence of positive organizational characteristics, and presence of positive decision making characteristics). The PPEAS has an overall Cronbach's alpha of 0.86 with subscale alpha's from 0.73 - 0.89 (Siedlecki & Hixson, 2011). The Collaborative Behavior Scale – Shortened (CBSS) has eight items with a 1-4 point Likert scale (1 = rarely; 4 = nearly always) and produces an overall score to measure the degree of collaborative behaviors. The CBSS has reported a Cronbach's alpha of 0.96 (Stichler, 2013). Recruitment via convenience sampling included 355 nurses and 82 physicians who completed the quantitative instruments. One focused qualitative question (*If you could improve collaboration between physicians and nurses, what two strategies/priorities/areas would you suggest?*) resulted in responses from 144 nurses and 53 physicians. Data was analyzed using SPSS, Version 22 and by first cycle holistic and second cycle thematic coding.

Results: Analysis of quantitative data was completed using descriptive statistics, t-tests, one-way analysis of variance analysis and post-hoc Sheffé. Physician respondents were predominantly male (81.35%), with a mean age of 51.95 years and 19.7 mean years in practice. The majority were board certified (93.7%) and primary practice areas were surgical (45.0%), medical (27.5%), or anesthesia (21.3%). Nurse respondents were predominantly female (90.95%), with a mean age of 44.17 years, and 17.51 mean years in practice. Most nurses had bachelor's degrees in nursing (67.0%), and 51.3% had a specialty certification. Primary practice areas were inpatient units (acute care 22.6%; progressive care 22.1%, intensive care 21.0%). Comparing the two professions, physicians generally rated collaboration significantly higher than nurses as measured by the PPEAS overall score (physicians $M = 8.05$, $SD = 1.36$; nurses $M = 7.69$, $SD = 1.39$, $p = .037$) and CBSS (physicians $M = 3.40$, $SD = 0.55$; nurses $M = 2.69$, $SD = 0.76$, $p < .001$). Two PPEAS subscale scores were also significantly higher for physicians than nurses. On positive physician characteristics, physician scores ($M = 8.02$, $SD = 1.37$) were significantly higher than nurses ($M = 6.73$, $SD = 2.05$, $p < .001$) and positive decision-making characteristics were also

higher (physicians $M=7.84$, $SD = 2.06$; nurses $M = 7.02$, $SD = 2.22$, $p = .003$). Nurses ($M = 8.87$, $SD = 1.42$) scored higher than physicians ($M = 8.05$, $SD = 1.82$, $p < .001$) on the positive organizational characteristics. There were no significant differences between professions on the presence of positive nurse characteristics. Physician perceptions of collaboration did not vary by primary practice area. Nurse perceptions of collaboration varied significantly by practice area for the PPEAS overall score, the CBBS, and the two subscale of positive physician characteristics and positive decision-making characteristics ($p < .001$) Post hoc Sheffé comparison tests revealed, in general, nurses working in the emergency department and procedural areas rated collaboration significantly higher than nurses in other areas. Despite the close physical proximity of their work environment, nurses working in the operating room scored collaboration lower than nurses working in most other departments ($p < .05$).

Qualitative data analysis produced four interpersonal and interactional themes of rounding, respect, roles, and communication.

Conclusion: Physician respondents perceived a greater level of collaboration than nurse participants, which is congruent with prior quantitative research findings (Nair et al., 2012; Wauben et al., 2011). The distinct differences in nurses' collaboration scores by practice area support the concept of unit level influences on interpersonal relationships (Donaldson & Mohr, 2000). Qualitative data analysis revealed respect and rounding as methods to improve collaboration from a nursing perspective, while physicians emphasized role delineation as a potential improvement area. Improved communication was a priority emphasized by both professions.

Nurse leaders can influence the interprofessional environment by recognizing entity level measures of collaboration may not be reflective of a unit level work environment. Assessment of provider interprofessional dynamics at the unit or department level is paramount to addressing and improving relationships in the clinical setting. As the current study has shown, collaborative perspectives vary by role and settings. Successful interventions to improve interprofessional practice should recognize these differences and tailor strategies based on an understanding of the specific practice environment. In this study, the richness of exploring collaboration through both quantitative and qualitative methods resulted in a more robust assessment of the interprofessional environment. Collaborative interprofessional interactions are critical to achieve and sustain quality patient outcomes and interprofessional role satisfaction.

Post-Graduation Follow-Up of Graduates of an Interprofessional Simulation Curriculum: Is IPE Important in Clinical Settings?

Sharon Cannon, EdD, RN, ANEF, USA
Saju Joseph, MD, FACS, USA
Adrian R. Mulig, BSN, RN, CVRN, USA

Abstract

Interprofessional Education (IPE) has become an integral part of education in all health sciences, however little data exists to determine if this model is helpful in clinical practice. Too often, there is a gap between education and practice. We present our post-graduate results for our IPE simulation curriculum for the Nursing, Medicine, and PA programs.

Patient care is always provided by multidisciplinary teams in the hospital; however education of students continues to be isolated and conducted in silos. Recently, interprofessional education has been utilized to maximize the learning environment, create interactive learning, and teach non-cognitive aspects of health care. Numerous models have been used to quantify the benefit of these curricula, but follow up of graduates has been difficult due to many factors.

Transition to practice is often the most difficult for health care students. While clinical knowledge is easily assessed, employers spend a great deal of time developing a collaborative work environment, effective communication, and professional rapport. Our IPE curriculum was started to replicate these issues and encourage students to improve their communication and teamwork. To assess the effectiveness of our curriculum, we followed all students prospectively and assessed their development after they began their career using interviews and Likert surveys. We believe this is the only way to show validation for our curriculum. Since the goal of this program is to enhance teamwork, communication, and rapport amongst professionals, it is very difficult to quantify the effectiveness and as a result, we rely on subjective experiences of the graduates. Finally, since this program is integrated into other educational models and the student's experience is cumulative, confounding is inherent in the data but minimized.

There were 17 of 28 graduates who responded and all 17 of them believed IPE was important for their career and thought it had improved their communication skills and teamwork. All respondents would suggest the curriculum to current students and 95% thought it should be mandatory. Finally, a number of graduates were asked about this curriculum by their employer during the interview process.

Obviously, the sample size is small but it had positive results. We believe that this data shows the effectiveness of our curriculum. As part of our institution's emphasis on IPE, curriculum utilizing the simulation centers will become an integral part of the core IPE initiative. Finally, the fact that employers are asking about our curriculum at interviews may represent improved preparedness of the graduates compared to other students and may be an advantage in the job market. In addition, having professionals who interact in patient care can have a major impact on patient satisfaction and build a culture of teamwork in the practice setting.

Empirical Evidence of Theorized Clinical Nurse Leader Integrated Care Delivery Model Domains

Elizabeth Spiva, PhD, MSN, BSN, RN, USA

Miriam Bender, PhD, RN, USA

Wei Su, PhD, MS, USA

Lisle Hites, PhD, MEd, USA

Abstract

Background: The National Academy of Medicine acknowledges healthcare delivery redesign and innovative models of care are essential for improving care quality and safety (Institute of Medicine, 2011). Registered nurses (RN) comprise the largest healthcare workforce in the United States and are in a vital position to shape clinical microsystems into spaces where interdisciplinary teams work together to deliver high quality patient care. The evidence for nursing presence to reduce patient mortality and morbidity is robust (Aiken et al., 2011; Needleman et al., 2011). How nursing practice should best be organized and implemented to consistently achieve quality outcomes is less clear (Needleman, 2015). Preliminary data support a new nursing model, Clinical Nurse Leader integrated care delivery, as an effective approach to redesigning microsystem nursing care delivery to achieve consistent quality outcomes. A recently validated conceptual model describes domains of organizational readiness and structuring that are necessary for CNL integrated care delivery to be successful and produce quality and safety outcomes (Bender, 2014). Confirmatory factor analysis and structural equation modeling validated the measurement (a CNL Practice Survey) and model structure (Bender et al., in press). The validated model provides a framework to assess CNL-integrated care delivery and practice across diverse care settings, and better understand how model domains have been operationalized in health systems with CNL initiatives. The model domains include Readiness (for CNL-integrated care delivery), Structuring (of CNL-integrated care delivery), CNL Practice (communication, relationship building, teamwork, supporting staff engagement), Outcomes (improved microsystem care dynamics and quality/safety outcomes), and Value (The CNL is perceived by clinicians and administrators as adding value to the ways care is delivered).

Purpose: The study purpose was to assess the presence of and specify the operationalization of model domains at one health system with active CNLs in its hospitals and ambulatory practice.

Methods: The setting was a health system comprised of four affiliated hospitals and an ambulatory practice that launched its CNL initiatives in 2011. The health system partnered with a local university to educate RN employees who expressed interest in the CNL role, and covered 100% of employee's tuition. The university provided the curriculum and classes were conducted at the healthcare system. Employees signed a 2-year commitment to CNL positions after graduation. A mixed methods design was used to (a) measure the presence of conceptual model domains after the health system's CNL rollout and (b) compare observed operationalization components to the hypothesized components derived from the CNL practice model. All employees involved in the system's CNL initiative were eligible to take the electronically administered CNL Practice Survey. A purposeful sample of this population was approached to participate in interviews and focus groups conducted on-site or via telephone. Survey data were exported from Qualtrics into SPSS 22 and analyzed using descriptive statistics. Interview/focus group data were analyzed using deductive and inductive qualitative content analyses. Qualitative data were mapped to the professional role from which the data was generated to enable descriptive analysis of coding variation. Qualitative data was first coded onto the existing CNL practice model domains and components. Data coded onto model components were then inductively analyzed to derive categories corresponding to the system's operationalization of model domains/components. Findings were mapped back onto the model to confirm or not, theorized patterns and identify any new or emerging patterns.

Findings: There were 209 valid surveys analyzed and 57 interviews conducted, including patients, nurse leaders, unit managers, clinical RNs, advanced practice RNs, physicians, CNLs, clinical nurse specialists and clinical educators. Survey data confirmed health system settings operationalized all model domains and components to a greater or lesser extent, and confirmed associations between model domains. As

for CNL practice itself, 38% of respondents reported CNLs practiced on one unit; 23% reported CNL practice on more than one unit; 16% in administration; and 22% of respondents did not know where CNLs spent most of their time. In terms of consistent practice, 44% of respondents reported CNLs activities were performed consistently, 24% reported consistency for a portion of the workweek, and 23% didn't know. The average overall health system success score for the CNL initiative was 76% (out of 100, SD 23). CNLs reported a slightly greater success rate of 80% (SD 17). In terms of the CNL practice model, all locations scored lowest in the "Readiness for CNL integrated care delivery" (70%, SD 21), and highest in the "CNL Practice" domain (79%, SD 25). Qualitative data confirmed all CNL care delivery model domains were present. Nurse leaders and unit managers provided the most coded information about Readiness for and Structuring of the CNL-integrated care delivery model. Patients and physicians provided the most information about actual CNL practices. Patients, physicians and clinical RNs provided the most information about the care delivery model's outcomes. Physicians also had the most to say about the care model's value. Clear expectations for CNL practice, system-wide yet tailored education about the care delivery redesign, and CNL readiness for practice were the top implementation strategies. Structuring of care delivery redesign included changes in evaluation, reporting and communication structures, with the main focus for CNL workflow at the microsystem level. Outcomes were operationalized as engagement with and enactment/consistency of best practices, CNL professional growth, process and not task thinking, and shared understandings of care processes. Value was operationalized as trust in CNLs and an assumption that their practice is a necessary function of microsystem care delivery. Value did not emerge if there was ambiguity about expectations for practice or when CNLs were not visible in the microsystem, supporting the theorized model pathway.

Discussion: Findings indicate the empirical operational category that most concretely linked the concepts Readiness through Structuring to Practice and Value was 'clarity on expected practice.' Clarity of CNL functions within a care delivery microsystem was consequential to CNL readiness for practice, system-wide education to orient clinicians and leaders to the new care delivery model, administrative reporting, communication and evaluation practices, CNL workflow and activities, and perceived outcomes and value of the care delivery model. Furthermore, there was a learning curve to perceiving the care model as beneficial and valuable. For example, it was only as small wins were achieved improving and stabilizing care processes over time that "stability allowed different [positive] aspects [of the care delivery model] to be seen." The findings suggest a transformation in understanding of nursing practice, from a traditional focus on patients or particular processes (discharges, education) towards an active clinical practice holistically focused on microsystem care processes. This 'microsystem nursing practice' entails patients, staff, other professionals, resources, policies, existing routines and cultures, and aims to catalyze improvement through relationships, communication, team building and supporting engagement. It does this via a CNL workflow that for many at first appears simply "wrong," for example not having a patient assignment, but over time is considered part of "the woven thread" of microsystem care, the outcome of which one director powerfully articulated as the entire microsystem team knowing "what works in the clinical flow so quality is happening at the same time as practice."

Conclusion: The findings provide preliminary empirical confirmation of the CNL practice model and greater clarity and specification of how health system settings have operationalized model domains within their local contexts. The next step is to compare identified operationalization characteristics against other health system's CNL initiatives to determine: (a) the extent to which operationalization varies (or not) across contexts; (b) how context influences variation; and (c) the effects on outcomes. Results will drive progress in measuring and comparing CNL practice in a standardized way across diverse care settings. This systematic, theory-informed program of research has great potential to produce the evidence needed to ensure transferability to health systems considering care delivery redesign, including implementation strategies that facilitate adoption and success.

L 01 - Evidence-Based Practice in Nursing Education

Are Students Prepared to Engage in Evidence-Based Practice (EBP)? Developing Essential EBP Skills

Sharon Stahl Wexler, PhD, MA, BSN, RN, GCNS-BC, FNGNA, USA

Esma Paljevic, EdD, MSN, BSN, RN, CPNP, USA

Marie-Claire Roberts, PhD, RN, USA

Lin J. Drury, PhD, RN, FNGNA, USA

Noreen Bridget Brennan, PhD, RN-BC, USA

Abstract

Background: Over the past six years we reimagined EBP throughout our undergraduate program using the AACN Baccalaureate Essentials as our guide. Student and faculty feedback was positive, work products were excellent. We measured EBP competencies for each cohort and were able to demonstrate success, however we did not have a cumulative measure of all of the students over time.

Purpose: To measure EBP competencies and knowledge of students in the undergraduate program.

Methods: IRB approval was obtained from the university. The ACE Evidence Based Readiness Inventory (ACE-ERI) is an online instrument that measures self-reported competencies in EBP. The instrument is based on nationally established EBP competencies and has strong validity and reliability. It has been utilized in both clinician and student populations. The tool incorporates the EBP competencies, a knowledge test focusing on knowledge transformation and demographic information. The ACE ERI is distributed to students via an email invitation at the beginning and end of their EBP course as well as at the end of their program. Data is anonymous and reported in aggregate. In order to encourage students to complete the survey, a certificate of completion is generated for students.

Results: The ACE ERI has been administered to 18 cohorts over the past five years. There is greater than a 90% return rate for both pre and post surveys. Student knowledge increased as did level of confidence in EBP competencies. Pretest and posttest mean scores for ACE-ERI competencies were compared. Statistical significance was achieved for all twenty competencies ($p < 0.001$). Analyses were run to investigate the correlations between the questions and the demographic variables. There were no statistically significant relationships indicating that the variation in the results was not related to the demographics of the students.

Conclusion: Student knowledge and competency in EBP increased significantly. We use the ACE-ERI to measure EBP knowledge and competency on an ongoing basis. Further analyses are being conducted to ascertain which specific features of our EBP model are most successful.

L 01 - Evidence-Based Practice in Nursing Education

Empowering Nursing Through Evidence: Putting Evidence-Based Practice Back in the Classroom

Melanie C. Neumeier, MN, RN, Canada

Leah Phillips, PhD, MA, BA (Hons), Canada

Abstract

Using evidence to inform practice is essential to ensure safe, quality care in all areas of nursing. In Canada, Registered Nurses (RNs) and Licensed Practical Nurses (LPNs) are required to engage in evidence informed practice as an entry to practice competency (CCNRN, 2012, CCPNR, 2013). However, despite this expectation, and research findings that nurses generally have a positive attitude toward evidence-based practice (Yoder, et al, 2014) globally there is poor uptake in the application of this process.

Thiel and Ghosh (2008) conducted a cross-sectional survey of 121 practicing nurses in the Midwestern United States to determine how they accessed information and their readiness to engage in evidence-based practice. Results of this survey concluded that while 75% of nurses indicated they were familiar with evidence-based practice processes, only 24% stated they used a health database like CINAHL when they needed information. The majority of respondents (72.5%) indicated instead that they used nursing colleagues and peers as their primary source of practice information. A similar study conducted in Ireland by O'leary and Mhaolrunaigh (2011) to examine the information seeking behaviours of practicing nurses found again that most nurses accessed other people, especially their colleagues when seeking information and making decisions on care. Yoder et al (2014) conducted a survey of 1112 practicing nurses in the United States to determine what types of knowledge RNs working in the hospital system use in their practice and to what extent they utilize research findings. Their results showed little difference from previous studies. Only 11% of respondents stated that they did not know very much about EBP. However, when asked about how they access information in practice 75% of nurses surveyed stated they relied on personal experience as their primary source of knowledge and only 23% noted using nursing research journals. When asked about how they accessed nursing information on-line, 71% stated they used Google while less than half (45%) reported using databases like CINAHL or MEDLINE. This evidence clearly outlines a 'gap' between the expectation of EBP and the actual implementation of EBP.

To determine if this trend held true for our local context we surveyed 750 Alberta LPNs about their sources of practice knowledge. The top 3 identified sources of knowledge were: individual clients, personal experience, and nursing school. The use of personal experience as a source of knowledge was positively correlated with age and years of practice, and using nursing school as a knowledge source was negatively correlated with years of practice. Using individual clients as a source of knowledge was not correlated with age, employment, or years of practice.

Recognizing that our nursing population was also experiencing a gap between the expectation and implementation of EBP, we looked to the literature to examine the barriers that prevent nurses from engaging in EBP. The most common barriers identified by nurses were a lack of time and a lack of skill (Chang & Crowe, 2011; Hewitt-Taylor, Heaslip, & Rowe, 2012, Majid, et al, 2011, Wallin, Bostrom, & Gustavsson, 2012). In their study of 1,486 practicing nurses in Singapore, Madji et al (2011) found that nurses had limited skills in searching the literature and understanding the evidence. The majority of nurses were unable to adequately perform search strategies for given nursing topics and less than 25% were familiar with Boolean operators. In addition to the lack of literature searching skills, the nurses in this study also indicated that inadequate understanding of statistical terms and research jargon limited their ability to engage in EBP. These nurses indicated that additional training in EBP skills would help them to implement EBP. Hewitt-Taylor et al. (2012) in their study of Finnish nurses noted that nurses lacked confidence in their ability to use research in practice. They suggested that interventions to support EBP implementation should focus on helping practicing nurses develop the skills required to understand what makes research usable by focusing on the process of deciding what information is needed, searching for this information, and then evaluating the utility of that information. Chang and Crow (2011) noted that

nurses had limited confidence in their ability to find, appraise, and then implement evidence into their clinical practice, but that exposure to education on EBP enhanced nurses' self-efficacy in engaging with EBP. This finding is supported by a study of 1,256 Swedish nurses that noted that the nurses with the highest levels of EBP capability beliefs used research findings in practice more than twice as often and engaged in the implementation of evidence seven times as often as those with lower capability beliefs (Wallin et al, 2012).

In order to improve EBP implementation in Alberta, we created an accessible education program that targets essential EBP skills. This program emphasizes the development of practitioner self-efficacy, and the utility of research to practice. The program consists of a series of three interactive webinars designed to increase nurses' skills in EBP and their self-efficacy for carrying out those skills in practice through a strong clinical focus. This focus on clinical versus academic application of EBP skills helps demonstrate the relevance and utility of research for practice and enhances the real-world application of EBP for practicing nurses (Christie, Hamill, & Power, 2012). The webinars were evaluated using a pre-test/post-test design and statistically significant improvements were reported for each webinar in the targeted learning areas. This webinar series remains available to practicing nurses and is currently housed on the CLPNA website and on the Global Health Network.

Despite the success of the webinar series it is important to acknowledge that individual skill building supports only one part of the equation, and to create a culture of evidence-based practice, overall educational and system changes must also occur. Following the PRECEDE/PROCEED framework, we collaborated with Alberta institutions that offer the LPN program to determine what their needs are for embedding EBP skills into the LPN curriculum. A focus group was held with key participants from the educational system and then a survey was sent out to educators across the province. Data on the predisposing, enabling, and reinforcing factors affecting EBP interventions in curriculum were gathered. This data was used in collaboration with a partner school to develop, pilot test, and implement an EBP intervention that embeds EBP skills within the nursing curriculum.

L 01 - Evidence-Based Practice in Nursing Education

Impact of Community- and Hospital-Based Nurses' Beliefs Regarding Evidence-Based Practice on Mentoring Student Nurses

Joanne Brooke, MSc, BSc, RN, CPsychol, United Kingdom

Catherine Lynch, MSc, RN, MA, PGCert, BSc (Hons), DPSN, United Kingdom

Abstract

Background: Evidence-based practice (EBP) promotes clinical judgements that are based on the best available evidence, with less emphasis on authoritative opinions and traditions. The integration of best available evidence is associated with improved patient outcomes, reduced treatment costs and need for clinical interventions (Melnyk et al. 2012; Levin et al. 2011). Student nurses in the UK and Slovenia understood the importance of EBP and research in their future careers, but struggled to conceptualise how they could maintain these skills on leaving the academic setting as perceived a lack of involvement in EBP and research by clinical nurses (Brooke et al. 2015).

In the UK, student nurses are supported by nurse mentors in clinical settings. The Nursing Midwifery Council's guidelines (NMC 2010) for nurse mentorship include the acquisition of skills to search, find and review research to change or support their practice, and enable student nurses to understand and implement evidence-based care across both community and hospital settings.

A review of contemporary literature explored EBP beliefs, knowledge and skills of nurses working in acute and community settings, the findings supported the traditional barriers of a lack of time, knowledge, and skills, however nurses' held more positive beliefs towards EBP, but this was not associated with an increase in their intentions to implement EBP (Mallion and Brooke 2016).

The understanding of nurses' beliefs regarding EBP is essential, as they are pivotal in supporting student nurses in clinical placements to begin the process of implementing EBP. The aim of this study was to explore the impact of community- and hospital-based nurses' beliefs of evidence-based practice and how this influences their strategies to support student nurses to understand and implement evidence-based practice.

Methods: Data were collected via 7 focus groups in 2015 with 33 community-based nurse mentors from one community NHS Foundation Trust, and via 4 focus groups in 2016 with 28 hospital-based nurses from one acute NHS Foundation Trust. Participants included: nurses from band 5-8, from different specialities across the two settings. The interview view schedule was developed from previous literature and relevant for both community and hospital mentors. All community-based focus groups were facilitated by the first author, hospital-based focus groups were facilitated by both authors. Data was analysed using thematic analysis, from a social constructionism approach (Burr 2016). All transcripts were read several times in order to become familiar with the text, relevant extracts were highlighted and coded. These codes were developed into a number of themes. The initial analysis was completed by the first author and reviewed by the second author, before being refined and organised into overarching themes (Braun and Clarke 2006).

Results: Themes from both community- and hospital-based nurse mentors included: 1) our practice is evidence-based; community-based nurses cited local and national guidelines to justify their practice, while hospital-based nurses were adamant their practice was evidence-based, but they just didn't use that language. 2) time as a barrier to mentor student nurses; time was reported as a limitation by all nurses, with the exception of community-based district nurses who used the time spent traveling between patients homes to support students. A unique theme to community-based nurses was the importance of; being current as a nurse practitioner, a mentor and a role model. Community-based nurses discussed the importance of inspiring student nurses to become actively involved in developing their own practice, and this required mentors to be current. A unique theme to hospital-based nurses was; evidence-based practice is essential for harm free care. Hospital-based nurses discussed the importance of

understanding harm and the implementation of evidence-based practice was assurance that they were doing their patients no harm.

Discussion: All nurse mentors reported providing evidence-based care, community mentors explicitly described guidelines and policies that supported their practice. Whereas, hospital nurses openly admitted they did not use the term 'evidence-based practice' with student nurses, but neither did student nurses ask them for the evidence behind the care they were providing. The use of the same terminology used in Higher Education Institutes and in student nurses practice placements may support a connection between theory and practice. Time has been recognised as a barrier when mentoring student nurses, but hospital nurses felt time was a barrier to implement evidence-based practice. Hospital nurses spoke about the importance of evidence-based practice to support harm free care, when community nurses focused on their need to remain current to support students understanding of evidence-based practice. An understanding of the issues across community- and hospital-based settings is important and will support the development of tailored mentorship/training programmes, which will aid the continued development of nurses' evidence-based practice and techniques to enable them to implement practical examples when mentoring student nurses.

L 10 - Global Perspectives on Multi-Drug-Resistant Infections

Antimicrobial Stewardship: A Comprehensive Literature Review of the Nursing Role in Preventing Multi-Drug-Resistant Infections

Casey N. May, USA

Kaitlyn E. Thormahlen, USA

Renee M. Vittone, USA

Celina C. Calo, USA

Abstract

Purpose: Antimicrobial Stewardship Programs (ASPs) have been developed through collaboration across multiple disciplines and integrated into facilities to combat multi-drug resistant organisms. The purpose of these programs is primarily to educate clinicians on appropriate antibiotic use, and to implement evidence-based standards of practice in order to improve patient safety and quality of patient care. There is much controversy regarding interdisciplinary roles in antibiotic stewardship. This literature review aims to bring to the forefront the already present, yet largely understated role of the nurse. It is likely that physicians, pharmacists, and nurses do not recognize what they can do to prevent the over prescription and improper use of antibiotics. According to Olans (2015), many nurses do not directly see their impact in antimicrobial stewardship programs. Nurses are the heart of the healthcare team; they are the sole members who see patients on an around-the-clock basis. One of the most important factors when discussing what nurses can do to address the issue is to get nurses themselves to recognize that they do in fact have a role in an antibiotic stewardship. The purpose of this integrated literature review is to determine the nurse's role in antimicrobial stewardship in preventing multi-drug resistant infections in the hospitalized patient.

Methods: The inclusion criteria for selected studies included primary research articles published within the last five years, which incorporated various search terms stated below. Both quantitative and qualitative studies were included. The quantitative studies were of experimental, quasi-experimental, cross-sectional, and longitudinal cohort design. The qualitative studies were of phenomenological design. There were 19 primary research articles and one Cochrane review used. Including a Cochrane review was significant to our literature review because it provided us with a strong, evidence-based, systematic review of published healthcare research. Databases used were CINAHL and Ovid. Search terms used were "nursing", "nursing role", "nursing care", "nursing interventions", "microbial", "antibiotic stewardship", "multi-drug resistance", "infection control", and "patient education".

Results: Though increasing research has been conducted regarding ASPs in recent years, these programs are still relatively new, dating back only about 15 years. Research has shifted from studying "miracle drugs" to studying the increase in antibiotic resistance, related infections, and the roles healthcare providers play in maintaining the health of the public. As previously noted, the gold standard for ASPs is the CDC's "Core Elements of Hospital Antibiotic Stewardship Programs" which only mentions "nurse" four times (CDC, 2014). The focus while examining the articles obtained for the literature review was identifying similar themes that group members felt targeted ASPs, while simultaneously determining how often "nurse" was mentioned. It was quickly discovered that only 50% of articles included in the table displayed the word "nurse". The thematic analysis revealed the following themes: overprescription, hand hygiene, education, acquisition of knowledge and compilation of available data, and protocol. The results are broken down by theme, and then further ordered by inclusion or exclusion of the nurse. Articles with multiple themes were included in one or more sections.

Conclusion: ASPs are a vital factor in reducing the spread of multi-drug resistant organisms. Multi-drug resistance has become an international phenomenon and a strong threat to the human population. Therefore, it is imperative that ASPs continue to be developed and implemented. According to the IOM, nurses play a vital role on the interdisciplinary team, yet the nurse's role in ASPs has not been explicitly stated. The themes throughout the literature review include the impact that proper assessment or screening has on the overprescription of antibiotics, the importance of the basic yet fundamental tool of

hand hygiene in preventing the spread of multi-drug resistant organisms, how education can disseminate previous and upcoming knowledge, and how improved infection protocols can establish new expectations for the entire interdisciplinary team. Each of these initiatives should be clearly stated as a responsibility to be carried out by the nurse. Further research is necessary to provide structured guidelines that explicitly include the role of the nurse in antimicrobial stewardship in preventing multi-drug resistant infections in the hospitalized patient.

L 10 - Global Perspectives on Multi-Drug-Resistant Infections

A Multicultural Approach to Decreasing Unnecessary Antibiotic Prescribing for Pharyngitis

Mercedes Camacho-Walsh, RN, FNP-BC, USA
Corinne Schultz Ellis, DNP, RN, BC, USA

Abstract

Antimicrobial resistance is a global crisis. In the United States alone, two million people are infected every year with untreatable microbes, resulting in 23,000 deaths (CDC, 2014). Over-prescribing of antibiotics has been cited as major contributor to the crisis. (WHO, 2015). According to the CDC Morbidity and Mortality Weekly Report (2011), 50% of antibiotic prescriptions in the United States are unnecessary. Non-prescription antibiotics account for 19-100% of antibiotic use outside northern Europe and North America, with increased antimicrobial resistance in countries with greater use (Morgan, Okeke, Laxminarayan, Perencevich & Weisenberg, 2011).

International guidelines for pharyngitis approach diagnostic scoring and the use of rapid antigen testing differently, but they largely concur on the need to decrease unnecessary antibiotic prescribing (Shullman, 2014; Ebell, 2014; Cohen, et al, 2015; and Hoare & Ward & Arroll, 2016). Differences in the perceived benefit of rapid antigen tests to aid in the detection and treatment of streptococcal pharyngitis have also been addressed (Lean, Arnup, Danchin & Steer, 2014; Steward, et al, 2014; and Cohen, et al, 2016). A 2103 Cochrane review (Spinks) examined the actual rate of rheumatic fever in various populations, identified complications due to untreated Streptococcal pharyngitis, and the described the natural course of the disease.

Using the 2012 Infectious Disease Society of America Guidelines, Ellis & Camacho (2015) devised a management algorithm for prescribing antibiotics based on clinical presentation, rapid antigen test results, and likelihood of complications according to age and comorbidities. The algorithm provides clinicians with a succinct evidence-based pathway for clinical management of pharyngitis and opens dialogue with multicultural patients concerning their ideas, concerns and expectations.

Despite the vast amount of clinical evidence, many clinicians continue to overprescribe antibiotics. Barriers to clinician antibiotic stewardship are lack of knowledge of clinical practice guidelines and their application, and lack of understanding of patient expectations in different cultural settings. Perceived pressure to prescribe antibiotics, and failure to ascertain the actual expectations of patients can lead to unnecessary antibiotic prescribing (Mathys, 2009, and Mustafa, Wood & Elwyn, 2014). Cultural differences may account for increased use and expectations of antibiotic prescribing, but it is significantly less than that perceived by clinicians (Watkins, Lousisek, Sanchez, Albert, Roberts & Kicks, 2015).

Combating the spread of global antimicrobial resistance requires cooperation of clinicians around the world. The purpose of this presentation is to reduce unnecessary antibiotic prescribing across different cultures. This presentation demonstrates application of key clinical guideline recommendations, and addresses patient cultural considerations and expectations. A seven-minute trilingual video (English, Spanish and Arabic with English subtitles) uses a multicultural setting to depict sample clinical scenarios. The video demonstrates brief and friendly discussions with patients on the risk of infection and potential complications, versus the risk of developing resistance to antibiotics. Alternative treatment modalities for pharyngitis are also presented.

L 10 - Global Perspectives on Multi-Drug-Resistant Infections

What Works to Improve Staff Compliance With Multi-Drug-Resistant Organism (MDRO) Screening

Monina Gesmundo, MN (Hons), PGDip HSc, PGCertTertiaryTch, BSN, RN, RM, CNS, New Zealand

Abstract

Purpose of the presentation: To present the evaluation of multi-modal interventions on the staff MDRO admission screening compliance rate in various departments of a secondary public hospital in New Zealand

Target Audience: The target audience of this presentation are staff nurses, nurse educators, nurse managers, quality improvement advisers and infection control practitioners who are keen to identify interventions that work in improving staff compliance to MDRO admission screening

Objective: To evaluate the effect of multi-modal interventions on the staff MDRO admission screening compliance rate in various departments of a secondary public hospital

Research question: What is the effect of multi-modal infection prevention and control interventions on the staff MDRO admission screening compliance rate in various departments of a secondary public hospital?

Design: A retrospective review of monthly MDRO admission screening audits was done to compare the compliance rate before and after multi-modal interventions were implemented. The audit was conducted in the care of older people and elective surgical department of a public secondary hospital in Auckland, New Zealand from December 2010 to November 2014.

Setting: Two departments of a public secondary hospital in Auckland, New Zealand

Methods: Monthly MDRO admission screen audits were done in a representative ward of each department for the purpose of quality improvement. Audits were conducted by generating a monthly list of patients who were eligible to be screened for MDRO on admission to the ward. Twenty patients were randomly selected from the monthly list for a specified period of time to evaluate whether nurses screened them for MDRO within 24 hours of admission. Eligibility to be screened is based on the criteria published in the organisational policy for MDRO management. Nursing staff compliance rate with the MDRO admission screen policy was computed using frequency and percentage.

Multi-modal interventions focusing on the nursing staff were implemented by the infection control practitioner. Interventions include: monthly MDRO admission screen compliance audits, regular reporting of audit result, feedback with regard to missed screens, regular education sessions with the nursing staff and staff encouragement from both the infection control practitioner and nurse manager.

Compliance rates were reported to the charge nurse managers on a monthly basis through an e-mail. Compliance rates of greater than 90% were celebrated and reinforced, whereas a drop in the compliance rate or a compliance rate of < 90% was followed up with the nurse manager. Regular 10-15 minute-education sessions during staff handovers were done by the infection control practitioner to present the audit results, to provide input, to answer queries and to encourage the staff to do better. Nurse managers also encourage staff to improve screening compliance rate.

Data analysis utilized Microsoft Excel Software in quantitative data collation and encoding. MDRO admission screen audits were presented using descriptive statistics such as frequency, percentage, mean, median and mode. Standard deviation was used to show data variability. T-test was utilized to test for a significant difference in the overall compliance rate before and after the multi-modal interventions were introduced. T-test is a parametric procedure of testing the difference in group means. The level of significance was set at $P < 0.05$ to identify a significant difference in the compliance rate.

Results: Results show that the MDRO admission screen compliance rate in the two departments were variable. The average compliance rate from October, 2012 to November, 2014 in the elective surgical department is 85.75% compared to 75.91% from December, 2010 to September, 2012 (Table 1).

Table 1. MDRO admission screen compliance at the elective surgical department

		Surgical Department	
	Before*	Mean	After**
Mean		75.90909091	85.75
Number of patient records audited		1670	2058
Number of monthly audits completed		22	24

*Period coverage is from December, 2010 to September, 2012

**Period coverage is from October, 2012 to November, 2014

In the care of older people department, results show that the MDRO admission screen compliance was also variable. The average MDRO admission screen compliance rate from August, 2013 to October, 2014 is 96.80% compared to 83.84% from December, 2010 to July 2013 (Table 2).

Variability in the compliance may be due to patient acuity, staff mix, thorough history-taking of the patient, review of previous admissions, completeness of handover, staff knowledge of the organisational policy, staff motivation to adhere to organisational policy and availability of staff support.

Table 2. MDRO admission screen compliance at the health of older people department

		Health of Older People	
	Before***	Mean	After****
Mean		83.83870968	96.8
Number of patient records audited		2599	1452
Number of monthly audits completed		31	15

*** Period coverage is from December, 2010 to July 2013

****Period coverage is from August, 2013 to October, 2014

Statistical analysis of the overall MDRO admission screening compliance rate before and after the interventions showed a significant difference ($P < 0.05$) in the compliance rate in both departments. A two-sample T-test with unequal variance was utilized in the statistical analysis given the variability in the screening rate and count. Table 3 provides a summary of the statistical testing done. The last column shows that there is a significant difference in the compliance rate in the surgical department ($P < 0.009$) and the care of older people department ($P < 0.00003$)

Table 3. Descriptive summary of statistical testing of the MDRO admission screen compliance rate before and after the interventions

Departments	Before		After		T-Test ($P < 0.05$)
	Number of Audits	Mean Compliance Rate	Number of Audits	Mean Compliance Rate	
Surgical Department	22	75.91	24	85.75	0.009324379
Care of Older People	31	83.84	15	96.80	0.000036141

Conclusion: The multi-modal interventions addressed to nurses had a significant impact on the MDRO admission screening compliance rate in various departments of a tertiary public hospital. While various factors may affect the staff MDRO admission screening compliance rate, the rate could be kept at a high level through regular audits, regular reporting of audit result, regular education sessions and consistent staff encouragement.

M 01 - Simulation and Transition to Practice

Evaluation of Three-Dimensional Computerized Simulation: Innovative Pedagogy to Prepare Graduate Nursing Students for Clinical Practice

Carole E. Jenson, DNP, APRN, CNS, ACNS-BC, CME, CCRN-K, USA

Abstract

Introduction: Preparing graduate nursing students to respond to the complexities of a rapidly changing health care environment is a major challenge for nurse educators and nurse mentors. Clinical skill and patient assessment determine trajectory of patient's health care, directly impacting patient outcomes. Assessment skills, clinical reasoning and decision making, and the ability to work with others are imperative for competent clinical practice. Literature reveals that many graduate nursing students are entering into clinical areas unprepared in the areas of patient assessment, diagnostic reasoning, clinical decision making, and team participation (Grossman & Conelius, 2015). Traditionally, these skills were practiced with direct patient care during clinical or job experiences. Decreased availability of clinical sites coupled with fewer clinical mentors further encourages the need for innovative pedagogy. To provide high quality and safe patient care in a cost effective manner, graduate students need to be prepared with assessment skills and ability to work with diverse populations and situations before entering the healthcare environment. Studies report that computerized simulation is interactive, enjoyable, stimulating for the learner, and one pedagogy that needs to be explored. Additionally, literature supports the benefits of patient simulation to improve clinical performance, problem-solving skills, and self-confidence.

Simulation also allows for the student to experience consequences of their actions and improve self-awareness (Nuraini, Afifah, Agustini, and Pujasari, 2015). Three-dimensional computerized simulation (TDCS) is an on-line interactive program that simulates real-life nursing experiences using virtual patients, also referred to as Avatars. This program is computer accessed allowing unlimited practice at any time in a risk-free environment without compromising patient care. TDCS program requires students to interact with on-line virtual patients through therapeutic conversation. The virtual patients are culturally diverse and of various ages requiring students to incorporate knowledge of cultural and age appropriate care.

Purpose: The purpose of this mixed method prospective study was to evaluate the use of a computerized simulation program as one pedagogy to prepare graduate nursing students for clinical practice. Impact of this study will provide a body of evidence regarding active learning in nursing.

Literature Review: CINAL and PubMed databases were searched using the key words nursing education, computerized technology, and interactive learning. The search resulted in 467 returns and was further narrowed by restricting to peer reviewed, published in the last four years, and written in English. Twenty eight articles meet the restricted search criteria. Following review of articles, 20 were selected from the 28 to inform this project. Literature varies widely in level of evidence, with few high quality or high level of evidence studies available. Waltz, Jenkins, and Han (2014) conducted a literature review on learning methods in health and nursing education and the impact of active learning methods. Twenty two studies were reviewed and only one provided a randomized control trial. The authors concluded that there is insufficient empirical evidence regarding active learning methods in nursing. **Design:** Subjects consisted of graduate nursing students taking Advanced Health Assessment class at a Midwestern University over three semesters in 2014-2016 and clinical mentors from Midwestern Healthcare Facilities. Seventy graduate nursing students voluntarily participated in evaluating the use of TDCS. Seven of the surveys were eliminated for not answering all questions or not completing either the before use survey or the after use survey. Sixty three ($N=63$) students completed surveys in entirety. **Methods:** Integrative review of the literature was conducted on the use of computerized simulation as a teaching strategy for graduate nursing students. Selection of TDCS program used for this evaluation followed extensive research of companies that offered computerized simulation for healthcare. Selection criteria included: designed for advanced practice, user friendly, cost effective, and ability to provide feedback to the user. The program selected met criteria and program design correlated with the universities nursing curriculum. Evaluation of the program consisted of a 10 question survey using a five-point Likert scale ranging from strongly disagree to strongly agree. On the first class day of the semester, before students were introduced to TDCS, students were provided the opportunity to complete the survey. At the end of the semester, after using TDCS for fourteen weeks, the same survey was administered. Formative evaluation was conducted with students and student's clinical mentors each semester. TDCS was used adjacent

with face-to-face class time; the class met for 5.5 hours weekly. Surveys were evaluated using Bowkers Test for Symmetry of Disagreement and formative information was categorized into themes. **Ethics:** Study was approved by the University's Institutional Review Board. **Conclusions:** Integrative literature review supports the need for testing innovative pedagogy to prepare students for clinical practice. Studies have demonstrated that computerized simulation may be beneficial in student's perceived self-efficacy in a variety of skills, knowledge of leadership styles, and assessment and management of patients. Using p values from Bowkers Test for Symmetry of Disagreement, the findings from the surveys demonstrated that nine of the questions were statistically significant with values between $p < .0001$ and $p < .0062$ for the use of TDCS to prepare graduate nursing students for clinical practice. One question was not statistically significant ($p < .2367$). Results from statistical analysis of the surveys and themes generated from formative evaluations will be presented. Recommendations and implications for clinical practice will be discussed.

M 01 - Simulation and Transition to Practice

Simulation and Transitioning to Professional Practice

Carrie A. Bailey, PhD, MSN, BS, APRN-BC, RN, CHSE, USA

Abstract

The purpose of this study was to understand how new graduate nurses perceive the value of simulation in making the transition into professional practice. This study will use a descriptive qualitative approach with a sample of first year nurses. Kolb's Experiential Learning Model serves as this study's conceptual framework. For the current study, the sample consisted of 10 newly graduated, female nurses with less than one year of experience working in the hospital setting were interviewed. Data analysis included interviews and transcription by the researcher. Finally, participants were asked about themes to increase rigor. Four themes emerged from this research: 1) how simulation is being used, 2) the perceived value of simulation, 3) simulation versus "real life," and 4) simulation and preparation for practice.

This study showed that simulation is being used in nursing programs, but in different ways. For the most part, the newly licensed graduate nurses were satisfied with their simulation experiences. They were often able to reflect on their experiences, which helped them transition to professional practice. Even though high-fidelity simulations differ from working with real patients, participants appreciated the familiarity such simulations gave them for possible patient care scenarios. Simulation also was shown to increase skill exposure and confidence.

With recent and continuing changes in healthcare and nursing education, it is fair to assume that simulation is not only here to stay but will its use will continue to increase. Nursing programs and educators need to know how best to use this teaching method to provide a safe, skilled nursing workforce by producing well-prepared graduates. The themes and recommendations that emerged from this study can act as a starting point in further researcher to exploit simulation to the fullest extent possible in preparing newly graduated nurses to transition to practice and make an impact on the health and wellbeing of their patients.

M 02 - Support Initiatives to Promote Health

Home-Care Management Concerns and Perspectives By Patients With Head-and-Neck Cancer and Their Family Caregivers

Verna Hendricks-Ferguson, PhD, RN, CHPPN, FPCN, FAAN, USA

Margaret Bultas, PhD, RN, CPNP-PC, USA

Rebecca Ott, BSN, RN, USA

Crystal Weaver, MA, PLPC, CRC, MT-BC, USA

Abstract

Purpose: To describe the concerns and perspectives related to symptoms and home-care, tube-feeding management needs by both patients with head and neck cancer (HNC) and their primary family caregivers.

Adult patients diagnosed with head and neck cancer (HNC) experience significant emotional distress due to difficult and embarrassing side effects associated with radiation-oncology treatments and the high risk of having a poor prognosis. An estimated 600,000 new cases of HNC are diagnosed each year globally. Also, adults diagnosed with HNC constitute 3% to 5% of all diagnosed malignancies in the United States, with 59,340 patients (43,390 men and 15,950 women) being diagnosed annually (Cancer Net, 2015). Adult patients with HNC often experience significant weight loss (e.g., 30 to 50 pounds) during radiation oncology treatments and could benefit from tube feedings to support their nutritional status and to manage difficult oral symptoms (e.g., loss of taste, oral pain, swallowing difficulties). Family caregivers (FCs) play an essential role in the home care of patients with HNC, often requiring them to engage in daily caregiving responsibilities related to tube-feeding management. Although FCs are committed to helping their loved ones, the experience of family caregiving can be very stressful due to demanding caregiving responsibilities. FCs are required to manage challenging illness-related symptoms (e.g., oral symptoms, inability to speak, significant weight loss), make daily home-care decisions, identify potential emergency-care needs in the home setting, and provide emotional care and support to the HNC patient. Also, FCs face the additional challenge and stress of needing to learn and master skills necessary to prepare and manage tube feedings for the HNC patient. For health-care providers to better support family members in their home-caregiving role, research is needed that examines HNC patients and FCs' perspectives and concerns about care needs during and following radiation treatments. To date, limited published evidence exists related to understanding the perspectives and concerns of both patients and their FCs about symptoms and home-care, tube-feeding management stressors.

Methods: A descriptive, exploratory, retrospective qualitative design was used for this study. A convenience sample of 20 participants (i.e., 10 HNC patients and 10 FCs) were recruited and enrolled in this study from the radiation oncology clinic at a major Midwest medical center in the US. HNC patients were eligible to take part in the study if they were: (a) aged 18 years or older; (b) able to read and speak English; (c) diagnosed with any type of HNC and had completed radiation oncology treatments within the previous 4 weeks; and (d) willing to provide written, informed consent and to participate in an interview. FCs were eligible to take part in the study if they were: (a) aged 18 years or older, (b) able to read and speak English, (c) identified by the patient as the primary individual providing their home care; and (d) willing to provide written, informed consent and participate in an interview. FCs were broadly defined for this study to include those individuals who provide HNC patients with unpaid help relative to their home care during and following radiation-oncology treatments.

The primary nurse at the radiation-oncology clinic who routinely provided oncology nursing care to HNC patients assisted with screening patients for eligibility and consenting eligible patients and their FCs. Interview data were collected via audio-taped interviews that were conducted either during face-to-face appointments in the radiation-oncology clinic or by telephone. The interview location was determined according to the participants' preferences. Interviews were conducted by the principal investigator (PI). A structured interview guide developed by the PI was used to guide the participants' scheduled interviews. Audio-taped interviews and demographic data were the primary data sources collected from HNC patients and their FCs. The Demographic Form included questions to collect the participants' age,

gender, race, education, marital status, and diagnosis and facilitated consent procedures and interview procedures. The Interview Guide included questions based on input from experienced radiation-oncology nurses that care for HNC patients and published HNC literature.

Collected interview data were conducted using open-ended questions to elicit the concerns and perspectives of HNC patients and FCs about symptoms and symptom-management strategies during and following radiation oncology treatments. Data were analyzed using Krippendorff's method of semantic content-analysis. Semantic content-analysis included the following steps: first, each phrase of every response to interview questions were analyzed for meaning (i.e. symptoms and symptom-management strategies) and categorized according to those meanings; second, each categorized meaning was counted for frequency; third, labels were applied to categorized phrases; and fourth, a dictionary was developed, defining each factor. Two members of the study team jointly reviewed the de-identified transcript data and assigned categories to key phrases. A strength of this qualitative method is that the researchers categorized the data and counted the frequency of analyzed responses. Also, the members of the study team verified the accuracy of the analyzed data from the transcripts. The reliability estimates for each analyzed-data response ranged from 95% to 100% across all the interviews.

Results: A total of 20 adults participated in this study (i.e., 10 patients with HNC and 10 FCs). Demographic information for the enrolled HNC-patient participants included: (a) 60% (n=6) were male and 40% (n=4) were female; (b) 80% (n=8) were married; (c) 100% were Caucasian; (d) mean age was 61 years; and (e) 100% had completed 6 weeks of radiation- oncology treatments. Demographic information for the enrolled FCs included: (a) 77% (n=7) were female; (b) 80% (n=8) were married to the HNC patient; (c) 98% were Caucasian; and (d) mean age was 61 years. Following are the three most common coded meaning phrases and the total summary of the counted meaning phrases according to frequency. The three most common symptoms of concern reported by HNC patients included: (a) pain symptoms (i.e., throat/jaw, pain, mouth sores, ear pain, headache) which included 91 meaning phrases; (b) dry mouth and swallowing difficulties which included 71 meaning phrases; and (c) significant weight loss (e.g., 35-50 pound weight loss) which included 57 meaning phrases. The three most common home-care concerns reported by HCs included: (a) negative coping responses by the HNC patient (i.e., irritated, scared, demanding, moody, depressed, angry & short tempered, easily annoyed) which included 134 meaning phrases; (b) alterations in oral taste (e.g., no taste, little taste, food tasted like tin or metal at times) which included 41 meaning phrases; and (c) significant weight loss (i.e., 35-50 pounds during 6 weeks of radiation-oncology treatments) which included 37 meaning phrases. Also, 100% of the patients and FCs indicated the interview questions were appropriate and that the questions caused them no emotional distress.

Conclusion: HNC patients and their FCs experience significant challenges during and following the patients' radiation-oncology treatments. Also, oncology nurses are uniquely positioned to provide education and psychosocial support to patients with HNC and their FCs, assisting each to develop positive coping strategies during cancer treatments. Formulating an individualized plan of educational and psychosocial support for HNC patients and their FCs is also an example of the palliative care philosophy for oncology nurses to consider and integrate into the care of all oncology patients. Still, more evidence-based research is needed to equip oncology nurses to plan effective educational strategies to help FCs in their assistance with delivery of symptom-control measures and psychosocial support to patients with HNC related to difficult oral symptoms and fears regarding communication, especially with children in their family. The findings of this study provide evidence for the need to develop an educational and psychosocially focused intervention on tube-feeding management in the home by FCs of patients with HNC.

M 02 - Support Initiatives to Promote Health

Effects of Support Groups on the Primary Family Caregivers

Chi-Hsuan Asphodel Yang, PhD, RN, Taiwan
Shu-Chin Lin, MSN, BSN, RN, Taiwan

Abstract

Objective: The purpose of this study was to investigate the effect of a support group for primary family caregivers of elderly with dementia on both the caregiver's burden and the quality of life.

Methods: A 2-group quasi-experimental study, using a pre-and post-test repeated measure method, was conducted to investigate the study outcomes. Recruited through from a medical center in central Taiwan, 72 primary family caregivers were assigned to the control (n = 38) and the experimental groups (n = 34), based on participants' choices. The experimental group participated at the support group that comprised of five sessions; each session lasted for three hours, two hours of education on the disease process and care strategies and one hour of discussion, question and answer. The support group met every two weeks. The control group received a health teaching pamphlet on dementia at their medical visit. Data from both group were collected, at the same time, three times: first at baseline, the second time at upon immediate completion of the support group and the third time at one month after the second data collection. A demographic questionnaire developed by the researcher, the Chinese version of Caregiver Burden Inventory by developed Novak & Guest (1989) and translated by Cho (2002) and Taiwan version of WHOQOL-BREF, translated by Yao (2001) were used to collect data. Descriptive statistics, chi-square, *t*-test, paired *t*-test, ANOVA, Pearson correlation, and repeated measurements ANOVA were used to answer the research questions and to test study hypotheses. The significant level was set at 0.05. Data were analyzed using SPSS 12.0 software.

Results: The results of this study were as follow: (a) the participating caregivers showed a moderate degree of caregiver's burden (total score = 1234) with mean scores of 48.71 (SD = 13.74) and 45.68 (SD = 11.70) for the experimental and the control groups, respectively; (b) moderate levels of quality of life (total score = 1234) were found with either the experimental group (M = 51.81; SD = 8.67) or the control group (M = 49.68; SD = 9.43); (c) every one point increased in caregiver's burden, there would be a decrease of 0.65 in caregiver's burden ($p = .036$); the caregiver's burden would explain 31.5% variance of caregiver's quality of life ($p = .000$); (d) length of time as a caregiver was related to the level of caregiver's burden; every one month increase in length of time, there would be an increase of 0.045 in caregiver's burden ($p = .036$); (e) the support group intervention had a positive impact on the caregiver's burden and the quality of life; (f) participants at the experimental group had better caregivers' burdens and better qualities of lives than those in control group did at immediate completion of the support group and at 1-month follow up.

Conclusions and Implication: Results of this study may serve as a reference for healthcare professionals when planning care for elderly with dementia and their families. A support group should be considered as a routine care regimen to provide holistic care and to improve the overall well-beings of family caregivers.

M 03 - Ethical Matters in Nursing Education

Beyond Silos: An Interprofessional, Campus-Wide Ethics Education Program

Cathy L. Rozmus, PhD, RN, USA
Nathan Steven Carlin, PhD, MDiv, Rev., USA
Angela M. Polczynski, MBA, BBA, USA
Lorraine Frazier, PhD, RN, FAAN, USA

Abstract

Purpose: Ethics education is essential to the education of all health care professionals (Kurtz & Starbird, 2016). Improvements in technology have led to new issues and dilemmas that previously existed only in science fiction films including end-of-life decision-making and genomic health care. Nurses are daily facing issues regarding conflict over end-of-life care, allocation of scarce resources, patient privacy versus the benefits to another, and the use of genetics in prevention and treatment of diseases. While health care professions have attempted to educate students in their profession about ethics and ethical decision-making, few institutions have attempted an interprofessional approach to teaching ethics across the campus. The majority of those that have done so have only evaluated knowledge gains instead of application of ethical decision-making skills (Beigy et al., 2016; Caldicott & Braun, 2011; Kurtz & Starbird, 2016; de la Garza, Phuoc, Throneberry, Blumenthal-Barby, McCullough, & Coverdale, 2016; Rozmus & Carlin, 2013; Watts, Medeiros, Mulhearn, Steele, Connelly & Mumford, 2016). The purpose of this study was to evaluate an interprofessional approach to ethics education to all students across an academic health science center. The specific aims were to (1) compare student perception of ethics education before and after the implementation of the campus wide ethics program; and (2) determine changes in student ethical decision-making skills following implementation of a campus wide ethics program.

Methods: This study was a quasi-experimental design with seniors graduating prior to the intervention serving as the control group. The setting was a comprehensive health science center in the southwestern United States with a student population of 4,800 students in six schools including a medical school, school of dentistry, school of public health, school of nursing, school of biomedical informatics, and graduate school of biomedical sciences. The university is located in a large urban medical center. Institutional Review Board approval was obtained prior to any data collection.

All students enrolled in the university participated in the intervention. However, samples of graduating students were used for evaluation of the intervention. A total of 437 students from the six schools participated in the evaluation survey prior to the intervention, 288 participated in the survey in the third year of the intervention and 251 participated in the survey in the fifth year of the intervention for a total sample size of 976 students for the evaluation. The total number of student participants is estimated at 18,000.

The intervention consisted of a campus wide series of activities including faculty development across all six schools and the creation of faculty resources. All incoming students in the university completed an introductory ethics module that has been previously reported (Rozmus, Carlin, Polczynski, Spike, & Buday, 2015) Additional interventions included “just-in-time” research ethics modules, online courses, ethics simulations, interprofessional ethics case studies, interprofessional grand rounds and an interprofessional ethics and history course. Activities included both face-to-face activities and online activities.

Evaluation consisted of an online survey with two parts. The first section asked students for their self-assessment of their ethics education including the amount of time on ethics during course instruction and practical training. They were asked to evaluate their comfort level in identifying and solving ethical issues. The second section asked them to identify an ethical issue or dilemma, outline options of addressing the issue, describe their personal action to resolve the issue, and state professional values relevant to the situation. Answers to the second section were evaluated using the Health Professional Ethics Rubric (Carlin et al., 2011). Answers to the open ended questions were rated as 1=insufficient response, 2=

acceptable response and a score of 3= proficient response. Interrater reliability was calculated for all raters in all three time periods and was above .90.

Results: A total of 976 students from the six schools completed the questionnaire. There were 96 respondents from the Graduate School of Biomedical Sciences, 148 from the Medical School, 42 from the School of Biomedical Informatics, 139 from the School of Dentistry, 175 from the School of Nursing, and 278 from the School of Public Health. Ninety-eight of the students did not identify their school. Despite efforts to increase ethics in the curricula, students' perception of the time spent on the content in course instruction decreased from baseline to the 5th year survey ($p < .05$). There was no difference reported in students' overall comfort level with their abilities to deal with ethical issues. Student ethical decision making skills were higher at the three year evaluation (range 1.23-1.97) for all indicators ($p < .05$) except for identifying options to address the issue. For the 5th year surveys, responses were higher for all four indicators (identifying an ethical issue, identifying options of addressing the issue, identifying their personal action to resolve the issue and identifying professional values relevant to the situation) between the pre-intervention assessment (range 1.13-1.39) and the 5th year evaluation (range 1.35-2.01) ($p < .01$) and between the 5th year evaluation and the 3rd year evaluation ($p < .05$).

Conclusion: After participation in an interprofessional campus-wide effort on health professions ethics, students demonstrated higher ethical decision-making scores according to the Health Professional Ethics Rubric. However, their scores still did not reach the proficiency level identified in the rubric. Examination of the effectiveness of each part of the intervention is needed to determine what is most helpful in enhancing students' ethical decision-making skills. For example, 100% of students in the interprofessional ethics and history course were able to score proficient using the rubric on a course assignment similar to the questionnaire used in the program evaluation.

Students had the most difficulty relating the options for addressing the issue to professional values or an ethical framework. This item most likely indicates the highest level of critical thinking. The other three items only require self-awareness of issues and option to address the issue while thinking through the options from an ethical framework requires a more objective and critical review of the situation and options.

Barriers to interprofessional education were similar to previous reports-- students were on different schedules and in different locations. Online courses appeared to be the most effective in reducing these barriers. One advantage to the online format is that students don't necessarily know the profession of the students they are interacting with in the discussion, thus eliminating some of the biases of professional stereotyping.

M 17 - Creating Patient-Centered Care

A 10-Year Journey Toward an Accountable and Sustainable Patient-Centered Care Model

Jose M. Aguilera, MNA, MCom, RN, FCNA, AFACHSM, Australia
Kim N. Walker, PhD, RN, Australia

Abstract

Purpose: The provision of an accountable and sustainable healthcare system is a major challenge worldwide. The delivery of a patient-centred care model that is accessible, safe, reliable and affordable remains elusive for many organisations. Over the past decade, St Vincent's Private Hospital Sydney has implemented three frameworks – the Balanced Scorecard, the Magnet Recognition Program® and a revenue cycle management program – to address this challenge and strive towards the delivery of an accountable and sustainable patient-centred care model. The aim of this research was to analyse the financial, clinical and cultural impact of the three frameworks implemented at St Vincent's Private Hospital to improve its overall performance and sustainability.

Methods: The research design adopted was a modified sequential, explanatory mixed-method organisational single-case study design. The quantitative component of the study consisted of a cost-benefit analysis of the past 10 years of the implementation of the Balanced Scorecard, the Magnet Recognition Program® and a prospective analysis of the implementation of a revenue cycle management program. The qualitative component of the research study comprised semi-structured interviews and focus groups to analyse the impact of these frameworks on the participants' roles and functions and linking their feedback with the findings of the quantitative component of the study.

Results: The overall findings suggest that the combined impact of these three frameworks may have assisted St Vincent's Private Hospital in its journey towards an accountable and sustainable patient-centred care model. The quantitative component of the study established that improved quality and safety outcomes, patient and staff experience, and greater efficiencies and savings may have been realised through the individual as well as the combined implementation of these frameworks. The qualitative component of the study explained the varying degrees of understanding of these frameworks by the nursing staff, and how the frameworks may have assisted them in achieving improved performance. In terms of the level of support for the three programs from the nursing staff, the study indicated that the Magnet Recognition Program® received the highest level, which was quite significant. The Balanced Scorecard was second in the level of support received and the revenue cycle management program was third.

Conclusion: Analysis of the individual and cumulative impact of the Balanced Scorecard, the Magnet Recognition Program® and the revenue cycle management program, indicates that using these frameworks in combination may have assisted St Vincent's Private Hospital in improving its overall performance. In addition, the findings of this research advocate and support the incorporation of these three frameworks into a single, integrated patient-centred care model. However, further research is required to test this proposition empirically.

M 17 - Creating Patient-Centered Care Defensive Practices of Nurses

Nuray Turan, PhD, RN, Turkey
Nurten Kaya, PhD, RN, Turkey

Abstract

Purpose: Nowadays, defensive practices are usually seen as a situation which is performed by physicians, members of health care team, in order not to take a risk. Defensive practice occurs whenever a practitioner gives a higher priority to selfprotection from blame than to the best interests of the patient. Defensive practice is commonly attributed to concern at malpractice litigation, in particular financial liability. There is no data on whether nurses perform defensive practices. This study was carried out in descriptive type to determine the defensive practice status of nurses.

Methods: While the nurses working in a university hospital constituted the population of the study, the sample of the study consisted of 30 nurses who were selected by random sampling method.

Results: It was determined that 55.7% (n=167) of the nurses, who were included within the scope of the research, sometimes refrained from making mistake in nursing care, 60.3% (n=181) of them never administered any drug she thought it was unnecessary, 55% of them never kept away from the patients who are more likely to file a lawsuit to protect themselves, 50% (n=150) of them sometimes explained nursing practices in more detail to protect themselves from the allegations of malpractice, 46.7% of them (n=140) never avoided practices with high complications, 66% (n=198) of them always kept the records in a more detailed way to protect themselves from allegations of malpractice, and 52.7% (n=158) of them defined the risk of encountering with a malpractice case at any time according to the conditions of the environment.

Conclusion: These data obtained have indicated that nurses sometimes perform defensive practices. Thus, it is necessary to develop and implement strategies to prevent nurses from performing defensive practices in order not to make concessions on quality in the care of a healthy/sick individual and to ensure a fair distribution of the health system resources.

N 01 - Promoting Evidence-Based Practice Globally

An International Collaboration to Promote Evidence-Based Practice (EBP) in Japan

Chiyo Matsuoka, PhD, RN, CSW, Japan
Ikuko Sakai, PhD, MHS, BSc, RN, PHN, Japan
Hiroki Fukahori, PhD, RN, PHN, Japan
Kana Kurokochi, PhD, RN, PHN, Japan
Ai Tomotaki, MHS, RN, PHN, Japan
Laura Cullen, DNP, RN, FAAN, USA

Abstract

Purpose: To promote adoption and evaluation of evidence-based practice (EBP) through an international collaboration of experts in Japan and the United States.

Background: The importance of EBP in nursing has gained recognition in Japan. However, knowledge and strategy to promote and implement EBP have not been widely applied. An initiative developed with the goal of applying EBP models and resources to fit health care and nursing care in Japan. The Iowa Model was selected as the framework for the EBP process. The EBP Implementation Guide and book with resources and tools provided direction for application. An approach that can be beneficial is developing strategic partnerships among practice and academics. The partnership built upon existing expertise to expand application of EBP in academic and practice settings across Japan.

Process: A team of experts at Chiba University, Tokyo Medical and Dental University and Bukkyo University in Japan reviewed EBP process models and recognized the need for emphasis on implementation to achieve improved practice and outcomes. The team selected the Iowa Model and EBP Implementation Model as frameworks for the collaboration. To initiate the partnership an international EBP expert was invited as a visiting professor. Key leaders participated in advanced training in the U.S. and reflected upon application in Japan. Translation of tools and resources into Japanese is underway. Development of a memorandum of understanding facilitates communication and clear commitments for the partnership.

Results: Deliverables are carefully considered to reflect identified needs for the Japanese nursing community. Criteria for selection of EBP models were developed. Educational programs focused on application in both academia and practice settings. Program reach built upon recognized experts among the Japanese nursing community. Discussions built a collaboration that could function through open sharing of resources. A key deliverable is development of a Japanese translation of resources for application of EBP.

Additional findings include that some planning and project management was required in order to promote application of EBP models and implementation of EBP in Japan. The EBP implementation process was adapted for use within academicians' clinical nursing research as a part of clinical nursing education which often carried out medical institutions in Japan. Clinical nurses were the target audience for adoption to improve practice and outcomes.

Next Steps: The collaboration is on-going and next steps include the implementation and evaluation of the intervention study which adopted the EBP process in clinical nursing research for the chief nurses and staff nurses working at the convalescence rehabilitation hospitals in Japan. This study is on-going and is due to be ended by March, 2017. After evaluation, a modified EBP model according to actual condition of Japan is being developed based on the Iowa Model and the EBP Implementation Guide and book.

Conclusion: Provision of evidence-based health care is a global priority. Organizations and experts can create collaborations that become effective partnerships. Learning was a positive experience for nurses in Japan and the U.S. Building upon existing expertise creates a win-win for nurses and patients in both countries.

N 01 - Promoting Evidence-Based Practice Globally

Evidence-Based Leadership Institute: A Model to Develop Nurse Leaders

M. Christine Alichnie, PhD, RN, USA
Betsy M. Snook, MEd, BSN, RN, USA

Abstract

Many nurse leaders begin their leadership career having excelled in the clinical arena. However, being a competent bedside nurse does not guarantee an easy transition into a manager/leadership role. Frequently, they assume expanded roles and responsibilities without adequate education, resources, or support. In the landmark Institute of Medicine's Report (*IOM Report*), recommendation number seven states "...nursing associations should prepare the nursing workforce to assume leadership positions across all levels". Likewise, a subsequent *IOM Progress Report* continues to address the challenges of nurses leading the charge for health reforms based on outcomes from evidence-based research. This translational research provides a solid foundation for health care policy reforms and system changes.

Pennsylvania State Nurses Association (PSNA) represents over 218,000 registered nurses whose vision is "nurses shaping the future of healthcare". Likewise, the association's mission statement identifies four major foci; leading, advocating, educating, and connecting with registered nurses across the Commonwealth. Therefore, identifying the skill sets that will be needed by nurse leaders in the future and creating evidence-based educational models to assure these skills are present is essential to the nursing profession and healthcare systems. With health care and health care delivery systems being characterized by rapid change and new challenges, it is imperative that future nurse leaders have the competencies to create a safe, quality, and effective health care environment for patients, families, and health care workers. This Leadership Institute also supports continuous lifelong learning; another recommendation from the IOM initial report and its subsequent progress report.

Thus, the purpose of this Leadership Institute is to bridge the competency gap between the transition from staff nurse to nurse manager/leader. This transition is achieved by providing evidence-based knowledge and competencies in a supportive and trusting learning environment. Application of these competencies is evidenced through a real world problem-based project. Key features of the presentation must include identification of a real world problem in one's institution, a hypothesis, measureable evidence-based research, analysis of data, and conclusions with recommendations. Participants are guided over a six month period by seasoned nurse leaders who serve as mentors. The Leadership Institute culminates with individual project presentations to their organizational leadership and colleagues.

Key elements of the Leadership Institute model include an application process for both the participant and the mentor, electronic mentor/mentee screening/ matching process, an orientation program for both the mentor and mentee that launches the relationship, didactic instruction using a variety of teaching methodologies, use of diverse technologies including social media to allow for flexibility in communication between the mentor and participant, on-going communication and collaboration with the program coordinator, guidelines and exit interviews to facilitate a smooth ending, presentation of a real-world, real-time professional project using problem-based learning methodology, and data collection- analyzing formative and summative data on both subjective (satisfaction) and objective success metrics to shape further programmatic decisions and to identify long-term patterns and opportunities for improvement. Evaluations were conducted using a combination of web-based and hard copy questionnaires, surveys, and interviews with registered nurses and mentors who completed the program. The end result is an evidence-based model to develop nurse leaders.

N 02 - Cultural Awareness in Nursing Education

Developing Cultural Competence in Practicing Nurses: A Qualitative Inquiry

Michelle L. Edmonds, PhD, MSN, BSN, FNP-BC, CNE, USA

Jeane Richards, EdD, RN, USA

Abstract

Background/Introduction: Multicultural societies are becoming more prevalent across the globe. Nurses, providing holistic care to patients from many cultures, must demonstrate cultural competency in their daily practice so as to provide patient-centered care (Maher-Lorentz, 2008). The American Nurses Association has, since 1991, advocated for culturally appropriate nursing care to be delivered to patients in all settings (ANA, 1991). The Joint Commission has indicated the importance of culturally appropriate communication for patient-centered care and included this in the 2012 accreditation standards (The Joint Commission, 2010). Research regarding culturally-competent care among nursing students has been recently conducted in nursing education. However, few studies, both empirical and qualitative, are available to understand the perceived experience of nurses caring for clients of diverse cultural backgrounds. Starr and Wallace (2009) explored the self-reported cultural competence of 31 Public Health Nurses practicing in a Public Health Department in the Southeastern United States. They concluded that “the nurses had cultural competence knowledge and attitudes but were unable to fully and consistently enact these in practice.” (Starr & Wallace, 2009, p. 48). Cioffi (2006) interviewed eight acute care nurses practicing in Australia and concluded that relationships between these nurses and culturally diverse patients were strained and detached. Additional information is needed to demonstrate the perceived relationships between nurses and culturally diverse patients in order to develop strategies to promote safe, effective culturally sensitive care. Such information can be used to create programs to educate practicing nurses on culturally competent care and improve patient outcomes in the clinical setting.

Method: The research question for this qualitative inquiry was: How do practicing staff nurses perceive and report their development of cultural competence? A subsequent research question for this qualitative inquiry is: How do practicing staff nurses perceive their experiences caring for and working with people from a culture different from their own culture? Ten participants comprised the purposive sample of staff RNs practicing at a Level 1 Trauma Center who responded to advertisement to participate. This facility was selected for its diverse patient population and staff composition. Participants were from any educational preparation (ADN, BSN, and MSN) and any length of nursing experience who deliver direct patient care. In-depth, semi-structured individual interviews were conducted and all findings in written or oral dissemination used a pseudonym to blind the employer and others to protect the participant identities. A \$50 honorarium was provided upon completion of the interview.

Data collection from this study addresses the following objectives:

- Explore the participants’ definition of cultural competence;
- Identify any formal training in culturally-competent care and any theory-practice gaps;
- Elicit perceived experiences of participants who provide care for clients with different cultural backgrounds than their own;
- Highlight any positive or negative experiences reported by staff RNs who care for clients with diverse cultural backgrounds; and
- Illuminate the perceived value of developing concepts of cultural competence (skills, awareness, knowledge).

Data analysis was conducted simultaneously with data collection. Each researcher analyzed the verbatim individually before coming together to find consensus in the final interpretation of themes.

Findings: The sample was comprised of 10 practicing RNs at one hospital in the Northeast Region of Florida. Nine participants were White and one was African-American with 80% female and 20% male. Most (80%) participants had a BSN degree while 2 had an ADN degree with one of these currently enrolled in a BSN program. Half (50%) of the participants had less than 5 years of experience as an RN

while 25% had 6-10 years of experience, and 25% with greater than 20 years of experience. The majority of participants reported that they received cultural competence training previously as part of a college course, online education, or employer-sponsored programs. All reported previous experience with patients of cultural backgrounds that were different from their own including patients from the Middle East, Asia, Latin America, and the Pacific Islands among others. Approximately 65% of participants ranked their cultural competence level as 4-7 on a scale of 0 (no cultural competence) to 10 (highly culturally competent).

Three themes were constructed from analyzing the data:

- Recognizing Culture and Cultural Competence: Acknowledging Differences and Respecting Viewpoints
- Negotiating Cultural Competence: Overcoming Barriers to Achieve Benefits
- Moving Toward Cultural Competence: Developing, Practicing, and Engaging

Recognizing Culture and Cultural Competence was described as understanding culture to be a “way of living”. Cultural competence was the awareness of differences and accepting them by “being OK with it.” Competence does not imply expertise but having the knowledge that differences exist and the RN “cannot know it all.” Participants’ reflections noted that central to this theme is a cultural understanding and respect.

Negotiating Cultural Competence was the balancing act between recognizing the benefits and needing to overcome the barriers in successful delivery of culturally competent care. Barriers that were gleaned from the transcripts were language barriers, lack of knowledge of cultures, family involvement, specific requests for like-gendered care, and lack of time. The participants recognized the many benefits of providing culturally competent care as better patient outcomes, patient satisfaction, nursing care was facilitated and “easier”, increased patient understanding of their medical condition, and financial benefit for the hospital.

Moving Toward Cultural Competence was expressed as the ability to establish trust/rapport with the client through providing culturally competent care. All participants had a good understanding of the definition of culture. The participants remarked that a movement toward cultural competence was vital for “good nursing care” and that it took time and effort on the part of the nurse to be accommodate a client’s culture. If culturally competent care was not provided, participants noted that they experienced internal conflict.

Conclusion/Recommendations: Findings from this study were congruent with Campinha-Bacote’s Process of Cultural Competence in the Delivery of Healthcare Services (2002, 2010). Her model highlights the centrality of cultural encounters in becoming culturally competent and further developed through ongoing cultural encounters. Having multiple encounters with patients from other cultures aids the practitioner in developing the other constructs of cultural awareness, skill, knowledge, and desire. Limitations to the findings of this study included a small, homogenous sample of self-reporting participants from one hospital who were offered an honorarium for their time. Despite these limitations, the researchers are confident that saturation was achieved in the data collection phase. One unanticipated finding that was realized and may have influenced the findings was the fact that many participants in this study have lived abroad in military or mission work.

Findings from this study have implications for nursing practice and education. Participants expressed the need for mandatory formal education and continuing educational opportunities for nurses on the topics of cultural competence as well as multiple ongoing encounters with diverse patient populations to promote confidence and competence in providing cultural care. Nurse educators need to facilitate opportunities for students to examine their own cultural beliefs and values. In addition, they should arrange repeated encounters with diverse patient populations through clinical learning experiences and integrate formal education within the curricula to apply theory to practice.

N 02 - Cultural Awareness in Nursing Education

Mentoring the Culturally Diverse Nursing Student

Barbara B. Blozen, EdD, MA, RN, CNL, USA

Abstract

A structured mentoring program for diverse nursing students was developed and implemented for the culturally diverse Associate Degree Graduate Nurse (ADGN) to address the mentees' concerns and issues and assist them through their journey of completion of their bachelor's degree in nursing.

Purpose: This research study looked to determine how mentoring support for the culturally diverse Associate Degree Graduate Nurse impacted their journey through completion of their bachelor's degree in nursing.

To meet strategic national goals of increasing access to quality health care, reducing health disparities and improving health equity in all U.S. populations, schools of nursing are seeking to diversify the nursing workforce to optimize provider alignment with challenged communities by enrolling students from these settings (U.S. Department of Health and Human Services, 2014). Retaining and graduating the culturally diverse Associate Degree Nurse will benefit many; such as the diverse population with whom they are more likely to work, as people frequently seek health care from providers of their own race or ethnicity (Dapremont, 2011). The American Association of Colleges of Nursing (2014) has appealed for an increasingly diverse nursing workforce and for learning environments that engage and support students. As schools of nursing increase enrollment of the culturally-diverse nursing student, they must also increase the support for this student. Mentoring has been identified as an essential component in the education of the culturally diverse nursing student. Bleich et al., 2015; Bond et al., 2012; Brooks Carthon et al., 2014; Carter et al., 2015 found to retain the culturally-diverse nursing student initiatives must include financial support, mentorship, social and academic support, and professional counseling.

Many, if not all disciplines have a variety of definitions for mentoring, however none are concise nor uniform. Most disciplines include role modeling, support, guidance, education and psychosocial support in their definition of mentoring and nursing is no exception. As nursing becomes more complex, patients more critical, and students more challenging to teach, mentoring becomes more essential for clinicians and educators. Whether it is a new staff nurse working at the bedside or an experienced nurse contemplating a change into a leadership or academic role, having a mentor can support and facilitate the nurse in this new role.

Methods: The participants in this research study were a cohort group of students who were awarded a Health Resources and Service Administration (HRSA) Grant. The grant supports projects that increase nursing education opportunities for individuals who are from disadvantaged backgrounds, including racial and ethnic minorities that are underrepresented among registered nurses. This cohort group was provided with mentoring, personal and social counseling, academic support services, scholarships and stipends, to ensure the successful completion of their bachelor's degree by each of the participants who are from disadvantaged backgrounds, including racial and ethnic minorities. The students attended monthly mentoring meetings. The 14 participants were diverse; seven were Hispanic/Latino, one of whom was male and seven were African American. After informed consent, mentees were given a 26 question Likert survey to determine how supported and skilled they felt after having the benefit of a mentor for the previous year.

Results: The five constructs rated the highest were communication, trust, role modeling, networking and enhancing professional development, all of which had a mean of 5.43 or higher. Baseline data were collected on ethnic identity, social support, and GPA's. Journaling revealed valuable information about challenges faced by mentees.

Conclusion: The mentoring program supported students and culminated in all 14 Associate Degree Graduate Nurses graduating with their baccalaureate degree and securing employment. All graduates

have gone back to their communities to present to their neighborhood schools about the program and mentorship received. The findings contribute to sparse research examining the support and further development and evaluation of mentoring programs for nursing students.

N 03 - Evidence-Based Educational Strategies

The Case for Including Sleep Content in Nursing Curricula

Lucille C. Gambardella, PhD, MSN, APN-BC, CNE, ANEF, USA
Lyron Deputy, MSN, MBA, APN-BC, USA

Abstract

Introduction: The importance of sleep for overall health is at the forefront of the media and the literature. Emphasis on the effects of sleep deprivation are highlighted in vehicular accidents such as the Amtrak train crash in Hoboken, NJ (NY Times, 2016) and in overall workplace performance for a variety of employee positions. Including sleep in all assessment processes by health care providers is becoming a topic of critical discussion as a need in the educational domain of provider preparation. Nursing curricula are not an exception and as nurses students must learn the dynamics of normal sleep and sleep physiology in order to provide sleep care for health promotion and illness prevention. (Redeker & McEnany, 2011) Conducting a survey to determine the current extent of the inclusion of sleep content was implemented at the Sigma Theta Tau International Honor Society of Nursing Research Congress in Cape Town, South Africa in July, 2016. The survey was available in the exhibit hall during the Congress exhibit hours and participants had the option to complete the survey voluntarily and anonymously.

Evidence Based Methodology: Participants representing 12 countries voluntarily completed the survey and provided information about their home school's educational program in nursing relative to the presence or absence of sleep content. If the program included sleep content, participants were asked to indicate which course(s) included the sleep content and to list some of the content covered in the classroom/clinical setting. If the program did not provide sleep content, participants were asked if sleep content should be included and in which courses it should be taught. Finally participants were asked if sleep assessment should be considered as the next vital sign. All data was analyzed and quantified using the SPSS statistical software that provides quantitative, descriptive results for the outcomes discussion.

Outcome Findings: Participants who completed surveys represented 12 countries and all levels of nursing programs including diploma, associate degree, bachelor of science in nursing and master of science in nursing. Fifty-seven percent of the faculty reports that sleep content was not included in their home school nursing curriculum. Forty-three percent of the faculty report that the curriculum did include sleep content, primarily in the Fundamentals of Nursing course (as related to rest and comfort) or in Nursing Care of Children (as related to normal growth and development). Overall 98% of faculty believed sleep content should be included in a nursing curriculum whether their program included the content or not. The courses most frequently listed as appropriate for sleep content were Fundamentals of Nursing, Psychiatric/Mental Health Nursing, and Community health Nursing. Sixty percent of the faculty responding agreed that sleep could be considered as the next vital sign. However, two considerations evolved as concerns if this were to become a reality. First, how would it be measured and standardized as a quantitative measure for consistent application and second, how would it be universally taught, with evidence based criteria, in all health care provider programs, not just nursing.

Conclusions:

1. An overwhelming percentage of nursing faculty believe that sleep content should be included in the nursing curriculum of all level of programs.
2. Sixty percent of faculty believe sleep assessment as a vital sign is a plausible next step if the ability to standardize and quantify a measurement could be achieved.
3. Further exploration of this initiative from an evidence-based perspective is needed to successfully accomplish inclusion of sleep content in curricular programs of nursing and other health care providers.

N 03 - Evidence-Based Educational Strategies

Debriefing for Meaningful Learning (DML): Connecting the Dots

Ann Scott, MSN, RN, CCRN, CNE, USA
Courtney Catledge, DNP, APRN, FNP-BC, USA

Abstract

Debriefing for meaningful learning (DML) is a facilitated approach to learning. It combines experiential learning with reflective discussion. It is commonly utilized in nursing education in combination with high fidelity simulation (HFS) (Dreifuerst, 2015). Through the use of debriefing by meaningful learning technique and concept mapping, students are challenged to think critically. DML enhances students' clinical reasoning and judgment skills through reflective learning. The method of reflection supports students' ability to translate their thinking, in the context of clinical experience or experiential learning, into actionable knowledge and decision making, thereby enhancing learning and fostering new reasoning and understanding that can be used in subsequent clinical encounters (Zigmont, Kappus, Sudikoff, 2011).

DML offers a three phase approach to learning which include the 3 D's, diffusing, deepening, and discovering (Zigmont, Kappus, Sudikoff, 2011). Each phase will be explored and expanded upon giving insight into the reflective learning process which allows students to connect the dots between theory and practice. DML technique is a student led learning experience with the faculty serving in a facilitator role. Debriefing allows dissemination of active learning to every member of the group as participants are more able to fully think through and discuss what has transpired, gain a more in-depth understanding and appreciation of knowledge, and retain knowledge and skills for future application.

A variety of DML techniques will be explored with the aim of showcasing how DML can be employed in various student and faculty interactions including to explore experiences post completion of group work, formative and summative evaluation of student research groups, and student led organization as well as throughout advisement interactions. This project will explore how DML helps students connect the dots from theory to practice using the 3 D's and find creative ways to incorporate DML into academic encounters resulting in improved outcomes and enhanced student success.

O 01 - Cultural Awareness in Public Health

Experience of Immigrant Care and the Need for Cultural-Competence Training Among Public Healthcare Providers

Duckhee Chae, PhD, RN, Korea, Republic of (South)
Jin-A Lee, MSN, RN, Korea, Republic of (South)
Hyun-Lye Kim, PhD, RN, Korea, Republic of (South)
Asami Keiko, BSN, RN, Korea, Republic of (South)

Abstract

Purpose: As the number of foreigners residing in Korea increased by five times during last two decades, Korean public health care providers are facing the diversity of race, ethnicity, and culture of clients. This study was to explore the experiences of public health care providers in providing health care service for immigrants living in Korea and to clarify educational needs for culturally competent care.

Methods: A qualitative description research design was used with five focus groups of 25 public health care providers from five community health centers in G city, South Korea. Focus group interviews were conducted at a time and place convenient to the participants using semi-structured interview guidelines. Audio-recorded interviews ranged 70 to 90 minutes and were immediately transcribed by the researcher. The data were analyzed using conventional qualitative analysis techniques.

Results: All participants were female and ranging in age from 22 years to 54 years. Most participants were public health nurses (76.9%), followed by dietitian (11.5%) and social workers (11.5%). The majority of immigrant clients were young married immigrant women who were situated in multi-layered vulnerability, and unequal power relationship between the couple. They also lacked of awareness of health behaviors. Public health care providers experienced difficulty in identification, enrollment, and retention of immigrants in health care programs, approach towards the most vulnerable group of immigrants, communication, building therapeutic relationships, inconsistency of the service program, and lack of systematic support. Most public health care providers had no prior cultural competence training. They needed to have cultural competence training as an essential continuing education course. They preferred eLearning course which consists of 6-8 sessions which lasts 20-30 minute each.

Conclusion: Public health care providers primarily provided maternal and child healthcare service to vulnerable young married immigrant women. They were situated in multiple challenges because of the vulnerability of the clients and the lack of preparedness for culturally competent care. It is suggested to develop cultural competence training through eLearning that reflects the situation experienced by public health care providers along with systematic support.

O 01 - Cultural Awareness in Public Health

Achieving Clinical Learning Outcomes in a Community/Public Health Nursing Course Through an International Immersion Experience

Brandy E. Strahan, PhD, RN, USA
Faith Garrett, EdD, MSN, RN, CNE, USA

Abstract

International clinical immersion experiences are valuable in that students are exposed to diverse cultures and ways of living, but these experiences can also provide an unconventional setting for clinical learning and the opportunity for culturally congruent care. Research has shown international immersion experiences to be beneficial in providing students comparison of U.S. health care systems to international systems, collaborate and form symbiotic partnerships with other institutions and providers, and share knowledge related to specific healthcare disparities. These experiences also enhance professional and personal development, enrich the understanding of healthcare concepts, and validate global citizenship. Clearly, international immersion experiences offer valid high impact learning opportunities for students and may prove to be a solution to limited clinical sites with increased competition for available placement. Thus, an international immersion experience in baccalaureate nursing may indeed provide a resolution for such courses as Community and Public Health Nursing. The purpose of this project was to determine if clinical course learning outcomes could be achieved in an international immersion experience.

Partnering with the Social Work Department, the School of Nursing planned a six-day clinical immersion experience for undergraduate nursing students in Guatemala. Twenty-eight pre-licensure nursing students enrolled in Community and Public Health Nursing completed a 13-week theoretical course prior to the international immersion experience. The students received an orientation to the country including its historical and political perspectives, social classes, geography, cultural practices, and healthcare education and delivery systems. The University Study Abroad Office also provided a general informational session regarding international travel as an undergraduate student. Upon completion of the theoretical course, students participated in the clinical immersion experience and provided care in remote and rural villages of Guatemala in the Department of Zacapa.

Clinical learning outcomes achieved in the international immersion experience were: (1) understanding and application of an ecological perspective to practice, (2) incorporation of evidence-based practice to aid in health promotion, (3) use of social and environmental factors of health to enable student to work effectively with diverse populations, (4) integration of vital statistics and population data in planning health services in the community setting, and (5) identification of team strategies, both interdisciplinary and transdisciplinary, that would improve community health.

The international immersion experience provided students a unique clinical learning environment that promoted successful achievement of student learning outcomes. Student journaling revealed increased cultural awareness, resourcefulness, positivity with the experience, and gratitude. Challenges encountered during the immersion experience included communication barriers, lack of resources and equitable distribution, and various ethical dilemmas. Future recommendations for the international immersion experience include collaboration with advanced practice graduate students, formal division of clinical groups, and improved translation services. This project demonstrates that clinical learning outcomes can be achieved in alternative learning environments such as international immersion experiences.

O 02 - Evidence-Based Initiatives on Sleep

Brief Behavioral Therapy for Insomnia in Lung Cancer Survivors: A RCT

Grace E. Dean, PhD, RN, USA

Suzanne S. Dickerson, DNS, RN, USA

Abstract

Purpose: Insomnia occurs in approximately 50 to 80% of lung cancer survivors and is associated with fatigue and daytime sleepiness, anxiety and depression, physical and cognitive functional impairment, all of which diminish quality of life and may even influence survival. Recent research has demonstrated that early integration of symptom management into treatment plans leads to meaningful improvements in quality of life, mood and survival in patients newly diagnosed with lung cancer. However, few studies have focused on insomnia.

Although cognitive behavioral therapy for insomnia (CBT-I) is a well-established and effective treatment, there remains a pressing need to study CBT-I in lung cancer survivors because they are different from other cancer patients. Smoking history, pre-existing chronic obstructive pulmonary disease, and the effects of lung cancer treatment, in particular, partial lung resection and postoperative radiotherapy can result in impaired pulmonary function resulting in hyperarousal from pain, cough and dyspnea leading to a worsening of insomnia. In addition, the appropriate dose and frequency of CBT-I in comorbid insomnia has not been determined. CBT-I consists of sleep restriction, stimulus control, relaxation, sleep hygiene education and cognitive therapy that focuses on dysfunctional sleep-related thoughts and unhelpful sleep behaviors that may exacerbate insomnia. CBT-I is the standard treatment for insomnia; however the length of treatment and the insufficient number of psychologists trained to deliver CBT-I make this unrealistic. Nurses are uniquely positioned to deliver a modified version of CBT-I, i.e., Brief Behavioral Therapy-Insomnia (BBT-I) involving sleep restriction, stimulus control, sleep hygiene education and brief telephone therapy. This study determined the efficacy of BBT-I compared to an attention control condition (healthy eating education) on the symptom of insomnia in lung cancer survivors.

Methods: Lung cancer survivors were randomized to either the experimental (BBT-I) or an attention control (healthy eating) condition. The study inclusion criteria were Insomnia Severity Index >7, pathologically confirmed stage I/II non-small cell lung cancer > 6 weeks from surgical tumor removal, able to complete data collection instruments and >21 years of age. Exclusion criteria included other untreated pre-existing sleep disorders or unstable medical or psychiatric illnesses. Participants completed a demographic and lung cancer treatment survey. Objective measures included screening for sleep apnea using the overnight ApneaLink device that utilizes oximetry, nasal airflow and an abdominal respiratory belt. Continuous non-dominant wrist movement was also recorded with actigraphy for 14-days before and after the interventions. Subjective measures before and after the interventions included Insomnia Severity Index (ISI), Pittsburgh Sleep Quality Index, Dysfunctional Beliefs & Attitudes About Sleep, Epworth Sleepiness Scale, Profile of Moods Fatigue Scale, Hospital Anxiety and Depression Scale, Functional Assessment of Cancer Therapy-Lung and 14-day sleep diaries. The primary outcome sleep measure was ISI.

Results: Among 44 participants who consented to participate in this study, 4 were referred for sleep apnea treatment, 40 completed baseline assessments, 2 withdrew, and 28 participants completed follow-up assessments. Demographic features at baseline included 66 years of age (+ 7.6; range 53-82), 40% (n=16) male, 87.5% (n=35) Caucasian, 50% (n=20) married, BMI 27.7 (+ 5.8), and 10% (n=4) never smokers. Disease and treatment characteristics included 80% (n=32) adenocarcinoma, 60% (n=24) stage 1A, and 90% (n=36) lobectomy. Forty participants were randomized to either the experimental intervention or the attention control, 28 completed follow up assessments. The primary outcome variable was ISI. At baseline there was no significant difference between the groups (p=.12). At follow up assessment, the mean ISI for the experimental intervention was 6.40 + 4.98, while the attention control mean was 14.10 + 4.48 (p=.001) with an effect size of 1.61. Additional new findings revealed that more than a third of the sample required referral to a pulmonologist for further evaluation: 4/44 (9%) screened

positive for sleep apnea requiring referral for definitive diagnosis of sleep apnea and 12/44 (27%) had low nighttime oxygenation that required referral for supplemental oxygen.

Conclusion: This study demonstrated efficacy of an effective, well-known intervention in the lung cancer survivorship population for the first time and will inform a larger study to evaluate implementation strategies that will promote the dissemination and sustainability of this intervention. The ultimate goal is to offer practical, evidence-based implementable interventions that improve the quality of life for cancer survivors with insomnia.

O 02 - Evidence-Based Initiatives on Sleep

Emerging Nursing Roles in Collaborative Management of Sleep-Disordered Breathing and Obstructive Sleep Apnea (OSA)

Kimberly Harper, MS, RN, USA

Edel Owens, MMedSc, BNS, RN, Ireland

Abstract

Background: Current concepts in the rapidly expanding field of sleep medicine, specifically Obstructive Sleep Apnoea (OSA) management, provide a significant challenge to already overburdened healthcare demands internationally. Sleep related medical disorders are highly prevalent reportedly affecting at least 4% of the adult population alone. An overview of the physiology and significance of sleep disordered breathing speaks to the current modern understanding of this chronic disease process. The data regarding the incidence and prevalence of OSA highlights the growing significance of the condition and the potential for downstream organ damage effects if left undiagnosed or untreated. Sleep apnoea is known to be associated with significant morbidity and mortality and has a demonstrated association with heightened risk of cardiovascular and cerebrovascular events. From a public policy perspective the documented increased risks of sufferers being involved in road traffic accidents and workplace accidents when the condition is not recognised, or left untreated, is a growing concern.

Known risk factors have contributed to the development of several screening protocols that can help identify potential patient populations in a relatively cost efficient manner. Once preliminary screening is complete, polysomnography (PSG) sleep laboratory based studies, can be carried out where merited. This is especially true for suspected severe presentations of this condition. PSG remains the gold standard for definitive diagnosis and categorisation of sleep disordered breathing conditions. More recently due to the significant logistical and economic constraints of sleep laboratory facility availability, physician overseen and reported home sleep testing (HST) has been introduced. These more limited studies provide less comprehensive data but through the development of newer technologies are now becoming more commonplace.

Methodology: Once physician lead medical diagnosis of OSA, and its relative severity, has been made, various therapeutic approaches can be prescribed. These can include lifestyle and behavioural changes, frequently with associated weight management, alongside standard mainstream therapeutic interventions. Currently continuous positive airway pressure (CPAP) and variations such as nasal CPAP, are the gold standard for management of diagnosed OSA especially in more severe spectrum presentations. Due however to documented difficulty with CPAP compliance on an ongoing basis for some patients, alternative oral appliance therapy (OAT) can also be requested by a treating physician and onward referral to a dental specialist made. OAT consists of specific custom fabricated dental appliances designed to dilate the upper airway while sleeping that can provide a viable, validated, therapeutic approach. While mean disease alleviation (MDA) levels for OAT compared to CPAP are reported as approximately 56-64%. In many instances these devices are less obtrusive and better tolerated by patients and subsequently used more consistently nightly by patients on an ongoing long-term basis.

Evolving nursing practice in this area currently focuses on the collaborative management of various manifestations of sleep disordered breathing in partnership with physicians, surgeons, specialist dentists and other allied healthcare professionals. Definitions of professional (nursing) roles and competencies in this field are however required. Quality care requires safe, timely, effective and efficient delivery of diagnostic and interventional treatment modalities. Organisational considerations include establishment of inclusive healthcare professional network with appropriate facilities models. This allows the establishment and subsequent codifying of the most up to date sleep medicine protocols. These protocols can then be deployed for the benefit of the greatest number of patients through the designing of an effective service delivery platform.

Results: The expanding role of the specialist/advanced nurse practitioner is a key central feature of this evolving service delivery architecture and can help maintain the focus on a more patient-centred

approach. This is achieved by providing continuity and oversight of screening modalities, diagnostic and monitoring prescribed treatment intervention outcomes. Various existing and emerging diagnostic and treatment interventions, and, new digital technologies will of course influence and hopefully streamline key service delivery options providing appropriate metrics for continuous outcome data evaluation.

In the field of sleep medicine therapeutic interventions and outcomes require demonstrated adherence to prescribed therapies. Due to the progressive nature of OSA, protocols detailing ongoing monitoring of adherence and efficacy are essential aspects of the longer-term successful management of this condition. Data compilation here must also be carried out in a cost-effective, efficient, equitable and timely manner. OSA is a chronic illness and therapies must also adapt to changing personal circumstances, in for example the natural ageing process, in delivering predictable outcomes for our patients on an ongoing basis.

Conclusion: Specialist nurse practitioners with specific knowledge based skill sets and experience, when provided with the necessary technological and organisational resources are ideally positioned to collaborate and will have a central role in the delivery of the highest levels of quality care to this target patient OSA cohort, on an ongoing basis.

O 03 - Improving Patient Outcomes Through Partnerships

Enhancing a Community's Health Through an Innovative Partnership With a Public Utility Company

Georgia Karine Crow, PhD, RN, FAAN, USA
Adelita Cantu, PhD, RN, USA

Abstract

Baccalaureate and RN to MSN Population/Public Health Nursing students partnered with a public utility company to engage in a creative method to enhance the community's health. CPS Energy is a non-profit electricity provider, the nation's largest, that is owned and operated by the municipality it serves. In the summer of 2015, UT Health San Antonio School of Nursing and CPS Energy engaged in a partnership to promote more environmentally healthy homes. CPS' Casa Verde Weatherization Program is an energy efficient program designed to help families in need to reduce their monthly utility bills, to provide protection for the residents from San Antonio's weather variances, and to act as a deterrent related to the air pollution caused by pollen allergens.

San Antonio is ranked 24th as one of the most challenging cities to live in for people with allergies. San Antonio's summer temperatures average 95 ° F (35 ° C) with the warmest months being July and August. However, it is not unusual during these months for the days to range between 100 ° F (37.778 ° C) to 105 ° F (40.55 ° C) with the highest recorded to be 111 ° F (43.89 ° C). Winter months' temperatures range between 17°- 36 ° F (5 ° – 24 ° C) with the coldest days being in January and February (National Climatic Data Center, 2013, San Antonio Temperatures, 2013). With the combined issues of high temperatures and air pollution, San Antonio's residents are subjected to environmental health risk. In 2014, The United Nations Environmental Programme identified the worst environmental health risk as air pollution. These combined health risk if not mitigated result in death, stroke, chronic conditions and allergic responses.

Since public health core functions Essential VI: Assurance ensures support for health and safety and Essential VII: Health Promotion and Risk reduction actions are to modify conditions that increases wellbeing and decrease risk of adverse health outcomes, the Population/Public Health course implemented this partnership through the clinical course. The setting for implementation was determined by identifying homes in vulnerable census tracts within San Antonio. As part of their assignment, students assessed their identified census tract using community assessment guidelines. During their community windshield survey particular attention was placed on the observed type of housing. Homes built in 1970 and earlier that contained window air condition units or no identifiable means of cooling or heating the home were identified, visually assessed, and address determined.

Once potential homes that may meet criteria for the CPS Energy's program, Casa Verde, were identified, efforts to inform the residents about the program began. These efforts included providing the identified addresses to CPS. CPS would send a post card to the resident providing information about available programs for their homes; students would walk door – to – door to the identified homes and place plastic bag door hangers, which had more detailed information and how to access available programs, on each home (over 1400 homes to date have been identified); and students would identify through the community assessment (if they were not assigned to a community agency) an agency that would be willing to become an ongoing partner with CPS energy. This agency would host community meetings for the residents to meet the CPS representatives who would provide more information about the Casa Verde program, demonstrate how energy cost would be lowered and health and safety would be increased by participating in the program, and assist the homeowners in signing up for a one of the available programs. These community meetings would include as an incentive a free health fair or a presentation by someone who has had their house weatherized and would describe the benefits. Students in collaboration with the agencies developed process/formative program evaluation outcomes to determine success in their efforts.

This project provided CPS Energy a way to identify residential homes and contact home owners that could benefit from the Casa Verde Weatherization Program as well as provided a community venue for

presenting available programs to them. Participating in this partnership allowed students to demonstrate through formative and summative evaluation their developing community assessment skills and work with agencies to promote sustainable primary prevention activities that would mitigate both weather and air polluting sequelae. The project has been instrumental in student understanding about the social determinants for health and the connection between housing and health. This understanding is critical to our future healthcare workforce to have a deeper and richer understanding of the context of where patients and community residents reside and how that impacts health outcomes and the community's health.

O 03 - Improving Patient Outcomes Through Partnerships

The Role of an Academic Practice Partnership in Enriching Student Learning and Improving Patient Outcomes

Anastasia Y. Rose, MEd, MSN/MHA, RN, CCRN-K, USA

Sherrill L. Hooke, MEd, RN, CGRN, CCCTM, USA

Ashley D. Roach, MS, RN, CNL, USA

Abstract

Purpose: The United States Department of Veterans Affairs (DVA) has long been a champion in developing academic practice partnerships and there is growing evidence that supports the benefits of these collaborations (Beal, 2012; Bvumbwe, 2016). The Veterans Health Administration (VA) Nursing Academic Partnerships (VANAP) are education and practice collaborations between VA facilities and schools of nursing designed to ensure quality veteran care now and in the future. The purpose of this presentation is to describe the evolution, development and benefits of a local VANAP partnership in facilitating clinical practice improvement initiatives and integrating veteran-centric content into a baccalaureate nursing curriculum.

Background: There are approximately 21.4 million living United States veterans, representing seven percent of the total population (U.S. Census Bureau, 2016). The VA serves a unique population of patients linked by service to the country in times of peace, war, and social unrest. In addition to the common medical concerns found in the general population, veterans experience unique conditions that are associated with service in the military, or experience health concerns in greater percentages than seen in the private sector. Some of these conditions include military sexual trauma (MST), traumatic brain injury (TBI), post-traumatic stress disorder (PTSD), and complications from exposure to nuclear, biological, and chemical warfare (Johnson, Boudiab, Freundl, Anthony, Gmerek, & Carter, 2013).

Oregon VANAP is an innovative education and practice collaboration between VA facilities and the Oregon Health & Science University (OHSU) School of Nursing (SON) (Department of Veterans Affairs, Veterans Health Administration, 2013). Through the partnership between academic and clinical areas, VANAP seeks to address the complex and unique care needs of the veteran population by promoting safe and effective care within and across health care settings (Department of Veterans Affairs, Veterans Health Administration, 2013). Faculty members in this partnership are drawn from both school of nursing and VA staff who join together as a team to educate nurses and improve clinical outcomes for veterans.

Process: In order to integrate veteran content into the existing nursing curriculum, VANAP faculty members identified and collaborated with key stakeholders in the undergraduate nursing program. Faculty conducted a literature review to identify key veteran care concepts based on prevalence and importance. They then examined the curriculum for areas where veteran content was already being taught and identified gaps where additional material could be added. To engage students using multiple learning modalities they utilized veteran-centric case studies, simulations and concept-based learning activities in addition to traditional methods of assigned readings and lecture. This strategy of content integration exposed students to veteran-specific information while also teaching concepts that could be broadly applied to a variety of populations.

In addition to enhancing nursing school curriculum, VANAP faculty worked with VA staff on three clinical practice improvement projects: fall reduction in the inpatient setting, women veterans' health, and amputation prevention. Faculty collaborated with direct care nursing staff, nurse leaders, and other interdisciplinary team members to develop and implement plans to address these issues. The faculty utilized a variety of evidence-based interventions to effect change including conducting gap analyses and needs assessments, developing patient and staff education, and conducting focus groups.

Outcomes: VANAP faculty members were successfully able to integrate veteran-centric content into all courses of the undergraduate curriculum. A content integration map was developed outlining specific

content and where it was being taught. To share resources with other faculty teaching similar courses, this map was disseminated to other nursing schools in the region via a nursing school consortium.

Some outcomes of the quality improvement initiatives were a decrease in the number of falls and 30-day readmissions related to amputation risk. A preliminary comparison of average fall rates were lowered by 57% per 1,000 patient days on the medical-surgical floors and the percentage of falls with injuries decreased by 62%. Twenty-two fewer readmissions related to vascular complications were realized on an inpatient unit during a six-month review after VANAP faculty interventions as compared to the preceding six months before VANAP involvement. This represented a 47% decrease in vascular related readmissions.

Conclusions: Veterans are a population with unique health care needs. Integrating veteran-centric content into the nursing curriculum and educating students on evidence-based practice promotes the best possible care for veterans and their families. The benefit of such work will result in more culturally competent nurses working in and outside of VA facilities. Faculty were able to play key roles in designing and implementing quality, evidence-based improvement initiatives at the practice institution while maintaining teaching positions at the academic institution. Involving stakeholders early in the process, maintaining frequent communication, integrating collective feedback and establishing meaningful evaluation processes allowed creation of a program that met student, faculty and veteran needs. Future evaluation will include assessing the sustainability of this project as well as its impact on student knowledge and application of veteran content. This exemplar has the potential to serve as a model for others seeking to develop relationships between academic and practice institutions.

O 04 - Mentoring in Academia

Nursing Faculty Members; Perceptions of Characteristics of Mentors for Research in Nursing

Susan M. Baxley, PhD, RN, USA

Kristina S. Ibitayo, PhD, RN, USA

Mary Lou Bond, PhD, RN, CNE, ANEF, FAAN, USA

Abstract

Purpose: Based on the assumption that researchers who conduct nursing studies either have been mentored by other scholars or perceive the need for guidance as they begin their research, this study described the actual or perceived characteristics of mentors who guided them. The conceptual framework for this study is based on the *Global Mentoring Process Model* (Baxley & Ibitayo, 2012). The purpose of this study is to explore the perceptions of nursing faculty members regarding the characteristics of their mentors, if existent, as they were/are conducting research in nursing and the desired characteristics of a mentor important to building their program of nursing research. The characteristics of an organization and the supportive organizational characteristics in which to conduct the research were also explored.

Methods: Data using the 16-item *Education Research Mentor* instrument were collected from faculty members who have: published nursing education research in five peer-reviewed journals between years of 2005-2015, belong to a nursing research society, or a nursing education organization. The instrument, *Education Research Mentor* (Baxley, 2015), was developed from the literature and conceptual framework (Grossman, 2007; Baxley & Ibitayo, et al., 2014, Olson, 2014; Zachary & Fischler, 2015; Zachary, 2005, 2007). In this survey, each item is measured using a 5-point Likert type scale (unimportant, somewhat unimportant, somewhat important, important, extremely important). For instrument validity, the question on the Characteristics of the Environment showed a Cronbach's Alpha of 0.862, and the Cronbach's Alpha for the question on the Characteristics of Mentor was 0.988. The level of significance was set at 0.05 for this study.

Results: Descriptive and parametric statistics and a summary of open-ended responses were collected. The study participants were 29 to 75 years old, and the mean age was 35 years. The majority were who completed the survey were female (145) and 7 were male ($N=152$). The ethnicity of most participants was White, non-Hispanic (89%). Seventy four participants were tenured faculty. In addition, out of all the participants 82 percent had a mentor and 66 percent had a research mentor.

For those who had a mentor, the most desired mentor characteristics were: knowledge (88%), available (79%), competent (78%), supportive (75%). The least desired mentor characteristics were socializing (23%) and inspirational (39%). The same mentor characteristics were also desired by faculty members who did not have a mentor.

If participants answered "no" to having a mentor, a Spearman Rho was run for age to identify an association between variables, showing a positive correlation at ($p < 0.05$) for Competent (0.28) Sharing (.046), and Trustworthy (.027).

If they answered "no" on having a mentor, a Spearman Rho was also run for gender, showing a showing a positive correlation at ($p < 0.05$) for Available (.01), Competent (.01), Knowledgeable (.01), Resourceful (.027), Committed (.03), Collaborative (.023), Trustworthy (.02).

A one way Analysis of Variance (ANOVA) was computed to examine differences between the mentor characteristics and Ethnicity and Tenure status. Results showed a statistical significance at ($p < 0.05$) for Trustworthy, Knowledge, Competence, and Available.

On a 5-point Likert type scale on the characteristics of an environment promoting nursing research, respondents rated these characteristics as "Very Important" or "Extremely Important": Supportive of Mentoring (98%), Integrate Mentoring into the Organization (95%), Fosters Professional Development

(97%), Empowered (98%), and Administration Provides Resources (94%). The majority of responses were in the "Very Important" or "Extremely Important" categories. There were only a few responses in the "Unimportant" or "Somewhat Unimportant" categories: Fosters Personal Development (8%), Non-Competitive (7%), and Health Balance in Work and Personal Life (7%).

Exemplars of Open-Ended Questions: Participants responded to the open-ended questions providing additional insight to the question related to other characteristics of a research mentor. The respondents indicated personal ideas of what they consider important in a mentor.

"Willing to be kind, fully critical, develop my thinking and analysis"

"A research mentor needs to be a visionary as well as knowledge and experience."

"Doesn't answer my questions but tries to direct me to sources so I can answer my own question."

"The most important characteristic is that the mentor genuinely cares about the mentee and invests time and energy into the professional success of the mentee."

"The mentor offers the opportunity to work on their own research and to publish"

"Positive, knowledgeable, encouraging, helpful, expert in research."

"Patience and the ability to listen to my concerns about the process."

"She created an environment in which success breed(s) success."

While most were positive, one offered that mentor relationships are not always helpful.

"Mentor very busy, not enough time, fragmented approach."

When asked what they considered an ideal environment for mentoring, they described it as being supportive and collaborative while looking at the workload of those mentoring is considered important.

"Mentoring occurs best in an environment of collaboration and shared vision where supporting each other's success is more important than any one individual accomplishment."

"Supportive, non-confrontational"

"An environment that supports the activity is one that is transparent, inclusive, and is focused on the success of its members."

"Valued by all stakeholders, this may include that is part of workload"

"One in which there is enough time"

"Protected time for mentoring built into the culture and teaching schedule instead of time squeezed in between all other responsibilities."

They also suggested that mentors and mentees should be provided preparation prior to entering into a mentoring relationship; "Preparation of both mentors and mentees regarding what the relationship can and should be."

When the participants were asked to share other suggestions about how mentoring is related to strengthening nursing science they expressed that nursing needs to provide more assistance for mentoring to strengthen the relationships.

“Mentoring is so important; I wish nursing did a better job promoting the mentor- mentee relationship”
“Need more of it”

“Mentoring is the crux of developing strong partnership, network between faculty, and preventing burnout/turnover. It is a fundamental support system.”

“I do not think that many institutions have an ideal environment.”

“Having a mentor will mean the difference between advancing nursing science or watching it stagnate.”

“The commitment to mentor is often less of an issue than the time allotted to the process.”

“Mentoring means more than just a label. It should be a mutually agreed upon relationship with goals, objectives, and some accountability measures.”

“There are numerous levels and areas where mentoring leverages our assets. As a senior faculty, I always tell new faculty that they should have many mentors in teaching, research and service, and ideally both internal and external to their school of nursing. I see mentoring as the protective factor for incivility and if we want to attract and retain quality nurse faculty, we need to increase our mentoring efforts.”

One responded that mentoring is not the only thing that is important to advance nursing science; “Mentoring is a reciprocal relationship...protégés also require tutoring...avoid considering it the panacea for all that may challenge developing nurse scientists.” Participants had definite ideas on what characteristics a mentor should possess. Of the mentor characteristics that were looked at in this study, the majority of participants thought that most characteristics were “important” or “somewhat important”.

Conclusion: While the mean age of participants was 35 in our study, the nurse faculty range in the NLN study was from 46 to 60. According to NLN, out of 13,307 respondents. 22 percent of full-time nurse faculty are tenured, and an additional 16 percent are on the tenure-track (NLN Faculty Census Survey, 2015). The rank of full-time nurse educators in 2015 was 10,730 White, non-Hispanics (81%).

These findings lay the foundation for developing tools to systematically identify and recruit those individuals who possess the skills desired to conduct research so that such skills can be recognized, honed and used to further advance global health and nursing. Future studies need to include participants of diverse ethnicities. These findings will provide information to develop an evaluation of the institution's culture for mentoring and ways nursing leadership can provide an environment with a culture for mentoring of their faculty members and support nursing research.

O 04 - Mentoring in Academia

Advancing the Science of Nursing Education Through Peer Mentoring

Jeanette McNeill, DrPH, CNE, ANEF, USA

Alison Merrill, PhD, RN, CNE, USA

Katrina Einhellig, PhD, MSN, BSN, RN, CNE, USA

Kristin Schams, DNP, CNE, CHSE, USA

Abstract

Background and Significance: The shortage of qualified faculty to teach nursing at the associate, baccalaureate or higher degree level is a challenge to nursing education and practice and has contributed to the nursing shortage in the United States. Increasingly, PhD programs in nursing and most Doctorate of Nursing Practice programs do not explicitly prepare graduates as educators. Students in some programs have electives in nursing education available to them, but often a new doctoral prepared nurse begins a faculty position with little or no teaching experience or educational course work. Similarly, faculty with master's preparation, often teaching in Associate Degree programs, may not have had specific educational preparation for their role. At all educational levels, those new to the faculty role are often expert clinicians, but not experienced educators. Faculty development becomes the task of the school of nursing, and may or may not provide enough preparation or mentoring for the novice to feel confident in the new role. Certification as a nurse educator (CNE) with specific preparation on several areas of competency identified by the National League for Nursing (NLN) can help bridge this gap in preparation to be a nurse educator. Further, the certification as a CNE aligns with the NLN and Johnson and Johnson Faculty Leadership and Mentoring program which seeks to identify goals for nurse mentorships and ways to enhance mentorship programs throughout nursing. The NLN has designated six essential leadership characteristics that guide nursing educators toward paths that increase professionalism and ensure competence: knowledge, risk taking, change agents, visionary, passion, and relationship builder (Young, 2011). The CNE review course encourages nurse educators to increase their knowledge base and further their understanding of teaching pedagogies and best practices in education. Peer mentors also foster other educators to take risks as they prepare and sit for the challenging CNE exam. Within this process, it enhances the passion that educators feel for the profession of teaching, and they finish the course with a renewed sense of purpose and a vision for the future. The CNE course offered in this setting provides a mentorship model that enhances the abilities of the educators involved in this course, as well as fostering relationships within the academic setting that are focused on continued improvement of all educators and a collegiality that maximizes the learning environment.

Purpose: At a Rocky Mountain area university school of nursing, an initiative was undertaken to increase the number of Certified Nurse Educators (CNE). The School of Nursing (SON) recognized the value of the NLN Certified Nurse Educator designation in promoting excellence and recognizing the advanced specialty of the academic nurse educator. Faculty holding the CNE credential serve as role models and mentors to the healthcare and academic communities, as well as to students. This model of excellence is especially relevant to PhD in Nursing Education programs.

Methods: The CNE's in the setting developed the course which included both face to face CNE workshops sessions and a online platform providing supplemental learning materials. The test blueprint for the exam was used to plan course objectives, topics and strategies; the sessions were conceived, developed, and implemented by experienced full-time faculty who already hold CNE certification. Topics included the eight identified educator competencies. Content emphasis was determined by the percentage weighting for each area on the exam: Facilitate learning, facilitate learner development and socialization, use assessment and evaluation strategies, participate in curriculum design and program evaluation, engaging in continuous quality improvement, functioning as a change agent and leader, participating in the academic environment and the nurse educator as a scholar. Strategies were selected to foster discussion and interaction among participants, and provide opportunities for mentoring by the CNE faculty, consistent with evidence based approaches outlined by Billings and Halstead (2015). The CNE preparatory textbook (Caputi, 2015) and other resources were provided by the SON for use of faculty preparing for the exam; examples of case studies and CNE example questions were used to

facilitate application to classroom and clinical learning. Nine full time and two adjunct faculty participated in the first offering of this course as they prepared to take the CNE exam.

Outcomes: Successful completion of the exam was, and continues to be, the intended outcome of this faculty development activity, adding to the ranks of CNEs at the SON. Thus far, there has been a 100% pass rate for those taking the exam. Additionally, the peer review process has been revitalized with several requests for peer review of teaching as a result of attention to evidence based strategies and engagement in continuous quality improvement. Continuation of the initiative and sustainability of the review course have been addressed through updating materials and continued access to the course website for all interested faculty.

O 06 - Preventing Falls Using Evidence-Based Practice

Evaluation of the Efficacy of Repeat Falls Risk Assessments Using the Morse Falls Scale

Mary Beth Harrington, PhD, RN, ACNS-BC, ANP-BC, CCRN-K, USA

Abstract

Purpose: Patient falls have been identified as a potentially preventable, nurse sensitive outcome. Routine assessment of fall risk is required by the Joint Commission (2015). The rate of falls in the United States is approximately 3.5 falls per 1,000 patient days, with 1 injurious fall per 1,000 patient days. They are the most commonly reported adverse events in hospitals, constituting approximately 40% reports. Patient falls delay recovery, cause psychological harm and can decrease independence and mobility due to either physical harm or fear of falling again. As of October, 2008, Medicare no longer provides reimbursement for care required due to inpatient falls. The first step in fall prevention is identification of individuals at risk. The MSF has been studied extensively and has demonstrated good sensitivity and negative predictive value. The majority of the studies of, or utilizing, the MFS have used a measurement at a single point in time. However, repeated observations are required in most institutions. Most facilities, including the VA Boston HealthCare System require repeated measurements during the patient's hospitalization, ranging between every 48 hours to as often as every shift. However, there is little evidence to support the frequency at which the assessment should be done. The research question for this study is; What is the efficacy of repeated MFS measurements in hospitalized patients?

Methods: Patients who sustained a fall between October 1, 2014 and September 31, 2015 were identified from the institutional incident report database. The electronic health records of 50 of those patients were randomly selected to be reviewed retrospectively. Data collected included patient age, gender, the date and time of all Morse Fall scores, including the total score and the score for each individual item, time and date of any falls, and dates of any transfers between units. Any score which was a change, either increasing or decreasing, was compared to documentation in the progress notes. In the event of a discrepancy, the progress note data was identified as valid and a corrected score was calculated. For example, if the MFS indicated no IV, but the progress note documented an IV dressing or change, the appropriate points were added to the score and error was flagged. All raw data, including both documented and corrected scores, when applicable, were entered into an Excel spreadsheet. All data was rechecked for accuracy, then de-identified. The spread sheet was password protected and stored behind the VA firewall. Scores were dichotomized into those below 45 and those above 45, the high risk cutoff at our institution. Each patient's scores were reviewed for any significant change, defined as a raw score change sufficient to move that patient into the other group.

Results: After correcting for calculation errors, 70% of patients had no change in their MFS, having scored in the high risk group on admission and remaining there throughout their hospital stay. Four scores (8%) changed to high risk due to a fall. Two scores (4%) increased due to a change in mental status. Six patients (12%) had changes in their scores due to changes in the nursing assessment of gait, or the presence of an IV. Generally, these changes resulted in a temporary decrease, briefly bringing them out of the high risk group. For 50 patients, there were 890 MSF assessment, estimated to represent 75 hours of nursing time. There was a discrepancy in 361 (41%) of the assessments. 5.4% of the discrepancies were due to errors in addition. Other errors included omitting history of falls, comorbidities, presence of an IV, ambulatory aids, and mental status issues, such as confusion. Gait assessment fluctuations were commonly due to assigning 0 points for bedrest during the night shift.

Conclusion: There is little change in the corrected MFS score of adult patients during their hospitalization. Frequent repetition of the MSF assessment consumes nursing time, a valuable and limited resource. Performance of the MSF assessment during the night shift is particularly problematic. Our data suggests that assessment on admission, transfer, after a fall or any change in mental status would be a more efficient approach to identifying patients at risk and that, once a patient is identified as at high risk, they should remain there and not require any further MFS assessments.

O 06 - Preventing Falls Using Evidence-Based Practice

Prevalence and Trends of Falls on a Surgical Unit

Tru Brynes, MSN, RN, CNL, CMSRN, USA

Abstract

Background: Falls are the most common adverse events in hospitalized patients contributing to pain, suffering, morbidity, and mortality (Aydin, Donaldson, Aronow, Fridman, Brown, 2015). Falls increases healthcare costs, with each fall ranging from \$14,000 to \$ 35,000. The rate of falls in United States (US) hospitals is approximately 3.1 to 11. 5 per 1,000 patient days, varying by unit type. Neurosurgery, neurology, and medical units have the highest fall rates (Bouldin et al., 2014). Many falls risk factors identified include intrinsic, extrinsic, and environmental factors (Urquhart Wilber, 2013). Henceforth, fall prevention strategies should include a multimodal action plan to promote patient safety (Williams, Szekendi, Thomas, 2014). 5 Tower's fall performance ranges from 1.28 to 3.54 per 1,000 patient days from 2014 to 2016. In 2016, the patient fall rate has consistently underperformed compared to the national benchmark.

Purpose: The purpose of this quality improvement project was to examine the trend of patient falls on a post-surgical unit at an 11,000-bed hospital in the US to develop interventions based on the findings to prevent falls. The purpose of this project is follows:

- Assess and analyze the staffing pattern when patients fell
- Determine the times and days patient falls are more likely to occur
- Examine common risk factors related to patient falls

Description of method: Seventy post-fall records were reviewed from 2014-2016 utilizing the electronic medical record (EMR). The post-fall records indicated time, date, unit census, medications, injury, and number of registered nurses (RNs) and certified nursing assistants (CNAs)/ health care tech (HCTs).

Results: The data showed that females were at a slightly higher risk than males for falling (51% compared to 49%). Most falls occurred during dayshift. The times patient falls occurred were 1 AM, 5 AM, 6 AM, 10 AM, 1 PM, 3 PM, 4 PM, and 7 PM. It appeared that the unit would have a fall about every 2-3 hours. The peak times were at 1AM and 1 PM with the highest number of patient falls. Interestingly, most falls occurred when the unit was staffed adequately (1:5 nurse to patient ratio and 1:12 HCT/CNA to patient ratio). The common risk factors for patient falls were age, confusion, impulsiveness, and toileting assistance. The highest risk age group were geriatric patients age 65 years and older with 44%. The remaining risks per age group were 27% for age group range from 50-64 years old, 29% for age group range from 30-49 years old, 4% for age group range from 18-29 years old. The most common reason for patient falls was bathroom help. The data showed 39% of the time patients fell in the bathroom or went to the bathroom alone without assistance. Patients who were confused and impulsive were also most likely to fall. Only nine percent of patients who fell were 24-hours post-anesthesia during this period.

Conclusion / Implications: This project addressed the clinical questions and helped the unit develop strategies for fall preventions. Developing a bed alarm criteria that would fit the unit population could potentially improve the fall rate. Additionally, we have identified and correlated the time of patient falls with nursing tasks. Patient falls occurred early in the morning when staff were passing medication or morning labs were being drawn and patients got up to use the bathroom without calling for assistance. Bathroom usage after meals and during staff lunches have been identified as the reasons why patients fell. Therefore, it is important to communicate with staff about these findings and provide education to help improve patient safety. Hardwiring the purposeful rounding or toileting program to decrease fall rates could improve patient safety. With the addition of cardiac monitors to the unit in 2015, there was an increase in the geriatric population and medical population with multiple comorbidities admitted to the unit. This could have contributed to the increased number of falls. Currently, there are nurses who underwent geriatric advanced training to become geriatric resource nurses (GRNs) to help improve patient outcomes in geriatric population.

O 07 - Promoting Clinical Outcomes in Veterans Caring for Military Combat Veterans With Post-Traumatic Stress Disorder (PTSD)

Tanya Marie Benjamin-Wilson, DHSc, MPH, MSN, CHES, RN, APHN-BC, USA

Abstract

Post-Traumatic Stress Disorder (PTSD) is a growing problem of concern within the military. Veterans serving in combat are more likely to develop PTSD symptoms resulting from participation in wartime conflicts and exposure to traumatic events. Younger veterans with multiple predisposing factors are at an increased risk. The signs and symptoms of PTSD closely mirror the signs and symptoms of other mental health conditions. This can lead to problems with appropriate diagnosis and treatment. Military combat veterans with untreated or misdiagnosed PTSD symptoms are at risk for interference with social, physical, and professional functioning. Problems related to non-existent or inadequate PTSD treatment include alcohol abuse, domestic violence, and the breakdown of close personal and professional relationships. In worst case scenarios, individuals exhibiting signs of PTSD may become homeless, susceptible to criminal activity, and suicidal. Health providers need to be aware of the most up-to-date information regarding the recognition, treatment, and management of PTSD. Evidence from the literature suggests that technology-based interventions may be a more favorable therapeutic treatment option as opposed to numerous talk sessions with a trained therapist. The information provided will assist health care professionals such as (a) physicians, (b) psychologists, (c) physician assistants, (d) registered nurses, (e) nurse practitioners, and (f) social workers in providing better quality of care for military combat veterans in need of mental health services. This educational presentation can be used as a guide for both military and non-military affiliated multidisciplinary professionals in need of basic knowledge and information regarding PTSD. This research will (a) address the most important concepts related to understanding PTSD, (b) PTSD treatment interventions, (c) factors that may interfere with treating PTSD, and (d) access to care issues for military combat veterans in need of services. Mental health issues have historically been stigmatized within all branches of the military. Increased knowledge relating to PTSD may help to change the military cultural norm that favors the non-reporting of signs and symptoms indicative of a mental health disorder. The long held constraints of a professional military environment and culture should not be preserved in the face of serious risks and consequences to the (a) physical, (b) emotional, and (c) psychosocial well-being of dedicated service members. Combat veterans with signs and symptoms of PTSD or any other mental health disorder should be encouraged to seek treatment as soon as possible to prevent negative progression of the disorder and its associated unfavorable outcomes. It is recommended that military administrative officials, with input from health care providers, seriously (a) review, (b) revise, (c) update, or (d) implement policies and procedures that will introduce positive changes in relation to matters concerning military mental health. These changes should foster an environment and culture conducive to military service members feeling free to seek mental health services without fear of (a) bias, (b) stigma, (c) retaliation, or (d) any other negative repercussions, including immediate dismissal from military service.

O 07 - Promoting Clinical Outcomes in Veterans

Supporting Veterans With Chronic Pain: Using 5As Framework to Improve Self-Care

Joseph F. Burkard, DNSc, MSNA, BSN, RN, CRNA, USA

Abstract

Introduction: Active-duty military personnel and veterans are disproportionately affected by chronic pain. More than 50% of veterans' report pain in primary care. Human Rights Watch, 2014 states that conventional pain management includes prescription opioids and lack emphasis on self-care management. A multimodal approach is needed to support self-management, improve quality of life, and decrease pain. Glasgow, Emont, & Miller, 2006's the 5A's is an evidence-based approach shown to improve self-care management, consisting of "Ask, Assess, Advise, Assist, Arrange". Development of a patient-centered care plan and goal for follow-up allows for continued monitoring of treatment effectiveness and compliance.

Objectives: To implement a Nurse Practitioner (NP) telephone follow-up guided by the 5A's framework among veterans with chronic pain in a primary care setting. This pilot evidence-based project aimed to improve follow-up of self-care management in order to decrease pain, increase quality of life, and decrease pain medication use.

Methodology: The Iowa Model of evidence-based practice guided this project. Baseline data was retrieved from 26 medical records of veterans with chronic musculoskeletal pain from September 2015 to June 2016. The pilot project was implemented from June 2016 to November 2016 among a total of 14 veterans. A monthly telephone follow-up using the 5A's framework was made by NP, which reinforced self-care, developed patient-centered goals, and established a follow-up plan. Outcome data was collected monthly including pain scores (Numeric Pain Rating Scale), quality of life scores (American Chronic Pain Association Scale), and number of pain medications. After 3 months, average pre/post intervention data was analyzed to evaluate project effectiveness.

Results/Outcomes: Evaluation of pre/post project implementation data among 14 veterans revealed a decrease in average pain scores from baseline, an increase in average quality of life scores, and no significant change in average pain medication use. Average pain scores decreased 1.44 from baseline (95% confidence interval, .605, 2.27) and was statistically significant at $p < .003$. Average quality of life scores increased 2.08 (95% confidence interval, 1.0, 3.15) and was statistically significant at $p < .001$. 13 out of 14 veterans (93%) completed all 3 telephone follow-ups.

Conclusions: This pilot evidence-based project revealed a monthly NP telephone intervention may improve overall quality of care among chronic pain veterans. Results illustrated a decrease in average pain scores, increase in average quality of life scores, and no significant change in average pain medication use compared to baseline. The intervention also improved follow-up compliance. Limitations include length of study and timing of project implementation due to variable schedules of veterans and provider. Future research is warranted and may consider using scheduled telephone follow-up appointments that are incorporated into the schedule in order to improve project plan process.

Implications for Clinical Practice: 5A's is an evidence-based framework that may be adapted to promote self-care of chronic pain and establish goals for follow-up in a primary care setting. The use of telephone intervention may potentially serve as a substitute for routine chronic pain follow-up visits or as a supplement to improve quality of care for veterans. The results aim to provide further insight and new knowledge on ways to continuously improve pain management among the veteran population, allowing them to return to their baseline quality of life as closely as possible.

O 08 - Simulation in Nursing Education

Evaluating the Outcomes of a Registered Nurse Empathy Education Program in an Academic Medical Center

Dawn M. Gubanc-Anderson, DNP, RN, NEA-BC, CHEP, FACHE, USA

Abstract

Oncology patients face many challenges in our current health care system. Some of the most notable include an increasing number of medical errors, escalating cost, and a lack of healthcare-provider compassion (Schwartz & Bohay, 2012). Such challenges have the potential to create a patient care experience that is both dehumanizing and dissatisfying (Rogers, Karlsen & Addington-Hall, 2000). When patients do not experience empathy in the healthcare setting, they miss opportunities to build a therapeutic relationship with their provider, may encounter additional pain and anxiety, and are more likely to be non-compliant with medication regimes (Kelley, Kraft-Todd, Schapia, Kossowsky, & Reiss, 2014). Patients and their families may feel alienated, unheard, or disenchanting when not treated with dignity and respect, hallmarks of empathic communication (Wald & Reis, 2010). Dwamena, et al., (2013) states that a lack of empathy can even increase the risk that patients will initiate litigation against providers. Additionally, it has been established that healthcare providers who give patients the impression they do not believe or understand them can worsen patients' symptoms by creating anger and distress (Greville-Harris & Dieppe, 2015).

In addition to having a negative effect on patients, a lack of empathy can also have a financial impact on a healthcare organization. The Centers for Medicare & Medicaid (CMS) in the United States created a Hospital Value-Based Purchasing (VBP) Program which rewards acute-care hospitals with incentive payments for the quality of care they provide to people with Medicare (Giordano et al., 2009). The VBP program uses, in part, data from the Hospital Consumer Assessment of Healthcare Providers (HCAHPS) survey, which includes many questions focused on nurse communication (Giordano et al., 2009). When nurses lack empathy, it places patient satisfaction and patient outcomes at risk (Paley, 2014) and can decrease a hospital's incentive payments from CMS.

To address the potential lack of healthcare provider empathy in the oncology population, a cost-effective, readily accessible web-based training program was created. This web-based empathy training module for the oncology registered nurse was created using the Communicate with C.A.R.E. Model[®]. The Communicate with Care Model[®] program was designed by applying the following principles from the educational literature: (1) lecture-style methods alone are ineffective; (2) adult learning principles must be used; (3) teaching needs to include skills practice; (4) teaching must attend to learner attitudes and emotions; (5) the learning environment must integrate knowledge, skills, and attitudes; and (6) reinforcement is critical for the learning process.

Despite the fact that relationship-based care is a cornerstone of good nursing practice, and empathic communication is part of such care (Koloroutis, 2004), nurses rarely receive empathy training (Herbek & Yammarino, 1990). Even though health care providers differ in their innate capacities, as with any other skill in healthcare, clinical empathy can be taught and acquired (Buckman et al., 2011). When nurses receive empathy education, many positive outcomes impact both the patient and the provider. For example, possessing an empathy skill set allows a registered nurse to feel empowered and prepared for his/her shift (LaSala & Bjarnason, 2010). It may even improve employee engagement as the nurse may feel more confident in his/her abilities (Tulsky, et al., 2011). Engaging in an empathic way can also lead to greater nursing satisfaction related to the quality of their work (Tulsky, et al., 2011). Empathy has also been shown to decrease caregiver fatigue in those who practice it (Tulsky, et al., 2011). And patient outcomes seem to improve after provider empathy training as well. An Italian study analyzed the clinical outcomes of more than 20,000 patients with diabetes. These patients were assigned to three different groups of physicians who were pre-evaluated for their levels of empathy. Physicians with the highest empathy scores achieved the best clinical outcomes for their patients; their patients had statistically significant lower levels of diabetic complications than the groups in which physicians had scored lower in empathy. Dwamena, et al., (2013) concludes that effective provider-patient communication improves

patients' symptoms, emotional health, physiologic responses, and pain levels, creating a very strong argument that teaching empathy skills can have many favorable outcomes (Kelley, Kraft-Todd, Schapia, Kossowsky, & Reiss, 2014).

Although little research on empathy training in nursing has been done, there are types of training that have been shown to be effective (Lane & Rollnick, 2007). Human simulation has been used as a successful learning strategy for empathy instruction for health care providers and can provide the opportunity for provider's self-awareness and values assessment (Cook et al., 2011; Gonzalez et al., 2010; Mullen & Kothe, 2010). Simulation has been widely used as an educational tool in both "live" and "recorded" educational offerings (Vaniaere, Timmerman, Stevens, & Gastmans, 2012). The evidence suggests that human simulation methodology is effective for both new knowledge acquisition and knowledge retention (Gair, 2012). Tulsy et al., (2011) have demonstrated that web-based physician empathy education significantly increases the patient's trust in the provider's care and builds self-confidence in the provider using the skills. Web-based training offers a cost-effective solution and can be accessible to a large number of participants. The use of a web-based educational tutorial including patient simulations may prove to be a valid and reliable solution to educate nurses on empathy skills (Cook et al., 2011).

Methods: In this pre-post quality improvement project, 24 oncology nurses were instructed on the cognitive and affective skills required for empathic communication. The primary goal was to increase registered nurses' comfort level with using empathic communication skills.

Empathy confidence levels of the participating nurses were assessed before the nurses watched the training video, and measured again immediately after completing the web-based training program. The results of this quality improvement project support previous findings that empathy skills can be taught to healthcare providers. It also reinforces the research that human simulation is an effective teaching strategy in healthcare. This quality improvement project demonstrated an overall improvement in Jefferson Empathy Scale (JES) scores, $t(24) = .78, p = .000$. Additionally, individual item comparisons revealed a statistically significant increase in the JES questions related to "perspective taking" $p = .000$, and the "compassionate care" subscale $p = .000$. While the third subscale "walking in patients shoes" did show an increase in the pre and post score, it was not statistically significant; $p = .108$.

These findings demonstrate that web-based learning using human simulation can provide a teaching methodology that satisfies practicing oncology nurses. Additionally, this empathy training program can increase a Registered Nurse's comfort and confidence in using empathic skills. These findings warrant additional research in this area in a larger sample, varying settings and nursing specialties, as well as in student nurse education.

O 08 - Simulation in Nursing Education

Pediatric Emergency Department (PED) Simulation: Undergraduate Nursing Students' Experience

Mary Rochelle Schultz, MSN, RN, CPNP-PC, USA

Rita Ann Dello Stritto, PhD, RN, CNS, ENP, ACNP-BC, FAANP, USA

Abstract

Background: Finding clinical placements for undergraduate nursing students is an increasing challenge. The National Council of State Boards of Nursing Simulation Study (2014) found that high quality simulation produces educational outcomes comparable to traditional clinical hours. Students report that high fidelity simulation has a positive impact on their problem solving, is more realistic, and makes learning more active than low fidelity simulation (Butler, Veltre, Brady, 2009). The undergraduate students in the simulation experience have participated in multiple simulations applying the space industries integrated model to a simulated hospital environment (Ayers, et al., 2015). Students play the role of patients. Using live models or standardized patients in simulation increases students' critical thinking and communication skills (Maharaj, 2015). This same model of utilizing students as patient actors in a simulated hospital was implemented in the pediatric course. Twenty students spent 50% of their clinical hours in the simulation lab and 50% in the children's hospital. However, we discovered that students had difficulty accepting their peers, playing the pediatric patient role, as realistic. Students playing the patient role limited the age range of the scenarios that could be implemented to older school age or adolescent patients.

Intervention: A high fidelity pediatric emergency department simulation (PEDS), with children of all ages playing the patient role, was developed as an innovative solution to these problems. Volunteer children and parents played the patient and parent roles. Patients presented with a variety of scripted illnesses and injuries and were moulaged accordingly. Twenty undergraduate students rotated through the roles of triage and bedside nurses. Faculty wrote the scripts, coordinated the activities, and moulaged patients. Nurse practitioner faculty played the providers.

Evaluation: Students response to the experience was positive. The majority of the students expressed that the PEDS was an excellent learning experience. They were able to interact with children of a variety of ages. Students in the PEDS were able to function independently in a safe environment.

O 09 - Technology in Practice

The Integration of Virtual Monitoring Technology to Empower Advanced Practice Nurses to Optimize Health Outcomes

Eugene Lewis, MSN, RN, ACNP-BC, USA

Carole Kulik, DNP, RN, ACNP, HCIC, USA

Abstract

BACKGROUND: The use of virtual monitoring in Homebased Primary Care through technology enhanced patient reporting provides automated environmental monitoring to monitor symptoms and medication compliance is an effective way for Advanced Practice Nurses to provide timely care, practice to full scope of practice and serve populations with limited access.

OBJECTIVE: This program aimed to implement the feasibility and acceptability of virtual symptom and compliance management systems with patients in rural communities receiving Home Based Primary Care, Assessment in the changes of patient outcomes from baseline and implementation of the virtual monitoring will be evaluated for effectiveness, cost reduction and hospitalizations.

METHODS: Repeated patient measures, chart abstractions, interviews and completion of reported outcomes measures at baseline and annually are assessed and provider survey and interviews.

RESULTS: Dramatic improvements were seen in the continuity of care, compliance with medications, and significant reduction in hospital admissions. Clinical improvements in patient blood pressure, glucose, Drug levels, anxiety, and self-care self-efficacy were also observed. Clinicians perceived the use of "real-time" monitoring data and risk algorithms positively contributing to improved clinical care and improved time efficiency and satisfaction. Reducing the complexity of the system was seen as important to promote the utility of technology by both patients, families and providers.

CONCLUSIONS: The connection between the Advanced Practice Nurse, clinical staff and the patient is critical to the success of the virtual monitoring program in Home Based Primary Care. Integrating monthly visits to the home into the clinical program reinforces the importance of using the virtual monitoring equipment to the patient. The results annually suggest that monitoring patient symptoms using technology, computer or mobile based is feasible in rural communities and acceptable in practice.

IMPLICATIONS FOR PRACTICE: Future research would be most beneficial if the use of this technology expanded the number of applications and expanded the scope of the system to encompass a wider range of supportive care needs. Opportunities for a limitless number of technology enhanced applications.

O 09 - Technology in Practice

Bridging the Gap to Equal Access to Professional Development Meetings With Remote Virtual Technology

Francisca J. Farrar, EdD, MSN, USA

Deborah Ellison, PhD, MSN, RN, USA

Abstract

Nurses face many challenges to balance work, lifelong learning, and personal life. Nursing is a caring profession that is physically and mentally draining. With the growing demands upon the nursing profession to provide evidence-based practice that promotes safe, accountable, and quality care, nurses must learn to balance their schedule to attend professional development activities and stay abreast of current issues. Nurses are encouraged to be active in their professional organization and attend continuing education events. The purpose of this paper is to explore the relationship between technology and remote virtual attendances at professional nursing meetings that have professional development activities.

The Tennessee Nurses Association Music City District 3 has 500 active members that pay dues regularly, geographically covers 18 counties in middle Tennessee from the border of Kentucky to the border of Alabama, and has an average of 20 members attending district meetings. A new president of the district was concerned about the inactivity of the majority of the members. This attendance and engagement problem led to a search for a solution from evidence-based literature to answer three research questions: 1) What are the barriers to attending meetings? 2) How can remote technology increase engagement in meetings? and 3) How can remote technology bridge the gap to equal access to meetings and professional development activities?

A search of the literature found that technology using remote web conferencing was a valid tool to provide remote access to meetings and professional development. It was found that remote web conferencing was cost effective and increased engagement of users. Two specific studies applied to this research study. The Association for Professional Development surveyed membership to determine technology usage and educational needs. Harper, Durkin, Orthoefer, Powers, and Tassinari (2014) found that technology was an emerging trend to facilitate learning and further research was needed to guide the impact of this expanding technology. A survey was conducted via an online survey to 3,400 members with a response rate of 39% (Harper et al., 2014). Telecommunication was found to be used by 32% of members for staff education using web conferencing (Harper, et al., 2014). Knapp, Fletcher, Taylor, Can, and Goetz (2011) discussed the development of a distance-learning model using web conferencing using a pilot test that provided an in-service on HIV testing at four full-service facilities and their associated satellite clinics that expanded over six states. The teleconferencing system was found to be cost-effective, reach remote clinics, and provided valuable education (Knapp et al., 2015).

This research study combined the following two models to serve as a framework to create a culture of change. Clark, Glazer, Edwards, and Pryse (2016) transformed their nursing program from the use of PowerPoint to an interactive engagement using an iPad with access to an iBook. The substitution, Augmentation, Modification, and Redefinition (SAMR) framework was used to transform the technology adoption. An iBook was substituted for the traditional lecture. In augmentation the iPad was used to record a skill to review later. Modification allowed the teacher to provide feedback and empowered skill acquisition. Redefinition allowed technology to develop new methods of teaching (Clark, et al., 2016). They concluded that faculty can create a culture of change to support technology using the SAMR Model. Winter (2016) used a different model to transform professional development with technology. The High-Performing (HPP) model was used that consists of four developmental levels. The restrictive level operates in the past, is ridged, and change is limited. The responsive level operates in the present but learners are passive while the leader owns the issues. The proactive level is future oriented with the educator role being a coach and facilitator. The progressive level is a global holistic approach with standards of excellence. This is a high performing stage and adoption of change. In the high-performing level all parties are engaged with ownership and accountability. Learning is transformed to a practice of

excellence (Winter, 2016). Technology transformation occurs at the high-performing level with embracement of technology, research, and professional development (Winter, 2016).

The literature search included a global application for remote teleconferencing and found barriers do exist in using technology globally and need to be considered. Irinoye, Ayandiran, Fakunle, and Mtshali (2016) conducted a survey about nurses' perceptions and barriers to the use of information communication technology in a teaching hospital in Nigeria. Data from the study found that 37.8% of nurse respondents had not had any formal training in informatics technology while 55.6% of the nurses reported lack of access to informatics technology. Barriers were identified as inadequate number of computers, unreliable network connections, poor system design, discouragement by colleagues, high work demand, inadequate informatics knowledge, lack of training and skills, and lack of encouragement (Irinoye, et al., 2016). The authors call for more education in nursing education programs and in-services on informatics technology because this skill is needed for evidence-based practice. The 2016 World Congress on Continuing Professional Development: Advancing Learning and Care in the Health Professions used webcast live for more than 12 hours of Congress sessions to create live and on demand presentations. The webcasts were archived until the next Congress in 2020 (Turco and Baron, 2016).

Available web conferencing software was researched to match the needs of the district. A user friendly cloud-based video communication software was selected that provided remote video conferencing in which a link could be sent to members to access the district meeting and educational program. The software provided members the ability to remotely enter the web conference by online access by a computer, iPad, or smart phone. It also provided the option of calling into the meeting. The software allowed a host to control the recording and save the meeting using a code number to upload the meeting and educational program to the district website for access to the meeting post web conferencing. Remote members had the ability to ask a question via telephone or in a chat room. This communication feature empowered engagement of members and virtual participation in the meeting. Saving of the meeting empowered entering the meeting at their leisure and the code number allowed validation of attending the educational activity and receiving a continuing education certificate.

District members received an email about pilot testing of a district meeting using remote access. An announcement was also posted in the Tennessee Nurses Association newsletter. The pilot test revealed the need for a microphone for audience questions and the need for an attachable video camera to show the speaker and scan the audience to create a virtual meeting. The pilot testing of the remote access increased attendance from 20 to 40 members doubling the regular attendance number. After the pilot test, an email was sent to members about the remote access availability with a link to the web conference for the next scheduled meeting. The attendance in person was 60 and remotely was 20. The attendance number increased from the average 20 members to 80 members. Remote members were allowed to ask questions and interact with the members in person and the speaker.

A survey monkey was sent to 400 members that provided email addresses post intervention that consisted of ten questions ranging from 1 to 5 with five rating strongly agreeing. One hundred surveys were returned with a 25% return rate. Research question 1: Barriers to attending meetings were a) conflict with work schedule and fatigue with a score of 4.40, Research question 2: Technology intervention to increase access scores were a) ability to receive remote continuing education units score was 4.52, b) ability to access the uploaded meeting to the website at leisure score was 4.38, c) Remote access empowers engagement score was 4.38, d) remote access to live attendance score was 4.37, and e) the use of live video conference of meeting score was 4.37. Research question 3: The belief that remote access can transform activity and engagement in meetings score was 4.56. Data analysis reveals that technological remote access can increase attendance at meetings, alleviate barriers to attending meetings, and can transform engagement at virtual meetings via remote web conferencing.

Remote access availability can transform nursing by providing equal access to professional meetings. Virtual meetings can increase attendance and engagement amongst members. Meetings uploaded to a website can provide access to meetings and continuing education activities. This study validates that remote availability bridges the gap to access to sharing meetings from a district to global level.

Evidence-Based Value and Availability of Self-Help Groups for Mood Disorders in U.S. and Ireland

Valerie N. Markley, DNP, MSN, BSN, RN, USA

Abstract

Research validates a three-pronged approach as best practice for the treatment of mood disorders: medication (when warranted), therapy, and self-help. Peer support groups are a major option for self-help. Millions of individuals in the U.S. and around the world, including Ireland, are currently using and benefitting from self-help groups. Numerous studies have demonstrated the effectiveness of such groups both short-term and long-term. Self-help groups are made up of individuals sharing similar problems and life situations. They provide emotional support to each other, share means of coping, learn new strategies for improvement, and suggest new resources and information on available providers. They share insights gained from first-hand experiences and promote hope and empowerment. Such groups are self-governed, cost-free, and readily available for every major disorder listed by the World Health Organization including both physical and emotional problems, habits and addictions, bereavement, and parenting. There are also groups for the significant others and supporters of those with the disorders. These groups are increasingly recognized as viable and efficient means of supplementing and extending typical care components. In addition, as it says in the AA Big Book (AA, 2002), in order to help yourself, you have to help others.

The World Health Organization (WHO) ranks depression (unipolar) as the fourth leading cause of disease burden, accounting for 4.4% of total DALY's--disability-adjusted life-years (WHO, 2012). Authors conclude from this data that the burden of depression worldwide represents a major public health problem affecting clients and society at large. They note that although variations occur, trends and patterns of illness tend to be very similar throughout the world. Recent statistics from the National Comorbidity Survey Replication (NCS-R) Study report a 12-month prevalence for all mood disorders in U.S. adults between the ages of 18-65 as 9.5% and having a lifetime prevalence of 20.8% (NIMH, 2011). The total economic impact of mood disorders is extreme and places an enormous burden on the health care industry. Millions of depressed individuals never receive treatment. Health care providers could refer their clients to self-help support groups as an additional resource for care.

This presentation will present evidence to support an understanding of and value for self-help support groups for mood disorders and compare and contrast self-help group resources for mood disorders available in the U.S. and Ireland, both Northern and Southern Ireland.

A Multiple Case Study: Mental Health Nurses' Experiences Using Psychosocial Interventions in Ireland

Siobhan Smyth, MSc, RPN, DipCPN, RNT, PGDipCHSE, BNS (Hons), Ireland

Abstract

Background: In this research, PSI-trained mental health nurses (MHNs) were asked to share their interpretations of using psychosocial interventions (PSI) in practice. Given their unique relationship with clients and family members, MHNs are urged internationally to promote PSI. Yet, there was no qualitative study located that explicitly explored how PSI-nurses are practising specialised skills in the Irish context. Moreover, given the changes introduced by recent policy reforms, it was timely to explore how these nurses were adapting and reconfiguring their nursing practice.

Purpose: This study explored psychosocial intervention-trained MHNs' experiences of using PSI in their care of persons with a mental health problem.

Methods: Consistent with the goal of understanding experience, a qualitative approach was adopted using a multiple case study design that comprised of four cases. These four cases were the public sector Health Service Executive (HSE) sites where the nurses work. A total of 40 PSI-trained MHNs were observed and interviewed in acute inpatient and community care settings. An observational guide, adopted from the literature (Spradley 1980) and Richie & Spencer's (1994) framework were used to guide the analysis. Data were analysed within and cross the cases supported by NVivo (10) software.

Results: Through the analysis, three major themes emerged:

1. PSI-trained MHNs understanding and use of PSI;
2. Facilitators supporting the use of PSI by PSI-trained MHNs;
3. Obstacles limiting the use of PSI by PSI-trained MHNs.

Overall, the findings showed that participants' views towards PSI were positive. Yet, participants perceived that their daily work was largely curtailed by many obstacles in practice that challenged them in implementing PSI. These obstacles, noted in the findings, included: not having enough time, shortage of nursing staff, lack of education and training, and the inherent ineffective multidisciplinary image of PSI-nurses. However, participants reported that a supportive and collaborative organisational culture and on-going education and training, where clinical leadership and clinical supervision were available, facilitated the implementation of PSI. Findings also revealed that PSI-trained nurses were more inclined to offer lower level skills with clients whose mental-health problems were more severe, such as schizophrenia and psychosis. Conversely, the higher-level PSI were used with the clients who had less severe mental health problems. The findings also indicated that there needs to be a greater consensus among all mental health care professionals about the skills that PSI-nurses explicitly engage with in practice.

Conclusion: This multiple case study offers answers to the overall aim and addressed the objectives for this research. Many of findings are relevant within the context of current debates about PSI, and can be used to improve mental health nursing practice and contribute to the continued development of mental health nursing in various settings. This study informs practice, policy, education and research. Mental organisations must play a key role in supporting PSI-nurses if recovery orientated practices are the way forward in the mental health services. Finally, it is the MHNs' professional duty to welcome the challenges of PSI implementation in their nursing practice.

P 02 - Evidence-Based Patient Safety

Patient Safety Culture in Neonatal Intensive Care Units (NICUs): What Is the Evidence?

Angelita M. Hensman, MS, RNC-NIC, USA

Abstract

The patient safety culture of a unit and/or organization plays an important role in patient safety. Patient safety issues were brought to the forefront of health care by the Institute of Medicine report, and it has been defined as “freedom from accidental injury” (Kohn, Corrigan, & Donaldson, 2000, p. 4). Preventable harm and error continues to have an impact on patients in intensive care units, and particularly on vulnerable infants in Neonatal Intensive Care Units (NICUs). It can also impact families and caregivers. Understanding the current evidence on safety culture within NICUs can inform nurses, and facilitate research and training to improve evidence-based patient safety practices in this vulnerable population.

Purpose: Perform a literature review to explore the current evidence on patient safety culture in NICUs and implications for future research and practice.

Method: The following databases were searched: PubMed, CINAHL, Cochrane Database of Systematic Reviews, Web of Science Core Collection, Google Scholar, Scopus and Dissertation Abstracts International. The search was limited to peer-reviewed research in English from 2011 to 2016 to obtain current evidence. The following search terms used were used: “patient safety culture” OR “safety culture” AND “NICU” OR the MESH term “Intensive Care Unit, Neonatal “

Findings: Although a great deal of research on safety culture can be found in intensive care units there is minimal research being done in NICUs. Research in NICUs in the past five years involves survey, cross-sectional and descriptive studies which is categorized as level II for evidence (Polit & Beck, 2014). An awareness of safety culture is necessary to improve the quality of healthcare in an organization. Safety culture awareness helps us receive as well as interpret the stimuli from the environment and select and organize it (Hemmat, Atashzadeh-Shoorideh, Mehrabi, & Zayeri, 2015). A positive patient safety culture encompasses good communication, attitudes, perceptions, values and mutual trust shared by individuals and groups within an organization or unit. Management of resources and awareness of inappropriate or unacceptable dimensions of safety culture are important. Expectations and actions of management/supervisors in promoting safety were the most important dimension in safety culture surveys making management involvement absolutely necessary. Frequency of error reporting had the lowest positive responses indicating that nurses tend to not report errors for fear of reprisal (Hemmat, Atashzadeh-Shoorideh, Mehrabi, & Zayeri, 2015). A reporting culture that is non-punitive is needed to improve the frequency of error reporting (Reason, 1998). Profit, et al., (2014) found that caregiver burnout is prevalent in NICU’s and is associated with lower perceptions of patient safety. It was also found to be less prevalent among physicians compared to non-physicians, and more burnout contributed to a lower teamwork climate in the NICU. Reducing burnout therefore improves teamwork and leads to reductions in medical error (Sexton, et al., 2014). It is important to determine if caregiver burnout affects patient outcomes (Profit, et al., 2014). Structured teamwork and training initiatives can positively impact staff safety attitudes and these improvements in safety attitudes could be sustained over a one-year period (Murphy, Laptook, & Bender, 2015). Tools such as the Safety Attitudes Questionnaire have been used to measure safety culture among hospitals and units but more evidence on its use in the NICU setting is needed (Profit, et al., 2012).

Conclusion: Safety culture questionnaires need more validation in the NICU setting. Current evidence shows that patient safety culture varies a great deal among NICU’s with physicians rating it more positively than nurses. Management involvement and support, allocation of resources, structured teamwork training and communication, a non-punitive approach or “just” culture, and positive overall perceptions of patient safety are characteristics that impact patient safety culture in NICU’s. More research is needed on caregiver (especially nursing) burnout and patient safety culture in NICUs. Future studies should also examine how the safety culture within NICUs impacts patient and nursing

outcomes. These findings on the current evidence (2011-2016) on patient safety culture in NICU's could be used to promote evidence-based teaching and learning for NICU nurses, staff and management. It can also be used to develop nursing research to promote the transformation of nursing knowledge and practice, and for the implementation of training programs to improve the safety culture within NICUs thereby reducing preventable harm in this vulnerable population and promoting health.

P 02 - Evidence-Based Patient Safety

Innovative, International, and Interprofessional: Nursing and Engineering Technology Students Creating New Patient Safety Technology

Pamela Karagory, DNP, MBA, MSB, BSN, RN, CNE, USA

Diane Hountz, DNP, ANP, RN, USA

Jane M. Kirkpatrick, PhD, MSN, BSN, RN, ANEF, USA

Sara A. McComb, PhD, MSES, BSIE, PE, USA

Abstract

Background: The role of the professional nurse is undergoing a rapid paradigm shift, with leadership and problem solving becoming cornerstones of nursing practice and key to their role as a member of the interprofessional team. This remodeling of the professional nurses' roles and responsibilities requires a refocus in socializing students to the profession, interprofessional collaboration, and requires transforming the academic curriculum to include knowledge, skills and attitudes that reflect the role requirements of the professional nurse in today's healthcare environment. To prepare students to become change agents in improving the care of patients, communities, and populations, active learning and participation in contextual problems and solutions must be experienced. The healthcare safety crisis in the United States requires new approaches, continuous improvement, and interprofessional education that transcends the traditional healthcare disciplines. Nursing has the unique opportunity to champion grassroots efforts to enact change through their immersion and direct influence on patient care, safety, and technology development that support patient centered care and positive healthcare outcomes. As educators, our job is to prepare the newest members of the profession with the tools, skills, motivation, and interprofessional education opportunities to carry out these efforts. Indeed, fundamental nursing skills are expanding to include quality improvement, interprofessional teamwork, and systems thinking (Ironsides & McNelis, 2011). The acquisition of these essential skills requires developing experiential learning opportunities that bridge the classroom and practice contexts. National and international service learning, built upon strong academic partnerships, provides the mechanism for successful implementation (Voss et al., 2015).

Purpose: One point of care that creates the greatest risk for nursing back injuries is assisting and transferring patients from the bed to the chair (OSHA, 2013). This high risk and ongoing problem is placing financial burdens on healthcare organizations and career ending injuries for nursing staff (OSHA, 2013). This presentation will describe a pilot Quality Improvement project that partnered senior nursing and engineering technology students in addressing patient transfer/mobility problems through the planning, design, development, building, and testing of a bed to chair transfer device. This active learning and interprofessional team approach allowed the students to collaborate, share their unique knowledge, skills and gain valuable insight into the complexity of creating an efficient, cost effective, and sustainable medical device.

Method: The interprofessional and international project occurred over two academic semesters and required a student team charter, weekly live and Skype work sessions, delineated project roles and responsibilities, and specific product guidelines defined by the project sponsor. The interprofessional work was guided by nursing best practices with four nursing students from a large Midwestern University leading several stages of the project work while gaining a deeper understanding of engineering design guidelines, materials, and hydraulics requirements. Engineering technology team members included a four team cohort from a large Midwestern University and a team from a College of Engineering in the Netherlands. The student designed device was presented by the interprofessional student team at an international conference in the Netherlands in May 2016. This opportunity provided the student team to showcase their work during a travel abroad experience enhancing cultural understanding and global educational engagement.

Participants/Sample: A qualitative approach was used to evaluate the student's perspective of the quality improvement project outcome. Qualitative surveys were developed and distributed and a focus group with students was conducted. Initial results and themes suggest that the nursing students found this interprofessional learning opportunity challenging, empowering, and critical in recognizing the

significance and value of the collaboration and synergy between nursing and engineering technology. Findings and identified themes will guide future development, modification, standardization, and expansion of nursing and engineering IPE educational opportunities.

This initial work demonstrates the efficacy of nursing and engineering technology IPE, particularly with respect to empowering the next generation of nursing leaders to enact change through a fundamental understanding of conceptual design, product analytical models, and technology testing. Engineering technology students gained valuable insight into project management, added value of end user participation, and a greater understanding of the challenges and needs of healthcare technology development. Further project evaluation is needed to quantify (1) the effects of the IPE project in the acquisition of team and quality improvement skills, (2) the benefits to students and project sponsors through this collaborative experience, and (3) the impact on long-term interprofessional engagement and professional identity.

P 03 - Global Disease Prevention in Influenza

Influenza Virus: The Evolution of a Deadly Virus in Our World

Cathy M. St. Pierre, PhD, APRN, FNP, FAANP, USA

Abstract

Despite significant advances in health care today and the fact that influenza illness is a preventable disease, Influenza virus continues to be a significant cause of morbidity and mortality in the world. Influenza continues to rank in the top 10 causes of death in the world and infects up to 5 million people annually (WHO, 2014). The Influenza virus is composed of three types: A, B and C. Initially, Influenza virus A was thought to be only present in birds and poultry. However, in recent years, it has come to light that strains of the Influenza virus A, known as the Hemagglutinin proteins (HA) and Neuraminidase (NA) protein has infected humans (CDC, 2015). Since that time, the HA, NA (known as H#, N#) strains have continued to mutate and it is now known that up to there are 18 subtypes of H proteins and 11 known subtypes of the N proteins (CDC, 2015). Because of the mutation of these influenza virus proteins over the past several years (2003-2015), mortality rates from influenza, in several countries has risen to greater than 50% (WHO, 2015). In 2012, the Global Influenza Initiative (GII) was created to establish the scientific evidence for the worldwide burden of disease attributable to Influenza virus (Paget, 2015).

Generally, the “flu” infects up to 20% of the general population and will result in over 500,000 deaths each year. Unfortunately, some of our most vulnerable populations: infants, pregnant females and the elderly, are at greatest risk for contracting this disease (Cheng et al, 2015). For example, In 2010, 90% of the influenza deaths that occurred in the USA, were in the elderly population (Heron, 2013). This is despite the fact that the elderly population as a whole, represent the highest compliance rates for immunization (65%).

This presentation will focus on the evolution of influenza viruses throughout the world and the current strategies in place to monitor disease incidence, prevalence and current recommendations for prevention and treatment of both the general and at risk populations. The new quadrivalent and high-dose vaccines will also be discussed as well as policies related to the risk, benefits and effectiveness of these vaccines. (Demicheli et al, 2014).

P 03 - Global Disease Prevention in Influenza

An Evidence-Based Educational Strategy to Improve Influenza Vaccination Rates Among Hospital Nurses

Terri L. Spoltore, DNP, MSN, RN, CCRN, USA

Patrick Albert Palmieri, DHSc, EdS, PGDip(Oxon), MBA, MSN, RN, CPHQ, CPHRM, FISQua, FACHE, FAAN, USA

Oscar Lee, PhD, RN, CNE, USA

Abstract

Background: Seasonal influenza, or the flu, impacts over 3 million people each year. Within the health sector, nosocomial infection and absenteeism are frequently associated with the flu. The Centers for Disease Control and Prevention (CDC) recommend flu vaccination for all eligible individuals, especially health care workers (HCWs). Interventions associated with increased HCW vaccination include educational programs and occupational health campaigns to address misconceptions regarding vaccine safety and efficacy. This project evaluated the impact of a voluntary, web-based education module to encourage registered nurse (RN) vaccination. The logic and health belief models served as the theoretical frameworks.

Methods: The project used a quantitative research method with a quasi-experimental nonequivalent control group to test the effectiveness of a web-based influenza virus and vaccination professional educational module in HealthStream®. Because both the comparison group and the intervention group were convenience (non-randomized) samples, a quasi-experimental design was necessary. The participants self-selected. The groups were pre-existing and nonequivalent. The selection of this design was most appropriate for this study because it offered a larger cross section of nurses. This design also limited the potential for interaction between the two groups of participants and limited any potential bias. A brief anonymous paper survey method limited the participant's time commitment required for completion but allowed for collection of sufficient data to gain insight into similarities, differences, and trends to make predictions about the sample population. The anonymous survey also allowed for data collection from a large population without cumbersome effort on my part. Lastly, the selection of this method will allow continued data collection with the same methodology with other groups of participants in future studies.

The web-based educational module was developed to address knowledge gaps identified from the literature. The program was made available to all RNs through an existing internal web-based computerized program, HealthStream®. This approach was a familiar learning method for the participants and a standard education delivery method in the project setting. The educational program was made available during the employee influenza vaccination campaign. Nurses in the intervention group (IHNV) had access to the educational program and were notified about the program through a flyer (Appendix C), which was distributed in both printed and digital format. Nurses at IHNV were also invited to participate in the program through an email announcement (Appendix D). Finally, the nursing leaders at the IHNV site were encouraged to include the availability of the educational program in their routine staff meeting agendas. Nurses in the comparison group (IHNE), who did not receive the educational program, were made aware of the study when they presented for vaccination or declination.

A four-question survey was used to collect data from two nonequivalent groups: (a) RNs at IHNV who received the intervention (web-based education) and (b) RNs working at IHNE, who did not. The use of a comparison group located in another hospital limited the risk of bias related to information sharing between nurses who participated in the education and their colleagues who may not have participated. As each RN presented to the IHNV or IHNE influenza vaccine clinic or occupational health office, he or she was provided the standard vaccine consent or declination form.

After vaccine administration or completion of the declination form, participants were asked to complete the study tool. The tool allowed participants to self-select whether or not they participated in the intervention and to indicate whether they opted to receive or decline the seasonal influenza vaccine. Other pertinent influenza and demographic information was also collected; however, anonymity was

maintained. Surveys for data collection were returned immediately following completion to the secured lock box located at the site of vaccine administration.

Results: A total of 192 surveys were returned during the data collection period of approximately 3 weeks. During this time, both sites conducted “amnesty” days on which noncompliant employees were allowed to attend the flu vaccine clinic and either receive the vaccination or complete a declination form. A total of 116 surveys (60.4%) were returned at the IHNV campus, and 76 were returned at the Elmer campus (39.6%). The education program, implemented at IHNV only, received a total of 145 views. Of those returning surveys at the IHNV campus, 79 (41.1%) reported having viewed the education. Clinical (bedside) RNs constituted the largest group of respondents ($n=132$, 68.8%). The majority of respondents worked in a medical–surgical specialty (35.5%) and prepared at the BSN level (67.2%). Most RNs who accepted the vaccine, regardless of their primary work site, had been vaccinated the previous year as well (79.7%). Interestingly, only 5.7% of respondents reported having previously contracted the flu within the last 2 years.

Vaccine acceptance rates, overall, were similar between the two campuses. In fact, acceptance rates at IHNV (where the education was made available) were slightly lower (81.1%) than acceptance rates at IHN (84.2%; $\chi^2=0.318$, $p=0.573$). However, vaccine acceptance rates among participants who reported completing the educational program were significantly higher (91.1%) than among those who reported not having viewed the education program (76.1%; $\chi^2=7.210$, $p=0.007$). A significant difference in the vaccine acceptance rate was not seen in relation to any of the other demographic variables (nursing specialty, nursing role, academic degree). When comparing the prior year’s decision to vaccinate or not, a significant difference was seen in the percentage of RNs who chose vaccination this year. Specifically, 87% of RNs who received the vaccine the previous year were revaccinated this year, while only 12.4% of those who were previously vaccinated refused vaccination this year ($\chi^2=14.465$, $p<0.01$). Only 11 RNs reported having had influenza in the previous 2 years; of those, 10 were vaccinated this year, and one was not.

Discussion: The current literature suggests that the most common reason for influenza vaccine refusal involves misconceptions regarding the safety and efficacy of the influenza vaccine. As such, the program was designed to address these misconceptions by providing factual information about influenza severity, vaccination safety, and historical efficacy. This information appears to have addressed the reasons previously unvaccinated RNs chose vaccination. In total, 39 RNs reported not having received the vaccine last year; of those, 11 completed the education and all but one chose to receive the vaccination this year. In addition, all of the individuals who previously had the flu and who participated in education accepted the vaccination this year.

The findings demonstrate that the educational program effectively addressed the most common barriers to vaccination in that individuals who participated in the educational program were vaccinated at a significantly higher rate than those who did not. Interestingly, the vaccination rates at the IHNE campus (comparison site) were slightly higher than the IHNV campus (intervention site). The findings suggest that the educational program influenced the individual’s vaccination choice; however, the impact on vaccine decision did not spread from these educated individuals to the overall hospital population. One possible explanation is that individuals thoughtfully considered the program’s effectiveness and benefit to patients yet did not share or discuss their choice with others.

Conclusion: This project demonstrated a simple but tailored web-based educational program is effective in converting RNs to vaccination acceptance. Increased vaccination produces societal change by reducing nosocomial and community influenza transmission. Reduced influenza infection improves community health as well as patient safety. Future work should address community-wide HCW education initiatives and evaluate their impact on quality and financial indicators at the hospital and community levels.

P 04 - Global Strategies in Maternal Care

Social Networking for Improved Maternal Child Health in Rural Settings

Autumn Argent, MSN, BSN, RNC-OB, CCE, USA
Erika Ruth Gavenus, MS, BS, USA

Abstract

Purpose: The purpose of this presentation will be to identify key areas of replication of a social networking nutrition program that took place in a remote area of Kenya, Africa, and the development of similar program possibilities in remote areas of northern Arizona amongst the Navajo, Hopi, and Hispanic populations. The social networking nutrition program is an intensive, community led, 12-week nutrition curriculum that supported nutrition interventions for young mothers, pregnant women, infants, children, and their families. The goals of the program were to improve maternal and child health, empower women to practicing exclusive breastfeeding irrespective of their HIV status, improve early childhood nutrition with appropriate child feeding, create awareness in the prevention of malnutrition in Mfangano Island, improve household food security, clear up myths and misconception surrounding family nutrition, and increase male involvement in family health. The specific population of interest within Arizona includes teenage and young mothers who are at higher risk for malnutrition or under-nutrition during pregnancy and breastfeeding due to population disparities. The population served in the Kenyan study included young, single mothers, combined families, widowed mothers, and mothers who were HIV positive. The program goals are applicable to the population being considered for program replication.

Methods: A total of seven focus groups were conducted with three participant groups over five weeks during the summer of 2016. Focus groups were conducted in the native Dhuluo language. All focus groups were recorded, transcribed in Dhuluo, translated to English, and then back translated to Dhuluo for verification. Atlas.ti was used for qualitative data analysis. Two independent researchers review the transcripts for themes.

Results: Three themes were identified based on the transcribed information from the focus groups. Nutritional balance: new knowledge of "balanced diet," diversity of foods, and kitchen gardens. Multi-dimensional support: community, social network, family, support; reduced incidence of disease; knowledge sharing; increased involvement of partner in choosing food and childcare. Community collaboration: increased business opportunities for women, increased food trading, and improved childcare.

Conclusion: The nutrition curriculum program showed great success while in practice, but success was not sustained long after the curriculum sessions ended. Recommendations, based on the identified themes, were provided to the community based organization for program revisions and expansion. Further research needs to be done to identify key geographic areas for program modification and expansion in Arizona.

P 04 - Global Strategies in Maternal Care

The Use of Donabedian Quality Model to Implement Quantification of Blood Loss: Preventing Maternal Hemorrhage

Deborah Reneé Jones, DNP, RNC-OB, WHNP-BC, USA

Abstract

Background: Worldwide, obstetric hemorrhage is the most common complication of childbirth and is the most preventable cause of maternal mortality. A leading cause of preventable maternal mortality is obstetric hemorrhage impacting 1% to 4% of all births worldwide. From the World Health Organization (WHO), an estimated 140,000 women die every year from postpartum hemorrhage. The Healthy People Report 2020 target is to reduce this incident to 28%.

Proven preventable healthcare interventions can help manage or prevent maternal hemorrhage. These interventions include adoption of patient safety bundles: evidence based recommendations for practice and care to improve outcomes. One of the bundles includes quantification of blood loss. To date, numerous studies have identified a relationship between obstetrical hemorrhage and inadequate blood loss assessment. Visual estimation of blood loss during delivery has been a consistent theme and is inaccurate.

The proposed recommendation is to accurately quantify blood loss, the gravimetric method, by weighing all soiled linens and subtracting the dry weight. In the United States, the Association of Women's Health, Obstetrics, and Neonatal Nurses, the American College of Obstetrics and Gynecology and the California Maternal Quality Care Collaborative have presented a position statement indicating quantification of blood loss at every birth, however, this has not been the case until recently. When any pregnant woman delivers in a hospital, there is an existing assumption that quality, emergency care for obstetric hemorrhage will be received. Until recently, this assumption of quality care and preventability of obstetric hemorrhage has been questioned. Multiple studies have shown 93% of obstetric hemorrhage is preventable and clinician error as evidence by a delay in recognition and management of blood loss was the major factor contributing to the morbidity and mortality

Framework for presentation: This presentation will discuss the significance of the obstetric hemorrhage throughout the United States and world. More importantly, a review of literature and management strategies discussing recognition and response to an obstetric hemorrhage through Donabedian's Quality Model will be presented.

Donabedian's Quality Model provides a structured, organized way to improve the process of management of blood loss for the obstetric patient. According to Donabedian, the model is a simple, linear, diagram illustrating structure (having the right things), process (doing things right), and outcome (having the right things happen). Each component has an effect or direct influence on the next.

For the process portion of Donabedian's model, a prospective cohort design was used for evidence-based implementation examining the impact of quantification of blood loss measurement for identification of hemorrhage during birth. The primary purpose was to evaluate visual versus quantitative assessment methods in order to implement an accurate measurement of blood loss during delivery. A secondary purpose was to utilize simulation by creating in-situ simulations of deliveries to test the processes, identify barriers and opportunities while in a safe, well-controlled environment. Through Donabedian's model, the outcome was implementation of quantified blood loss at all deliveries and policy was changed. A total of 52 births were initially evaluated for visual estimation and quantitative blood loss. During this study, the average blood loss for Cesarean birth was 1200 mL and for vaginal birth 400 mL. Secondly, physicians and nurses consistently underestimated ($p < 0.0001$) blood loss by 21% to 28% at delivery. Registered nurses were inconsistent in underestimating blood loss. Through this evidence based process, maternal hemorrhage was recognized sooner and the healthcare team responded to save the life a mother. To conclude, using a derivation of Donabedian's classic structure, process, and outcomes framework would allow administrators, physicians and nursing staff the opportunity to examine the influence and

implementation of quantification of blood loss during every birth thereby decreasing maternal hemorrhage and decreasing hospital stay.

Implications for practice: The nurse is a key provider in the recognition of blood loss and mobilizing the healthcare team for positive outcomes. By understanding the current review of evidence, it is critical that nurses review the current process in their facility and implement standards for hemorrhage assessment and management. It is recognized that hospitals carry a significant burden in the prevention of adverse outcomes. Maternal hemorrhage is a direct result of interactions between healthcare team members. Evidence indicates the gravimetric method by quantifying blood loss is essential to prevent maternal mortality associated with obstetric hemorrhage. As a result, the opportunity to improve characteristics (structure and processes) affecting safe patient outcomes during birth is of utmost importance.

P 06 - Influences on Test Taking in Nursing Education

Test Anxiety Levels in Undergraduate Nursing Students

Jamie Beth Rivera, MSN, RN, CPN, USA

Abstract

BACKGROUND/PURPOSE: For many undergraduate nursing students, performing well in required coursework is important. However, nursing students often face pressure-filled academic situation and worrying about them may inhibit their ability to demonstrate actual knowledge of course material. This can, in turn, interfere with students completing their undergraduate programs or with choosing to pursue advanced nursing degrees following graduation. The purpose of this study was to assess and compare test anxiety levels of sophomore and senior undergraduate nursing students.

METHODS: A convenience sample was utilized for this descriptive survey. A total of 219 nursing students completed a scale that consisted of 26 statements focusing on the cognitive domain of test anxiety. Scores could range from 26 to 104 with higher values indicating greater anxiety. Three cut-points were applied to define low (26-59), moderate (60-69), and high (70-104) anxiety groups.

RESULTS: Internal validity of the instrument was supported by a Cronbach's alpha of 0.94. The total mean score was $M = 67.5$ ($SD = \pm 15.03$) and corresponded to a moderate level of anxiety. Mean score comparisons were conducted and showed a sophomore ($N = 111$) mean anxiety level of 71.2 ($SD = \pm 14.39$) and senior ($N = 108$) anxiety level of 63.6 ($SD = \pm 14.77$). The sophomore and senior anxiety levels were significantly different ($p < .001$). Mean score comparisons between male ($M = 66.04$ $SD \pm 14.24$ $N=23$) and female ($M = 67.64$ $SD \pm 15.16$ $N= 193$) students revealed no significant difference ($p = 0.61$). Students who had a GPA below a 3.0 had significantly higher anxiety levels ($M = 83.3$) than students who reported a GPA above a 3.0 ($M = 66.4$, $p < .001$).

CONCLUSION: Overall, nursing students have moderate-to-high test anxiety levels. Sophomore nursing students have higher mean levels than senior students and students who have a GPA below 3.0 have higher levels than those with GPA above 3.0. There was no difference in anxiety between male and female students. Strategies that improve managing test anxiety, such as early assessment, increased awareness, and providing anxiety-reducing interventions for students, may be appropriate additions to undergraduate nursing curricula.

P 06 - Influences on Test Taking in Nursing Education

Academic and Social Factors That Affect BSN Students Who Fail the NCLEX-RN® Exam After Graduation

Kelly J. Betts, EdD, RN, CNE, USA

Abstract

Problem/Purpose: Each year a small cohort of graduates from the UAMS CON BSN Program graduate and do not pass the NCLEX-RN® Exam on the first and subsequent attempts. The purpose of this study was to evaluate graduates from the last four years who have not been successful on the first or subsequent attempts at the NCLEX-RN® Exam to assess if there are certain trends or patterns that occur while they were in the BSN program that may have contributed to their NCLEX-RN® Failure. Identification of trends can help BSN faculty better provide academic support to students once it is understood what factors may be causing the negative outcomes.

Significance: Being able to identify trends in social and academic behaviors that lead to not being successful on the NCLEX-RN® Exam after graduation will allow faculty and academic coaches in the UAMS CON to implement early identification and remediation strategies that will better prepare students for the NCLEX-RN® Licensure exam. Findings will disseminated to other academic educators via abstract submission and publication of a manuscript.

Research Aims:

1. Determine if students who have failed the NCLEX-RN® Exam after graduation exhibit trends or patterns in academic performance using variables such as the TEAS V Entrance Exam Scores, Critical Thinking Exam Scores, and the RN Predictor Standardized Exam Scores.
2. Evaluate graduate students' experiences on what challenges they felt led to not being successful on the NCLEX-RN® Exam using qualitative interviewing.
3. Based on the results of the study, identify academic coaching measures that will enhance future success with at risk students prior to graduation.

Research Questions:

1. What are the academic characteristics of these students while they are in the BSN program related to academic success?
2. What are the contributing factors that cause students to be unsuccessful on the NCLEX-RN® Exam?
3. What are students' perceptions of the causes of their failure on the NCLEX-RN® Exam?

Background/Literature Review

Assumptions-Anecdotal evaluation of students who have historically not been successful on the NCLEX-RN® exam have exhibited academic risk factors throughout the nursing program. However, a statistical data analysis has not been performed to find out if there is indeed a significant relationship between NCLEX-RN® failures, and those who have performed poorly on the TEAS V Admission Exam, the RN Predictor Exam, and the Critical Thinking Exam. Our experience as faculty have taught us that some students who come into the program and struggle with the standardized exams and not meet the benchmarks have required several academic coaching sessions and remediation in nursing content to help them improve repeated standardized testing. Anecdotal feedback from the academic coach has also proposed that social and personal factors can also play a key role in students who are at academic risk while in the nursing program. For years, nursing faculty and administrators have tried to find the best models for predicting NCLEX-RN® success, but there continues to be a knowledge gap as to what that module truly looks like. Many studies have been published that have given information related to success predictors such as pre-admission testing, admission GPA, and benchmarking exams during the program, but have lacked the ability to determine an exact science. Of late, one particular study by McCarthy et al (2014) studied what were the predictors of NCLEX-RN® success by evaluating pre-nursing versus nursing aptitude scores from the ATI TEAS V, and various standardized exams students complete throughout their nursing program. The results revealed significance for almost all academic variables with

the NCLEX-RN®. There was a strong correlation between academic and nursing aptitudes. Students who scored high on predictor variables identified (pre-nursing GPA, TEAS Reading, TEAS Math, TEAS Science, and TEAS English) also scored high on ATI Fundamentals, ATI Medical Surgical, ATI Nursing Care or Children, ATI Mental Health, and ATI Maternal Newborn exams. It also concluded that TEAS and GPA sub-scores were also good predictors of success. Another study by Abele, Penprase and Ternes (2013) evaluated undergraduate prerequisite and nursing courses that may serve as predictors of success for students completing a BSN program and sitting for the NCLEX-RN® Exam. The students evaluated in this study were on academic probation and at risk students and failed at least one pre-nursing or nursing course. The most common courses failed pre-nursing were the biological sciences and the medical surgical and psychiatric mental health courses in the nursing program. The results revealed that those students failing two or more courses (pre-nursing and nursing) were less likely to complete the program.

Methodology-This study combined quantitative descriptive analysis and face to face interviews with thematic analysis as a mix-methods approach. **Subjects/Setting-**Graduates who failed the NCLEX-RN® Licensing exam from May 2012-May 2015 were identified using the UAMS College of Nursing's (UAMS CON) academic database. The sample of graduates were evaluated from the May or December graduating classes in the years of 2012-2015. The study interviews took place at the University of Arkansas for Medical Sciences College of Nursing. The students are graduates of the BSN program and have taken at least 1 attempt of the licensure exam. **Instrument-**The quantitative portion of the study was a retrospective review of academic test scores and demographic using the ATI database and student records. The qualitative methods used a semi-structured interview guide during interviews to capture graduate feedback. **Procedure-**The study was approved by the University of Arkansas for Medical Sciences Investigational Review Board. Graduates who did not pass the NCLEX-RN Licensing exam over the last 5 years (May 2012-May 2016) were identified. Once identified, retrospective review of their academic performance while in the BSN program was reviewed: TEAS V Scores, ATI Critical Thinking Exam Scores, ATI RN Predictor Scores, Demographic data, admission GPA, Graduation GPA and Number of academic coaching sessions attended while in the program. Graduates who did not pass the NCLEX RN Exam were contacted by the investigator and asked to participate in a face to face interview that asked questions regarding the topic of why they felt they were unsuccessful on the NCLEX-RN Exam. An interview guide was used to collect qualitative data. Each interview was recorded and transcribed word for word into an interview script after obtaining the participant's permission. Thematic analysis was used to determine major themes in the data. **Data Analysis-**Quantitative data analysis consisted of descriptive statistics (frequencies, means, and standard deviations as appropriate) identifying student demographic data related to sex and race and academic demographic data consisting of admission cumulative GPA, Graduation Cumulative GPA, and admission TEAS V Exam Score(s). Data using face to face interviews and thematic analysis of interview narratives for each participant was used to identify themes throughout each interview that may help the researcher understand situational, social, and environmental factors that may have contributed to the negative outcomes of NCLEX-RN failure for each student.

Results- Graduation GPA was much lower than entrance GPA, Average TEAS V Scores were 66.8 (lower end of average) and mean Comprehensive Predictor Scores were 69.7 (N=43). Thematic Analysis indicated that major risk factors included length of time from graduation to testing date, lack of preparation for the licensure exam, and differences in the testing environment in the program versus NCLEX-RN testing environment.

Global Health for the Young Professional: How to Align Your Work With Global Initiatives

Lindsey N. Horrell, BSN, RN, USA
Christine M. Darling, MPA, BS, USA
Cynthia Vlasich, MBA, BSN, RN, USA

Abstract

This presentation outlines a variety of initiatives that provide young professionals of all disciplines the opportunity to become involved in nursing and midwifery's global health agenda. Presenters will provide a thorough review of the United Nations' (UN) Sustainable Development Goals (SDGs), with special emphasis on ways these goals can be implemented in one's own practice and research at the local, regional and international levels. A variety of opportunities focused on global health through Sigma Theta Tau International (STTI) will be discussed. Presenters will provide an overview of the purpose and mission of the Global Advisory Panel on the Future of Nursing & Midwifery (GAPFON), which seeks to advance nursing and midwifery's ability to lead interdisciplinary responses to the most pressing healthcare issues facing our global society (Klopper & Hill, 2015). Findings from GAPFON's recent listening tour held with key stakeholders across the globe will be reviewed. In addition, action plans that young professionals may participate in to advance culturally relevant efforts to achieve the SDGs by 2030 will be discussed. Information will also be shared about STTI's special consultative status with the United Nations Economic and Social Council (ECOSOC) (STTI, 2016). Information about upcoming application dates to serve as STTI UN Youth Representatives will be available. Finally, the presenters will discuss a number of institutes and grant programs available through STTI to provide both emerging and experienced healthcare leaders the resources necessary to influence policy and to improve the health outcomes of people and populations worldwide. Information will focus on the Emerging Global Leaders Institute and the STTI Global Nursing Research Grant, which was established to fund nursing research focused on addressing global health disparities. In outlining each of these programs and initiatives, presenters will provide young professionals the tools necessary to become further involved with international health initiatives and to align one's own work with nursing and midwifery's global health agenda.

P 07 - International Collaborations to Promote Health Partnerships Among Nonprofit Organizations: Assessing the Impact on Global Health

Jacqueline Cassagnol, MSN, RN, PMC, USA

Abstract

Partnership among nonprofit organizations are intended to achieve greater impact than any organization could generate on its own. The purpose of this project is to assess the impact of partnership among an international organization and nonprofit organizations on global health. The partnership is between Worldwide Community First Responder, Inc. (WCFR) and nonprofit organizations in the USA and Haiti. The nonprofit organizations include: Haitian American Nurses Association, Sigma Theta Tau International, and Volunteer New York. In order to facilitate an in-depth examination of the project impact, a case study methodology was employed. Communities worldwide have benefited from the services that WCFR has provided through partnership. A reflection of WCFR partnership shows that the partnership impacts education by providing education to community members worldwide about fatal health conditions and preventative measures. The partnership also impacts training by providing worldwide community-based first response and first aid training. The services that WCFR provides can serve as a source of research for faculty and students. The projects engage faculty and students at Faculte des Sciences Infirmieres de Leogane (FSIL), a nursing school in Haiti. Faculty and students respond directly to community needs by conducting community health assessments through surveys; analyzing data collected and recommending interventions to improve community health. Additionally, faculty guide students in assessing communities risk and vulnerability for disasters; and developing disaster preparedness plans including first response and first aid training. These opportunities help students practice critical thinking, and problem-solving skills necessary for professional life. Moreover, the projects engage participants in promoting healthy lifestyles in their community, and making their community safer, better prepared, and more resilient to disasters. Through the projects, WCFR seeks to empower individuals in their communities and save lives. The partnership between WCFR and nonprofit organizations has proven to be beneficial for all stakeholders. WCFR research findings and initiatives are impacting nursing practice, education, training, research and health globally. Although these projects were initiated in the United States and Haiti, they can be utilized for successful partnerships on projects that save lives in other parts of the world.

P 08 - Promoting Clinical Outcomes in the Cardiac Patient Implementation of an Evidence-Based Practice Checklist to Reduce 30-Day Readmission for Patients With Heart Failure

Susan Giscombe, MS, APRN, FNP-c, USA

Diana Lyn Baptiste, DNP, MSN, RN, USA

Melissa Jones Holley, DNP, MSN, BSN, APRN, FNP-c, USA

Abstract

Purpose: One of the leading causes of hospital admissions is cardiovascular disease. Innovations in technology and the advancement in science the aged population has increased and now has lent to more people being diagnosed with heart failure. As of 2013, it is reported that 5.1 million Americans are living with HF and this is one of the leading cause of hospitalizations across the country. Decompensation of HF will cause patients to seek treatment and often they are admitted into the hospital. And of those patients admitted approximately 25% of them will return within 30-days of discharge for worsening symptoms or an entirely different illness. It is reported HF readmissions may be preventable in up to 50% of the cases. Factors contributing to preventable readmissions include inconsistent in-patient care, physician errors, incorrect medication and/or dose titration and inadequate discharge planning. The cost for caring for HF patients is \$34 billion annually and it is estimated that by 2030 to go as high as \$70 billion dollars. Policy makers and payers have focused on this trend and are holding hospitals accountable for these readmissions. The American Heart Association/ American College of Cardiology guidelines provide specific recommendations for pharmacological and non-pharmacological therapies in the treatment of patients with heart failure. The purpose of this project was to implement an evidence-based clinical intervention to support clinicians in providing quality care in a safe and consistent manner, with a goal of decreasing the likelihood of patients with heart failure returning to the hospital within 30-days after discharge.

Methods: Our study was conducted at a 255-bed tertiary hospital in a rural region of the northeastern United States. We piloted a discharge checklist for two months, to be used by providers when discharging patients hospitalized for heart failure. This discharge checklist was developed based on recommendations from the American Heart Association/ American College of Cardiology that included prescribing medications from up to seven drug classifications such as diuretics, beta blockers, aldosterone antagonists, and nitrates. Recommended non-pharmacological therapies included patient education related to dietary and lifestyle modifications, as well as post-discharge follow-up. The checklist was added to electronic medical record. Physicians were educated regarding use the checklist when discharging all patients who were initially admitted for heart failure. We evaluated readmission rates for two groups of (N=96) patients who were discharged from the hospital in the pre and post intervention periods.

Results: Prior to the intervention, readmission rates for the hospital were at 27% from the period of September 2015 to November, 2015. In the post intervention period, readmissions decreased to 17% from September 2016 to November, 2016.

Conclusion: A well-designed discharge plan remains a critical component of the patient discharge process, necessary to improve outcomes and reduce readmission. Consistent with previous studies, the implementation of evidence-based discharge checklists based on the American Heart Association/ American College of Cardiology recommendations can reduce the percentage of patients who are readmitted within 30 days of initial hospitalization. Nurses are uniquely qualified to promote use of checklists among providers in efforts to improve health outcomes. Further study is necessary to examine barriers to using discharge checklists by providers.

P 08 - Promoting Clinical Outcomes in the Cardiac Patient

Advanced Nurse-Led Referral Versus ED Physician Referral to a Nurse-Led Chest Pain Clinic: Patient Outcomes

Shirley J. Ingram, MsC, RGN, RANP, RNP, NFESC, Ireland
Gabrielle McKee, PhD, BA (Mod), Ireland
Mary B. Quirke, PhD, MA, Ireland
Niamh Kelly, MsC, RGN, RANP, Ireland

Abstract

Background: The role of registered advanced nurse practitioner (RANP) in Ireland is in its infancy compared to the US. The SCAPE study¹ recommended that future research focus on capturing specific clinical outcomes related to advanced nursing practice, however identifying the outcomes of advanced nursing practice is complex. Existing evidence shows similar outcomes for nurse practitioners and physician care in the US² and better RANP radiological diagnostic skills in Ireland³ yet there is a dearth of literature showing better outcomes of RANP led services to usual physician led care.

Internationally chest pain is a common presentation to Emergency Departments (ED), accounting for 5-10% of ED visits annually and a quarter of hospital admissions⁴. Over 90% of chest pain presentations are unrelated to acute coronary syndromes (ACS)⁵ with less standardised protocols and treatment for this group. An alternative nurse led chest pain service was set up to assess non-ACS chest pain patients presenting to the ED for possible stable coronary artery disease (SCAD). The service consists of two components i) advanced nurse-led consultation in the ED and ii) advanced nurse-led chest pain clinic review < 72 hours after discharge. The aim of the study was to compare patient outcomes post chest pain clinic review by referral type; Advanced nurse-led v ED Physician.

Methods: The study took place in a large tertiary level acute urban teaching hospital in Dublin, Ireland as a one site cross sectional study of patients attending the chest pain clinic over two years. Utilising an accelerated diagnostic protocol (ADP), referrals to the clinic were by the advanced cardiology nurse-led service during consult hours and out-of-hours by the ED physicians. Data was extracted from case notes and analysed using SPSS version 20. Ethical approval was given by the local research ethics committee.

Results: 1041 patients were referred to the nurse-led chest pain clinic, 45% by the nurse-led service. The nurse referred statistically significantly more patients who had; pre-existing vascular disease (24% vs 13%), positive exercise stress test (21% vs 12%), a final diagnosis of stable coronary artery disease (19% vs 11%), were older (56.5 yrs. vs 52.3 yrs.); and less patients with final diagnoses of musculoskeletal (5% vs 13%) and other non-cardiac pain (36% vs 45%) when compared to the ED physician referrals. This reflects appropriate patient selection following nursing-led assessment in the ED with a statistically significant diagnosis of coronary heart disease by the nurse-led service.

Conclusions: This study provides evidence of a successful alternate nurse led model utilising a cardiology advanced nurse practitioner-led service for patients who present to the emergency department with chest pain. It fills a gap in the literature regarding patient outcomes, directly comparing advanced nursing practice with the medical model, evidencing the effectiveness and clinical leadership of RANP led care.

Q 01 - Patient-Centered Outcomes

Enhancing Nursing Care in Rural Public Hospital Network Through Utilizing Transforming Care at Bedside Framework

Salah-Addin H. Aqtash, PhD, RN, CPHQ, USA

Abstract

Purpose: To discuss the experience of a Rural Public Hospitals Network (RPHN) in the United Arab Emirates (UAE) in successfully implementing the Transforming Care at the Bedside (TCAB) framework and the impact of this implementation on improving patient outcomes.

Introduction: Transforming Care at the Bedside was established as an innovative approach by the Robert Wood Johnson Foundation (RWJF) in collaboration with the Institute for Healthcare Improvement (IHI) to improve the delivery of care as well as work environment in hospitals through empowering front-line nursing staff. The program utilized bottom up approach by allowing front line nurses to develop and implement ideas of change compared to the traditional top down approaches. The TCAB framework has four essential domains including safe and reliable care, vitality and teamwork, patient centered care and value added care process.

Discussion: One of the most important challenges that faced the senior leadership of the RPHN in the UAE was dealing with the growing and continuing expectations of patients and their families. Consequently, a core responsibility for the nursing leadership in this network was to constantly explore innovative ways and means to ensure the delivery of nursing care that meet or exceed the expectations of patients. Given the popularity the TCAB gained in improving nursing care in many hospitals, the nursing leadership in this RPHN made an executive decision to utilize this framework to guide a quality improvement project focusing on improving the provided care. The leadership has established a TCAB taskforce team chaired by a nurse manager with significant quality experience to work on the implementation and provided the team with all needed resources to help them succeed. After surveying frontline staff and conducting the introductory sessions in the targeted units, the team identified issues related to two domains in the TCAB framework including patient centered care and vitality and team work. The team then initiated the necessary corrective measures through utilizing the PDCA cycle.

Conclusion: The implementation of this innovative framework helped the nursing leadership in identifying some of the gaps in the provided care and consequently developing the necessary action plans to amend them. As a result of the action plans, significant changes have been noted in patients' feedback. We conclude that the RPHN nursing executive team was successful in utilizing this framework in empowering front line nurses to improve the quality and safety of care as well as improve patients' positive outcomes.

Q 01 - Patient-Centered Outcomes

"Patient-Reported Outcome Measures" Enhance the Nursing Process and Patient-Centered Care in Heart Failure

Marguerite M. Russo, PhD, MS, CRNP-F, ACHPN, USA

Abstract

Purpose: Despite costly advances in heart failure management, heart failure is characterized by pervasive adverse and complex symptoms, functional decline, and poor quality of life. The purpose of this study is to incorporate Patient Reported Outcome Measure (PROM) data into the nursing process, augmenting usual nursing assessments with robust patient specific reports. This study aims to detect unmet care needs identified by integrating patient reported data in the nursing assessment, via PROMs measuring multidimensional symptoms, and health related quality of life, and testing their associations with other nursing assessment factors.

Methods: This cross sectional, correlational study used data collected from 88 individuals undergoing inpatient heart failure treatment in a large urban academic medical center (50% male, average age 67±6.9, median duration of heart failure >4 years, mean vEF =32%). Following consent, patients completed a 30 minute interview consisting of valid, reliable 'patient reported outcome measures' of symptom burden, and health related quality of life. PROM data augmented nursing assessments and disease, treatment, and social characteristics abstracted from medical records. Data analyses of assessment and PROM findings were conducted using correlation, non parametric statistics and regression models.

Results: 'Patient reported outcome measures' had good internal reliability (Cronbach's alpha >.8). The most prevalent symptoms reported (75-97%), were xerostomia, dyspnea, fatigue, pain, worry and sleep disruption. Statistically significant differences were detected in symptom burden associated with gender; symptom frequency, severity and or associated distress was increased in women participants compared with men ($r=-.21$, $p=.048$). Increased symptom burden associations with decreased functional status were statistically significant, beginning at the 40% threshold on the Karnofsky Performance Scale ($r=.40$, $p=.001$) assessed in the participants.

Conclusion: 'Patient reported outcome measures' contribute unique findings to inform the nursing process and patient centered heart failure treatment. Care quality opportunities identified in this sample include multidimensional symptom management, functional support, disease and treatment education, and advance care planning; all components of primary palliative care.

Q 02 - Professional Nursing Initiatives

New Jersey-Bermuda Perianesthesia Nursing Collaborative

Linda Wilson, PhD, RN, CPAN, CAPA, BC, CNE, CHSE-A, ANEF, FAAN, USA
Helen S. Kane, MSN, MBA, RN, CCRN, USA

Abstract

This session will present the New Jersey Bermuda Perianesthesia Nursing Collaborative which is a professional specialty nursing collaboration between perianesthesia nurses in the state of New Jersey and the county of Bermuda.

Collaboration initiated with the desire for the Bermuda perianesthesia nurses to be formally active in the specialty of perianesthesia nursing which required membership in a formal state or country based perianesthesia nursing specialty organization. International nursing partnerships require extensive foresight and planning to create partnerships that are beneficial for all parties involved (George & Meadows-Oliver, 2013). Several collaborative meeting took place between the New Jersey perianesthesia nursing leadership and the perianesthesia nurses of the country of Bermuda to develop the plan for this formal collaboration. The decision was made to develop a collaborative formal professional nursing specialty organization for perianesthesia nurses in Bermuda as well as New Jersey and surrounding states in the United States.

The priorities for this New Jersey Bermuda perianesthesia nursing organization included all aspects of perianesthesia nursing including clinical practice, research, standards, education, networking, certification information, professional resources and much more. Once formalized, the Bermuda perianesthesia nurses joined the New Jersey perianesthesia nurses as active members of this collaborative. Bermuda perianesthesia nurses are eligible to run for office and serve in any capacity on the organizations' board of directors.

The New Jersey Bermuda Perianesthesia Nurses Association (NJBPANA) offers an educational continuing nursing education conference every fall and spring in the United States and an international conference at least every other year in Hamilton, Bermuda (NJBPANA, 2016). The international conference in Bermuda is planned collaboratively with the Bermuda perianesthesia nurses and includes presentations from experts both in the United States and Bermuda. The perianesthesia nurses from the United States and Bermuda also have the opportunity to meet and network annually at the American Society of Perianesthesia Nurses national conference which is held at a different location throughout the United States every year.

The biggest challenge for this international perianesthesia collaborative is the distance between the state of New Jersey in the United States and the county of Bermuda. This organization was able to overcome this challenge with the use of technology, ongoing networking and collaboration as well as continuing education conferences being offered in both the United States and the country of Bermuda. This international perianesthesia nursing collaborative has been very successful and has already had one President from the Bermuda perianesthesia nurses. The board of directors for this collaborative continue to look for ways to increase participation, enhance resources and monitor outcomes.

Q 02 - Professional Nursing Initiatives

Exploration of the Impact Undergraduate Health Policy Education Had on Nurses' Political Astuteness and Involvement

Carol Ann Amann, PhD, RN-BC, CDP, FNGNA, USA

Abstract

A common barrier to political or health policy involvement is related to the lack knowledge and preparation of nurses to become involved in health policy and politics. Political competence and mentoring is considered a necessary component of nursing education if nurses are expected to be active within the political arena (Ferguson & Drenkard, 2003). To effectively promote health policy, professional nurses need introductory knowledge of the political environment. When offered in undergraduate nursing programs, the education is constrained in scope and practice to a small number of baccalaureate nursing students during their formal education. Practicing nurses who desire to further their knowledge and expertise through mentoring programs in health policy are hampered by insufficient numbers of nursing professionals and mentors within this specialty (Spenceley, Reutter, & Allen, 2006).

Current research has been limited to non existent on this subject matter. To further explore these findings a phenomenological research study was completed to determine the impact an undergraduate baccalaureate level nursing course in health policy and political involvement had on registered nurses political astuteness and involvement. The study was conducted using a purposive sample of registered nurses who were prior nursing students enrolled in a health policy course. Of the 24 students enrolled, 21 students participated in the research. An open-ended question format using nine semi- structured questions was formulated to guide the interview session for the purpose of this research. Five overarching themes emerged: (1) Education as a Foundation to Political Advocacy, (2) Health Policy Involvement, (3) Characteristics of a Politically Involved Nurse, (4) Perceived Barriers to Political Involvement, and (5) Academia Leading the Way. Results indicated that health policy education was a valued component of the registered nurses undergraduate education. Participants utilized their health policy/political foundation to pursue health policy roles within their health care organizations and on a local, state or federal level to positively impact health policy. Obstacles to health policy/political involvement were identified as organizational barriers, fear of retribution, shortage of mentors, and lack of time were the primary deterrents to nurses involvement in health policy/political activity.

Q 03 - Promoting Alternative Health Practices

Patients Being Weaned From the Ventilator: Positive Effects of Guided Imagery

Frank McVay, BSN, RN, USA
Elizabeth Spiva, PhD, MSN, BSN, RN, USA
Patricia L. Hart, PhD, RN, USA

Abstract

Background/Significance: Mechanical ventilation (MV) is a life-sustaining treatment for respiratory compromised patients with an estimated cost of \$27 billion a year. Patients requiring MV may experience anxiety, psychological and emotional distress and delusional memories. Guided imagery may reduce the frequency and severity of these symptoms. Therefore, a study was conducted to assess the effects of guided imagery on sedation levels, sedative and analgesic volume consumption, and physiological responses of patients being weaned from mechanical ventilation and to assess nurse perception of feasibility and satisfaction of using guided imagery as an intervention

Methods: Forty-two patients were selected from two community acute care hospitals. One hospital served as the comparison group and provided routine care (no intervention) while the other hospital provided the guided imagery intervention. The intervention included two sessions, each lasting 60 minutes, offered during morning weaning trials from mechanical ventilation. Measurements were recorded in groups at baseline and 30- and 60- minute intervals and included vital signs and Richmond Agitation-Sedation Scale (RASS) score. Researchers developed four questions addressing feasibility and satisfaction for using guided imagery as intervention; survey rated on 5-point Likert scale. Nurses directly involved with patients receiving intervention completed surveys.

Results: Sedative and analgesic medication volume consumption were recorded 24 hours prior to and after the intervention. The guided imagery group had significantly improved RASS scores and reduced sedative and analgesic volume consumption. During the second session, oxygen saturation levels significantly improved compared to the comparison group. Guided imagery group had 4.88 less days requiring mechanical ventilation and 1.4 reduction in hospital length of stay compared to the comparison group. Of 42 surveys distributed, 23 nurses (55%) completed survey with mean scores for each question ranging from 4.09 to 4.83. Nurses felt guided imagery was an effective nursing intervention ($M = 4.83$, $SD = .39$), successfully incorporated into weaning process ($M = 4.09$, $SD = .95$), simple to implement ($M = 4.13$, $SD = 1.0$), and intervention met intended purpose ($M = 4.09$, $SD = 1.08$).

Discussion: Guided imagery may be a part of the multimodal treatment approach and serve as a substitute to administering high doses of sedatives to assist with keeping the patient calm and relaxed. Nurses perceived the intervention as effective and easily incorporated into the weaning process.

Conclusion: Guided imagery may be complementary and alternative medicine intervention to provide during mechanical ventilation weaning trials. Guided imagery appeared to be an effective, safe and feasible intervention to use in patients being weaned from mechanical ventilation.

Q 03 - Promoting Alternative Health Practices

Promoting a Restraint-Free Culture Through Sensory Modulation

Colleen Marie Glair, MSN, RN, PMHCNS-BC, USA

Caitlin E. Belvin, MS, OTR/L, USA

Marnie A. Dodson, MSN, RN, USA

Abstract

The American Nurses Association (ANA) promotes registered nurse participation in reducing patient restraint and seclusion in health care settings. Restraining or secluding patients either directly or indirectly is viewed as contrary to the fundamental goals and ethical traditions of the nursing profession, which upholds the autonomy and inherent dignity of each patient (ANA 2012). The American Psychological Nurses' Association (APNA) supports the psychiatric-mental health nurses', critical role in the provision effective treatment and milieu leadership to maximize the individual's ability to effectively manage potentially dangerous behaviors in the psychiatric setting (APNA 2014). The profession of occupational therapy emerged from some of the earliest restraint and seclusion efforts, realizing the need for more humane and nurturing interventions for people with mental health and rehabilitation needs (AOTA, 2014). Sensory modulation is a client centered approach used by occupational therapists to help individuals who are distressed and agitated regain a sense of calm by using a range of tools to moderate sensory input (Champagne, 2004 and 2011) Regulatory standards from The Joint Commission require staff to be able to demonstrate strategies to identify staff and patient behaviors, events, and environmental factors that may trigger circumstances that require the use of restraint or seclusion as well as the use of nonphysical intervention skills (TJC, 2010). Given the safety, ethical, professional, regulatory and legal standards related to reducing restraint, it is imperative that alternative, evidenced based strategies be employed throughout our health care settings.

Sensory Modulation teaches patient's self-regulation skills and improves the rapport between staff and patients by giving them additional opportunities for therapeutic communication, prevention of escalation and aggression, and tangible alternatives to PRN medications. Trauma informed care is patient strength based approach to care, as a least ninety per cent of public mental health consumers have been exposed to trauma (Felitti V. J. & Anda R. F. 2010). Instead of talk based therapies sensory approaches provide experiential opportunities to help individuals recognize and regulate their unique sensory experiences. By using sensory modulation strategies in combination with a trauma informed approach to care, patients can feel empowered by identifying their own individual preferences and can feel more secure knowing that staff will work with them during times of crisis to prevent seclusion and restraint episodes. Patients can also identify their own signs of escalation and aggression and alternative methods for coping during times of stress which can translate beyond the inpatient setting and can be used at home after discharge. Additionally, is that nursing staff can feel empowered with the knowledge provided by patients and suggest patient identified methods of calming during times of stress instead of blindly offering cookie cutter suggestions and care based on tradition instead of evidenced based care.

A sensory modulation program was developed and implemented on the inpatient behavioral health unit at Virginia Hospital Center in 2016. The process utilized a team collaborative approach with input from patients, nursing, occupational therapy, quality management, infection control, clinical practice committee, employee health, environmental services, and the department of facilities and engineering. A designated sensory space was created on the unit; equipped with a glider chair, beanbag chairs, a large mural, and a multitude of sensory supplies. The development of online training modules on sensory modulation and trauma informed care augmented the initial implementation of personalized safety and crisis prevention forms completed collaboratively by both the patients and staff. Individual sensory modulation competencies were completed by nursing and therapy staff. Trained staff, in collaboration with occupational therapy, presently provides bi-weekly recovery plan review groups with the patients to emphasize the use of sensory modulation in recovery.

Data was collected on restraint usage on the behavioral health unit from January 2015, through June 2016. Following institution of the program in January 2016, there has been a decrease in total numbers of

restraints on the unit. Data was also collected on the number of behavioral health staff injured due to workplace violence injuries involving patients and the number of restricted and lost work days as a result of injuries from January 2015, to the present.

Results suggest that the use of sensory modulation is an effective strategy in decreasing patient agitation; employee workplace violence related injuries and lost or restricted workdays due to injury. This has allowed for proper staffing in order to provide safe and high quality patient-centered care. Additionally, the application of sensory modulation could reach beyond the inpatient behavioral health setting and be implemented for patients on acute care units throughout the hospital in the future using sensory carts. Furthermore, there are additional implications for utilizing sensory modulation, as a self-care strategy to decrease provider stress is also an avenue, which holds promise.

Q 06 - Global Surgical Safety Concerns

Prevention of Retained Surgical Items: Practice of Surgical Counts in Rwandan Operating Rooms

Gilbert R. Karonkano, RN, Rwanda

David Ryamukuru, RN, Rwanda

Joselyne Mukantwali, RN, Rwanda

Thierry Uwera, RN, Rwanda

Emmanuel Munyaneza, RN, Rwanda

Eric Sindayigaya, RN, Rwanda

Anita Collins, PhD, RN, RM, Rwanda

Abstract

Introduction: Patient safety is a global healthcare challenge, and surgery, in particular, is a dangerous procedure to human health (Andrew Howard, n.d.; Carvalho et al., 2015). Worldwide, annually, over 234 million surgical operations are performed with an average complications rate of 3–16%. This rate is not only a major cause of morbidity and mortality, but also a major financial burden for both the patients and their families. This also affects the healthcare facilities and their personnel (Melekie & Getahun, 2015). Prevention of surgical retained item (RSI) is an important responsibility of a surgical team. RSI prevention results in positive surgical outcomes and prevent unnecessary cost and long hospital stay. (Norton, Martin, & Micheli, 2012). RSI is serious adverse event and may include sponges, sharps, and instruments. An RSI is never-event resulting from unintentional occurrence in which surgical item is left in a patient during the course of surgical or invasive procedure and is associated with serious negative patient surgical outcomes that may end in death (Steelman, Schaapveld, Perkhounkova, Storm, & Mathias, 2015; Spruce, 2016).

Among others RSI prevention strategies, surgical count remains the most accessible and reliable way to avoid unintentional retention of surgical item. This high risk and high frequency operating room exercise requires multidisciplinary team involvement and attention to guiding police and procedure (Edel, 2012). The surgical count consists of counting the instruments, sponges, sharps, and other supplies used during a surgical procedure. Failure of performing this very crucial task to patient safety is associated with many complications after surgery (Moss, Kneedler, Pfister, & Major, 2014). This paper is a report from the one month experience of the Peri Operative students of the MSN program in operating rooms in Rwanda, with emphasis on surgical count

Purpose: The purpose of this paper is to study the current practice in operating rooms of Rwandan hospitals to better understand surgical count in Rwandan context in order to improve the vital element of surgical patient safety. Studies such on adherence to recommended count practice procedure, nature and incidence of breakdown in surgical count, effect of standardizing surgical count documentation, impact of available resources such as policy and supply may enlighten the surgical count situation in Rwanda and improve the safety of the surgical patient.

Method: Six Peri Operative track students of the MSN program along with their supervisor spend a month in the operating rooms in Rwanda and under took the project of recording their experience in relation to the practice of surgical counts in the operating rooms. The students spent ten hours for 3 days in a week with an hour for lunch break. They were posted in the Reception, Holding area, Induction room, PACU and Scrub room.

Based on the clinical experience in different operating rooms in Rwandan hospitals and reflecting on how the surgical count should be as per recommended practice, the students were able to come up with recommendations for further in-depth study in the prevention of retained surgical items in operating rooms in Rwanda

Conclusion: Surgical count remains the vital intervention for prevention of RSI. WHO, AORN, American college of surgeons and Joint commission recommend to use the surgical count protocol for all surgical

procedure with risk of RSI. Though there is some technological advancement toward prevention of RSI, manual counting is still the key intervention for RSI prevention.

Current practice in ORs of Rwandan hospitals reveals necessity to better understand surgical count in Rwandan context in order to improve the vital element of surgical patient safety. Studies such as adherence to recommended count practice procedure, nature and incidence of breakdown in surgical count, effect of standardizing surgical count documentation, impact of available resources such as policy and supply may enlighten the surgical count situation in Rwanda and improve the safety of the surgical patient.

Reducing inconsistency in surgical count practice requires health institutions to develop clear and concise policies and procedures to guide OR surgical teams on this. Furthermore, OR surgical team members should benefit OR safe practice teaching sessions that include among others; surgical count, teamwork and communication.

R 01 - Developing Nurse Leaders

Clinical Nurses and Executive Leaders Collaborating at the Bedside to Eliminate Hospital-Acquired Pressure Injuries

Patrice Duhon, MSN, RN, USA

Barbara J. Mayer, PhD, RN, CNS, USA

Abstract

Background: Hospital acquired pressure injury (HAPI) rates have not changed in the last eight quarters despite a large investment made in equipment and supplies, as well as education and training at a large academic teaching hospital. Clinical Nurses Leaders who pay close attention to work conditions and work environments give employees access to sufficient resources to be able to do their work effectively and have better organizational outcomes (Rich, LePine, & Crawford, 2010). Leaders that create work environments and work conditions that encourage employees to be self-motivated, assume responsibility for their job role, and provide opportunities for growth and development will have a higher level of productivity. Employee engagement is a key factor that helps to match the employee's values and beliefs with the organizational values and goals. Employees who are most likely to be engaged in job performance are the ones that believe their jobs have meaning and they are provided the tools to be successful (Joo, Jeung, & Yoon, 2010).

Aim: The goal of this project was to reduce the incidence of HAPI using a collaborative, shared-decision making approach between executive leaders, nursing managers, wound experts, and clinical nurses.

Methods: The Nursing Quality department's initial assessment revealed variability in structure, and variability in process of initial identification, reporting, assessment, and documentation of HAPI's. Clinical nurses, executive leaders, wound experts, and nurse managers formed a workgroup to identify the root cause of the current state problem, develop counter measures, design future state, and develop an implementation plan. A collaborative process called HAPI alert and Pressure Injury Prevention (PIP) Alerts was created. The purpose of the PIP alert was to assist the clinical nurses with diagnosing, staging, and implementing a treatment plan for Stage I/II, or Suspected Deep Tissue Injury (sDTI) pressure injuries. A communication algorithm was followed, alerting the unit manager, charge nurse, and clinical nurse specialist to respond to the bedside to determine treatment options. A HAPI Alert is activated when a stage III, IV, or unstageable PU is suspected. The team, consisting of the clinical nurse, unit manager, Chief Nursing Officer (CNO), Unit Director, Quality Manager, and Wound Ostomy Certified Nurse (WOCN) meets at the bedside to discuss the mechanism of injury, prevention strategies in place, the current condition of the patient, and any barriers to success.

Results: Since May 2014, 52% reduction in PU incidence and prevalence, virtual elimination of Stage III/IV PU, a potential cost savings of \$3,000,000.

Conclusion: Pressure injury prevention takes a collaborative approach from all levels of nursing. Continuous evaluation and individualization of processes are essential to delivering safe and effective patient-centered care. It is clear that implementing change in an organization is not an easy task but must be planned and calculated to be successful. Leaders who allow staff to be part of the decision making process are often successful with managing resistance to change. Implementing the HAPI alert team encouraged organizational leaders to work with the bedside workforce to come up with solutions collaboratively to reduce HAPI. When employees have a clear understanding of their job roles and responsibilities, accountability can be placed on performance and increased engagement occurs. This in turn motivates the staff to practice excellence and improve outcomes. This collaborative process is a best practice that is replicable in any health care organizations.

R 01 - Developing Nurse Leaders

Developing Future Nurse Leaders Through Shared Governance

Janette Moreno, DNP, RN, CCRN-K, NEA-BC, USA
Anita S. Girard, DNP, RN, CNL, CCRN, CPHQ, NEA-BC, USA
Wendy Foad, MS, BSN, RN, NEA-BC, USA

Abstract

Background: With the rapid transformation of the healthcare delivery system and the uncertainty of the number of nursing workforce, the country may be faced with nurses unprepared to assume key leadership positions. Approximately 67,000 nurse managers are expected to retire in five years (1). The difficulty in filling the nurse manager position may adversely impact the nursing work environment and the quality of patient care. Assessment of current state in an academic medical center showed that the time to fill the Assistant Patient Care Manager (APCM) position is approximately 215 days in 2014. The estimated cost of the turnover of nurse managers is approximately 75–125% of their annual salaries. **Action Taken:** Succession planning (SP) is an essential organization strategy that has emerged as a result of the impending nursing leadership shortage. A comprehensive literature review was conducted using the evidence-based succession planning framework by Titzer and Shirey. In 2014, the Shared Leadership Councils (SLC) implemented structure and processes based on the evidence-based SP framework, which consisted of four phases: assessment, planning, implementation, and outcomes monitoring. The strategic interventions were leadership development sessions, experiential learning, coaching/mentoring. The monthly 8-hour council days provided the council members experiential learning, leadership development, and coaching. Individualized leadership competencies were identified and a structured monthly leadership development program was implemented. **Outcomes:** The four components of a balanced scorecard used to evaluate the program were decrease number of days to fill vacant positions due to internal promotion, internal processes such as leadership bench strength, leadership competency progression, and participant perception based on Kanter's structural empowerment components. After 18 months of implementation, 32 SLC members were promoted to Assistant Patient Care Managers (APCM) (16) and other leadership positions (16). Internal promotion of SLC members to APCM positions resulted to a decrease in the number of days to fill vacant APCM position from 215 days to 23 days. Council members on the professional nurse development program increased from 22 to 45, indicating increased in leadership bench strength. Based on the pre and post assessment survey results, there is a statistical difference in the participant perception as a leader ($p = 0.0001$), indicating an increase in perception as a leader overtime. A statistical difference was also noted on the participant project ($p = 0.04$) and committee participation ($p = 0.03$), indicating increase involvement in continuous process improvement. The post survey on Kanter's structural empowerment components indicated statistically significant difference on the top box score ($p < 0.05$) as compared to the pre-survey, signifying higher perception on access to support, resources, information, and opportunities to learn and grow. The evidence-based SP framework is applicable in any settings as the organization aim to develop succession planning at all levels of care.

R 01 - Developing Nurse Leaders Nurses at the Forefront of Integration

*Jill Case-Wirth, MHA, BSN, RN, USA
Elizabeth Spiva, PhD, MSN, BSN, RN, USA*

Abstract

With government regulations and reimbursement pressures, health systems are looking for efficiencies that will lead to higher quality, improved access to healthcare and lower cost. On December 1, 2015 we signed an agreement to purchase five hospitals and assume the lease of another. Over the next four months, nurses took on significant integration-related roles and responsibilities. They followed a tight timeline with key activities, deliverables, and milestones to achieve for each phase of the integration from Day 1 pre-planning, scoping, validation, finalization and execution, to post-planning. The primary objectives of Phases I (due diligence), II (Day 1) and III (stabilization) were to minimize changes to current state operations while promoting operation continuity and to limit interruptions to patient care.

Guiding principles, governance structure, roles and responsibilities, and issue escalation process were initially established. Local leaders were identified to drive requirements including addressing situations that posed imminent risk to patient safety or required immediate action to minimize Day 1 disruption. As planning progressed, Day 1 requirements were refined. Additional items were identified as Post-Day 1 and supported business performance but were not critical to patient safety and operations on Day 1. These items were documented and addressed in Phase III. Nurses collaborated to create work plans and guide team efforts. Meetings included contract negotiation; workforce recruitment; planning and deploying systems, for example, nurse scheduling, payroll and accounting; cutover plan and the need for a command center to ensure downtime procedure and operations were supported during the first week of go-live. Thereafter, weekly conference calls and site visits were conducted with all levels of leadership and staff to provide updates and answer questions.

During Phase III, specialty-specific standardized, evidence-based practice tools were created to assess clinical practice. This included assessing care of the patient (entry to discharge); evaluating practice (including but not limited to emergency, perioperative, behavioral health and critical care); practice and regulatory standards; policies; competencies; workflow; technology/equipment; resources; staffing models; and environment of care/safety. Lean methods were used including process maps to plan granular steps which allowed teams to look for waste in processes that could be eliminated. Also, fishbone diagrams to identify potential causes for issues identified in Phases I and/or II and these causes were listed on the diagram. The team utilized the 5-Why technique to drill down and identify the root cause of each problem. Once the root causes were identified, the team brainstormed potential solutions that would have the greatest impact on the problem. Solutions were prioritized using a PICK chart. This chart helped the team to identify which solution would have the greatest impact with the least amount of effort. Teams created action plans/timelines to implement improvements, strategies and best practices.

Outcomes of teamwork, communication and countless hours to plan for a smooth and effective transition April 1, 2016 included identifying, managing, and closing 330 operational items. Nursing in collaboration with information technology (IT) created, implemented and deployed one central operational command center and five satellite operational command centers for post go-live support. Operations continued to function normally with no operational issues related to transition and consistent emergency room patient volumes remained with fewer patients 'left without being seen' compared to baselines. Supply chain contracts increased by 1,743 and 3,400 contracts were transitioned over from one system to current. Supply chain item master increased by 30,000. New technology was deployed including an electronic medical record in 52 physician practices with 496 employees trained. Following the successful transition, we are 19,600 team members and 2,900 members physician network strong supporting 11 inpatient hospitals, 240 medical office locations, eight urgent care centers, two health parks (another under construction), 16 imaging centers, pediatric center, nursing centers, hospice and homecare.

Phase III (stabilization) included prioritization and inventory of future needs and integration opportunities including clinical practice assessment findings for a total of 243 clinical operational items. We successfully closed these items and transitioned to Phase IV (integration) and began taking a closer look at processes and structures to determine how we can most efficiently treat patients and meet our community's healthcare needs. Over the next several months to two years, we will continue to better stabilize, plan and optimize for a truly integrated healthcare system.

S 01 - Alternative Practices in Women's Health

Effects of Aromatherapy Massage on Pregnant Women's Stress and Immune Function: A Randomized Controlled Trial

Jen-Jiuan Liaw, PhD, RN, Taiwan

Abstract

Purpose: Good maternal health can help predict public health challenges for families, communities, and health care systems by preventing preterm birth or child disability and enabling children to reach their full potential. Therefore, it is essential for clinicians to pay special attention to women's health, especially during pregnancy. The study's aims are to examine the effects of aromatherapy massage on women's stress and immune function during pregnancy.

Methods: This longitudinal, prospective, randomized controlled trial recruited 52 healthy pregnant women from a prenatal clinic in Taipei using convenience sampling. The participants were randomly assigned to the intervention ($n=24$) or control ($n=28$) group using Clinstat block randomization. The intervention group received 70 minutes of aromatherapy massage once biweekly for 20 weeks; the control group received only routine prenatal care. In both groups, participants' salivary cortisol and immunoglobulin A levels were collected before and after the intervention group received aromatherapy massage (every month from 16 to 36 weeks gestation) and were analysed using enzyme-linked immunoassay.

Results: The pregnant women in the intervention group had lower salivary cortisol ($P < 0.001$) and higher immunoglobulin A ($P < 0.001$) levels immediately after aromatherapy massage than those in the control group, which did not receive massage treatment. The findings suggest that differences in the pretest salivary immunoglobulin A levels at 32 ($P = 0.002$) and 36 ($P < 0.001$) weeks gestation were significantly higher than those at 16 weeks gestation between the two groups.

Conclusion: Complementary therapies are being incorporated into current medical practice. This study presented evidence that aromatherapy massage could significantly reduce stress and enhance immune function in pregnant women. Our study evidence can guide clinicians or midwives in providing aromatherapy massage to pregnant women throughout the pregnancy. To promote maternal and foetal health, it is essential for clinicians to incorporate aromatherapy massage into prenatal clinical practice. Maternity health care teams could work with personnel certified in aromatherapy massage and provide individualized stress-relief interventions to pregnant women based on their needs. The educational programme for midwifery could include training on complementary therapies and educate more midwives in providing aromatherapy massage or other complementary therapies to help promote health in pregnant women.

S 01 - Alternative Practices in Women's Health

The Home Birth Summits: Finding Common Ground to Transform Policy and Practice

Judith Lothian, PhD, LCCE, FAAN, USA

Abstract

Background/Purpose: Although recent high quality research supports the value and safety of planned home birth for healthy low risk women (Cheney, M. et al, 2014; Olsen, O.& Clausen, J., 2012; de Jonge, A., van der Goes, et al, 2009; Janssen, P., & Saxell, et al, 2009), in the US planned home birth continues to be controversial and, although the rate of planned home birth is increasing, only slightly more than 1% of women in the US give birth at home. (MacDorman, M., Matthews, M. & DeClerq, 2014). Professional guidelines, health and hospital policy, legal and ethical issues, insurance coverage, regulation and licensure of birth attendants, and access to home birth reflect in powerful ways the controversy. In 2011, the major stakeholders including obstetricians, pediatricians, midwives, nurses, childbirth educators, lawyers, legislators, insurance companies, birth advocates, representatives from government agencies and women met to address their shared responsibility in providing safe maternity care across birth settings. This first Home Birth Summit set the stage for an unprecedented and effective collaboration of stakeholders that has raised awareness, and created policy and practice change. The purpose of this session is to present the process of finding common ground related to home birth and the policy and practice changes that resulted from this work.

Methods: A steering committee of major stakeholders planned the first Home Birth Summit with *Future Search*, an organization that helps stakeholders from diverse and often opposing backgrounds and viewpoints to untangle the issues and find solutions. Seventy stakeholders with influence and authority were invited to participate. The goal was to develop “common ground”.

Results: The Home Birth Summit stakeholders agreed on nine Common Ground Statements related to: autonomy and choice, inter-professional collaboration and communication, reductions in disparities and equality in access to care, regulation and licensure of home birth providers, consumer engagement and advocacy, inter-professional education, liability reform, research, data collection and knowledge translation, and physiologic birth. The statements provided the foundation for action.

The presentation will discuss these common ground statements and 12 major outcomes:

- ACNM and ACOG approved joint guidelines for Transfer (home to hospital).
- Presentations nationally and internationally (International Congress of Midwives, Normal Birth conferences, ACNM, AWHONN, Lamaze International, Sigma Theta Tau Research, ACOG conferences).
- ACNM's consumer statement on normal physiologic birth and the BirthToolKit (Oct. 2014).
- ACNM's Healthy Birth Initiative.
- A renewed focus on the importance of normal physiologic birth from major organizations, like AWHONN's *Go the Full Forty* (2012-ongoing).
- ACOG updated their statement on planned home birth acknowledging women's right to choose their place of birth and calling for seamless transfer of women from home to hospital. August 2016.
- The *Institute of Medicine* meeting on Place of Birth was held in March 2013.
- The *Journal of Clinical Ethics* released a special issue on planned home birth in October 2013
- An increased number of insurance plans cover planned home birth
- An increase in research, both qualitative and quantitative, on planned home birth including the largest ever study of US planned home birth (Cheney, et al, 2014), and a MANA dataset on home birth.
- Publication of articles in major nursing and medical journals.
- The *Lancet* special issues on midwifery in July 2014 and summer 2016.
- ACNM and ACOG joint statement on collaborative practice with both nurse midwives and certified professional midwives.

Conclusions: The model of finding common ground among stakeholders of influence and authority holds promise as a creative and effective way to find solutions when there are competing interests that make evidence based policy and practice change difficult. This might be an effective strategy for nursing to consider.

S 02 - Health Practices for Immigrants

Impact of Social Support and Stress on Blood Pressure Among West African Immigrants

Ruth-Alma N. Turkson-Ocran, MPH, MSN, RN, FNP-BC, USA

Yvonne Commodore-Mensah, PhD, RN, USA

Ozioma A. Amadi, BSc, MPH, USA

Abstract

Purpose: Stress negatively impacts health outcomes of individuals and social support is essential for the maintenance of both physical and mental health. Chronic stress has been linked to hypertension and atherosclerosis which result in the development of cardiovascular disease.¹ Adequate social support has been linked to resilience to stress, decreased morbidity and mortality. Social support is an important aspect of immigrants' adaptation to a new environment and has been shown to positively influence their health status and well-being.² Higher social support is associated with a lower likelihood of hypertension in racial/ethnic minorities and immigrants. Stress has been associated with cardiovascular disease disparities in persons of African ancestry.³ West African immigrants (WAIs) are one of the rapidly growing racial/ethnic minority groups in the United States (US) but are an understudied, vulnerable population.⁴ Despite being at an increased risk for hypertension upon migration to the US, little is known about the impact of stress and social support have on blood pressure in WAIs. The purpose of this study was to examine the relationship between social support, stress, and blood pressure in a sample of WAIs.

Methods: In this pilot, community-based study, we examined the association between social support, stress, and mean systolic blood pressure in first-generation WAIs (N=59) residing in the Atlanta metropolitan area. Social support was measured by the 7-item Enhancing Recovery in Coronary Heart Disease (ENRICH) Social Support Inventory (ESSI7). Scores for the ESSI7 range from 8 to 34 with higher scores indicating higher levels of social support. Stress was assessed using the Perceived Stress Scale (PSS), scores on this scale range from 0 to 40 with a score of 20 and above indicating higher stress. We fitted multivariable linear regression models to examine the associations between social support, stress, and systolic blood pressure after adjusting for known confounders.

Results: The participants' ages ranged from 36 to 76 years; the mean age(\pm SD) of the sample was 47.2(\pm 9.9). Females made up 61% of the sample and 59% of the participants were born in Nigeria. Fifty-two percent of the participants had a household greater than \$50,000 despite at least 78% having at least a college education and only 68% had any health insurance coverage. A total of 36% of the sample were diagnosed with hypertension, 60% of these were being treated for hypertension. Eighty-three percent (83%) of those being treated had their hypertension under control. The mean(\pm SD) social support score in this study was 28.3(\pm 7.0) and the mean (\pm SD) Perceived Stress Scale score of the participants was 18.6(\pm 7.7). The mean(\pm SD) systolic blood pressure was 122.2(17.7). Social support was not significantly associated with systolic blood pressure. An inverse association was observed between perceived stress and mean systolic blood pressure ($r^2 = -0.295$, $p = 0.023$). This negative association persisted in a multiple linear regression model after adjusting for age, sex, BMI, and income ($\beta = -1.07$; 95%CI: -1.68, -.45; $p = 0.001$)

Conclusion: An inverse relationship was observed between perceived stress and mean systolic blood pressure, but there was no association between social support and mean systolic blood pressure. This finding is consistent with the findings of earlier studies and suggests that chronic stress in WAIs may lead to habituation and adaptation. Additional research is needed to examine the mechanisms by which stress impacts blood pressure among WAIs and examine the role of protective factors such as resilience to stress among WAIs.

S 02 - Health Practices for Immigrants

El Sol: An Interdisciplinary Center for Guatemalan Healthcare

Terri Rocafort, PhD, ANP-BC, USA

Abstract

The global migration of vulnerable populations influenced by both safety and economic factors in their home countries has developed into opportunities for interdisciplinary healthcare approaches to emerge in Jupiter, Florida. South Florida has a plethora of cultures. The My Clinic health project represented will describe a successful interdisciplinary care model implemented to care for undocumented Guatemalans within a local community. The undocumented workers in Jupiter are primarily from Jacaltenango, a valley town in the Huehuetenango region of the Western Highlands in Guatemala. The initial migration patterns began in the 1980's when political asylum and safety drove Guatemalans to South Florida ("El Sol," 2013) with migration centralizing to Jupiter, Florida during a period of economic growth. Jupiter has a 16% population of Hispanics with 10% of Hispanics assumed to be 200% below the poverty line. The El Sol Center came to existence in 2006 with concerned community leaders and the workers participating in solutions to benefit all persons residing in the village ("El Sol," 2013). In the period of a decade, the El Sol Center has developed a multifaceted approach to meet the needs of the vulnerable within the community. Fueled by interdisciplinary support of the healthcare community, El Sol has evolved to include My Clinic designed to meet the primary healthcare for the Guatemalan community in tandem with low income people in the local geographic area. El Sol has implemented programs utilizing educated community healthcare trainers, implemented ongoing educational classes, provides language, literacy and educational programs, and intersects successful nutrition programs including a community garden. Interdisciplinary collaboration is defined as "an interpersonal process characterized by healthcare professionals from multiple disciplines with shared objectives, decision-making, responsibility, and power working together to solve patient care problems" (Petri, 2010, p. 80). The successful interdisciplinary El Sol Center and healthcare aspect of My Clinic, will be presented and analyzed using the Life Course Theory (LCT). The LCT model includes three aspects for clinicians including 1) a whole-family, whole-community approach addressing social determinants of health, 2) to address early upstream determinants of health, and 3) participate in longitudinal, vertical, horizontal integration of services within medical and other service sectors (Fine and Kotelchuck, 2010). The development of My Clinic in 2013 was a natural progression of El Sol services developing longitudinally from identified needs amongst the population. Careful analysis and statistics of healthcare referrals grew annually and provided an impetus to consider developing a primary care clinic. A whole community approach was used with an interdisciplinary team inclusive of community leaders, insurance providers, physicians, Jupiter Medical Center, community volunteers, and El Sol directors. My Clinic focuses on primary care and health promotion, and disease prevention recognizing the economic impact of the services on the local community overall. The successful implementation of My Clinic resulted from the integration of healthcare services coupled with local foundation funding, volunteer advanced nursing and medical care, collaboration with the county health department, medical center, and social services. The model demonstrates longitudinal, vertical, and horizontal integration of services with multiple service sectors. Interprofessional collaboration remains a focus for nursing to impact population health (AACN, 2004). Globalization and migratory patterns presents unique opportunities for nurses within the local community of Jupiter, Florida. The role of nursing at the My Clinic includes nurse educators and volunteers, advanced nurse practitioners providing primary care, diabetes educators, and nursing within specialties at medical centers, and medical specialty locations. Information gleaned from the implementation of the El Sol center and presented from the Life Course Theory approach may be used by nurses worldwide in caring for a diverse migratory and vulnerable population.

S 03 - Workplace Cultures

Setting the Scene for Workplace Mental Health Promotion in a Swaziland Sugar Mill

Agnes A. Huiskamp, MA (Nsg), RN, RM, RPN, South Africa
Sifiso Manana, BA (Nsg), RN, Swaziland

Abstract

Purpose: The purpose of the study was to provide a descriptive summary of the mental health promotion needs related to the workplace of sugar mill factory workers in Swaziland.

Methods: A qualitative descriptive design was used and unstructured in-depth interviews were conducted with 20 purposively selected factory workers. Two questions were asked of the participants namely *Please tell me about your mental health (impilo yakho yengcodvo)* and *what do you think the workplace can do to help improve your mental health?* To clarify answers and responses probes were used to enrich the participants' descriptions. Data collection and analysis occurred concurrently until data saturation was achieved. The interviews were transcribed verbatim immediately after the interview and Tesch's (1992) method of data analysis was used.

Results: Two themes emerged from the interviews namely: Factors that influence mental health negatively (stressors) and mental health promotion needs in relation to the workplace. A major stressor for most of the participants was an inadequate salary. Other work related stressors that emanated from the data were heavy workloads and long hours, management style and approach, communication in the workplace and employee development. The factory workers were of the opinion that an increase in salary, improvement in conditions of employment and enhanced management and communication skills will ease the stressors. Furthermore, the participants indicated that health education and life skills education on financial management, mental health and stress management can facilitate the promotion of their mental health.

Conclusion: Mental health was not a familiar concept to the factory workers however stress was better known. Factory workers experience diverse conditions in the workplace as stressful. Economic factors such as the salary received caused a lot of stress for most participants. Factory workers want to learn more about mental health, stress and financial management and are of the opinion that if there is improvement in their working conditions and communication skills of supervisors and managers a more mentally healthier workplace can be created. The study can potentially set the scene for workplace mental health promotion gaining momentum in Swaziland.

S 03 - Workplace Cultures

Building the Healing Organization: Strategies for Successful Implementation, Cultural Transformation, and Sustaining High-Value Outcomes

Marie M. Shanahan, MA, RN, HN-BC, USA

Ann Marie Leichman, MSN, NEA-BC, USA

Veda L. Andrus, EdD, Hn-BC, USA

Abstract

Purpose: Becoming a healing organization for patients, families, employees and providers was the long-term goal of nursing leadership at this facility, a 451-bed full service acute care metro area US hospital. Re-awakening the team to the art of nursing occurred by engaging frontline nurses in a personal-professional transformation facilitated through an educational collaboration with nurse experts. Over a period of 15 years, nursing at all levels and all specialties developed, evolved and evaluated the infrastructure and practices that would result in a seismic culture change across acute and outpatient services. Today, this award winning and Magnet™ designated organization is recognized as national resource for holistic and integrative patient care (Christianson, Finch, Findlay, Jonas & Choate, 2007). In this presentation, the speakers will outline the route to success of this nurse-led innovation in creating the healing organization.

Background: The executive nursing team realized that an emphasis on technology coupled with an aggressive re-organization had created workplace stress and depleted the caring and compassionate internal resources of the nurse managers and clinical nurses. Nurses' ability to consistently deliver compassionate care is often impacted negatively by the stress they experience in the work environments (Dempsey, 2016). Patient satisfaction surveys bore this out and this in turn, captured the attention of several stakeholder groups within the organization. A call to action for re-infusing caring and empathy in nursing practice was answered by creating a partnership with experts in holistic nursing practice, integrative therapies and transformational leadership. Eliminating emotional exhaustion and burnout was a key objective within the nursing department in order to lower nurse stress levels, prevent widespread turnover and improve patient satisfaction (Van Bogaert, Clarke, Roelant, Meulemans & Van de Heyning, 2010). Holistic nursing was chosen as the foundation for the educational initiative due to its focus on nurse self-care and wellbeing and emphasis on caring-theory guided patient care.

Although holistic practice at this hospital began with a leadership vision, it quickly grew as a grassroots phenomenon that re-defined the usual methods employed to introduce organizational initiatives. The presentation will describe how nurse enthusiasm was nurtured while simultaneously providing the structure and practice standards needed to keep the vision growing, succeeding and measurable. A key to the organization's success was ensuring an evidence based approach to planning, engaging, educating, evaluating and guiding practice.

Approach, Structure and Process: Acknowledging the problem was the first step to engaging a weary nursing team. Honest discussion around the aftermath of organizational re-engineering on the team's nurse psyche and its effects on patient care opened the door to conceiving a plan to heal wounds and re-imagine a vibrant nursing workforce. What followed was house-wide development of a nursing vision calling for caring theory guided practice, nurse self-care and therapeutic healing environments that supported professional nurse growth and facilitated compassionate patient-nurse relationships.

With the nursing team energized around a holistic vision for practice, the nursing executives engaged nurse experts to deliver an educational platform that would transform nurse-to-nurse interactions, infuse greater caring in nurse-patient interactions and incorporate holistic and integrative therapies into patient care. (Shanahan, 2014). In addition, the educational methods had to support the shared governance process and have measurable outcomes. The nurse experts discussed the importance of nurse self-care as a key component to long-term engagement of nurses and a foundational component to the success of their vision. They included authentic communication, healing presence, psychoneuroimmunology, caring

theory, and spirituality in the curriculum that was delivered in-house to 25 nurses per cohort. The nurses were also taught personal renewal and resiliency skills to foster on the job support for nurse self-care.

As nurse participants cycled through the 4-session 10 month educational process, a Holistic Practice Council (HPC), reporting directly to the Professional Nurse Practice Council, comprising of cohort members and guided by the executive and expert teams was formed. The HPC was charged with developing appropriate policies and clinical integration standards for holistic practice based on the Scope and Standards of Holistic Nursing Practice (American Holistic Nurses Association and American Nurses Association, 2013). As the HPC matured, developing specific competencies and evaluation of practices were added to its scope. Critical to the success of the project was allowing the sequence and introduction of holistic practices to be determined by the HPC, to cultivate clinical nurse leadership through their shared governance model (Barden, Griffin, Donahue & Fitzpatrick, 2011).

Several interrelated components were responsible for the success of the project: a strong educational process that bridged leadership and frontline nursing concerns, expressed nursing leadership support, promoted grassroots enthusiasm and integration of holistic principles, and demonstrated significant achievement of organizational goals.

Outcomes and applications: Several outcomes of this culture change have occurred throughout the organization as a result of the initiative. A few of them are described in this abstract.

Professional Applications: Nurses are strongly encouraged to achieve certification and certified nurses are represented in all services area. There are now 75 (and growing) nationally board certified holistic nurses (HN-BC) and over 150 unit-based integrative healing resource nurses mentoring others in the organization. The holistic nursing certification rate is the highest of any organization nationally. The American Holistic Nurses Association recognized the organization in 2015 with its inaugural award for Institutional Excellence in Holistic Nursing. All nurses are taught the basics of holistic practice, beginning with interview screening and on-boarding orientation, and are required to attend a full day of education on holistic practice. To date, over 500 nurses have received the basic education and 260 have attended the in-depth 4 session program. Several nurses function in the role of full-time expert holistic practitioners promoting holistic practice throughout the organization. They are responsible for delivering integrative therapies to patients, families, nurses, providers and other employees. They meet with community groups and internal stakeholders. They keep abreast of current research in the field, updating practices, reporting to senior leadership and collecting data. Nurses in this organization apply evidence based integrative therapies in the treatment or promotion of patient surgical recovery, pain management, anxiety, sleeplessness, post-operative nausea, post chemotherapy nausea, maternal labor pain and anxiety, newborn restfulness and overall patient wellbeing. They combine therapeutic presence, holistic communication and assessment, guided imagery, clinical aromatherapy, music therapy, touch and energy therapies, medicinal harp melodies and pet therapies according to patient needs. They have presented their findings nationally and in publications.

Clinical application: Using the principle of holistic communication and leadership, the APRN leader of the Holistic Birth Program (HBP) sees pregnant women at several intervals prior to giving birth free of charge. Women and their significant others are introduced to multiple holistic interventions that are known to improve the birth experience, including relaxing hydrotherapy and aromatherapy. During the postpartum phase, the woman and her partner are provided with uninterrupted 2 hour bonding periods to encourage attachment. The HBP reported a C-section rate for spontaneous, term, vaginal, primipara, uncomplicated expected births of 14.2 percent compared to 36 percent for those not in the HBP.

Workforce application: A nurse PhD candidate studied the impact of nurse renewal room and reduction on nursing stress (Bodino, 2016). This organization has four nurse renewal rooms. Nurse renewal rooms are specifically designated spaces for nurses to rest and re-focus while they are on shift. Nurses are encouraged to use this space before, during and after their shift to avoid fatigue and enhance therapeutic presence. Nurses typically spend 15 minutes rejuvenating in these rooms in order to return to their patient care assignment relaxed and ready to re-engage with patients. There is a positive association between engaging in health promotion behaviors and the reduction of burnout (Neville & Cole, 2013).

Patient experience: The organization consistently surpasses state and national indices for the HCAHPS patient experience (most recently reported).

HCAHPS Questions	Hospital	State Average	National Average
Patients who reported their nurses "Always" communicated well	83%	76%	79%
Patients who reported their pain was "Always" well controlled	73%	69%	71%
Patient who gave their hospital a rating of 9 or 10 on a scale from 1 (lowest) to 10 (highest)	76%	64%	71%
Patients who reported YES they would definitely recommend the hospital	80%	66%	71%

Organizational application: Perhaps the most gratifying result of this healing initiative is the transformed culture. Nursing satisfaction is consistently high as is patient satisfaction. Especially telling is the impact on RN turnover and cost savings. In 2015, RN turnover rate stood at 9.0% in comparison to a national average of 17.1%. When compared to hospitals in the northeast region where the turnover rate stands at 14.6%, the cost avoidance for the organization is between \$2.1 million and \$3.2 million (as measured by the organization's CFO) when compared to hospitals with 350-500 beds on the national level.

Creating and maintaining a healing organization over time takes a comprehensive vision and commitment to caring and compassionate principles. It requires planning and executing with intentionality, creativity and the boldness to lead a path that is still unfolding. The impact of this path on the initially unforeseen creation of a healing organization is now clearly evident.

Prevalent Vitamin D Deficiency and Impact of Vitamin D Supplementation on Acute GVHD in HCT

Linda DuPuis-Rosen, BSN, RN, OCN, USA

Tara Coghlin Dickson, MS, RD, CSSD, USA

Abstract

Purpose: Vitamin D, an essential hormone with function ranging from mediating bone hemostasis to immune modulation, has been reported to be deficient in the majority of myeloablative allogeneic hematopoietic cell transplant (HCT) recipients and associated with diagnosis of chronic graft versus host disease (GVHD). There are two types of GVHD (acute and chronic) which carries a high mortality rate of 34% (Grade II-IV).

Current studies continue to support the finding that there is a high prevalence of vitamin D deficiency within HCT recipients. Rosenblatt et al [1] has shown vitamin D deficiency may increase the risk of acute GVHD due to the loss of known immunomodulatory effects of vitamin D. Ganetsky [2] reported that vitamin D deficiency measured at 30 days post-HCT was associated with increased risk of grade II-IV cutaneous acute GVHD ($p=0.05$). Ganetsky proposed that vitamin D might confer a protective effect against cutaneous acute GVHD via reduction in CCR4 expression. The concept of a protective effect may be best illustrated by Glotzbeker [3] who reported an incidence of chronic GVHD of 63.8% at two years post transplant in HCT recipients with a vitamin D level $<25\text{ng/ml}$, compared to an incidence of 23.8% in recipients with higher vitamin D levels ($>25\text{ng/ml}$, $p=0.009$).

We tested the hypothesis that vitamin D deficiency is associated with acute GVHD within 90 days after HCT.

Methods: Fifty consecutive allogeneic recipients were selected from the HCT database based on blood samples available pre-transplant, 30 days, and 90 days post HCT over two years. To gauge the impact of vitamin D levels in the HCT, we assessed vitamin D levels at three time points, pre-transplant, day +30 and day +90, for a total of 150 samples. The bio-samples were analyzed by liquid chromatography-tandem mass spectrometry (LC-MS/MS) for 25-OH vitamin D (D2, D3 and total). For analytical purposes vitamin D deficiency was defined as a vitamin D 25-OH level of less than 25 ng/ml. Clinical data was abstracted from the medical record with acute GVHD scoring system (already completed in patient records).

Results: Of the 50 patients, 74% had vitamin D deficiency (median 20 ± 8 ng/ml) pre-HCT, 86% had vitamin D deficiency at 30 days (median 16 ± 8 ng/ml, $p=.048$), and remained vitamin D deficient at 90 days post HCT (median 16 ± 10 ng/ml). Thirty percent of these 50 patients were diagnosed with Grade II-IV acute GVHD by 90 days post transplant. All patients with grade II-IV acute GVHD by 90 days had vitamin D deficiency (median 12 ± 6 ng/ml, range 5-23ng/ml, $p=.08$).

Conclusion: Given our findings as well as other recent research, it has compelled our Blood and Marrow Transplant (BMT) program to adopt a standard of care for monitoring and supplementing vitamin D. In developing our standard of care, we polled six BMT Centers across the US to identify their practice for monitoring and supplementing vitamin D. We learned that although many BMT centers were supplementing their patients, there were widely varying protocols among the centers. The frequency of vitamin D level checks were often inconsistent and the dosing for supplementation covered a wide range, and limited follow-up was reported. Implementation of the standard of care involved multiple forms of communication such as faculty meetings and updates, RN, APP and fellow in-services, RN coordinator meetings, newsletters, MD guidebook update, EPIC charting templates and smart phrases, communication between inpatient and outpatient teams, inclusion in pre and post transplant letter to referring MD. A vitamin D EPIC report was also developed to assess compliance outcomes and data analysis of adequate dosing.

Our implementation of the standard of care for monitoring and supplementing vitamin D occurred 18 months ago. We will continue to collect the data for two years to evaluate the impact of adequate vitamin D levels and its potential buffering of acute GVHD. Our hypothesis is that this new data will provide the needed evidence to elucidate the benefits of adequate vitamin D levels for the allogeneic HCT recipient population.

S 06 - Global Health Promotion

Screening Recommendations for Baby Boomers With Chronic Hepatitis C and the Uncertainties That Surround Them

Humberto Reinoso, PhD, FNP-BC, ENP-BC, USA

Abstract

Background: Globally approximately 130 to 184 million individuals are living with hepatitis C, which translates to one in every 12 individuals affected by viral hepatitis worldwide (Institute of Medicine [IOM], 2010). It is projected that anywhere from 3.5 to 5.3 million Americans living with viral hepatitis do not know they are infected (U.S. Department of Health and Human Services [HHS], 2011). Viral hepatitis infections are three to five times more frequent than HIV infections in the U.S. (IOM, 2010). Baby boomers, those individuals born during 1945 and 1965 comprise an estimated 27% of the U.S. population and account for approximately three-fourths of all hepatitis C infections (CDC, 2012). Uncertainty regarding the duration of an illness or its outcome has been reported as the greatest single psychological stressor for individuals with a life-threatening illness (Mishel, 1999). The majority of the time the diagnosis of hepatitis C is made when the individual is in the chronic stage of the condition and asymptomatic. The newly diagnosed chronic hepatitis C individual has to cope with the paradox of a new diagnosis of a chronic, sometimes advanced, condition. Chronic illness, in addition to chronic uncertainty as a psychological constant can have detrimental effects on an individual

Problem: The Institute of Medicine, the U.S. Department of Health and Human Services, the Centers for Disease Control and Prevention, and the U.S. Preventative Services Task Force have called attention to the silent epidemic of viral hepatitis. These scientific institutions have created action plans on prevention, screening, and treatment of individuals with viral hepatitis. New screening practices that target the baby boomer population are sure to identify numerous cases of chronic hepatitis C. There is a gap in the literature that fails to link the uncertainties faced by individuals diagnosed with hepatitis C and the factors attributing to those uncertainties.

Purpose: The purpose of this study was to explore new hepatitis C screening recommendations and to investigate the influence a set of predictor variables prescribed by Mishel's Uncertainty in Illness Theory had on baby boomers' perception of uncertainty.

Methods: A multiple regression analysis was used to determine if the independent variables (i.e., level of education, credible authority, social support, length of diagnosis, familiarity of events, and cognitive capacity) were predictors of the participants' level of uncertainty. Multiple regression analysis allows the researcher to predict one variable from several variables (Norman & Streiner, 2008). Data were collected by the researcher using a 53-item questionnaire. This questionnaire encompassed three standardized instruments, Mishel's Uncertainty in Illness Scale – Community Form (MUIS-C), Duke Social Support Index – Abbreviated (DSSI), the Health Care Orientation subscale of the Psychosocial Adjustment to Illness Scale – Self Report (PAIS-SR), and a researcher-designed demographic questionnaire. Data were analyzed using the Statistical Program for the Social Sciences (SPSS) 22.0 software.

Setting: The main recruitment procedures gather data from baby boomers that self identified as hepatitis C positive via virtual settings through the use of SurveyMonkey.

Results: Data were collected over an 8-week period from a convenience sample of baby boomers that self-identify as having hepatitis C ($N = 146$). Baby boomers aged 49 to 69 provided data for this study with an average participant age of 58 years old. The linear combination of the predictors revealed a significant regression model, $F(5,115) = 27.091$, $p < .001$, with a R^2 value of 0.54. Two of five predictors, credible authority ($\beta = .625$) and social support ($\beta = -.169$), were significant predictors of perceived level of uncertainty.

Conclusion: The majority of the time, the diagnosis of hepatitis C is made when the individual is in the chronic stage of the condition. The newly diagnosed hepatitis C individual has to cope with the paradox

and uncertainties of a new diagnosis of a chronic and sometimes advanced condition. Uncertainty, or the inability to structure meaning, can develop if the individual does not form a cognitive schema for illness events. A cognitive schema is the individual's subjective interpretation of illness, treatment, and hospitalization. By providing anticipatory guidance, healthcare providers are seen as credible sources of information and have the greatest influence on the individual's perception of uncertainty ($\beta = .625$). Social support shared an inverse relationship with uncertainty ($\beta = -.169$). Therefore, as social support increases, perceived levels of uncertainty decrease.

Implications: Study results contribute to the understanding of baby boomers diagnosed with hepatitis C and the uncertainties surrounding illness events. Viral hepatitis has been deemed the silent epidemic. Silence and uncertainty are a deadly combination. It is the responsibility of nurses to not only educate themselves, as credible sources of information but also to educate the general public and policymakers to break the silence and reduce uncertainty for those affected by hepatitis C. It is imperative for nurses and nurse practitioners to maintain current on practice guidelines and comprehend the role they play as liaisons of the healthcare delivery system. As liaisons, connecting individuals diagnosed with hepatitis C to treatment and resources in the community, nurses might further assist in navigating illness events and ultimately decrease uncertainty. Early identification and treatment of hepatitis C, as recommended by the scientific community, may reduce prevalence and complications of this condition.

A 07 - Disease Prevention in Oncology Patients

Development of a Decision Aid for Unaffected BRCA Mutation Carriers

Terri Jabaley Leonarczyk, PhD, RN, USA

Abstract

Purpose: Deleterious BRCA mutations confer high risks for developing breast and ovarian cancer (Chen & Parmigiani, 2007; Mavaddat, et al., 2013). For healthy women, diagnosis of a mutation is associated with emotional trauma, fear, and a sense of urgency to make health protective decisions. Cancer risk management decision making support needs are exigent and ongoing throughout the decision-making process. Women depict the process as a life journey (Jabaley Leonarczyk & Mawn, 2015). Priorities are survival, reducing the risk for cancer development, and maximizing quality of life (Stan et al., 2013). Making decisions necessitates a complex analysis of clinical variables, individual characteristics, and personal preferences. As emerging research elucidates the issues affecting cancer risk management decision making for BRCA+ women, guidelines evolve. Despite the rapid evolution of knowledge, evidence clearly supports risk management intervention. Primary health care providers, particularly those practicing in rural areas, lack resources for this population. Care may be fragmented, and specialists often view BRCA+ women through the lens of their specialty, neglecting the comprehensive approach needed (Jabaley Leonarczyk & Mawn, 2015).

Current decision support resources have various limitations. Clinical guidelines available online are not amenable to general population use, requiring a post graduate reading comprehension level and specialized knowledge in genomics and medicine (NCCN, 2016; Petrucelli, Daly, & Feldman, 2013; Schackmann, Munoz, Mills, Plevritis, & Kurian, 2013). In many studies, samples include both affected and unaffected mutation carriers, making it difficult to differentiate issues unique to each of these populations (Culver, et al., 2012; Llort, et al., 2015). Some resources do not address all options available to unaffected carriers (Metcalfe et al., 2007), and others exclude psychosocial issues impacting the decisional process (Petrucelli, Daly, & Feldman, 2013; Schackmann, Munoz, Mills, Plevritis, & Kurian, 2013).

The purpose of this study was to develop an evidence-based, comprehensive decision aid for women who are unaffected BRCA mutation carriers. Specific aims were to develop an aid based on decisional theory; consistent with internationally accepted clinical guidelines; at a reading level suitable for general population use; and to conduct an analysis of the aid.

Methods: The Ottawa Decision Support Framework (O'Connor, 2006) guided the development of the decision aid. According to the method recommended by Coulter, et al. (2013), the decision aid was developed by a steering committee and evaluated by twenty-two participants; seven experts and fifteen end users. Experts were genetic counselors and advanced practice nurses specializing in cancer genomics. End users were unaffected BRCA mutation carriers, recruited from the Facing our Risk of Cancer Empowered (FORCE), a support group for those with hereditary breast and ovarian cancer syndrome (HBOC). Quantitative and qualitative data were collected by survey.

Results: Expert reviewers were genetic counselors specializing in genetic cancer risk and advanced practice nurses specializing in cancer genomics. All were women. End user participants were all Caucasian women; all reported some level of college education; fifty percent reported a BRCA1 and fifty percent reported a BRCA2 mutation. The mean age of participants was 48.5 years; with an age range of 33-62. The mean time since receiving a positive BRCA mutation testing result was 5.2 years, with a range of 1-13 years. Results of the BRCA Decision Aid evaluation by expert reviewers revealed mean scores of 3.8 or higher on a four point likert scale from poor to excellent for organization, clarity, usefulness, comprehensiveness, and ease of understanding; and a mean score of 4.0 on a four point likert scale from not relevant to highly relevant for all sections of the decision aid. Results of the BRCA Decision Aid evaluation by end user reviewers revealed mean scores of 3.44 or higher on a four point likert scale from poor to excellent for organization, clarity, usefulness, comprehensiveness, and ease of understanding; and mean scores of 3.43 or higher on a four point likert scale from not relevant to highly relevant for all

sections of the decision aid. Qualitative data indicated an increase in knowledge among end users reviewing the aid and the acute need for the tool in clinical practice among both experts and end users.

Conclusions: Quantitative findings from this study suggest that the decision aid is well-organized, clear, comprehensive, and highly relevant to the cancer risk management decision making experience of unaffected BRCA+ women. Qualitative findings suggest that the decision aid is needed in practice and that it increases knowledge among end users. Through use of the decision aid with patients, nurses have a means of improving the quality and integration of care for unaffected BRCA+ women by guiding and coaching, clarifying values, and monitoring and facilitating progress in the cancer risk management decision making process. The aid prompts consideration of the unique values, characteristics and preferences of each BRCA+ woman and supports active collaboration of all members of the interdisciplinary team caring for unaffected mutation carriers.

A 07 - Disease Prevention in Oncology Patients

A Global Perspective: Meaning, Coping, and Health of Younger and Older Women with Breast Cancer

Kathleen A. Sternas, PhD, MSN, BSN, RN, USA

Abstract

Breast cancer is a major global public health issue. It is the most common disease in women worldwide and the leading cause of death in females including women in Argentina, Uruguay and Brazil (Brunello et al., 2008; Kalogerakos et al., 2014). Breast cancer is the most common cancer in women under 50 years old (Howard-Anderson et al., 2012; Trachtenberg, 2012). Mortality rates are higher for African American women at all ages (Phillips & Cohen, 2011). Cancer risk is rising because of increasing lifespan. More younger women are being diagnosed with breast cancer which is likely due to multiple factors including nutritional deficiencies, exposure to environmental toxicity, smoking, elevated estrogen. Breast cancer screenings are detecting more breast cancer (Centers for Disease Control and Prevention, 2011; Kalogerakos et al., 2014).

Breast cancer effects women's quality of life (Devi and Hegney, 2011). In younger women, breast cancer may require different interventions than for older women because cancers are more advanced, aggressive and often involve a genetic origin (Centers for Disease Control and Prevention, 2011). Younger women often have different issues than older women including body image, relationships and family life issues, career and financial concerns (Helms et al., 2008). Howard-Anderson, et.al (2012) found younger women experienced psychosocial, menopause concerns, weight gain, and physical inactivity. Trachtenberg (2012) found younger breast cancer survivors have issues older survivors do not face: early possible menopause, pregnancy after diagnosis, more advanced cancer, higher mortality rates contributing to more depression. Younger and older women have some similar post-treatment needs: increased emotional support from family and friends; learning new coping strategies to manage daily stress and recurrence fears. Snobohm and Heiwe (2013) found young persons with cancer experienced stressors similar to older persons (feeling physically ill from cancer treatment and psychological distress) but also have different stressors related to their youth.

Phillips and Cohen (2011) explored the meaning of breast cancer risk for African American women. Themes identified: life changing experience; fears, support and concern for relationships; the health care experience; raising awareness; strong faith. Coping strategies included: physical exercise; seeking professional help; trying to regain control; using new ways of thinking and acting; seeking help from family/friends. Problem focused, emotion focused, meaning based, social coping and defense mechanisms were used. Manuel, et al. (2007) studied coping with breast cancer in women 50 years or younger. Coping strategies included: positive cognitive restructuring, physical activity, medications, resting, wishful thinking, making changes, social support for anger and depression. Support groups for young women with early breast cancer in Australia helped women cope and significantly decreased their psychological distress (Gunn et al., 2015). Devi and Hegney (2011) found that women use religion and spirituality to cope with breast cancer and improve quality of life.

Women experience physical and psychological distress following a diagnosis of breast cancer (Helms, et al., 2008; Howard-Anderson, et al., 2012). Avis et al. (2005) studied 202 women with stage I to III breast cancer, 50 or younger after breast cancer and found over 70% of the women reported aches, pains, unhappiness with appearance, hot flashes, painful intercourse and bladder control problems. Younger women has a lower Global QOL than a non-patient sample of younger women. Younger women with impaired QOL may need interventions related to menopausal, sexual, relationship and body image problems and fertility options and genetic counseling. Wong-Kim et al. (2005) studied quality of life (QOL) beliefs among US born and foreign born Chinese women with breast cancer. Both groups reported a stigma of breast cancer which is viewed as contagious. Foreign-born women reported more stigma than US born women. Having cancer was a reminder to take better care of themselves.

Hassan, et al. (2015) found anxiety and depression among Malaysian breast cancer patients. The young were at higher risk for anxiety and depression. Less financial support and being single were associated with depression. In contrast, Ng et al. (2015) found Malaysian breast cancer patients had low levels of depression and anxiety and better quality of life following breast cancer diagnosis. Higher quality of life was related to high levels of social support and spiritual coping. Devi and Hegney (2011) found that women use religion and spirituality to cope with breast cancer and improve quality of life.

Purpose: Breast cancer is perceived as a stressful experience for women. Factors which can impact on quality of life of women include meaning attached to having breast cancer, coping, and health. The purpose of this study was to investigate meaning (appraisal) of having breast cancer, the ways women cope with breast cancer, and their health.

Methods: This study focused on comparing meaning, coping and health of younger (age 29 to 58 years, n= 32) and older (age 60 to 80 years, n = 15) women following first time diagnosis of breast cancer who were scheduled for breast surgery. Lazarus and Folkman's stress-appraisal-coping **theoretical framework** guided the study. A letter of explanation about the study was shared with potential subjects who were referred by their surgeons. Telephone follow-up was used to ascertain interest in participating. An interview with a nurse was scheduled if inclusion criteria were met. Instruments included the Appraisal of Breast Cancer Scale, Ways of Coping Revised, Profile of Mood States, Resources Assessment which included questions on nutrition, exercise, breast care, finances.

Results: Perceived causes of breast cancer included poor eating habits, eating too much meat, taking estrogen, and injury to the breast. Older women had more positive meanings of having breast cancer than younger women. Women appraised breast cancer as a challenging experience with harmful losses. Women were challenged to maintain their self-esteem, feel good emotionally, and stay socially active. Concerns included: loss of independence; changes in finances; changes in social life; grieving and sleeping problems; and husbands' needs for education and support. Women receiving chemotherapy had more negative meanings of breast cancer than women receiving no additional treatments or hormonal or radiation therapy. Helpful ways of coping included: positive reappraisal, planful problem-solving, prayer, keeping busy, and taking one day at a time. Lumpectomy patients used more escape-avoidance coping than mastectomy patients ($t = -2.07$, $p = .044$). Women having a mastectomy versus a lumpectomy did not differ in their use of confrontive, distancing, self-controlling, seeks social support, accepts responsibility, planful problem solving and positive reappraisal coping.

Younger women had poorer health outcomes than older women with breast cancer. African-American women had less tension-anxiety ($t = -2.56$, $p = .014$), less confusion ($t = -2.27$, $p = .028$), more vigor ($t = 4.47$, $p < .001$), less mood disturbance ($t = -3.22$, $p = .002$) than Caucasians. Breast cancer resulted in both younger and older women taking more control over their health and life, and making positive lifestyle changes including implementing good nutritional habits, reducing caffeine and alcohol intake; quitting smoking, exercising more, regular breast care practices, i.e., BSE, regular physician visits, becoming closer to family and friends, and a stronger faith.

Conclusion: Implications include the need to identify women with negative meanings (appraisals) of having breast cancer since they have poorer outcomes, and to educate women about helpful coping strategies and lifestyle behaviors which can improve their health. Global research findings have implications for advancing practice, research, education and policy to meet the needs of younger and older women with breast cancer.

A 08 - Global Interprofessional Health Disparities

Application of Evidence-Based Practices to Global Interprofessional Collaborations Aimed at Reducing Hearing-Related Health Disparities

Tracey Smith Page, DNP, RN, FNP-BC, USA

Abstract

Purpose: This presentation will provide an overview of the evidence based interventions and practices utilized in the development and implementation of a sustainable community owned hearing screening program for children in Jinotega, Nicaragua. Hearing loss in children can lead to social isolation, academic failure, and emotional distress (Daud, Kamarulzaman, Rahman, & Zakaria, 2013). Subsequently, hearing loss that is not effectively identified and managed can have a negative impact on a community due to increased use of resources and decreased productivity over a lifetime. Unfortunately, hearing screenings for school-aged children in Nicaragua are not routinely performed despite evidence to support effectiveness in identifying hearing related deficits (Muñoz, Caballero, & White, 2014; Prieve, Schooling, Venediktov, & Franceschini, 2015). The magnitude of hearing related deficits in children in Jinotega, Nicaragua, is documented, along with probable causation and interventions, to support the implementation of sustainable community programs to address the issue. Research conducted by Saunders, Vaz, Greinwald, Lai, Morin & Moica (2007) stands as the only evidence in publication that quantitatively reports the discrepancy in hearing screening failure rates in Jinotega, Nicaragua, (18%) when compared to the United States (<4%) and provides valuable information that can be applied to evidence based interventions for this population.

Methods: Health care professionals, educators, spiritual leaders, students and community members worked together to develop and implement a child hearing screening program that consists of educational training and direct patient care opportunities. Educational programs were provided for Nicaraguan nursing students and key community stakeholders over two separate week-long visits to Nicaragua. Direct patient care was also performed as children in three locations in and around Jinotega, Nicaragua, received a well child exam, hearing screening and other select interventions based on need.

I selected pure-tone hearing screens as the base patient intervention for this program as the literature supports this as the preferred method for hearing screens in school-aged children (Saunders, et al. 2007; Prieve, Venediktov & Franceschini, 2015; Munoz, Caballero & White, 2014; Sekhur, Zalewski & Paul, 2013). There are challenges of implementing pure-tone hearing testing in an environment without a sound booth but evidence based interventions to help manipulate the environment and perform effective screens are available (Swanpoel, McClennan-Smith & Hall, 2013). Implementing a questionnaire aimed at identifying children at risk was considered and ruled out based on a literature review conducted by Munoz, Caballero & White (2014) as it was found to be ineffective in accurately identifying children at risk of hearing loss.

The optimal frequency of providing hearing screens in school-aged children remains unproven. The literature supports hearing screens in school-aged children (Prieve, Venediktov & Franceschini, 2015; Munoz, Caballero & White, 2014; Sekhur, Zalewski & Paul, 2013; Swanepoel, Maclennan-Smith & Hall, 2013) but the frequency in which they are performed varies. Nicaragua currently does not mandate hearing screens for school-aged children and only 34 states in the United States require hearing screens in school (Sekhar, Zalewski & Paul, 2013). The Jinotegan community was provided with information on which to base their future decisions as they assume ownership of the program.

Results: The clinical days were challenging as 302 children in three different locations were provided with well-child exams, treatment of acute health issues and hearing screenings. Speech language consults and ear lavages were also provided as needed. Although this is not a research project, basic data was collected for the purposes of program evaluation and future needs consideration. An astonishing 34% of the 302 children assessed failed some portion of the hearing screening resulting in a recommendation for either a rescreening in 3 to 6 months or immediate referral to a hearing specialist. The unexpected findings were discussed by the interprofessional team to determine the presence of a

possible process problem. The hearing screening process was reviewed and found to be sufficiently controlled for this environment (Swanepoel, Maclennan-Smith, & Hall, 2013). Anecdotally, the high level of hearing screening deficits is thought to be due to a large amount of earwax, visualization of tympanic membrane scarring indicative of previous trauma or infection and presence of fluid behind the tympanic membrane interfering with sound transmission. Well cited in the literature, interprofessional collaboration was a key element for the development, implementation, and sustainability of this program (Kara, Johnson, Nicely, Niemeier, & Hui, 2015; Norgaard, Draborg, Vestergaard, Odgaard, Cramer, & Sorensen, 2013).

Conclusion: Implications for nursing practice are abundant as multiple interventions and strategies were utilized to create a program using existing evidence with success. The actions are replicable and have great potential for use in a formal research study. The content of this presentation also strongly supports the Congress objective to promote transformation of knowledge and practice to advance global health and nursing.

A 08 - Global Interprofessional Health Disparities

Nurses Crossing Disciplines and Borders: A Participatory Research Approach to Global Water Challenges

Vicki L. Simpson, PhD, MSN, RN, CHES, USA

Abstract

Purpose: The purpose of this presentation is to: 1) describe an ongoing project to provide access to safe water and improved sanitation and hygiene for rural, underserved areas of the Dominican Republic, and 2) delineate the contributions/roles of nurses as part of a cross-disciplinary team in addressing complex global challenges. According to the United Nations (UN), 1.8 billion people globally use water contaminated by fecal matter while 2.4 billion lack access to basic sanitation services. Additionally, issues related to unsafe water, poor sanitation and hygiene are major contributors to death for children under the age of five worldwide. Ensuring access to water and sanitation for all is sixth on the list of the UN Sustainable Development Goals. Achieving this goal will not only reduce morbidity and mortality, but also help to improve nutrition, address poverty, inequalities, and disparities, and enhance school and work attendance and performance (United Nations-Water, 2016; World Health Organization [WHO], 2016). Global health challenges such as these are complex and require effective global health partnerships including nurses. To address these challenges, education for health professionals should support development of global health competencies including a focus on interprofessional collaboration and cross discipline problem solving (Opollo, Bond, Gray, Lail-Davis, 2012; Jogerst et al., 2015). Professional nursing organizations including Sigma Theta Tau International (STTI) and the American Association of Colleges of Nursing (AACN) encourage nurses to work towards the UN Sustainable Development Goals through collaboration, identification of key goals, and the building of bidirectional reciprocal relationships to create ongoing sustainable efforts (Dalmida et al., 2016; Interprofessional Education Collaborative Expert Panel, 2011). Providing opportunities for nursing students to apply their skills and knowledge to meet global needs can support development of leadership skills, increase commitment to global health, and enhance the ability to provide culturally relevant care (Jogerst et al., 2015). This presentation will describe strategies and activities which have been used to sustain this initiative since 2012, including the impact on students, faculty and communities in the Dominican Republic, and plans for expansion.

Methods: An initiative began in 2012 using a cross disciplinary, service-learning approach to provide holistic solutions for safe water access for an underserved, rural community in the Dominican Republic. Initial faculty and students (graduate and undergraduate) represented the disciplines of nursing, agricultural economics, civil engineering, environmental and ecological engineering, and biological and food sciences. The class began as faculty driven and led; over time the course has evolved to being fully student driven with faculty guidance and support. Classes early in the process provided background from all disciplines to support understanding of the issue from multiple perspectives, an overview of the participatory research approach to be used, and discussions of possible solutions to provide access to safe water in collaboration with the selected community. As the class enters its fifth year, the focus has broadened to encompass sanitation and hygiene in addition to access to safe water and work has begun with three other communities in the Dominican Republic. Additionally, other disciplines have joined the project. Class time is now focused upon supporting ongoing communication and collaboration with the communities in the Dominican Republic, discussion of cultural, political, economic, and health aspects of water, sanitation, and hygiene issues, development of potential solutions to meet the needs of the communities, and identification of strategies to evaluate impact. Communication with the community is frequent and supports true collaboration and shared responsibility for the design, implementation, and management of solutions to provide access to safe water and improve sanitation and hygiene. Such collaboration is vital to effective global health partnerships and sustainability.

Every year, two to three visits to the Dominican Republic are made by faculty and students to maintain presence and enhance community trust. Various activities occur during these visits including: 1) meetings with community members, representatives from local service organizations, political representatives, and local health providers, 2) data collection via household surveys, focus groups, and visits to local health clinics, and 3) assessment of local resources available to support system design and implementation.

Results: Since the projects inception, 60-70 students have been involved, including 16 undergraduate nursing students. In 2014, the first system was built at a primary school located in the center of a poor rural community outside of Santiago. Several events surrounded the ribbon cutting ceremony including training related to safe operation and use of the system as well as education efforts led by the nursing students including a water, sanitation, and hygiene curriculum for implementation at the local schools and in the community. Since 2014, trips to the Dominican Republic have included visits to three new communities, along with return visits to the initial community to provide continued support, guidance and adaptations as needed for the water system. The process has not been without challenges, however each challenge is tackled collaboratively by the faculty, students and communities who consistently strive to reach the identified goals. The participatory research approach has allowed community members to participate in research, project design and review of policies which impact the issues surrounding access to safe water. For students, the impact has been truly transformative on both personal and professional levels. Knowledge of the complementary skill sets other disciplines bring to projects such as these has been broadened. Skills related to formal presentations, grant writing, manuscript preparation, leadership, fundraising, collaboration, and communication with non-English speaking populations have been enhanced. Students have witnessed issues not commonly seen in the US such as lack of access to soap and clean water for handwashing or water to flush a toilet as well as the giving nature of the Dominican people. This has led to development of respect, humility, and appreciation for the Dominican people; behaviors which are reciprocated by the communities they work with. As a result of this experience, several students have chosen to work in the public health arena locally and globally while others have gone on to additional degree programs in public health.

Conclusions: This project has provided many benefits in addition to access to safe water for the community. Nursing students as well as students from other disciplines have been able to develop global competencies and a respect for cultural diversity and the role it plays in providing care to populations. Nurse educators have a responsibility to prepare nurses to function competently in relation to global issues (Wilson et al., 2012); projects such as these provide support for the development of such skills and competencies. Students who have participated in this project are able to reflect upon their feelings of global connectedness and the ways in which this experience has influenced and enhanced their education as well as their choice of future careers. These experiences can support development of individuals who can help lead the charge to address global health challenges.

A 09 - HPV Vaccine Promotion

Completeness of Human Papilloma Virus (HPV) Vaccination: A Systematic Review of the Literature

Hee Sun Kang, PhD, RN, Korea, Republic of (South)

Jennie C. De Gagne, PhD, DNP, RN-BC, CNE, ANEF, USA

Ye Dong Son, MSN, RN, Korea, Republic of (South)

Abstract

Purpose: Human Papilloma Virus (HPV) vaccination is known to be effective for preventing cervical cancer and condyloma. For its maximum effects, it is important not only to initiate HPV vaccination, but also to complete it on time. However, it has been reported that the completeness rate of HPV vaccination is lower than its initiation rate. The aim of this study was to systematically review the intervention studies on HPV vaccination completion.

Methods: A systematic review of intervention studies examining the completeness of HPV vaccination in women (adolescents and young women) from 2006 to 2016 was conducted. The main outcome assessed was completion rate. We searched the databases of Web of Science, PubMed, and Cumulative Index to Nursing and Allied Health Literature, for relevant articles. Reference lists of included articles were also hand-searched. Two reviewers independently completed data extraction and bias assessments using standardized forms. Originally, the possibilities of pooling data were considered, but the data were analyzed narratively because of the heterogeneity of the types of interventions.

Results: Five studies were identified and reviewed. Intervention strategies were DVD education on HPV and reminder/recall systems using either electronic or non-electronic methods. Electronic reminders were either fixed without options or were preference-based, which allowed parents or women (adolescents or young women) to select one or two options among e-mail, text, automated telephone message, Facebook message, etc. Non-electronic reminders were letter, standard mail, phone call, etc. The rates of HPV vaccination completeness increased with the interventions. However, the completeness rate of HPV vaccination, remaining unsatisfactory, was lower than its initiation rate. The reviewed studies have mainly been conducted in a high income country.

Conclusion: Educational or reminder interventions on HPV vaccination could contribute to the promotion of HPV vaccination completion. However, this review highlights that more high quality studies are needed to explore the barriers to completion and to identify the best way to promote vaccination completion.

A 09 - HPV Vaccine Promotion

Knowledge, Attitude, and Intention to Obtain HPV Vaccination Among Undergraduate College Students in St. Lucia

Esther Shirley Daniel, PhD, RN, RM, Trinidad and Tobago

Tisha Nelson, MSN, RN, Saint Lucia

Gloria Ramdeen Mootoo, MSc (ClinPsy), RN, RM, Trinidad and Tobago

Abstract

Purpose: The purpose of this study was to investigate if there were any differences in the Knowledge, attitude and intention to obtain HPV vaccination among the male and female undergraduates of a selected Community College in St. Lucia.

Methods: A descriptive, quantitative and cross-sectional study. Previous research conducted of HPV has indicated many misconceptions and misperceptions of HPV and HPV vaccinations. Education and knowledge on HPV plays a significant role in the intention of receiving HPV vaccinations (Lambert, 2014). It is important to recognize benefits and barriers to obtaining HPV vaccinations to increase vaccination rates.

In the review of literature findings, problems pertaining to minimal knowledge level and awareness of HPV vaccine and cultural hurdles of HPV vaccination were discussed. The studies incorporated in this review showed a general lack of knowledge about HPV and HPV vaccine among males and females in some Caribbean countries as well as international countries such as China (Ribeiro et al., 2015; Lambert, 2014; Perrotte et al., 2011; Villa, 2012). On the other hand, knowledge deficit about HPV is not the only issue for males and female in the Caribbean but also the high cost attributed to the HPV vaccine (Stocker et al., 2013). Additional studies in Western countries, comparatively well-developed society, also showed similar deficiency in knowledge of HPV. As the deficiency of knowledge could be one of the obstacles for acceptance of HPV vaccine, the findings from current research suggest that there is an instantaneous and dire need for public education on HPV and its vaccines. Notwithstanding the low level of knowledge and awareness about HPV and HPV vaccines, studies conveyed relatively high intentions and optimistic attitudes toward HPV vaccination among males as well as females (Kim, 2015; Stocker et al., 2010, and Yanikkerem & Koker, 2013).

In general the various studies revealed some concerns about HPV vaccine efficacy, vaccine safety and side effects, overall cost of vaccine and the availability of insurance coverage for same (Fesenfeld, Hutubessy & Jit, 2014; Jit et al., 2014; and Laprise et al., 2014).

The present study was the first of its kind to be conducted in St. Lucia and an attempt was made to study the Knowledge, attitude and intention to obtain HPV vaccination among male and female undergraduate students at the selected Community College in St. Lucia.

The participants ($n=100$) were selected using stratified random sampling. Samples were drawn from five Departments viz Department of Arts, Science and General Studies; Department of Health Sciences; Department of Agriculture; Department of Teacher Education; and Department of Technical, management Studies. The objectives of the study were; to determine the knowledge, attitude and intention to obtain HPV vaccination among subjects and to examine the association of knowledge, attitude and intention to obtain HPV vaccination with selected social, demographic variables among subjects. Criteria for selection of the sample included respondents who were: Male or female between the ages of 18 to 26, willing to participate voluntarily. And full time students studying in the five main departments at the selected Community College. Exclusion criteria was respondents who were part time, on-line students and who did not give consent for the study. The Health Belief Model (HBM) was utilized as a framework for this study.

Ethical approval was obtained from the UWI Campus Ethics Committee as well as the college Ethics Board to conduct the study. Subjects of this research study had the right to consent freely in the absence

of coercion. They were offered the right to refuse to participate, or to withdraw at any time with no explanation, and without consequences or coercion of any kind.

Self-administered questionnaire were distributed to 100 undergraduate, full-time students at the selected college, in St. Lucia to assess socio-demographic characteristics, knowledge, and statements on vaccinations. Self-administered questionnaire included demographic profile and knowledge of HPV and HPV (10 items) vaccination (24 Items) Responses to items were rated using a 3-point Likert scale ranging from 3 (yes) to 1 (don't know) point and an Opinionnaire on attitude and intention to obtain of the HPV vaccination (15 items). Responses to items were rated using a 5-point Likert scale ranging from 4 (strongly agree) to 0 (strongly disagree). Scoring and Interpretation of reliability & validity of the tool was established through test retest method. Data were analyzed using SPSS. Multivariable statistical methods were applied to identify independent predictors for HPV-vaccine uptake among participants.

Limitations of the study is that it focused on the geographical region of St. Lucia which may not necessarily be applicable to other Caribbean territories.

Results: The analysis of the data was based on the research question; What is the Knowledge, attitude and intention to obtain HPV vaccination among the male and female undergraduates at the selected Community College in St. Lucia? Are there differences in knowledge, attitude and intention to obtain HPV vaccine that may impact one's likelihood of seeking medical aid? How informed are the subjects on HPV vaccination and it effectiveness in preventing cancer (cervical, oral) at the Sir Arthur Lewis Community College in St. Lucia?

The analysis of results showed majority, 56% of respondents were of African race and 93% do not have migration background. Nearly 75% respondents had past sexual intercourse. Most of the respondents 69% were not aware of HPV vaccination, 92% of them were not vaccinated against HPV, 51% of them felt the need for vaccination while 49% not. Majority of the respondents, 92% did not have history of abnormal pap smear or HPV infection, while 54% had not heard of the virus. However 46% confirmed that they had heard of the virus. Nearly 51% of the respondents had heard about the HPV vaccine while, 49% did not do not.

What was interesting though was almost 50% of the respondents felt a need for vaccination and heard of the virus and HPV vaccine. High T-values were found significant in the means of knowledge of HPV (1.35+0.57), HPV (1.08+0.75), HPV Causes (0.98+0.84), HPV and gender (1.04+0.53), HPV is preventable (0.84+0.54) and HPV infection is serious (0.68+0.54). All 6 variables showed P-values much less than the significance level ($p < 0.05$).

Factor Analysis of knowledge, attitude and intention to obtain HPV vaccination with selected social, demographic variables among subjects was measured against 26 variables. HPV vaccine cause short term problems like fever or discomfort had fairly high correlation with Factor 1 (4.368), HPV vaccine is being pushed to make money for drug companies had fairly high correlation with Factor 2 (3.332), if a teenage girl gets the HPV vaccine, more likely to have sex had fairly high correlation with Factor 3 (2.204), HPV vaccine is unsafe had fairly high correlation with Factor 4 (1.935), the risk that HPV can cause diseases like cancer is too little had fairly high correlation with Factor 5 (1.693), not enough information about the HPV vaccine to decide whether to take it or not had fairly high correlation with Factor 6 (1.372), HPV vaccine is effective in preventing genital warts had fairly high correlation with Factor 7 (1.159), belief that the vaccine has too many side-effects had fairly high correlation with Factor 8 (1.101), and in general against vaccination had fairly high correlation with Factor 9 (1.006).

However the factor analysis of intention to obtain HPV did not show any significance.

Component matrix was done for all the 9 factors. Factor 6 and 9 did not explain any variance when compared with other factors. In the second component matrix, except factor 9 all factors showed correlation. In the third component matrix, except factor 7 and 8, all factors showed correlation.

A scree plot displays the eigenvalues associated with a component or factor in descending order versus the number of the component or factor. A factor analysis was conducted on 26 different characteristics of HPV. This scree plot shows that 9 of those factors explain most of the variability because the line starts to straighten after factor 9. The slope is changing after 2 variables which means that most of the variance is explained by initial two factors. The remaining factors explain a very small proportion of the variability and are likely unimportant.

Conclusion: In conclusion despite risk acknowledgment the researcher had identified, the results revealed significant lack of public health promotion. Although HPV is very much prevalent in St. Lucia and it's the causative factor for cancer in both men and women, not enough is being done to create awareness about HPV. Secondly, the vaccine is unavailable in St. Lucia. Thirdly, the high cost of the vaccine (\$500 US) and HPV test (\$275 EC) have proven to be a deterrent to obtain the aforementioned. HPV vaccine uptake was low among the participants; only 7 out of the 100 participants had been vaccinated and had received it in the United States. Although low vaccine uptake 53% agreed that there was a dire need for vaccination.

A 10 - Effects of Intensive Care on Quality of Life

Living a Lie: The Biographical Disruption of Intensive Care Unit (ICU) Survivors

Beverley Ewens, PhD, BSc (Hons), RN, Australia

Abstract

Introduction: Millions of people across the world are admitted to intensive care units each year. This is expected to rise with increases in population and life expectancy. In tandem with this, the standard and capability of clinical care provided has improved significantly over the last three decades. An evolving body of evidence has confirmed that significant percentages of survivors are frequently and profoundly affected by their intensive care experience. Patients who would not have survived a critical health event 30 years ago now survive; with the concomitant rise of survivors the potential for developing emotional sequelae leading to chronic illness increases with only a few returning to pre-morbid life-styles. The cost therefore of survivorship in this population in financial and human terms, is significant.

Background: Major levels of physiological disturbance are apparent in ICU patients as they experience at least one, and frequently more body system/s failure that usually require invasive therapies to promote survival. Therapies often include deep sedation, ventilation and a variety of other invasive procedures, which in themselves are known to precipitate adverse physical and psychological consequences. As a result of these interventions, and in particular sedation, survivors experience an enforced disconnection from reality and are unable to reconcile their memories with what actually happened to them. This state can endure for weeks and even months in some instances. The consequences of this twilight existence and the associated invasive therapies have been likened by some patients to a torture-like existence. The experience of an ICU admission is clearly a stressful, potentially traumatic event for survivors and their families. The agreed definition of a traumatic event is one where individuals are confronted with unusual stress and are forced to cope with an unexpected and unfamiliar situation and which is an overwhelming, physical, emotional or social experience. In this instance, intensive care survivors may experience a level of trauma where the individual either perceives a risk of death to themselves or witnesses this in others, precipitating a psychological stress response. Although studies have identified the ICU experience for survivors, there has been limited research which provides an insight into survivors' experiences during recovery through their individual lens. Identifying the unique perspective of survivors during recovery, support strategies can be implemented which address this disruption to the self and aid a meaningful recovery. The therapeutic benefits of narrative discourse in trauma survivors have been well recognised. Writing a coherent story following a traumatic experience is positively linked to improved coping and recovery and enabling the individual to re-create their stories brings about positive change and healthier outlook of the self. In the health care context storytelling has been explored in many areas of practice including dementia care, chronic illness management and maternal health. Storytelling in these settings has been linked to maintaining dignity, being emancipatory and increasing coping. Despite applications of storytelling elsewhere in health care it has not been widely reported in the study of ICU survivors although there has been some application with family members.

Purpose: The purpose of this research was to explore the recovery stories of people who have been discharged from ICU during the first five months of recovery following a critical illness or event.

Methods: Data were collected from diaries, face to face interviews, memos and field notes. Participants diarised for three months commencing two months after hospital discharge. At five months following discharge participants were interviewed about the content of their diaries and the symbols and signifiers within them to create a shared meaning of their experiences. Analysis of diaries and interviews were undertaken using two frameworks. This process enabled the identification of themes throughout participants' stories and offers a unique portrait of recovery through their individual lens.

Results: All of the participants considered their lives had irreparably changed as a result of their experience. The biographical methods provided a safe and creative way to reveal inner thoughts and feelings which may not have been revealed using other methods. This unique view through the lens of the survivor identified how unsupported by health care professionals they felt following discharge. Turmoil

existed between survivors' surface and inner worlds as they struggled to conform to the constraints of what recovery should be; imposed by the biomedical model. The process of constructing their stories enabled participants to reflect upon their experiences of recovery and bring a sense of coherence to their experiences.

Conclusion: The use of guided reflection in the initial months following discharge from ICU creates a story which enables survivors to harness this 'space for thought' to provide a way forward from their trauma event or life disruption. Engaging with survivors during this vulnerable period and enabling them to reflect upon their experiences and pre-morbid lives assists them to re-focus upon the here and now as they recover and to reconcile the space between who they once were and who they are now. This study has implications for practice and research and has provided the impetus for further exploration of diarising as an intervention and the role of storytelling in this and other populations. Identifying the unique perspective of survivors during recovery, support strategies can be implemented which address this disruption to the self and aid a meaningful recovery.

A 10 - Effects of Intensive Care on Quality of Life

Impact of Prior Intensive Care Unit (ICU) Experience on ICU Patients' Family Members' Psychological Distress

Chrystal L. Lewis, PhD, RN, USA

Jessica Z. Taylor, PhD, LPC, NCC, USA

Abstract

Purpose: Psychological distress including anxiety, depression, and stress in family members of intensive care unit (ICU) patients is a well-documented phenomenon across a wide variety of countries including, but not limited to, Brazil, Italy, China, Greece, France, and the United States (Chiang et al., 2016; Davidson, Jones, & Bienvenu, 2012; Fumis, Ranzani, Faria, & Schettino, 2015; Konstanti, Gouva, Dragioti, Nakos, & Koulouras, 2016; Mistraletti et al., 2016; Pochard et al., 2001). A real clinical example of the impact a family member's psychological distress has for nursing occurs with the comprehension of simple concepts, such as that of time. In one instance, a family was unable to grasp the concept of time when the end of a nurse's shift occurred; yet, this same family was being asked to make crucial life or death decisions. The clinical example presented here embodies what we have learned from advances in neurobiology, which have demonstrated that humans under stress have a reduced recall capacity and recognition performance (Schwabe & Wolf, 2010).

Having a family member in the ICU goes beyond stress for some individuals, and actually leads to the development of post-traumatic stress disorder (PTSD) (Sundararajan et al., 2014). The overstimulating influence of technology present in the ICU environment has been identified as a contributing factor to anxiety in ICU patient family members (Fumis & Deheinzeln, 2009). Relatively recently, research conceptualized this persistent psychological distress experienced by family members of ICU patients as *Postintensive Care Syndrome (PICS) – family* (Davidson, Jones, & Bienvenu, 2012). Despite the acknowledgment that PICS - family may occur for up to four years after an ICU experience, no known research has investigated whether previous ICU experience contributes to ICU patient family members' experiences of anxiety, depression, and stress symptoms. This particular lack of literature is intriguing when considered with the recommendation from 1996 by Jamerson et al. for nurses to assess the family members' prior experiences with ICUs as part of the ICU education process for the family members.

As part of a multi-phase study investigating ICU family member's experience of psychological distress, the sub-aim presented here was to determine if current levels of anxiety, depression, and acute stress disorder symptoms differ significantly among family members of ICU patients, depending upon previous ICU experience.

Methods: This study used a prospective, descriptive study design. Data collection occurred between 2013 and 2014. Family members (n=127) from patients admitted within the past 72 hours to the medical, surgical, cardiac, and neuro ICUs were recruited from the ICU waiting rooms at a medium sized community hospital in the Southeastern United States. Participants completed the Hospital Anxiety and Depression Scale (HADS), the Impact of Events Scale-Revised (IES-R), the Acute Stress Disorder Scale (ASDS), and a demographic survey. IRB approval was granted as an expedited review.

Results: A multivariate analysis of variance (MANOVA) revealed that family members of ICU patients who had a prior ICU experience within the past two years (n= 56) were significantly more likely to report anxiety, depression, and stress symptoms than family members of ICU patients who had not had a prior ICU experience within the past two years, $\Lambda = .92$, $F [4,122] = 2.70$, $p = .034$, partial $\eta^2 = .08$, observed power = .74

Conclusion: Nursing intuition suggests novice ICU family members experience more psychological distress and need more support during a family member's ICU admission. However, the results of this study show that family member's psychological distress is actually higher with previous ICU experience. These findings are of important consideration in light of nursing practice's continued disregard of Jameson et al.'s (1996) recommendation for nursing to assess previous ICU experience. The ICU patient

family members' experience of psychological distress transcends a single culture or country. As a global health phenomenon, nursing needs to assess family members' previous ICU experience when providing family-centered care for ICU patients and families and determine how the families would prefer to be supportive. In addition, collaboration with chaplain services, social services, counseling services, and patient advocates is encouraged to assist with addressing how the family member's previous ICU experience is impacting their current psychological distress. Collaborating support professionals' acknowledgement and normalization of family members' psychological distress related to previous ICU experience can provide family members with a safe outlet to share openly and honestly about their affective experiences in a way that does not burden the patient. Furthermore, support professionals could facilitate support group experiences for family members with previous ICU experience to provide them with a safe group of understanding others who can provide them with support so that they may better support the patient.

A 11 - Adolescent Health

Perceptions of Health, Healthy Decision-Making, and Living: A Study of Young Mothers Living in Jamaica

Katherine M. Haigh, MSN, APRN, CNP, USA

Judith Herrman, PhD, MS, BSN, RN, ANEF, FAAN, USA

Kathleen Luckner, BSN, RN, USA

Abstract

Purpose: Adolescent health, including sexual health and pregnancy, are topics of concern for healthcare providers, family members, communities, and teens around the world. These concerns and their ramifications are apparent in the Caribbean nation of Jamaica. In a population based study done in Jamaica, of the total participants aged 15-19, one-third of females and half of the males reported being sexually active within the last year (Ishida, Stupp & McDonald, 2011). While the Age Specific Fertility Rate (ASFR) for adolescents in this same age group is declining, the Jamaica National Family Planning Board (JNFB) (2008), reports there are still 72 births per 1000 women identified in 2008, previously in 2002, there were 79 per 1,000. And, in 2008, approximately 82% of these pregnancies were unplanned (JNFB, 2008). Pregnancy is not the only a concern for these Jamaican teens, as teenage pregnancy is unlawful in the country and sexually transmitted infections (STIs) are still a veritable risk. With 79% of females between the ages of 15-24 reporting using contraception at first sexual intercourse as a help to keeping pregnancy rates down, only 49% of females reported using a condom at last intercourse, and 48% of females reporting using a condom with each encounter with a non-steady partner. (Serbanescue, Ruiz & Suchdev, 2010; JNFB, 2008). This lapse in condom use and possibly barrier contraception use, is detrimental to the reproductive health of these young adults and gravely indicates the need for further education. While the literature is replete with sexual health information and curricula directed toward adolescents, there is a paucity of knowledge regarding this specific group of teenagers living in Jamaica. Identifying health interventions is crucial to this population's well-being. Young mothers may incur health risks associated with lifestyle and decision-making; availability of supports and resources; and challenges related to stress and time limitations associated with pregnancy, breastfeeding and parenting. Teen perceptions about health, healthy decision-making and healthy lifestyles may guide development of interventions designed to promote health. Nursing students, as part of a service learning activity, traveled to Jamaica to provide health instruction to young mothers in a residential home. The young mothers participated in focus groups, which provided beneficial information identifying some of the gaps in knowledge of general and sexual health in this vulnerable population. Thematic analysis of focus group transcripts and study findings may be useful as they inform health intervention development.

Methods: This qualitative study was conducted at a residential home for young mothers' in Kingston, Jamaica, during the spring of 2016. To be considered eligible to participate in the focus groups, the young women needed to be residents of the setting, aged 12-17 and either pregnant and/or parenting. The focus groups were conducted by the researchers and audiotaped; one researcher led the groups while another observed and took marginal notes during the process. The participants received \$10 (US) and a healthy snack. Data were analyzed for content, then organized into topics with frequency of responses used to construct themes.

Results: The participants in the discussion included thirteen teenage mothers, whose ages ranged from twelve years old to seventeen years old. The ages of their babies ranged from two weeks to nine months old. All thirteen girls were either currently attending school or planned on returning to school when their babies were old enough. From the discussion with the young mothers, three themes emerged. The themes were: Personal Meaning of Health, Considerations in Health Decision-Making, and Thoughts on Healthy Living.

Conclusion: The study of young mothers' perceptions about health, health decision-making, and healthy lifestyles yielded important insights into the thoughts and behaviors of young women in Jamaica. Due to social and political laws and beliefs, young women in Jamaica who become pregnant experience marginalization and duress associated with isolation, financial stressors, and stigma. These exacerbate

the vulnerability inherent of adolescence, pregnancy, and parenting. The nurse has an integral role to provide education, counseling, and resources to enhance the supports and reduce the challenges young mothers confront in their personal quests to attain and maintain health. Perhaps, even more important is the need for nursing advocacy to influence the gender issues associated with subjugating young women, with little stigma associated with fathering a pregnancy, to address bullying via empathy-building strategies, and providing interventions and resources to foster parenting, including mothering and fathering interventions, to ensure health of the current and future generations in Caribbean countries.

A 11 - Adolescent Health

Psychological Distress Among Adolescents in Laos, Mongolia, Nepal, and Sri Lanka

Heeyoung Lee, PhD, APRN- BC, USA

Eun Young Lee, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: Adolescence is a critical period for the emergence of a broad range of psychiatric disorders, which negatively impact psychosocial functioning and social cost. Global health projects primarily have addressed communicable disease—not mental health; moreover, limited research and resources are available to meet the needs of adolescents with mental health problems—particularly in low- and middle-income countries. The purpose of this study was to explore psychological distress and examine the relationship between distress and individual, family, and school factors among adolescents in Laos, Mongolia, Nepal, and Sri Lanka.

Methods: A total of 4,098 adolescents in Laos, Mongolia, Nepal, and Sri Lanka were surveyed as part of the Healthy School Development Project. The project was designed to develop school capacity for improving health among all school members and the school environment through tailored school health programs in the four countries. A self-report questionnaire was used to assess psychological distress (i.e., stress, loneliness, anxiety, sadness, suicidal thoughts, suicidal plans, and suicidal attempts), family factors (i.e., parent understanding and monitoring, and parent smoking and alcohol use), and school factors (i.e., having close friends, not bullied, school attendance, health education) among the participants. Data were collected from September to November in 2012 and 2013. Descriptive statistics, chi-squared testing, and logistic regression were used to analyze data collected in 2012.

Results: Over half of the participants were female (56.8%) and below 15 years of age (57.7%). Approximately 44% of the students reported good health status, and 33% reported the presence of psychosocial distress. Forty-four percent and 60% of the students reported that their parents understood them and monitor their activities, respectively. Most students (94%) had one or more close friends, and 20% were bullied. School attendance and providing health education were reported by 81% and 74% of respondents, respectively, as causing distress. Overall, older students were more vulnerable to psychosocial distress (OR=1.78; 95% CI 1.53-2.08), and factors associated with psychological distress comprised food insecurity (OR 1.51; 95% CI 1.05-2.17), family factors (i.e., parent understanding, parent monitoring, and parent smoking) ($p < .05$), and school factors (i.e., being bullied, school absence, and health education) ($p < .001$).

Conclusion: Approximately one-third of the adolescents reported psychological distress. Parent involvement and school environments can function as either protective factors or risk factors of psychological distress among adolescents in Laos, Mongolia, Nepal, and Sri Lanka. Interventions that (1) empower the family to ameliorate psychological distress (2) reduce the likelihood of bullying by peers at school and (3) provide effective health education programs are recommended for these four countries. Additionally, subsequent inquiry into adolescent mental health research and resources in low- and middle-income countries would contribute to reducing psychological distress among adolescents in these contexts.

A 12 - Pediatric Care and Safety

Risks and Protector Factors: Access to a Diagnosis and Services for a Child With Autism

Susan A. Bonis, PhD, RN, USA

Abstract

Purpose: Autism spectrum disorder (ASD) is a growing global issue (Autism Speaks, 2016; World Health Organization, 2016) characterized by verbal and nonverbal social communication deficits, including difficulty following rules for conversation and forming and maintaining relationships (APA, 2013). The child's ability to effectively engage in social and academic activities is impacted. Children often fall victim to criticism and bullying and respond with isolation, aggression, hostility, or self-injury (Schroeder, et al., 2014). These difficulties are compounded by inflexible adherence to routines and excessive response to sensory input (Author, 2012; 2016; Author & Sawin, 2016). A projected increase of 6-15% in ASD diagnoses per year makes ASD the fastest growing developmental disability in the country. These alarming statistics are associated with a projected increase in cost of ASD services from \$175-262 billion per year to \$200-400 billion per year (CDC, 2015).

One in 68 children in the United States and one in 160 children worldwide (World Health Organization, 2016) are diagnosed with autism spectrum disorder (ASD) (Baio, 2014; Childstats, 2015). Greater than 80% of their parents report they feel "stressed beyond their limits" (Bitsika, et al., 2013, p. 540). Their ability to parent effectively is affected, as well as the ability to manage their child's special needs and maintain the marital relationship (Ludlow, et al., 2011). Although parental stress has primarily been attributed to the child's challenging behaviors, few studies have focused on other factors that impact parental stress, such as seeking a diagnosis for their child and accessing services.

Many parents spend years moving from one healthcare provider to another in an attempt to find answers for their child's challenging behavioral and communication issues (Silva, et al., 2012), only to become increasingly concerned by the child's delayed development and odd repetitive patterns (Braddock, et al., 2014; Moh, et al., 2012; Nealy, et al., 2012). Healthcare providers frequently attribute the child's behavior to poor parenting and disregard parental concerns (Nealy, et al., 2012; Silva, et al., 2012).

Although some researchers have specifically studied age of diagnosis and have not found any association between later diagnosis and ethnic background (Williams, et al., 2015), others have identified that African-American and Hispanic children are diagnosed later than other children with similar symptoms (Fountain, 2011; Jo, et al., 2015; 2010; Rosenberg, et al., 2011; Valicenti-McDermott, et al., 2012). Researchers are in agreement that children from lower socioeconomic backgrounds (Harstad, et al., 2013; Rosenberg, et al., 2011; Valicenti-McDermott, 2012) and rural areas (Braddock, et al., 2014; Harstad, et al., 2013; Rosenberg, et al., 2011) also receive later diagnoses. Although parents from all backgrounds feel a sense of disparity related to autism diagnoses and care, specific factors related to access and utilization of services are poorly understood (Williams, et al., 2015).

Autism interventional services are effective in helping parents learn what works and what does not work in managing their child's behaviors (Thomas, et al., 2007). Frequent and consistent integration of methods learned in these programs have been successful in managing challenging behaviors (Steiner, et al., 2012) and improving social and communication skills (Siller, et al., 2013). Confidence and parenting self-efficacy increases and parents are better able to manage challenging behaviors with fewer conflicts (Bekhet, et al., 2012; Siller, et al., 2013; Whittingham, et al., 2009). Quality of the parent-child relationship improves (Whittingham, et al., 2009) and parents are better able to meet the overall needs of their child (Bekhet, et al., 2012). Although geographical availability and accessibility, cost and coverage by insurance (Carlson, et al., 2013; 2015; Rivard, et al., 2015) have been proposed as potential factors that affect use of services, little is known about parental needs and services available to meet those needs. Accordingly, the purpose of this study is to identify factors that affect access to diagnosis and services for parents of children with ASD. Knowing more about parental needs and access to services will contribute

to development of efficacious and appropriate means to meet the unique needs of these parents and their children with autism spectrum disorder

Methods: Focus groups and individual interviews were conducted with parents of children with ASD who were ages 3-37 years, who were ethnically and socioeconomically diverse, and highly educated. A semi-structured discussion guide was used that was developed with input from an advisory panel composed of parents of children with ASD. Discussion questions were focused on: 1) *factors that contribute to parent seeking healthcare for their child*, 2) *factors that affect access to an ASD diagnosis* 3) *parent responses to the ASD diagnosis*, and 4) *factors that affect access to ASD service*. All discussions were audio-recorded, transcribed, coded and thematically analyzed using a reflexive approach and inductive reasoning. The resultant themes were organized according to the framework of the Individual and Family Self-management Theory. APSS-PC ® version 20 was used to analyze thematic similarities and differences across and within demographic groups (ethnic, educational, and level of income).

Results: APSS-PC ® version 20 was used to determine frequencies, means and perform statistical tests. Analysis revealed parents visited their child's healthcare provider 3-30 times while seeking an ASD diagnosis over a period of 2-10 years. A priori Chi Square revealed no significant differences between income and ethnicity, education and ethnicity, and income and education. Mann-Whitney was then used, and no significant relationship was found between race/ethnicity and age of ASD diagnosis ($t=1.49$; $df=31$; $p= .144$) and no significant relationship existed between race/ethnicity and wait time ($t=-1.718$; $df=27$; $p= .097$). Contrary to published research findings, 55% of parents reported feeling their child's healthcare provider listened to their concerns, 48% had a good understanding of ASD, 50% respected their concerns and 48% were supportive of their concerns. However, 62% of parents believed their HCP had a negative view of ASD, which is consistent with previous findings. Thematic analysis of qualitative data revealed knowledge, awareness, acceptance and stigma were factors that affected access to diagnosis and services across all ethnic and socioeconomic groups. Access to diagnosis was earlier for children with profound physical delays and comorbid conditions and was delayed for higher functioning children. Mothers were more proactive than fathers in seeking answers for the child's challenging behaviors and delays, with African-American mothers being particularly persistent in accessing services for their children. Fathers frequently denied the diagnosis, which delayed access to services and affected the marital relationship. Parents also talked about needing support and networking opportunities, educational services to help manage their child's care, and professional services to assist in executive and transitional care of the child.

Conclusion: In this highly educated sample, parents across ethnic and socioeconomic backgrounds struggled to access a diagnosis for their child. Healthcare providers who are knowledgeable and supportive can facilitate earlier referral, diagnosis, and entry into interventional services. This is critically important, as early diagnosis and treatment are associated with improved brain function, enhanced social communication, and decreased need for costly services as the child develops. Parents also waited up to a year or more for intervention appointments post-diagnosis. Findings of this study will be used to create a film production of parents talking about their experiences accessing diagnoses and services for their child. The film will be used as an intervention to facilitate early diagnosis and access to services, shed light on the need for parent education and support services, and to affect policy and government budget allocations for autism-related services.

A 12 - Pediatric Care and Safety

Direct Clinical Application With Nurse-Led Research: Impact of "Boot Camp" Intervention for Caregiver Discharge Readiness

Mary Cazzell, PhD, RN, USA

Julie Van Orne, MSN, RN, CPN, USA

Kaylan Branson, MSN, RN, CPN, USA

Abstract

Purpose: The purpose of this clinical nurse-led interventional research study was to determine the effectiveness of a "boot camp" training-for-discharge program on 34 caregivers of 34 medically-dependent children (compared to retrospective data prior to January 2015 start of boot camp training) as measured by lengths of stay on a transitional care unit (TCU) and overall days in the hospital, total days of documented discharge teaching, and levels of caregiver stress and satisfaction with training. Unprepared or poorly trained caregivers for medically-dependent children could result in poor patient outcomes, added caregiver stressors such as psychological distress or "burn out", and increased financial strain on families and hospitals (DiZazzo-Miller, Samuel, Barnas, & Welker, 2014; Hendrix, Landerman, & Abernethy, 2013). Teaching parents, families, and caregivers to care for their complex medically-dependent children can be a challenge. These infants and children are often discharged home with tracheostomies, ventilators, feeding tubes, and other conditions that require specific learned skills or competencies to manage. A lack of individualized training can lead to inconsistent practice and poor patient outcomes once the patient is transferred home (Hendrix et al., 2013). When a patient lacks a well-trained caregiver, the discharge environment can be considered unsafe. The patient is directly affected by the training of their caregiver. If a caregiver is trained well and thoroughly, there is a higher likelihood that the patient will receive adequate care from their caregiver (Forster et al., 2013). The caregiver is affected by their training because an unprepared caregiver can be anxious, depressed, and unprepared for the complex care sometimes needed by patients (Hendrix et al., 2013). The medical team is affected because lack of a training program or inconsistent teaching for each caregiver can lead to confusion on how to properly prepare caregivers. Often, patients are limited in the amount of days allowed by insurance to be inpatient on a teaching floor or TCU. If the parents or caregivers are not trained within the allotted days, much of the inpatient stay is not reimbursed to the hospital or the caregivers are left with a substantial medical bill (O'Brien, & Dumas, 2013). It is more cost-effective to provide home health care than institutional medical care (Bookman, & Harrington, 2007). The economic value of the care provided by caregivers at home in the United States was estimated to be \$350 billion in 2006 (DiZazzo-Miller et al., 2014). The term "boot camp" typically refers to military basic training. This standardized training prepares military recruits for service by providing the basic tools to perform their duties in a structured format with time constraints (Kubin & Fogg, 2010). The term "boot camp" was chosen for this caregiver training program because the basic skills needed to care for their dependents will be taught in a structured format within a predetermined time frame.

Methods: Developed and implemented by two night-shift frontline nurses, the study utilized a quasi-experimental comparative intervention design. The study was conducted on the transitional care unit within a large metropolitan pediatric medical center in the southwestern United States; Institutional Review Board approval was obtained. Study sample included: (1) experimental group composed of prospectively-recruited caregivers (n = 34; average age 34 years; 88% female) and (2) a medical-condition-matched control group (n = 34; average age 5 months; 59% male; 74% respiratory failure diagnosis) where retrospective chart review data from pre-intervention TCU patients, prior to January 2015, were obtained for the length of stay and days of documented discharge teaching variables. In addition, this study also used a within-group repeated-measure study design for parental stress levels of experimental group caregivers at two time points: prior to start of boot camp training program and upon completion of program. The "boot camp" training program included: (1) admission care conference, (2) training contract, (3) structured daily training schedule, and (4) completion with nine structured training sessions (three hours of content per session). Outcome measurements included: (1) demographic data from 34 caregivers and their children, (2) pre- and post-intervention scores on parental stress levels from the 36-item Parenting Stress Index-4-Short Form with three subscales (PSI-4-SF; Abidin, 2012), (3)

caregiver satisfaction related to the training, and (4) comparisons of average or median lengths of stay of patients (on unit and in hospital) whose caregivers were enrolled in the experimental group and matched-control group of medically-dependent patients whose caregivers completed pre-boot camp training. Data analyses performed were descriptive data (means, standard deviations, medians, percentages, frequencies for all study measures, independent-sample Mann-Whitney *U* tests for non-normal data (total length of stay in hospital, length of stay on TCU), paired-sample *t* tests for total number of days of documented discharge training, and repeated measures analysis of variance (RMANOVA) for within-group PSI-4-SF scores.

Results: Results pre-and post- boot camp implementation included: (1) median unit length of stay (LOS; 77 versus 43 days [$p=0.004$]), decreased by 44%; (2) median hospital LOS (146.5 versus 82 days [$p=0.017$]), decreased by 44%; (3) average documented discharge training days (41.5 versus 15.7 days [$p<0.0001$]), decreased by 62%; (4) Parental Stress scores related to: (a) Perceived Parental Distress (26.7 versus 23.1 [$p<0.0001$]), (b) Dysfunctional Interaction (22.3 versus 20.5 [$p=0.012$]), (c) Perceived Difficult Child (23.4 versus 21.8 [$p=0.021$]), and (c) Total Parental Stress scores (72.8 versus 65.4 [$p<0.0001$]); and (4) Caregiver Satisfaction with Boot Camp Training (>90% were very satisfied). With DRG-related 42-50 day LOS limits, pre-boot camp 77-day LOS, and average daily unit cost of \$1974, savings were estimated between \$53,300 and \$69,900 per patient on the transitional care unit.

Conclusion: The boot camp training program significantly decreased days of documented discharge training, parental stress, and length of stay with positive financial impact. One lesson learned was the need for frequent communication between disciplines regarding research process and outcomes, to sustain support and buy-in. The structured training format and engagement of research team with unit frontline nurses have contributed to caregiver satisfaction and accountability as well as nursing staff engagement with the boot camp initiative. Based on study findings, senior nursing administration has agreed to develop a Family Educator position to track and evaluate boot camp discharge education and its outcomes on the transitional care unit. Next step will be the evaluation of correlations between caregiver boot camp training and patient early hospital readmissions. The implementation of a structured "boot camp" training program for caregivers led to increased staff comprehension on what is expected for the discharge training needed by caregivers of complex medically-dependent children. This model could be customized to other areas (adult and pediatric) where there are medically complex patients.

A 13 - Promoting Healthy Work Environments for the Clinical Nurse A Model-Based Ergonomic Risk Management Program to Reduce the Musculoskeletal Symptoms of ICU Nurses

*Duygu Sezgin, PhD, MScN, BScN, RN, Ireland
Melek Nihal Esin, PhD, MScN, BScN, RN, Turkey*

Abstract

Purpose: Nursing profession is identified as having the highest risk in terms of ergonomic risk. Nurses stand for long hours, do pushing, pulling, elevating movements, as a result of which, musculoskeletal disorders may easily develop (Rasmussen et al. 2013, Sezgin and Esin 2015). The prevalence of the musculoskeletal symptoms (MSS) of nurses working in the clinical settings is found to be between 69.55-88.2% in the literature (Samaei et al. 2015, Barkhordari et al. 2015, Ganiyu et al 2015). Having MSS decreases work performance, and increases work absenteeism, this affects patient care negatively and increases the illness costs (Lee et al. 2013, Lu et al. 2012, Khamisa et al. 2013) Musculoskeletal disorders may be prevented by effective ergonomic risk management programs. These programs include; body mechanics training, exercise education, giving educational materials and they do not require for the nurses to leave their daily work (Lim et al. 2011, Black et al. 2011, Odeen et al. 2013, Côté et al. 2013, Stigmar et al. 2013). The aim of this study is to evaluate the effects of ergonomic risk management program with a view to reduce MSS of the ICU nurses.

Methods: The study which is developed as “Pre-test post-test design for non-equivalent control groups” comprised in Istanbul, Turkey. The study population consists of two hospitals that are connected to Ministry of Health and have adult intensive care units. The data was collected from 8 ICUs including general, emergency, reanimation, coronary and neurology. The ICUs were evaluated and compared by their physical and ergonomic environmental characteristics. They are found to have the similar characteristics following the criterias such as architectural structural appropriateness, patient transfer equipments (lifts, stretchers) and bedside support areas.

The study sample included 116 nurses with high ergonomic risk who have been working in intensive care unit more than 6 months, and accepted to participate the study (Hospital A: 57, Hospital B: 59). The sample size was calculated by power analysis as 72 ICU nurses (36 in intervention group, 36 in control group). According to that, 35 nurses were selected for the intervention group and 37 nurses were selected for the control group by systematic sampling.

In the pre-test section of the study, the “Descriptives of Nurses and Ergonomic Risk Reporting Form” and “Rapid-Upper Limb Assessment (RULA)” tool were used to collect data about demographics of nurses and the level of ergonomic risks. An “Ergonomic Risk Management Program (ERMP)” was applied to the nurses in the intervention group. The ERMP is a health promotion program developed by using PRECEDE-PROCEED Model. The interventions included by the ERMP are (1) a video training lasts for two weeks which is related to the musculoskeletal risks and exercises to prevent them in the ICU settings without disrupting the works processes of the nurses (2) providing educational materials such as booklets and CDs including the training program (3) personal interviews about discussing the predisposing, reinforcing and enabling factors of behavior change (4) providing exercise mats for the nurses to be able to do the exercises shown during the video training. In 26 weeks following the intervention, SMS reminders were sent to the nurses every four weeks and there was a follow-up including ergonomic risk assessments in the first and third months. After this, the same data collection forms related to nurses’ levels of ergonomic risk were applied to the both groups.

The Statistical Package for Social Sciences 16.0 software was used in statistical analysis. The sociodemographic, ergonomic and working conditions of the nurses were displayed as number, percentage and mean. The paired samples t-test, Q-square test, the analysis of variance in repeated measures, and Cochran’s Q test were applied to evaluate and compare the association between the variables considering the homogeneity and the type. The findings were evaluated in between the 95% confidence interval.

Results: The mean age of the nurses was 27.71 ± 5.21 and 73.6% were female. The Body Mass Index of the nurses was 22.6 ± 3.1 , and 62.5% of them were not doing regular exercise. In the results of the study it is found that there was no difference between the intervention and control group for sociodemographic characteristics, general health and work conditions, MSS, level of pain and ergonomic risk scores ($p > 0.05$). Following this information, these two groups were identified as having similar characteristics before the ERMP intervention.

The legs and lower back were the body parts that MSS are mostly seen before and after the ERMP intervention. In the following month of ERMP intervention, the RULA arm, hand, wrist (score A), trunk, leg, feet (score B) and total scores were found to be decreased as, 0.79, 0.96 and 0.82 points for the patient turning movements and 0.82, 1.85 and 1.40 points for the bending down movements, respectively.

At the end of the ERMP follow-up by the sixth month, the nurses in the intervention group were found to have a significant increase on the frequency of exercise. Moreover, there was a significant decrease on the perceived MSS related pain intensity scores as 0.77 points ($p < 0.05$). The mean total RULA score of nurses for patient turning movement was found to be 4.39 ± 1.49 which means "immediate further analyses and modifications recommended". The mean total RULA score of the nurses for bending down movement was found to be 3.75 ± 1.64 which means "further analyses and modifications recommended". However, there was no significant change in the sick leave days in the intervention group before and after the ERMP.

Conclusion: This study revealed that ERMP was effective not only to reduce the ergonomic risks and MSS related pain level but also to increase the exercise frequency of the ICU nurses. The ergonomic risk management interventions intended at reducing the musculoskeletal symptoms will improve the quality of life of the nurses and their work performance in the long term. The programs focused on risk management and continuous risk assessment which is applied at the workplace could be recommended for the future studies. The study designs in relation to ergonomic risk prevention should be developed in a model based framework and also include visual technologies such as video films and valid measurement risk assessment tools in order to reduce MSS of the ICU nurses.

A 13 - Promoting Healthy Work Environments for the Clinical Nurse Evaluation of a Planned Rest/Nap for Hospital Night-Shift Nurses

Diane A. Drake, PhD, RN, USA

Monica Malcuit, BSN, RN, USA

Abstract

Purpose: The purpose of the study was to investigate a fatigue risk management intervention for surgical intensive care unit nurses working twelve-hour night shifts.

Background: The American Nurses Association (ANA) position statement addressing nurse fatigue identifies a shared responsibility between nurses and employers to diminish the risk of nurse fatigue, endorse a culture of safety and create balance in work-life settings. ANA recommendations emphasize nurses and employers work together and strategically implement fatigue countermeasures to reduce fatigue and sleepiness in the work place (ANA, 2014). Night shift nurses have significant risk to experience alterations in both waking and sleeping states because of disrupted circadian regulation (Lee, Gay & Alsten, 2014). Fatigue induced impairment may result in medication and medical errors, mislabeled lab samples and calculation errors. Fatigue studies conducted with other 24-hour professionals including law enforcement officers indicate shiftwork has a cumulative and debilitating effect on judgment and decision-making (Violanti, 2012).

Methods: A quasi-experimental descriptive design was used for the purpose of this study to investigate the feasibility and effects of a fatigue risk management strategy that included a planned rest/nap for nightshift registered nurses (RNs) working full-time on a Surgical Intensive Care Unit (SICU). The study team included nurse leaders who reported to the hospital chief nurse officer and the principal investigator was an administrative nursing supervisor. The specific aim of the study was to answer three research questions:

- 1) What was the rate of nurse participation in the fatigue risk management intervention?
- 2) Was participation in the planned rest/nap associated with changes in; a) nurse fatigue, b) nurse sleepiness and c) nurse sleep quality?
- 3) Was participation in the planned rest/nap associated with SICU unit changes in a) medication errors, and b) sleep room logistic difficulties?

Subjects: All SICU RNs working night shift were invited to participate in the study. Study eligibility required RNs to: (a) be an SICU nurse working night shift with an independent assignment for at least six months, (b) be scheduled to work during the study period, (c) not have a diagnosis of a primary sleep disorder, and (d) provide written consent to participate in the study.

Sample: There were 21 respondents during recruitment, 17 nurses met inclusion criteria and were enrolled. One nurse transitioned to day shift at week 6 and was dropped from the study. A total of 16 nurses completed the twelve-week study. Participation in the study was voluntary. Prior to initiation of recruitment, the study received approval from the healthcare system investigational review board (IRB).

Protocol: RN participants were asked to schedule a planned rest/nap during a thirty-minute lunch period in a designated rest/nap room. The rest/nap room was designed and arranged by nursing leaders and members of the study team with financial support from the CNO. Each RN was responsible to begin and end the rest/nap according to the planned scheduled time and return to work alert. Rest/naps schedules were coordinated each shift by RNs with the charge nurse who maintained a form listing tentative break times between the hours of 1- 4 a.m. RNs were encouraged to eat lunch during another fifteen-minute break and were provided with a "Nap Protocol" that clarified expectations of a planned rest/nap and nap room logistics. Taking a nap was not mandatory but sleep was encouraged if possible. If unable to sleep, resting was recommended.

Setting: The study took place at a Magnet designated, level II trauma center in South Orange County, California in a twenty bed SICU.

Data collection: Following informed consent, RNs provided descriptive information and completed three study questionnaires using a survey generator, Qualtrics[®].

Data entry and analysis: Study forms used a study code assigned to each RN and all data collected was kept confidential. There was no individual identification of RN participant in the data file or analysis of results. Statistical analysis was conducted using IBM Statistical Package for the Social Sciences (version 22). Descriptive statistics were used to describe sample characteristics of RNs. A percentile rest/nap participation was calculated using a summary of rest/nap log reports from each shift worked. An average (mean) was calculated from fatigue and sleep scores using six and twelve week survey responses. Weekly unit medication errors and sleep room logistic difficulties were summarized from pharmacy and study log reports.

Study measures: Each RN completed a planned rest/nap log. Descriptive measures included nurse age, years worked, nursing degree and chronotype and history of napping at work. Pre-test and week-six and week-twelve survey measures included the Pittsburgh Sleep Quality Index (PSQI), The Epworth Sleepiness Scale (ESS), the Occupational Fatigue Exhaustion and Recovery Scale (OFER) and the Chalder Fatigue Scale. Weekly medication error rate reports were provided by the pharmacy to the study team during the twelve-week study. Sleep room logistics difficulties were summarized from the nurse rest/nap logs.

Results: Sixteen nurses, thirteen females and three males completed the twelve-week study. The average age was 37. Highest education was BSN (11), and ADN (5). The range for continuous night shift work years was 2 – 23 years, mean 7.09 (7.36) years. Ten nurses reported chronotype more evening type (owls), and 6 were more morning type (larks). Nine RNs reported never napping at work prior to the study and seven RNs reported only occasionally napping at work prior to the study. Average RN rest/nap participation during the twelve-week study was 62% with a range of 42% - 86%. Of 573 shifts worked, 196 naps were taken and 160 rests were taken. The majority, twelve RNs reported taking a combination of rest and naps. Two RNs took naps only, and two RNs took rests only. Improvements were observed in the average scores of physical fatigue, inter-shift recovery, and sleepiness at six weeks and improvements again at twelve weeks. Improvements in chronic fatigue were observed and week six and stable at week twelve. Mental and acute fatigue scores improved at week six and were worse (increased) at week twelve. Sleep quality did not improve at week six, but did improve at week twelve. There was one “low risk” of harm to the patient medication error reported by pharmacy during the study period. There were four reports by RNs of difficulty with room logistics because the rest/nap room was not available (already scheduled). There were twelve reports the rest/nap room was noisy.

Conclusion: Although many hospital nursing units provide a break room where nurses may rest or eat away from patient care, designated rest/nap rooms are not commonly available to nursing staff. Hospital nurses have many reasons to not rest or nap during the work shift. Many nurses are concerned with lack of administrative support, perceived inability to work twelve hours, a culture that does not tolerate sleep on the job, sleep inertia, and inadequate facilities to promote quiet, clean, undisturbed, secure and private rest/napping. This twelve-week study demonstrated that nurses who previously would never rest or nap were able to rest/nap on most shifts work and report less physical fatigue, less sleepiness, and improved sleep quality. A planned rest/nap intervention was an effective fatigue risk management strategy. The findings in this study support the shared responsibility of fatigue risk management between nursing leadership and clinical nursing staff.

A 14 - Adherence in Hypertension Patients

Improved Adherence Status in Patients With Hypertension: A Community-Based Intervention

Thitipong Tankumpuan, MSN, BSN, RN, USA
Sakuntala Anuruang, PhD, RN, Australia
Debra Jackson, PhD, RN, FACN, United Kingdom
Louise D. Hickman, PhD, MPH, BN, RN, Australia
Michelle DiGiacomo, PhD, MHS (Hons), BA, Australia
Patricia Mary Davidson, PhD, MEd, BA, RN, FAAN, USA

Abstract

Purpose: Although high quality treatment and modern hypertension clinical practice guidelines have been developed worldwide, the outcomes of hypertension patients in Thailand are not optimal. Previous hypertension management interventions mostly focused on knowledge improvement with a short time follow-up of outcome. Moreover, the accessibility to advanced treatment is limited to metropolitan areas and for high socioeconomic status patients. Ignoring characteristics such as social determinants of health may cause the failure of the previous intervention. Implementing person-centered and integrated health services model (PC-IHS) such as community-based intervention is challenging for health care providers in Thailand to improve the hypertension management. The objectives of this study aim to predict the effect of community-based intervention and socioeconomic status influencing adherence status at baseline, 1, 3, and 6 months following a self-management intervention; and to evaluate the model selection of community-based intervention and other socioeconomic status influencing factors between improved and non-improved adherence status at the end of the study

Methods: A cross-sectional data analysis of each time phase of the parent study “Community-based intervention to promote self-management for rural dwelling older people with hypertension: mixed method study”. The study settings comprised of residents in 17 villages, and were users of the primary health care center in Nakhon Ratchasima Province, Thailand. All participants were separated into two groups based on geographical area and allocated into the intervention and the control group through a simple random technique. Both groups received routine care and a self-management tool kit. In addition, the intervention group received the four-week community-based intervention program which contained group activities, individual home visits by researcher. Multiple linear regression was applied to predict adherence status at each phase followed by stepwise regression with backward selection technique to select significant predictors. After 6 month, patients were categorized into improved and non-improved adherence status. Parametric and non-parametric were applied to compare general characteristics between groups. Then, multiple logistic regression was implemented to predict influencing factors between groups followed by a model selection using Akaike information criterion (AIC) with forward selection technique.

Results: A sample of 156 elderly with hypertension, 70 years old on average and mostly female (68.5%). 77 (49.36%) participants attended a community-based intervention. Patients who received intervention had significant lower adherence score (a higher score reflects a lower level of adherence) at 3 and 6 months after intervention by 1.66 points (95%CI 0.61-2.71, $p<0.001$), and 1.45 points (95%CI 0.47-2.42, $p<0.001$) respectively when adjusting other variables. Moreover, women had a statistically significantly lower adherence score than men at baseline and 3 months after intervention, patients with other comorbidities had significant lower adherence score than patients with hypertension only at all follow-up period. After six month from baseline, there were 74 (47.44%) participants who had improved adherence status. The community-based intervention was associated with a significant improvement in adherence adjusted for other variables (odds ratio = 2.65 [95% CI 1.32–5.35], $P=0.006$). The decreasing of waist circumference demonstrated a trend in improved adherence (odds ratio = 1.85 [95% CI 0.91–3.77], $P=0.09$). The final model that impacted on improve adherence by forward selection with AIC comprised of intervention, decreasing of waist circumference and marital status (LR χ^2 (4) =15.98, $P=0.003$, AIC=209.87)

Conclusion: This study provides evidence to support the use of community-based intervention as an effective adjunct to hospital-based care of patients with hypertension. Understanding the influencing factors between health outcomes and social determinants of health is critical for informing intervention development.

A 14 - Adherence in Hypertension Patients

Health Beliefs and Medication Adherence Among Omani Patients With Hypertension

Huda Al Noumani, PhD, RN, CNS, Oman

Jia-Rong Wu, PhD, RN, USA

Debra Barksdale, PhD, RN, FNP-BC, CNE, FAANP, FAAN, USA

George Knafel, PhD, USA

Gwen Sherwood, PhD, RN, FAAN, USA

Esra Al-Khasawneh, DNSc, MSN, RN, FAAN, Oman

Abstract

Hypertension (HTN) is a public health concern around the globe, which if not treated will lead to serious cardio and cerebrovascular complications. Antihypertensive medication is central in controlling BP and preventing HTN-related complications. Despite the effectiveness of medications, adherence to antihypertensive medications remains a challenge and less than 50% (WHO, 2013). Plenty of literature has reported different factors contributing to better or worse medication adherence in patients with HTN (AlGhurair, Hughes, Simpson, & Guirguis, 2012). Health beliefs about HTN and its medications are among patient-related factors that significantly related to antihypertensive medication adherence (AlGhurair et al., 2012). For example, stronger beliefs about HTN severity and susceptibility to its consequences, stronger beliefs about necessity of antihypertensive medications, higher self-efficacy, and fewer concerns about medication were associated with higher medication adherence (Kamran, Ahari, Biria, Malpour, & Heydari, 2015). These studies are consistent with the health beliefs model. In Oman, a high-income developing country, HTN prevalence is high and many studies have examined HTN prevalence and risk factors (Al-Maqbali, Temple-Smith, Ferler, & Blackberry, 2013; Al-Mawali, 2015). However, studies examining medication adherence and patients' beliefs and medication adherence are lacking. It is essential that clinicians assess patients' beliefs when aiming to improve medication adherence to plan effective and personalized plan of care.

Purpose: The aim of this study is to examine Omani patients adherence with antihypertensive medications and their beliefs regarding HTN severity, necessity of and concerns about medications, and medication adherence self-efficacy. The study also aims to examine the relationship between 1) patients' beliefs and medication adherence and 2) medication adherence and blood pressure (BP) control in Oman.

Methods: This cross-sectional study used descriptive correlation design and was conducted in Oman using 25 primary health care settings in 6 Omani governorates. Participants completed 4 questionnaires in Arabic version to measure medication adherence (Morisky medication adherence scale), beliefs about HTN severity (Brief illness perception questionnaire), beliefs about medication necessity and concerns (Beliefs about medicine questionnaire), and self-efficacy (Medication adherence self-efficacy scale). In this study, high medication adherence is defined as a Morisky scale of ≥ 6 . BP values of the day of the study were taken from patients' electronic medical records. Descriptive and Bivariate and multivariate logistic regression were used to conduct the analyses.

Results: The study included a total of 215 participants with HTN with a mean age of 54 years ($SD=13.1$). Study findings showed 68% of participants reported high adherence and 63% have uncontrolled BP. Majority of participants reported stronger beliefs about necessity of medication (mean score = 3.7, $SD = 0.9$), higher self-efficacy regarding their ability to adhere to medications (mean score = 3.4, $SD = 0.7$), fewer concerns about medication (mean score = 2.4, $SD = 0.8$), and believed that HTN is not a severe condition (mean score=25.8, $SD = 12.2$). Logistic regression analysis showed that higher self-efficacy ($OR=2.59$; 95% $CI 1.54-4.37$), stronger beliefs about medication necessity ($OR=1.98$; 95% $CI 1.21-3.23$), increased age ($OR=1.06$; 95% $CI 1.03-1.10$), and fewer medication concerns ($OR=0.34$; 95% $CI 0.20-0.57$) were significantly related to high medication adherence and explained 37% of variation in medication adherence. Furthermore, participants with high medication adherence were less likely to have their BP uncontrolled ($OR=0.47$; 95% $CI 0.24-0.93$) and explained 3% in BP control variation.

Conclusion: Findings regarding the relationship between medication adherence and beliefs about the necessity of and concerns about medication and self-efficacy are consistent with studies among patients with HTN and other chronic conditions. Although we did not find a significant relationship between medication adherence and beliefs about severity of HTN, the direction of the relationship was negative, which is inconsistent with majority of studies that reported a positive relationship. This inconsistency in findings could be related to cultural variation and the influence of unique Islamic beliefs on disease and treatment. Therefore, clinicians and researchers should be aware that beliefs might vary across cultures and/or within cultures.

Results of this study indicated that patients beliefs play significant role in medication adherence, which highlight the significance of assessing and incorporating patients' health beliefs in clinical practice by the clinicians (e.g., physicians, nurses). Moreover, strategies to improve medication adherence should incorporate beliefs as key component for effective and personalized plan of care for patients with HTN generally and Omani patients specifically.

A 15 - Research and Implementation

Strategies to Increase Research Productivity in a College of Nursing

Stephen J. Cavanagh, PhD, RN, FACHE, FAAN, USA

Abstract

Purpose: The purpose of this five-year evaluation case study (2011-2016) was to identify changes in faculty scholarly performance metrics associated with the introduction of a research strategic plan within a college of nursing in the United States of America.

Methods: The methods used in this case study included the collection of scholarly performance data (e.g. external funding, publications, etc.) and the research interests of nursing faculty. This data was obtained from self-reports, literature searches and official university research expenditure data. In addition, individual and small group interviews were held with nursing faculty as a means of clarifying personal research priorities. Data from these meetings (2011) were used as a focus for a number of faculty-wide discussions aimed at determining research priorities for the next 5 years. From these, a series of four research priorities were identified: symptom management, gerontology, health services, and social justice research. A national comparison of research active schools/colleges was also performed to gauge current research expenditures. Other data was calculated including a measure of 'tenure density' (ratio of tenure track and tenured faculty and the size of the undergraduate student body). This metric was calculated from data made available from the American Association of Colleges of Nursing (AACN). Data was also collected from a number of other sources, including faculty self-reports of scholarly output. Data was collected on the growth in faculty and student enrolment and on alumni and development fund-raising activities. All the above data was collected annually and entered into a database.

Results: The results and findings from this case study report the changes in research productivity following the introduction of a research strategic plan. Data showed that it was possible to identify a series of measures that may be indicative of future success in obtaining research funding. These were identified as a formal research strategy, growth in the faculty size, the determination of tenure density metric, the number of collaborative relationships outside of the college of nursing, growth in development funds, and financial investment in faculty development. One of the most important findings from this evaluation was the growth in submission of requests for external funding. During the study, the total number of grants submitted rose from 13 (2011) to 33 (2016), while external funding rose from \$48k to \$2.33m in the same time period, and included the awarding of a P20 center grant.

Conclusion: The findings of this evaluation study suggest the importance of developing research priorities as part of an overall research strategy for a college. Aligning these priorities with activities such as hiring new faculty and developing partnerships across campus was essential in developing a growing research and scholarly output. It was also recognized that the concept of tenure density might be an important measure to consider when developing a research strategy. This, in turn, may provide important insight into determining what the optimum college might be, based on faculty and student numbers. The idea of growing a research program based upon tenure density, however, needs further work in nursing. This study illustrates that many factors can influence the growth of research productivity, including fund-raising and inter-collegiate collaborations.

A 15 - Research and Implementation

Making Your Research More Robust With Implementation Science

Linda Costa, PhD, RN, NEA-BC, USA
Marianne Weiss, DNSc, RN, USA
Kathleen Bobay, PhD, APRN, BC, USA
Ronda Hughes, PhD, MHS, RN, CLNC, FAAN, USA
Susan A. Nuccio, MSN, RN, ACNS-BC, CGRN, USA
Sarah J. Bahr, MSN, RN-ACNS, USA
Danielle M. Siclovan, MSN, NE-BC, USA

Abstract

Purpose: Implementation science is the study of methods, interventions, and variables that promote uptake and use of research and other evidence-based practices by organization with the goal of improving health care quality. This study applies the Consolidated Framework for Implementation Research (CFIR) and its constructs to describe the implementation experiences of 34 Magnet hospitals in the United States and Saudi Arabia participating in the Readiness Evaluation and Discharge Intervention (READI) Study. The READI study seeks to implement discharge readiness as a standard of nursing practice. The study has three phases: Phase 1 nurses perspective of discharge readiness, Phase 2 patient perspective of readiness added to nurse perspective, and Phase 3 addition of a discharge action guide. The study is implemented over 12-months. Formative evaluation was used to gather information on the facilitators and challenges of the implementation process from the site Principle Investigators (PIs).

Methods: Each participating hospitals designated a site PI who was responsible for implementation of the READI study in their hospital including obtaining institutional review board (IRB) approval. The site PIs were invited to participate in an interview in the last phase of the READI study (Phase 1 + Phase 2+ Phase 3 [discharge action guide]). The interview guide was developed by the READI researchers using a Delphi process identifying CFIR constructs significant to the study process from among the 38 constructs in the framework. The constructs were used to develop an interview guide around eight themes. After IRB approval, each site PI was invited to participate in the interview using Go-to-Meeting. The national study team conducted each interview, one team member asked questions and one team member recorded notes. Interviews were recorded to clarify any missing information. NVivo 10 was used for analysis.

Results: CFIR constructs identified as important to the implementation process included the site PI role and recognition within the organization, the skills/attributes important to being the site PI, logistics planning with the unit staff, changes to hospital leadership particularly the Chief Nurse, engaging leaders, and identifying unit champions. When queried about adding the patient's perspective of discharge readiness (Phase 2), to the nurse's perspective (Phase 1), several site PIs identified positive changes in Hospital Consumer Assessment of Healthcare Providers and Systems (HCHAPS) scores, a patient satisfaction survey required by the Centers for Medicare and Medicaid Services (CMS) for all hospitals in the United States. Overall patients welcomed the dialogue with the nurse as part of their discharge care. Improvement in HCHAPS scores was an unexpected study finding.

Conclusion: The CFIR proved to an optimal framework for developing an interview guide for formative research. Although the main quantitative READI study outcome was to reduce unplanned readmissions, the formative evaluation process of interviewing site PIs identified additional outcomes that provide measures of study success important to hospitals: bringing research to bedside nurses, having practicing registered nurses see the value of participating in clinical research, and recognizing the importance of the patient s perspective of discharge readiness. The information gathered from key stakeholders (site PIs) provided additional evaluation information of study success and challenges from the organizations perspective

A 16 - Strategies in Disaster Preparedness

Crisis Leadership and Decision-Making: Hospital Administration and Nurse Leaders' Concerns for Disaster Response

Tener Goodwin Veenema, PhD, MSN, MPH, RN, CPNP, FAAN, USA

Katherine DeRuggiero, DNP, RN, USA

Sarah Lynn Losinski, MPH, RN, USA

Daniel Barnett, MD, MPH, USA

Abstract

Purpose: The purpose of this study was to characterize and explore the essential elements of effective hospital and nursing leadership during disasters and MCIs and to identify those events of greatest concern for response. Disaster and mass casualty incidents (MCIs) impose a huge burden on health care leaders. These events create a sudden, unanticipated demand for care referred to as 'patient surge' that has the potential to quickly overwhelm a hospital's capacity to function properly. The demand for health care services exceeds capacity to respond and the institution's normally acceptable patterns of operations and logistics are disrupted. Strong crisis leadership is critical for timely, effective and coordinated response. This requires that hospital administration and nursing leadership are competent in making rapid and complex decisions – often in the absence of complete information and involving the allocation of scarce resources (staff, medical equipment and supplies, pharmaceuticals, etc). It requires implementation of crisis standards of care.

Methods: A series of structured focus groups was conducted with a purposive sample of hospital administrators (n=36) and nurse leaders (n=17) in a large urban hospital in the U.S. Northeast widely recognized for its expertise in hospital emergency preparedness. Participants were asked a series of semi-structured questions related to observations of crisis leadership during recent disaster and MCI events. Data were collated and analyzed to determine events of greatest concern, impact of event on leadership decision-making, and perceived capacity for organizational surge.

Results: The results suggest hospital administration and nurse leaders harbor serious concerns regarding crisis leadership competence and organizational capacity to surge up in response to large scale community violence/civil unrest, biological event/pandemics, and acts of terrorism (fire/bombings/active shooters) that result in a mass tragedy. The results of hospital administration and nursing leadership decisions have the potential to directly impact staff and patient safety and quality of care and ultimately, patient outcomes. As such, there is compelling need to prepare hospital administrators and nurse leaders for crisis conditions resulting from disasters and MCIs.

Conclusion: Disaster and mass casualty incidents (MCIs) impose a huge burden on health care leaders and strong crisis leadership is critical for timely, effective and coordinated response. The purpose of this study was to characterize and explore the essential elements of effective hospital and nursing leadership during disasters and MCIs and to identify those events of greatest concern for response. The results suggest hospital administration and nurse leaders harbor serious concerns regarding crisis leadership competence and organizational capacity to surge up in response to large scale community violence/civil unrest, biological event/pandemics, and acts of terrorism (fire/bombings/active shooters) that result in a mass tragedy.

A 16 - Strategies in Disaster Preparedness

American Red Cross Simulation and Student Nurse Disaster Preparedness

Patricia Frohock Hanes, PhD, MAEd, MS-DPEM, RN, CNE, CLSSGB, USA
Anna Marie Hefner, PhD, MSN, BSN, RN, MaEd, CPNP, USA

Abstract

Background: Disasters, natural and man-made, are increasing world-wide. Student nurses are an under-utilized resource in disaster response. As pre-professionals with some training, they have the ability to increase response capacity during disasters. Nursing organizations in the United States such as the American Association of Colleges of Nursing (AACN) and the National League for Nursing (NLN) advocate some form of disaster nursing education across all levels of nursing (AACN, 2006, 2008, 20011; NLN, 2013). The International Council of Nurses (ICN) developed a list of core competencies for disasters in 2009; the National Student Nurses' Association in the United States (2012) promoted the training and use of student nurses during disasters. Nurses lack confidence and adequate education to participate in disaster activities (Hanes, 2016; Locke & Fung, 2014). In 2012 the American Red Cross introduced a four-hour hybrid disaster nursing course.

Purpose: This presentation will describe the conduction of a web-enhanced, low-fidelity disaster simulation and the results of an evaluative survey administered after a disaster simulation and hybrid (online and face-to-face) disaster nursing course with student nurses.

Conceptual Frameworks: Theories of learning styles, social cognitive learning, self-efficacy, volunteerism and human behavior theories.

Methods: The American Red Cross developed a disaster course to enable student nurses to increase awareness of their roles in disaster preparedness and how to actually participate in a disaster. The course consisted of a web-enhanced low-fidelity simulation with interactive injects where students responded to disaster scenarios. Students, placed in groups, discussed responses to web prompts, videos, and facilitator questions. Prior to the first administration of the course in 2014, the course had only been held once in the Los Angeles region. This four-hour, non-credit course was held on a Saturday morning; 100 nursing students participated. Unfortunately, due to space limitations, some students desiring to attend were unable to participate. Subsequent courses held in smaller venues were well attended; to date, approximately 200 students (and some faculty) have completed the course. Three hypotheses were explored: Hypothesis 1: Simulation will provide a supportive learning process in disaster preparedness. Hypothesis 2: Disaster simulation will increase self-efficacy in students in disaster situations. Hypothesis 3: Low-fidelity disaster simulations are an effective way to teach disaster preparedness.

Evaluative survey data was collected in four areas: demographics, simulation design, educational practices, and student satisfaction and self-efficacy.

Results: Demographics: Participants in this descriptive study consisted of 84.2% females and 8.9% males. Hypothesis 1: 88% of the participants agreed that the simulation design for disaster preparedness provided an opportunity for them to think critically about the scenarios and globally about their roles in disasters; 93% felt the simulation design supported the gaining of knowledge in disaster preparedness. Hypothesis 2: 87% of participants became more confident in their ability to provide care. They found the simulation challenged their comfort level allowing for learning from mistakes and holistically viewing the individual and the community. Hypothesis 3: The simulation provided a hands-on opportunity to see the classroom learning/skills gained applied in multiple realistic settings. Eighty-four percent found the variety in scenarios and delivery in the simulation increased both their knowledge and interest in, as well as response to, disasters. In the debriefing session conducted at the conclusion of the exercise, students reported a desire to learn more about disaster nursing and to volunteer for disaster organizations.

Conclusions: Student nurses are a valid asset in disaster preparedness and response and increase the region's capacity to respond in times of crisis. National and international nursing organizations have mandated that nursing students have preparation in disaster preparedness and response. Students are enthusiastic about having the opportunity to respond to disasters and are willing to work beyond their regular duties to participate in disaster-related learning activities. Future research must explore ways to effectively incorporate broad disaster nursing education into existing curricula while providing practical experiences via participation in simulations and/or actual disasters. More faculty need training to be prepared to teach this essential content. Further opportunities for nursing disaster education and research are needed in this evolving field.

B 05 - Factors Affecting Oncology Patients

Skin Toxicity Assessment in Breast Cancer Patients: A Study on Interobserver Variability and Self-Reported Measures

Kristiina Hyrkas, PhD, LicNSc, MNsc, RN, USA

Susan Getz, BSN, RN, OCN, USA

James R. Kavanagh, MSN, RN, ARNP-BC, OCN, USA

Nellie P. Bergeron, BSN, RN, OCN, USA

Julie A. Wildes, RN, OCN, USA

Ian J. Bristol, MD, ABR, USA

Abstract

Purpose: Radiation skin reactions are a common acute side effect in breast cancer patients undergoing curative radiotherapy (RT). The manifestation of acute skin toxicity ranges in many patients from erythema to dry desquamation, moist desquamation, and in rare cases, ulceration and necrosis. It has been estimated, that radiation induced skin reactions, also known as radiodermatitis, affects most of cancer patients (74% to 100%) receiving radiation therapy (Schurn et al. 2011). Risk factors for acute radiation skin reactions (ARSR) including treatment-related factors such as the radiation dose, volume, RT technique and previous treatment, type of surgery and previous chemotherapy, and patient-related factors such as body mass index (BMI), smoking status and previous skin damage have been reported in the literature with conflicting results (Sharp et al. 2013,b).

Although the majority of skin reactions heal within several weeks from completion of therapy, skin reactions may cause distressing symptoms to patients, and occasionally may be dose limiting or cause a therapy break (Banning, 2011). An extensive range of topical agents and dressings have been studied for prevention and management of radiodermatitis (Feight et al., 2011). For example, corticosteroid products have been tested in a few clinical trials, but so far, no clear benefits regarding the effect on ARSR have been demonstrated (Feight et al., 2011; Miller et al., 2011). The effects of Aloe Vera products have also been investigated in randomized controlled trials (RCTs) but failed to show significant benefits in preventing or minimizing ARSR (Hoopfer et al. 2015). Other types of products containing such agents as sucralfate, urea and hyaluronic acid have shown no or limited positive effects in preventing or reducing ARSR (Pinnix et al., 2012).

The effects of skin care products containing *Calendula officinalis* (marigold plant) on ARSR in patients with breast cancer have been investigated by Pommier and colleagues (2004) and also Sharp and colleagues (2013,a). In Pommier's study, patients in the experimental group, treated with *Calendula* cream had a statistically significant lower incidence of severe ARSR, pain and treatment interruptions in comparison with the patients in the control group, treated with trolamine. However, Sharp and colleagues (2013) did not find any differences in ARSR between patients randomized to two groups using either *Calendula* or *Essex* cream (i.e. an aqueous, moisturizing cream). These results called for further investigations. Therefore, we designed and conducted a randomized, open-label study to test whether skin care using topical *Calendula officinalis* was superior to aqueous cream (Aquaphor)/Aloe Vera in reducing the risk of severe ARSR in patients with breast cancer treated with adjuvant RT. We had also learned from the literature (Schurn et al. 2011) that only a few studies had been conducted on acute toxic effects experienced and assessed by patients undergoing curative RT and that there was a need for close investigation on the skin assessment scale in use.

The purpose of this study was to describe the skin toxicity assessments in breast cancer patients treated with radiotherapy, and the level of agreement and variability between observers'/ investigators' scorings. The objective was to evaluate up- or downgrading in the prospectively collected data on acute toxic effects, photos and patient-reported outcomes in our randomized, open-label study comparing *Calendula* versus Aquaphor/Aloe Vera.

Methods: In our study, skin assessments were conducted weekly (weeks 0 – 7) using the Radiation Therapy Oncology Group (RTOG) Acute Radiation Morbidity Scoring Criteria and documented in the data

collection tool by four RT nurses of our research team. An educational session was organized for these nurses, prior to the study, regarding the data collection and the RTOG Acute Radiation Morbidity Criteria, and including photos of skin reactions. All nurses of the research team completed a written quiz and scored correctly at least 85% or higher of the skin assessments. A refresher education was organized annually.

The RTOG scale grades ARSR from 0 to 4 (0= No change over baseline; 1= Follicular, faint, or dull erythema; epilation, dry desquamation, or decrease in sweating, 2= Tender, bright erythema; patchy, moist desquamation or moderate edema, 3= Confluent, moist desquamation other than skin folds; pitting edema, 4= Ulceration, hemorrhage, necrosis). In this study, we used the RTOG scores and digital photos that were taken of the treatment area on weeks 0, 2, 4, 6. The digital photos were reviewed and scored, using the RTOG, by a radiation therapy RN, physician/Radiation Oncologist and a research nurse. Self-reported skin care, reactions and symptoms from the irradiated area (i.e. skin reactions, sensation, skin color and pain) were documented in a home journal weekly by patients. The data from the patients' perspectives in this study were comprised of the documented skin reactions (i.e. reactions= yes or no; sensation/itchy skin=no, slight/mild, very; color=no, pink, red, very red, brown; pain=no, mild, moderate, severe) during weeks 2, 4 and 6.

Descriptive statistical methods were used. Interobserver variability was calculated using Cohen's and Fleiss' Kappa methods and correlations were determined with Spearman's correlation test. P-values of <.05 were considered statistically significant. The analyses were performed using the Statistical Analysis System (SAS) Version 9.1 and Statistical Package for Social Sciences (SPSS) Version 17.0.

Results: Patients (n=148) were enrolled between 4/10/13 – 3/8/16 and randomly assigned to the usual care (Aloe Vera/Aquaphor, n= 71, 48%) or intervention (Calendula, n= 77, 52.0%) groups. The women were primarily Caucasian (99.3%) with fair skin type (79.7%). Average age was 60.7 years (SD 9.25) with a BMI of 30.9 kg/m². They used the skin care products an average of 30 days and spent 33 days in the study. More than one in five subjects (22.1%) received silver sulfadiazine ointment for skin irritation over the course of radiation therapy and 4.2% experienced a break in radiation treatment. The majority of subjects (99%) reported daily skin cleaning per instructions, but adherence was reduced towards the end of the treatment. Self-reported skin reactions increased from 14% at week 1 to 80% by weeks 5 and 6. Most women (88% - 98%) reported no/or mild pain throughout the treatment.

No RTOG changes (99.3%) were documented during the appointment at week 0. However, the scores indicating follicular faint erythema increased during week 2 (29.1%) and week 4 (62.8%). At week 6, the documented scores indicated that all study subjects had skin reactions (follicular faint erythema= 42%, tender or bright erythema = 50%, confluent, moist desquamation=8%). The calculated interobserver variability decreased from moderate to fair agreement (Week 0: Fleiss' Kappa=0.328, p<.000; Week 2: Fleiss' Kappa=0.464, p<.000; Week 4: Fleiss' Kappa=0.292, p<.000; Week 6: Fleiss' Kappa=0.266, p<.001). Upgrading or downgrading the RTOG scores was more common during weeks 4 and 6. Over half of the study subjects (64%) reported no skin reactions during week 2, however over half had documented reactions during week 4 (77.4%) and week 6 (72.4%). Skin sensation changes were rare during week 2 (slight/mild=22.5%), but these increased during week 4 (slight/mild=63.2%) and week 6 (slight/mild=51.7; very=3.4%). Over half of the study subjects reported skin color changes during week 2 (no change=39.4%, pink=49.2%, red=10.6%, brown=0.8%), and these changes increased during week 4 (no change=5.1%, pink=55.6%, red=34.2%, very red =4.3%, brown=0.9%), and week 6 (no change=9.7%, pink=38.7%, red=35.5%, very red =12.9%, brown=3.2%). The documented RTOG scores correlated positively and significantly, but weakly with the self-reported skin reactions during weeks 2 and 4 (week 2: r=0.273, p<.01, week 4: r=0.251, p<.05), self-reported skin reactions during week 4 (r=0.197, p<.05) and self-reported skin color changes during week 2 (r=0.232, p<.05).

Conclusion: The results of this study demonstrate that the rating criteria of the RTOG scale are likely to be interpreted subjectively, especially during longitudinal observations when there are more acute radiation skin reactions. The education that was organized to the nurses of our research team may have decreased the variability between the documented scores and the scorings of the digital pictures. However, the variability and the upgrading or downgrading of the RTOG scores increased during weeks 4

and 6. The self-reported skin reactions supported the documented RTOG scores, but strong associations were not demonstrated. We conclude that more research is needed to determine the best, objective measures to evaluate radiodermatitis, including the experiences from a patient perspective.

B 05 - Factors Affecting Oncology Patients

Symptom Clusters and Oxidative Stress in Patients With High-Grade Brain Cancers: A Longitudinal Study

Sanghee Kim, PhD, MCN, RN, Korea, Republic of (South)

Abstract

Background: Cancer treatments can increase the levels of oxidative stress because of the mechanisms of cancer drugs and radiotherapy. Patients with cancer experience many concurrent symptoms, commonly referred to as “symptom clusters,” during the treatment periods. However, the relationship between oxidative stress and the symptom clusters have not been identified in patients with high-grade brain cancer.

Purpose: The purpose of this study was to identify a relationship between the symptom clusters and the levels of oxidative stress in patients with high-grade brain cancers undergoing concurrent chemoradiotherapy (CCRT).

Methods: Patients with high-grade primary brain cancers were asked to report their symptoms using the Memorial Symptom Assessment Scale, and the level of oxidative stress was evaluated on the basis of lipid ratios such as the total cholesterol (TC) to high-density lipoprotein (HDL)-cholesterol (TC/HDL-c), low-density lipoprotein (LDL)-cholesterol to HDL-cholesterol (LDL-c/HDL-c), and triglycerides to HDL-cholesterol (TG/HDL-c). This prospective longitudinal survey was conducted before CCRT was initiated, and at 2–3 weeks and 4–6 weeks after the initiation of CCRT.

Results: A total of 48 patients with newly diagnosed primary malignant brain cancers were enrolled. Six symptom clusters were identified, and two symptom clusters were present at each time point (i.e., the “negative emotion and neurocognition” cluster was reported before CCRT, “negative emotion and decreased vitality” and “gastrointestinal and decreased sensation” clusters were noted at 2–3 weeks, and “body image and decreased vitality” and “gastrointestinal” clusters were identified at 4–6 weeks). The lipid ratio was an indicator of the level of risk for oxidative stress at 2–3 weeks and 4–6 weeks. The symptom clusters at 2–3 weeks and 4–6 weeks demonstrated a significant relationship with the lipid ratio.

Conclusion: Symptom clusters and levels of oxidative stress in patients with high-grade brain cancer were altered during CCRT. In addition, the levels of oxidative stress correlated with symptom clusters, and these correlations could change during the course of CCRT. Therefore, oxidative stress in patients with high-grade brain cancer should be considered for symptom management during CCRT.

B 06 - Cultural Impact in Nursing Education

Evaluating an Online Global Community of Practice: Student Nurse Experiences of a Cross-Cultural Blogging Activity

Siobhan T. Wragg, MSc, MEd, RN, Australia
Nancy A. Edgecombe, PhD, MN, BN, OPN, RN-NP, Canada
Moira Stephens, PhD, MSc, BSc (Hons), CertEd, RN, Australia

Abstract

Purpose: Internationalization at Home, a concept developed in the Netherlands, enables students to have a global experience and engage with international students without leaving home (Teekens, 2015). The use of technology such as social media can provide a viable mechanism by which this can be achieved (Beleen & Jones, 2015; Chan & Nyback, 2015). Social media provides students with an opportunity to share ideas, develop digital communication skills and enrich their learning experience (Roland, Johnson & Swain, 2011; Schmitt, Sims-Giddens & Booth, 2012). The purpose of this project was to create an online community of practice using a blog to stimulate discussion between Canadian and Australian nursing students, focusing on culture and family.

Methods: Australian and Canadian nursing students participated in an international, cross-cultural blog activity that provided an opportunity to engage with each other through a shared blog experience. This learning and teaching activity was imbedded within a Bachelor of Nursing subject at each University. This activity was expected to expand their knowledge through interaction with students from another country, learn about other cultures and share ideas. Questions were posted by faculty to stimulate student discussion related to culture and family. The students posted their response to the questions and replied to each other's postings. Students who took part in the international blog were invited to evaluate the activity. The evaluation was in the form of an anonymous online questionnaire located within the respective schools eLearning platforms.

Results: Preliminary results indicate that students found this to be a worthwhile learning activity. They were interested in exploring each others personal and professional experience of culture and family through discussion with students from another country. Students reported that the blog was a useful medium for an international learning experience, which they also enjoyed.

Conclusion: Participating in the evaluation provided students with an opportunity to interact with nursing students from another country in a guided learning experience. Students then reflected on their blog experience and assisted instructors to identify the strengths and limitations of the learning activity, illuminate areas for improvement and determine if it would be worthwhile repeating in future. Communication through social media is fast becoming more relevant to nursing practice and the use of social media in nursing education will prepare students to effectively utilize social media and function in a global community of practice.

B 06 - Cultural Impact in Nursing Education

Long-Term Impact of Study Abroad in Undergraduate Nursing Education on RN Nursing Practice

Arlene E. Kent-Wilkinson, PhD, RN, CPMHN(C), Canada

Marie Dietrich Leurer, PhD, RN, Canada

Janet Luimes, MScN, RN-NP, Canada

Linda M. Ferguson, PhD, RN, Canada

B. Lee Murray, PhD, RN, Canada

Vicki Squires, PhD, MEd, BEd, Canada

Carmen M. Dell, BScN, BA, RN, Canada

Abstract

Purpose: Study abroad experiences often have a significant impact on the lives of university students. This impact is not always understood in terms of learning outcomes, lived experience perspectives, or the impact it has on future professional practice. The purpose of the study is to explore the long-term impact of the study abroad experience on subsequent nursing practice, from the perspective of alumnae registered nurses (RNs) in Canada, who in the last eight years had a study abroad clinical placement as part of their undergraduate nursing program. **Recent societal and educational trends.** Changing immigration patterns globally have resulted in more than 20 percent of Canadian residents being foreign-born. Recently, various levels of government have called for education that promotes international experiences in order to prepare graduates with the international knowledge and skills to work and live in an increasingly diverse and interdependent world. With Canadian healthcare systems experiencing increasing culturally diverse client populations, cultural competence is widely recognized as an essential component of undergraduate nursing education. Research that evaluates study abroad as a strategy to promote long-term cultural competence among nursing students is timely given recent government directives and population trends. Nursing educators worldwide are gradually recognizing the importance of exposing students to a range of learning experiences that will broaden their global perspective and enhance their cultural competency. These experiences generally occur with international exchanges, study abroad programs, university partnerships, and globally focused curriculum changes. **Background.** The College of Nursing, University of Saskatchewan has facilitated study abroad clinical placements since 1998 to at least 10 different countries. Currently, the College offers clinical placements as part of their undergraduate nursing program to: Australia, Finland, the Philippines, and Tanzania, however only Finland and Australia are reciprocal. Typically the clinical and cultural placements have been between five to twelve weeks. Since 1998, the College has facilitated outgoing placements to over 300 nursing students and hosted clinical placements to over 50 incoming nursing students. In 2013, faculty from the University of Saskatchewan formed as an International Research Group (IRG) to conduct research around the study abroad student experience. The first study, launched in 2013, was a five-year longitudinal *Study Abroad Survey of Factors Influencing Student Decisions to Study Abroad*. This research is IRG's second project, *Long-Term Self-Reported Impact of Study Abroad on Nursing Practice in Canada*, funded in 2016 by the Western and North-Western Region Canadian Association of Schools of Nursing (WNRCSN). **Literature review.** Study abroad refers to a wide range of credit-granting programs, courses and learning experiences that take place internationally. The nursing study abroad literature consists of two main topics: (1) long term impact of study abroad, and (2) short-term impact of study abroad, including benefits and barriers of study abroad. Research on the long-term impact of SA on nursing practice have been primarily limited to a hand-full of studies that used the International Education Survey (IES) to survey nursing and non-nursing samples. There was however two nursing studies found on the long-term impact of study abroad that did not use the IES tool. In addition to the numerous articles and research studies in the literature exploring the short-term impact of study abroad, the literature also addresses the barriers to study abroad, both in terms of making the decision to study abroad and to the drawbacks of the experience itself, personally and professionally. Concepts of 'culture shock' 'adaptation' and the challenges of the study abroad experience, underscore that negative as well as positive experiences may impact RNs in the long term, as well as short term. **Theoretical framework: Theory to practice.** Undergraduate nursing programs that include clinical study abroad experiences within the baccalaureate degree allow students the opportunity to consolidate their theoretical knowledge and apply

it in a clinical setting, particularly related to cultural competence, foundational nursing skills, and global health care systems. Positive short-term impacts of study abroad reported by Canadian nursing students participating in study abroad experiences, include increased personal and professional growth, awareness of cultural diversity, and a 'defining moment' in their educational program. However, does that growth transfer to the long-term impact of study abroad experiences on nursing practice? Does the study abroad experience help nurses to provide culturally competent care that is measurably better when they graduate, or help to accelerate this learning process? **Instrument: International Education Survey (IES).** In the mid-1990s, CeCelia Zorn, PhD, RNC developed and tested the IES tool. The survey has since been used in both short-term and long-term analyses and with nursing and non-nursing students. When students have the opportunity to study abroad, the experience affects multiple dimensions. Relative to the long-term impact on nursing practice, research to date on the short-term impact of study abroad can be summarized in the IES framework of: personal development, professional development (including cultural competence), global perspective, and intellectual development. **Reason for the study:** Although study abroad clinical placements are offered in almost half of Canadian nursing programs, the long-term impact on nursing practice in Canada has yet to be explored, despite widespread recognition that internationalization of the nursing curriculum is essential to prepare the nurse professional for the rapidly changing challenges of the 21st century. While there has been a significant amount of research assessing the beneficial short-term impact of study abroad, there is little research exploring the narrative perceptions of how such experiences affect participants' nursing practice over the long-term. **Research question.** What is the long-term impact on nursing practice of study abroad experience during the undergraduate nursing program, from the perspective of RNs in Canada? **Ethical approval.** A certificate of approval was granted from the University of Saskatchewan Research Ethics Board.

Methods: Invitations were sent to 168 alumnae registered nurses (RNs) to participate in a study to explore the long-term impact of study abroad on nursing practice. A descriptive survey design included categorical, structured and open-ended questions constructed to elicit narrative responses. The survey respondents were additionally invited to participate in an interview to capture rich data to further explore the impact of study abroad. The International Education Survey (IES), adapted to net responses to the quantitative questions, was hosted on Campus Labs, an online survey platform. Interpretive description qualitative methodology analyzed the comments to the open-ended survey and the interview questions, while descriptive statistics reported findings from the categorical questions. **Limitations.** Study limitations were: small sample size therefore study findings cannot be generalized beyond this research; limitation to baccalaureate degree graduates only; and, the possibility of self-selection, with students having a more positive experience being more willing to complete and return the survey when requested. Unlike the limitations of previous studies using the IES tool: the student experience was not confined to a single destination country; a replication of this study in the near future in Australia will serve as a comparison group with which to further validate the reliability and validity of the survey tool; and in addition, while previous studies have been descriptive in nature, this study added the results of additional rich data from separate qualitative interviews.

Results: In May 2016, 168 RN alumnae of the SA program were contacted, 35(21.7%) completed the survey, and 13 alumnae RNs additionally agreed to an interview. The data analysis was completed by the end of the year; results of the study will be reported at the STTI conference in 2017.

Conclusion: The 'long-term' impact of study abroad experiences researched to date have been from nursing programs who offered a single clinical placement mainly in a developing countries, but rarely from nursing programs who offered study abroad placements to a variety of both developing (countries in Africa, Asia, South America) and developed countries (Australia, United States, and countries in Europe). The researchers believe this is the first study to look at the perceived long-term impact of study abroad on participants' nursing practice in Canada, and the first study to compare the impact on practice from placements in both developed and developing countries. While research from study abroad experiences in developing countries provide a significant cultural contrast for nursing students from a developed country like Canada, nursing practice experiences in countries of similar economic development and with a unique Indigenous population provide unique and insightful outcomes. Outcomes may help justify the costs to students and time invested by the program and by the University, as to whether the study abroad

program is beneficial to the nurse as a practitioner, and to the system as a whole. **Implications for future research.** Future international study abroad research is needed to determine: what areas of study abroad experience are most effective; differences in nursing practice from country to country; measurement of cultural competence as a result of study abroad experiences; and, faculty perspectives of the student study abroad experience. This study provides the basis for a future collaborative research project exploring comparisons with a reciprocal country partner in Australia. Plans are underway to replicate this “impact study” in Australia.

B 07 - Global Interprofessional Health Promotion

Step Into Wellness: A Nurse Practitioner-Directed Interprofessional Intervention for Underserved Populations

Patricia A. Rouen, PhD, FNP-BC, USA

Janet M. Baiardi, PhD, FNP-BC, USA

Abstract

Purpose: In the United States (U.S.), national data demonstrate high mortality rates and poor health outcomes from chronic diseases among persons without insurance or fragmented access to healthcare (Bittoni, Wexler, Spees, Clinton & Taylor, 2015). The era of accountable care emphasizes health promotion and new strategies to build capacity for equitable population-focused care in the primary care and community health setting (Edmonds, Campbell & Gilder, 2016). A key principle in patient engagement for health includes a sense of belonging and authentic participation that is associated with better outcomes and quality of life (Porter, Pabo, & Lee, 2013). A growing body of evidence documents that culturally relevant community-based nutrition education (Ball, McNaughton, Le, Abbott, Stephens, & Crawford, 2016; Ko, Rodriguez, Yoon, Ravindran & Copeland, 2016) and physical activity programs (Conn, Chan, Banks, Ruppap & Scharff, 2014) are effective strategies in low income populations. Emerging data also show that social media strategies, such as text messaging, support successful health outcomes (Head, Noar, Iannarino & Harrington, 2013). As health advocates, nurse practitioners (NPs) are providers grounded in health promotion, system thinking and community-based care that are well-positioned to implement culturally-relevant health promotion interventions to the underserved communities and patients they serve. **Purpose:** Guided by the social-ecological framework, the purpose of this project was to initiate nurse practitioner-led interventions to support accountable care and improve nutrition and physical activity health outcomes in a diverse underserved population receiving care in an urban free primary care clinic.

Methods: We used a multi-level approach to engage the populations receiving care at the clinic along with the administrative and clinical staff, and established partnerships with community-based organizations to support the planned health interventions. A quasi-experimental pretest-posttest study design was used. We enrolled three cohorts of diverse participants (ages 19-64 years) in a 13 week program: seven weeks of nutrition education/cooking classes that included a curriculum customized to the clinic population and six weeks of physical activity (gentle yoga, pedometer-guided walking programs). The groups met weekly for two hours. Ethnically diverse professionals: registered dietitians, a professional chef and yoga instructor supported the program. The nurse practitioners sent weekly text messages that were either spiritual or motivational in nature to reinforce the program content. System-level interventions included implementing participant identification cards and patient satisfaction surveys revisions. Clinical outcomes included nutrition knowledge, perceived stress, steps walked, blood pressure, and body mass index (BMI). System level outcomes addressed program evaluation and patient satisfaction. Data were analyzed with descriptive statistics and paired t-tests.

Results: The 42 participants were primarily female (81%; N=34) with eight men and included blacks (76%), Hispanics (14%) and whites (10%). Three patients were homeless. Participant were on average 50 years old and obese (mean BMI: 31.6 kg/m²). Nutrition knowledge improved from baseline (58.6+13.7 vs. 83.5+14.0; p<0.001) as did steps walked (4448.6 + 2719 vs. 7564.6 + 4151.1; p=0.03). Systolic and diastolic blood pressure values did decline as did BMI but did not achieve significance. Perceived stress levels were unchanged. Program satisfaction data was positive. Participants reported the yoga relieved muscle aches and pains, they felt cared for and were pleased and relieved to have identification cards. The community agencies and the clinic were able to secure ongoing partnership agreements.

Conclusion: Nurse Practitioners are well-positioned to organize and implement culturally-relevant and evidence-based patient and system level innovations in community settings that are customized to promote health outcomes among the uninsured and underserved.

B 07 - Global Interprofessional Health Promotion

Global Interprofessional Study Abroad Impact on Nurse Practitioners' and Medical Students' Perceptions About Role Definition

Debra A. Kosko, DNP, RN, FNP-BC, USA

Deborah Chapa, PhD, RN, ACNP-BC, FNAP, FAANP, USA

Melvin S. Swanson, PhD, USA

Abstract

Purpose: Healthcare delivered by well-functioning teams results in improved clinical outcomes and lower costs. However, health professions students are typically educated in silos, seldom communicating across disciplines (Cox & Naylor, 2013). Once students graduate, the professional silos persist, resulting in fragmented care that increases cost and decreases quality. Therefore, educating health professions students about team-based care and how to work with other health professionals, known as Interprofessional Education (IPE), provides them the necessary skills to improve the healthcare delivery system and the lives of their patients upon graduation. The purpose of this project was to evaluate the impact of a 2 week interprofessional study abroad program on health professions student's readiness for interprofessional education (IPE).

Methods: This outcome-based summative program evaluation had a convenience sample of four family nurse practitioner (FNP) students and seven medical students. The education model was a two week immersion study abroad in Nicaragua where students provided patient care in FNP/medical student teams within a variety of clinical settings. The students attended debrief sessions throughout the experience that included discussions about IPE. All students and faculty stayed at the same hotel, shared meals and shared free time. Immediately before departing the US and immediately upon returning from the US, students received a web-based anonymous questionnaire via Qualtrics. An open-ended question was asked about the role of FNP's and physicians in healthcare. Several additional open-ended questions were added to the post-experience questionnaire. These questions inquired about the impact of the study abroad on future clinical practice and their impression about learning with students from another health profession.

Results: The phenomenological analysis compared medical student's responses to FNP student's responses. Both groups responded similarly when asked about learning with each other. Common themes included great experience, enhanced learning and well working teams. One NP student stated the experience highlighted a lack of knowledge as compared to medical students, while one medical student stated greater learning occurred because of working with FNP students who were experienced nurses. When asked about applying the study abroad experience to clinical practice, none of the FNP students identified learning with medical students as impactful while one medical student stated learning with FNP students provided needed preparation for future clinical practice. A dichotomy was found with responses about the role of each other's profession in healthcare delivery. There were no pre-travel responses from medical students while 4 of the 5 medical students provided post-travel responses. The theme of the responses was hierarchy. The medical students identified FNP students as physician extenders; that they are supervised by physicians and are below a physician. One FNP student responded pre-travel and one responded post-travel; both responses were also hierarchical such that the physician serves as a reference and was the health professional that guided patient care.

Conclusion: This study abroad provided students at our university a unique educational experience that enabled collaborative practice in a variety of clinical settings. Although the students worked in FNP/medical student teams and IPE core competency content was provided, an understanding of collaborative practice was not reflected in the qualitative data. Rather, the medical students and a FNP student used hierarchical terms to describe the relationship between the professions. An immersion experience abroad provides the opportunity for IPE, however, more research is needed in developing educational interventions that promote IPE and develop tools to measure IPE knowledge. This project will promote further development of interprofessional education models that can transform clinical practice. Study abroad models of IPE can also serve to promote interprofessional clinical practice globally.

Herbal Supplements: Safety and Research Support

Rosanne H. Pruitt, PhD, APRN, FNP-BC, USA
Ashley Lemanski, USA
Adam Carroll, USA

Abstract

Purpose: Herb usage is extensive worldwide, however consumers are often not aware of whether or not the herb has undergone research evaluation to determine if it actually works as advertised. Jordan, Cunningham, and Marles (2010) state that the general public often views herbs as a safer alternative to pharmaceutically manufactured drugs because herbal ingredients are naturally occurring in the environment. Garner (2013) found herbal use as high as 30% among minorities, however usage is frequently not shared with healthcare providers. Nurses and other health care professionals typically receive very little formal education about herbs.

Many herbs can be traced to ancient times however some interact with prescription medication enhancing or inhibiting action which may be unintended and harmful. Current research findings demonstrate that costly supplements may be no better than a placebo (McRorie & Chey, 2016) or outcomes may be worse for intervention groups (Beck, Dent & Baldwin, 2016). The purpose of this project is to fill a gap and provide evidence to inform practice by evaluating the quality of the research supporting commonly used herbs and translate the information into an easily accessible format for health care providers.

Methods: This project is the culmination of a two-year study evaluating commonly used herbs to determine the quality of the research support. The research support for 55 commonly used herbs and essential oils were reviewed with over 150 research studies, many of which were meta-analyses. Quality of evidence was determined based on clinical trials and/or meta-analysis with a rating of 1, if the research was limited to survey or correlational data or inconsistent results, a rating of 2. A rating of 3 was utilized when research was very limited often consisting of animal studies. For example, the research supporting the use of gamma linolenic acid for use with rheumatoid arthritis is robust rating 1, but less conclusive in the treatment of type 2 diabetes rating 2. Any side effects or precautions are also addressed.

Results: To increase knowledge of commonly used herbs, we have developed a chart to be used by nurses and other health care providers that summarizes the data in a handy format which will be available to attendees. A component of this project was a pilot to determine the utility of the information for provider use and a reflection from the patient as to the helpfulness of the discussing addressing vitamin and herb usage. The chart was also reviewed by health care providers for utility and revised as recommended.

Conclusion: Our goal was to fill a knowledge gap and provide evidence to inform practice by evaluating the quality of the research supporting commonly used herbs and translate the information into an easily accessible format for nurses and health care providers. Our focus is implications for adults age 18-65 with the precaution of working with a health care provider related to surgery, pregnancy or any acute or chronic health condition. Usage recommendations are consistent with health authorities as well as specialty organizations focused on specific populations or health conditions. A robust presentation will help attendees identify which herbs will improve common health symptoms.

B 08 - Health Promotion

Planning an Efficacy Study of a Web-Based Yoga Intervention Based on Feasibility Findings

Jane M. Flanagan, PhD, RN, ANP-BC, AHN-BC, USA

Abstract

Purpose: It is well known that the end of active cancer treatment (surgery, +/- chemotherapy, +/- radiation) is a very stressful time during which survivors report many physical and psychological concerns. In one study conducted with breast cancer survivors at the end of active treatment, participants reported that they felt abandoned and that they were on their own to manage care; however, they also reported not wanting to return to the hospital for care from providers. These women did report that they would like to be able to access information via the Internet. (xxx, xxx, Habin & Cashavelly, 2012). Further research suggests women want strategies to be vetted and/or created by their healthcare team to support wellness and healing (xxx, Wegler, xxx, Habin & xxx, 2016).

Research supports that yoga may help to reduce physical and psychological symptoms in breast cancer survivors (Chandwanti et al., 2014; Culos-Reed, Mackenzie, Sohl, Jesse, Zahavich, & Danhauer, 2012; Galantino, Desai, Greene, DeMichele, Stricker, & Mao, 2011; Kiecolt-Glaser et al., 2014; Mustain, 2013). However, there are limitations to in person yoga classes especially if they are not sensitive to the needs of breast cancer survivors.

While a web streamed video may be a self-care strategy women are seeking, research is needed to determine if this is a feasible approach, how patients perceive this strategy and what outcomes yoga may impact. The purpose of the first step in this research project was to:

1. Develop a yoga video created by a multidisciplinary team of breast cancer care providers that was tailored to breast cancer survivors.
2. To describe patients with breast cancer experience of using a web-streamed yoga video including, feasibility and barriers/facilitators to its use.
3. To inform the next step of the efficacy trial including the choice of appropriate outcome measures.

Methods:

The study employed an open ended qualitative descriptive design using conventional content analysis.

Video development

The video was created by an interdisciplinary team of breast cancer caregivers and incorporated movements similar to stretches prescribed post-operatively.

Data collection: Patients with early stage estrogen receptor positive breast cancer within one year of initiating adjuvant endocrine therapy were recruited in routine follow-up visits by their oncology providers. Patients who were enrolled received the video by email, were asked to complete a demographic questionnaire, view the video twice a week for four weeks and complete open-ended telephone interviews at three time points to determine how the video was used and perceived.

Data analysis: Conventional content analysis was used to understand the feasibility and patient experience of using the video.

Results: Fourteen women who had ended active treatment and were on adjuvant therapy participated in this study. The participants reported they were easily able to access the video, but only one described using the video as instructed (2 times per week for 4 weeks). The participants were interested in making some healthy lifestyle changes but implementation of change was challenging. Several participants did not understand this to be a mindfulness practice and instead expected it to be an exercise video. Therefore, they found it "boring". Others described feeling the need for more education on self-care

strategies, but reported being overwhelmed by taking on self-care as they were also returning to usual life responsibilities.

Conclusion: The web streamed intervention was an acceptable way to provide this intervention. Our findings indicate more education about yoga as a mindfulness based self-care strategy is needed. Further, mindfulness strategies (as opposed to exercise) should be practiced daily so it is not reasonable to assume that twice weekly would yield desirable results.

Persons with breast cancer who were not on adjuvant therapy expressed an interest in being enrolled in this study, but basing this work on previous work we did not include all breast cancer survivors ending active treatment and going forward we should. When we initiated this study, we were not sure what outcomes – physical or psychological may be impacted by a yoga video. The findings from this study have informed the outcome measures we will use in that they will be sensitive to a mindfulness based strategy such as well-being and anxiety as opposed to physical function. This study findings are limited in that the sample was a well-educated, all Caucasian sample.

B 09 - Improving Baccalaureate Nursing Program Care Models

The Transformation of Knowledge and Practice as Undergraduate Baccalaureate Nursing Students Actualize Caring

Donald N. Rose, PhD, MN, BScN, RN, Canada

Claire Mallette, PhD, MScN, BScN, RN, Canada

Karen Poole, MEd, MA (Nsg), RN, Canada

Abstract

Purpose: Caring has always been at the core of nursing education and practice. Yet there is little in the literature describing how undergraduate nursing students are taught or internalize caring. All 14 University Schools of Nursing (SON) in Ontario, Canada, state in different ways that they educate future nursing professionals to care for the person, the family and the community. But what does this really mean? What do we teach? How do we teach it? How effective are we? And how could we do better? The purpose of this multi-site, 18-month mixed-methods research was to examine how caring is defined, taught, integrated, measured and evaluated in nursing undergraduate curricula. The participants include senior BScN students, faculty members and recent BScN alumni (practicing for 2 to 3 years) from across the province.

Literature Review: Caring has been linked to nursing since the time of Florence Nightingale. Nightingale was committed to promoting health rather than illness and believed medical interventions were not as important as care (Grove, 1991). Since then, theories of caring in nursing have been developed and applied in research, education, and standards of care (Wojnar, 2009). The literature describes many theories, definitions, and perspectives of caring within nursing. Nursing theorists such as Watson (1979, 1988, 1999), Benner (1984), Benner and Wrubel (1989), Boykin (1994), Boykin & Schoenhofer (2001), and Roach (1984, 1989), all contributed to an understanding of what nursing care encompasses.

While the literature indicates there are many definitions and lenses to examine caring in nursing, common themes emerge describing the caring interaction as a process that encompasses knowledge, being present with another, and actions leading to outcomes. The researchers concluded that caring for this research study can best be captured through Swanson's (1991) mid-range theory based on the definition that caring is "a nurturing way of relating to a valued other toward whom one feels a personal sense of commitment and responsibility" (Swanson, 1991, p. 165). This process has also been described as being implemented with each nurse-client interaction that involves the nurses knowledge and understanding of the person's needs (knowing); the verbal and nonverbal interactions that occur during the therapeutic relationship (being); and through actions striving to achieve the best client outcomes (doing) (Wojnar, 2009).

Nursing education involves the teaching of knowledge and skills for professional practice and attitudes, beliefs and values that are central to becoming a professional nurse (Brown, 2011; Larson, Brady, Engelman, Prekins & Schultz, 2013). Nursing curricula are challenged in educating students to acquire the vast amount of knowledge needed to meet the demands of today's complex healthcare environment and professional licensing requirements. Teaching professional caring within nursing curricula is increasingly important since with the multiple demands there is always a risk that learning how to be a caring relational healthcare professional may become less of a priority (Spadoni, Doane, Sevean, & Poole, 2015).

Although caring for others is a basic human trait, caring nursing practices and competencies must be an essential component of nursing education (Wagner, 2008). Teaching caring science should occur both in theory and practice. The literature states that teaching strategies which foster caring in students include critical reflection, role playing, narrative inquiry, role modeling, dialogue, journaling, clinical simulations, case studies, and other critically reflective tools (Brown, 2011, Adamski, Parsons & Hooper, 2009, Watson, 1989). However, there is little literature describing how nursing students internalize caring (Brown, 2011).

Drawing on the literature review, the purpose of this research study is to examine how the knowledge of caring is taught to undergraduate nursing students in Ontario; how it is embedded into the curriculum and translated into actual teaching-learning processes (the process of knowing); how students embrace caring practices within themselves and clients (being); and the nursing interventions they implement demonstrating caring while meeting their client's needs (doing) to achieve positive outcomes as a student and graduate nurse.

Methods: Data were collected through a mixed method of focus groups with senior nursing students and practicing nursing alumni, and an online faculty survey. Focus groups explored student (n = 100) and practicing alumni perceptions (n = 24) of how caring is taught, effective and ineffective learning practices, and learning experiences that helped strengthen their caring abilities. Faculty members (n = 50) in each School of Nursing were sent an email inviting them to participate in an on-line anonymous survey that elicited feedback on a definition of caring for nursing education, strategies and activities faculty think are effective for teaching caring and in which year of study they are being taught. An online repository of leading practices and strategies is being developed and findings from the study are being presented to each of the 14 schools of nursing, as a foundation for transforming caring in Ontario nursing curricula.

Data Analysis: The 6 phases of thematic analysis based on Braun and Clarke (2006) were used to analyze the qualitative data. In Phase 1, familiarization of the data was done by reading through the entire data set to become immersed and intimately familiar with its content. Then, initial coding was conducted in Phase 2 to organize segments of data from the entire data set into meaningful codes. Phase 3 involved the examination of codes to identify significant broader patterns of meaning (potential themes) across the data. The initial 3 phases were conducted by the two co-principal investigators and three co-investigators who made up a steering committee. The reviews were conducted independently and then discussed by all members of the steering committee in order to reach consensus. In Phase 4, the themes were independently reviewed and revised by another member of the steering committee. This independent review and revision of themes involved re-examining the original data for relevant incidents of data for each potential theme; expanding, collapsing, or discarding of initial themes; generation of new themes; and re-discussion of themes with the full steering committee. The themes were presented as a model (Actualization of Caring) depicting the five themes and their interconnections. In Phase 5, the five themes were defined and named. Segments of text were then identified as exemplars for each theme. In the final phase, Phase 6, the literature review findings will be used to inform the themes for the final research report and manuscript. While these phases are meant to be sequential, each phase building on the previous phase, Braun and Clarke (2006) note that "analysis is typically a recursive process, with movement back and forth between different phases (p.86)."

Results: The findings indicate that students enter nursing programs with a personal identification of caring. Through their nursing program, they undergo a process of growth and development of professional caring with the goal of them graduating with a professional identity of caring that is sustained and fostered in practice. A professional identity of caring is achieved through caring pedagogy practices, clinical experiences, and relationships with peers, faculty and nurses. As students go through this process they demonstrated ongoing self-awareness of professional caring that is influenced by facilitators and barriers within educational and clinical environments. The results for each of these themes will be presented in greater depth during the presentation.

Conclusion: This study will inform which content, strategies, and practices in undergraduate nursing curricula are most effective in terms of fostering and maintaining caring in students and graduates. The findings will also facilitate future incorporation of more of these practices and content in Ontario university nursing programs with the development of the online repository. The researchers believe this online repository will be the first of its kind that not only schools within Ontario, but also SON's nationally and internationally will be able to access.

B 09 - Improving Baccalaureate Nursing Program Care Models Teaching Quality Improvement to Baccalaureate Nursing Students: Strategies That Work!

Laurie Bladen, PhD, MBA/HCM, RN, USA

Abstract

Purpose: The purpose of this presentation is to describe strategies that work in teaching quality improvement to baccalaureate nursing students. According to American Association of Colleges of Nursing (AACN) (2015) expected outcomes for graduates of baccalaureate nursing programs include scholarship for evidence-based practice, leadership, and the ability to promote health. Baccalaureate nurses are expected to use data and methods to continuously improve quality and safety of patient care (Dolansky & Moore, 2013; Phillips & Cullen, 2014; Quality Safety and Education for Nurses (QSEN), 2014). The mission of the Quality and Safety Education for Nursing is to address the challenge of assuring that nurses have the knowledge, skills and attitudes (KSA) necessary to improve the quality and safety of their patients in the world. According to the World Health Organization (WHO) (2011) as cited in White, Clark Lewis and Robson (2016) change management principles should be used to incorporate quality improvement practices in nursing education. A challenge for nurse educators is to identify instructional methods to promote success of these outcomes and to prepare graduates with the necessary quality improvement skills (Dotson & Lewis, 2013).

Clarion University of Pennsylvania in the United States offers students an opportunity to earn a baccalaureate degree in the RN to BSN online program that traditional is a 15 week or semester course. A pilot program for the RN to BSN program is offered to teach the same content in a 7-5 week term. Student learning outcomes and the delivery method for these courses are identical. The purpose of this quantitative study was to examine the knowledge, skills, and attitudes (KSAP) gap of students enrolled in a leadership course. This study was approved by Clarion University of Pennsylvania IRB#34-15-16.

A course revision in the RN to BSN program created an opportunity to provide students with an opportunity to learn the quality improvement process developing nursing vigilance. Nursing vigilance combines nursing knowledge, evidenced-based practice, and critical thinking that enable BSN graduates to engage in safety and quality care. Quality improvement teaching strategies should be part of a global nursing curriculum to help students recognize how to develop solutions to nursing practice and to avoid devastating safety errors. Application assignments empower nursing students to experience solving a nursing problem (Murray, Douglas, Girdley, & Jarzemy, 2010). This presentation is designed to provide information on teaching strategies to enable faculty to teach quality improvement in a baccalaureate online program. Information on the difference found between teaching quality improvement in a 15 week program versus a 7-5 week program will be presented. Challenges to teaching quality improvement in an online program will be discussed.

Methods: In the beginning of a 15-week (full semester) and a 7.5-week (accelerated term) course of NURS.457 Leadership in Nursing, students will be provided in the classroom and through email an introductory letter, which provides an explanation of the study. If students are interested in participating in the study, they are asked to email the researcher. The students who volunteer to be a participant will be emailed an informed consent and the modified QulSKA. Permission from the author of the QulSKA has provided permission to use and modify the instrument.

The QulSKA is a 73-item survey that measures knowledge, skills and attitude across the six core QSEN domains (patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics) (Dycus & McKeon, 2009). The results from the survey were expected to inform faculty of the development of targeted educational strategies focusing on the cognitive, behavioral, and affective needs of students in their understanding of the knowledge, skills, and attitudes of the QSEN core competencies in the Leadership in Nursing Class.

The students are asked to read and sign the informed consent. The signature on the informed consent can be electronically signed or it can be an ink signature. The researchers contact information is provided to the potential participants through e-mail and on the informed consent in case the participants had questions concerning the study or wish to withdraw. Participants will be assured that their participation in this study is voluntary; they can withdraw from the study at any time by contacting the researcher at the phone number or email listed on the informed consent. The potential participants will be informed that whether they participate or do not participate in this study it does not affect their grade in the class.

A four-digit code number will be assigned to each participant's informed consent and corresponding pretest and posttest. The pretest was given in the beginning of each course and the post-test will be given during the last weeks of each individual course. The participant's identity and the assigned four-digit code will be placed on a separate code sheet. Only the researcher had access to the code sheet that links the four-digit code to the individual participants. The code sheet is located on a different flash drive stored in a locked office in a locked drawer and only the researcher has the key. This code sheet is the only document that links the code to the participant. Following this process allows identification in case the participant chooses to withdraw from the study and allows the researcher to match the participant's individual survey to the informed consent.

Results: The results of this study revealed that students showed a significant difference for evidence-based practice, informatics, and quality (the QSEN core competencies) after taking the NURS 457 Leadership class. There is no significant difference in students learning the QSEN competencies between a class that is 15 weeks in length versus a class that is 7.5 weeks in length.

Although the 15 week mean score for safety, teamwork and collaboration was slightly higher; they were only significant at the .10 alpha level. Quality was the only core domain that was significant higher between the 15 week pretest and 7 week pretest.

Conclusion: The teaching strategy for having students develop a process improvement (PI) proposal for a nursing problem at their employment during a leadership class enables students to learn and design new processes using the QSEN competencies. The existence of gaps in the curriculum related to the QSEN competencies of evidence, based practice, informatics, and quality are now removed with the existence of the process improvement project. As a result of this study the RN-BSN nursing faculty is currently reviewing the curriculum courses to determine the student learning outcomes and practice experience assignments. A limitation to this study is the amount of students who participated in this study. There was a potential of 70 participants and 40 participated for a response rate of 57%.

B 10 - Interprofessional Education Collaborations

Interprofessional Education and Team-Based Learning in a Research Methods Course

Vicki Schug, PhD, RN, CNE, USA

Abstract

Purpose: Interprofessional education (IPE) assists in developing the workforce of the future in response to the need for “better patient/client care, improved health outcomes, and for achieving more efficient and affordable educational and health care systems” (IOM, 2013, p. 29). A hallmark of interprofessional education is the incorporation of interactive learning methods that promote the development of relational, team-based learning and attainment of interprofessional competencies of values/ethics for interprofessional practice, roles and responsibilities, interprofessional communication, and teams/teamwork. Interprofessional evidence-based practice is unique in that combining theoretical perspectives, expertise, and methods adds to the depth of understanding. For instance, Moyers (2016) defines interprofessional evidence-based practice as “a dynamic team process that blends the patient’s preferences and values, the expertise of practitioners, and multidisciplinary evidence to implement practice changes that challenge current disciplinary paradigms and biases to create an integrated approach to patient care” (Moyers, 2016, p.5). Problems are no longer discipline specific, but are patient problems that require multiple disciplines to solve through collaboration. Engaging students in an interprofessional collaborative research process, strengthens and expands their ability to use multiple sources of evidence and work as a team to improve patient outcomes.

Methods: Based on findings in the literature about introductory research/evidence-based practice course and the type of students taking the course, faculty selected the topic of football and concussions to focus the course. The connection between concussions and chronic traumatic encephalopathy is a controversial topic with many ethical, social, and cultural issues. Evidence was shared from a variety of disciplines, illustrating multiple research methods and a growing body of knowledge. The topic is current both in the research literature and social media. An innovative approach to teaching this interprofessional research methods course included the four essential elements of team-based learning pedagogy including the formation of strategically formed permanent teams, readiness assurance, application activities that promote critical thinking and team development, and peer evaluation (Michaelsen & Sweet, 2011). The goal of the course was to develop the capacity of nursing, exercise science, and nutrition science students to critically interpret research, apply scientific evidence in practice/service, and to participate in the research process within an interprofessional team that increases the body of knowledge for collaborative practice and interprofessional education. Faculty were challenged in creating a course that fostered an interest in research and evidence-based practice that would be continued following completion of the course. With enrolled students whose primary disciplines were nursing, nutrition science, and exercise and sports science, faculty created an opportunity to bring research of interest to the various student groups by selecting concussion in football players as an evidence-based practice focus throughout the course.

Results: The *Readiness for Interprofessional Learning Scale* (Parsell & Bligh, 1999) was administered at the beginning and conclusion of the course to assess IPE competencies in students. This tool contains nineteen items organized into 4 subscales (McFayden et al, 2005), 1) teamwork and collaboration, 2) negative professional identity, 3) positive professional identity, and 4) roles and responsibilities. Students score each statement with a level of agreement using a Likert scale of 1 (strongly disagree) to 5 (strongly agree). Scores on the RIPLS survey were analyzed using parametric and nonparametric tests. Mean scores for each subscale were high both at the beginning and end of the course with no statistically significant difference in subscale scores. This result was not surprising since the majority of students had completed several IPE courses prior to the research methods course; faculty were encouraged that student perceptions remained positive relative to working in interprofessional teams.

Conclusion: The ultimate goal of interprofessional education is to engage students in interactive learning that spans the length of their degree program and continues beyond graduation through professional

development and continuing education. Learning theory supports the notion of team-based pedagogy to facilitate student achievement of IPE competencies. The topic of concussion in football has been an excellent choice to provide interprofessional learning experiences for students; it provided a vehicle to present research and evidence that has social, political, and ethical implications. Working in teams and using evidence as a foundation for nursing practice are essential skills that will contribute to better patient outcomes.

B 10 - Interprofessional Education Collaborations

Nursing and Physical Therapy Students Learning and Collaborating Together

Mary Francis, PhD, RN, NP-BC, USA

Robert Wellmon, PhD, PT, DPT, NCS, Aland Islands

Kristin Lefebvre, PhD, PT, CCS, USA

Ellen Erdman, DPT, PT, HPCS, USA

Abstract

Purpose: The purpose of this study was to examine student's attitudes and beliefs regarding interprofessional learning (IPL) and collaboration (IPC) following an interprofessional transfer laboratory experience. The study also explored student's perception of professional identity and self-efficacy.

Methods: Forty-nine doctorate of physical therapy (DPT) students and 136 baccalaureate student nurses (BSN) were assigned into groups of 1 DPT and 2-3 BSN students. One week prior to the laboratory experience, the students attended a lecture discussing how to transfer a patient and the importance of mobility during a hospitalization. The lecture focused on the clinic decision making involved in deciding how to transferring a patient, the hazards of immobility for a patient, and the body mechanics involved in actually moving a patient. The student's expectations for the mobility lab were reviewed at this time. During the laboratory experience, five different clinical scenarios were provided to the students to allow them multiple opportunities to practice transferring a patient out of bed into a chair (variations included different weightbearing statuses, diagnoses and devices). The laboratory experience was scheduled for 90 minutes. Immediately following the laboratory experience all students participated in a 30-minute debriefing that included various DPT and BSN subgroups. Surveys were sent to participants one week prior to the experience to collect pre-experience data. Students completed their post- survey immediately following the debriefing. Valid and reliable measures of IPC and IPL were used to collect data. Measures included the Interprofessional Education Perspective Scale (IEPS), the Readiness for Interprofessional Learning scale (RIPLS), the Attitudes Toward Healthcare Teams Scale (ATHTS), the Confidence for Interprofessional Learning and Cooperation scale (CILC), and the Self-Efficacy for Experiential Learning (SEEL). ANOVA and paired sample T tests were performed using SPSS 21.0 to measure between and within group differences arising as a result of the experience.

Results: DPT and BSN students showed significant improvements in competency and autonomy ($p<.002$), perceived need for cooperation ($p<.005$), perception of actual cooperation ($p<.003$) as measured by the IEPS. In addition, student showed a significant improvement in team work and collaboration ($p<.001$) and professional identity ($p<.001$) as measured by the RIPLS. The ATHTS showed significant findings around improvements in team value ($p<.001$) and team efficiency ($p<.001$) and finally several items of the SEEL showed significant improvements around student perceptions of self efficacy ($p<.001$).

Conclusion: Study participants reported improvement in domains identified in the literature as important to interprofessional learning and collaboration following an interprofessional transfer laboratory experience. Areas of greatest improvement included student's perceptions of self-efficacy, team work, team value, team efficiency, competency and autonomy. Student's perceptions described during the debriefing were a new self-awareness of mobility skills and their ability to convey instructions to others. Students appreciated the opportunity to work with another discipline and felt it increased their understanding of professional roles.

B 11 - Stress and Burnout in the Nursing Profession

Nurses' Stress and Coping: In the Midst of Work and Back to School

Joyce A. Brill, PhD, RN, CPNP, USA

Paulette Dorney, PhD, RN, USA

Robert T. Brill, PhD, USA

Abstract

Purpose: Nursing tends to be a highly stressful occupation (Chen, Brown, Bowers, & Chang, 2015; Happell, Dwyer, Reid-Searl, Burke, Caperchione & Gaskin, 2013) demanding they draw on substantive coping resources to deal with their work stressors (Eslami-Akbar, Elahi, Mohammadi, & Khoshknab, 2015). The tapestry of stressors confronting health care providers requires they be adept with a full arsenal of coping skills. We hope to look at nurses' perceptions of stress levels and investigate any associations with particular types of coping strategies. Although such "coping profiles" for particular stressors will not be accompanied by any effectiveness criteria to help evaluate the efficacy of the coping, having some sense of the normative coping behaviors that tend to be elevated (positively correlated) when stressors are having higher levels of intensity can help us understand the current battleground for work stress.

In addition to the taxing demands in their work role context, many nurses are further challenging themselves by returning to the classroom for degrees in higher education. A meta-analysis by Almann (2011) discussed many societal influences pulling nurses into the higher education pipeline of professional development, along with some insights regarding their attitudes and perceptions that are helping and hindering this difficult decision and the subsequent sacrifices it entails.

The purpose of the present study was to explore levels of stress intensity and coping strategy frequency, as well as relationships between these groups of variables. Finally, stress levels and coping styles will be compared against some demographic variables.

Methods: Registered nurses returning to a small liberal arts school in the northeast were asked to complete an internet-based survey ($n = 51$, 31.48% return rate), which included the Nursing Stress Index (NSI: six dimensions specified in **Results**) and Brief Coping Questionnaire (BCQ: 14 dimensions specified in Results). In addition, demographic items and three open ended questions on the nurses' incentives, barriers and supports related to their decision to return to school were also collected. All student nurses from three types of programs (RN to BSN, Masters of Science in Nursing, and Nurse Practitioner Graduate program) were sent an email invitation with the survey link and asked for their voluntary participation.

Results: Quantitative responses from the 51 nursing students were coded into SPSS Version 23 in order to explore possible significant relationships between demographics, stress levels, and frequency of coping behaviors. In terms of demographics, neither gender nor racial background generated sufficient variability for analysis. Regarding curriculum program differences, the only significant difference was that the RN to BSN students reported significantly higher frequency of distraction coping methods ($M = 5.86$) compared to the advanced degree programs, both the Masters students ($M = 4.74$) and the Nurse Practitioners ($M = 4.31$), $F(2, 36) = 4.88$, $p < .05$. The age of the nurse yielded several significant correlations, including a negative relationship with stress due to dealing with patients ($r = -0.42$), and several times strongly positively associated with using the following coping strategies: Planning ($r = .51$), Advisory Support ($r = .38$), Acceptance ($r = .35$) and Religion ($r = .60$).

Five of the six stress dimensions of the NSI were significantly correlated with at least one dimension of coping. The only stressor not associated with any coping strategy was work-life conflict. Dealing with patients was the only stress source to have a significant negative correlation with a coping strategy (Religion: $r = -0.36$); while being positively correlated with Venting. For the following summary of paired variables, all correlations are significantly positive. Hours worked was correlated only with Distraction techniques. Stress due to Work Relationships was related to Distraction, Venting, Humor, and Religion;

while stress due to Conflicting Priorities was associated with Distraction, Behavior Disengagement, Venting, Planning, Humor and Self Blame. The stress of maintaining role competence and confidence was correlated with Denial, Behavior Disengagement, Venting, and Positive Reframing. Stress due to time pressures was correlated with 11 of the 14 coping strategies

In order to explore the incentives, barriers, and support structures for nurses returning to school for a baccalaureate or advanced degree in nursing, three open-ended questions were used. Thirty textual responses were obtained with ten participants from the RN to BSN program, fifteen participants from the Master's of Science program, and five participants from the Nurse Practitioner program. The textual responses, referred to as participant' statements, were subject to hand analysis using a five step method for each research question. Each response was read line by line, to identify key phrases. After review of key phrases, sub categories or cluster themes were identified. Following review of cluster themes or sub categories, researchers searched for processes, meanings, and actions to identify emergent themes or broader categories.

The resultant themes emerged providing a description of the experience of the adult learner returning to school. Themes identified regarding incentives included: personal goal, financial influence, employment requirement, and career advancement. Themes identified regarding barriers included: finances, balance, and challenges. Lastly, themes identified regarding solutions to return to school included: support, personal drive, career advancement, and finances. Results of thematic analysis was confirmed through the use of a peer group, analyzing the same data and comparing findings to aid in establishing trustworthiness of findings.

Conclusion: Given the high pressure and multi-faceted stressors that bombard nurses in their work environment, it is important to explore what coping strategies and demographic predictors are associated with such stressors. This study supports some interesting "coping profiles" that accompany the six dimensions of stress of the NSI. Age of the nurse was found to be a frequent predictor of coping behavior frequency suggesting that indeed experience seems to bolster adaptability and a greater wealth of coping strategies along with the discipline to employ them. Also, there are important qualitative themes that emerged from their narrative responses to the incentives, challenges, and sources of support that have allowed them to embrace the daunting task of returning to school.

Although the sample size limits the generalizability of the findings, the study encourages some discussion of implications for orientation of nurses into the field; as well as their ongoing professional development, particularly those returning to higher education for a degree. The results are also encouraging for continued exploration of the stress and coping dynamics among nurses, and better understanding the formidable journey of those nursing professionals who enter the pipeline of higher education to procure the critical degrees needed to maintain the collective high quality of standards, achievements, and learning within the profession.

B 11 - Stress and Burnout in the Nursing Profession

The Impact of Burnout on Doctorate Nursing Faculty's Intent to Leave Their Academic Position

Elizabeth Florez, PhD, RN, USA

Young-Me Lee, PhD, RN, USA

Nadia Spawn, MS, RN, USA

Jessica Bishop-Royse, PhD, N/A, USA

Abstract

Purpose: The demands placed on nursing educators puts them at high risk for burnout, leading to decreased job satisfaction and increased intent to leave their faculty positions. Despite the fact that nursing faculty are at great risk for job burnout; there are limited studies exploring the relationship between burnout and leaving their academic positions. The aim of this study is to address the national nursing faculty shortage by examining demographics, predictors including teaching preparation, and burnout to determine intent to leave nursing academia among PhD and DNP-prepared nursing faculty.

Methods: A descriptive survey research design was used to examine the relationships among the key study variables and identify the most significant factors related to faculty leaving. A national survey of doctorate faculty teaching in undergraduate and/or graduate nursing programs throughout the U.S. was administered via Qualtrics survey software. Logistical regression models were used to interpret data significance.

Results: A total of 146 nursing faculty responded to the online survey. 51.4% of the respondents (n=75) had a DNP degree and 48.6% (n=71) had a PhD degree. 61% of the respondents were over the age of 50 with the remaining 39% of the respondents between ages 20 and 49. PhD-prepared faculty reported higher emotional exhaustion compared to DNP-prepared faculty. Findings revealed that degree type (PhD versus DNP), age, and emotional exhaustion and depersonalization in burnout were significant predictors related to intent to leave nursing academia. Results indicated that younger faculty, PhD-prepared faculty, and higher reported levels of emotional exhaustion significantly determined intent to leave their positions. Depersonalization, conversely, was found to significantly decrease intent to leave.

Conclusion: The findings from this study found that PhD-prepared nursing faculty experienced more emotional exhaustion compared to the DNP-prepared faculty, a significant factor influencing decisions to leave nursing academia. To address the nursing faculty shortage issue, it is critical to create supportive and positive working environments to promote the well-being of both nursing faculty members and the institutions in which they work.

B 12 - Pediatric Pain Management

Untreated Procedural Pain Increases Urine Markers of Adenosine Triphosphate (ATP) Utilization in Preterm Neonates

Danilyn Mag-akat Angeles, PhD, RN, USA

Danilo Boskovic, PhD, USA

Abstract

Purpose: We previously published that a single dose of oral sucrose significantly increased plasma markers of adenosine triphosphate (ATP) utilization (hypoxanthine) and oxidative stress (xanthine, allantoin) in neonates undergoing a clinically required heel lance [1,2]. However, the effect of repeated doses of sucrose and other sweet solutions such as glucose on above markers is unknown.

Methods: Using a prospective randomized double blind clinical trial, we measured urinary markers of ATP utilization and oxidative stress in preterm neonates over days of life 3-7. Subjects were preterm neonates who are 28-34 weeks in gestation. Exclusion criteria include: significant cardiovascular and respiratory disease, IVH, NEC, on opioids or sedatives. After obtaining parental consent, subjects were randomly assigned to receive standard of care (control, n=12) or either 24% oral sucrose (n=14) or 30% oral glucose (n=13) two minutes before any tissue-damaging procedure (TDP). Demographic data for categorical variables were analyzed using Chi-square test. Repeated measures ANOVA for one between subject factor (group) and one within subject factor (time) were assessed to evaluate the effect of the procedures (control, 24% oral sucrose, 30% oral glucose) over time. Interaction terms in the General Linear Model were used for this purpose.

Results: We found that neonates who received 24% oral sucrose tend to have higher urinary concentration of xanthine compared to those who received 30% oral glucose, specifically at day of life 4. However, the highest urinary concentrations of xanthine (P=0.019) and uric acid (P=0.028) were found in control subjects who received the least amount of oral sucrose analgesia.

Conclusion: These data support our previous findings that untreated pain results in increased ATP utilization and oxidative stress [2]. In addition, this finding suggests that 30% oral glucose may be an acceptable and metabolically less demanding alternative to oral sucrose as a non-pharmacological intervention to procedural pain. Further studies are required to examine more effective ways to decrease procedural pain in preterm neonates.

B 12 - Pediatric Pain Management

Frontline Nurse-Initiated Interventional Research: Use of Distraction Versus Oral Midazolam in Reducing Pediatric Perioperative Anxiety

Barbara Stewart, MSN, RN, CPN, USA

Rebecca Severnak, ADN, RN, USA

Terri Pearcy, BSN, RN, CPN, USA

Abstract

Purpose: The purpose of this frontline nurse-initiated study was to examine if the use of interactive distraction (iPad™) was more or as effective in reducing preoperative anxiety, at parental separation and mask induction, as oral midazolam in children, four to twelve years old, undergoing outpatient surgery with a duration of 1-1/2 hours or less. The Seiden et al. (2014) study protocol was replicated in order to increase the body of evidence, but addressing their study limitations. In the Seiden et al. study, anesthesiologist researchers found no significant differences between interactive distraction and oral midazolam in pediatric perioperative patients. Preoperative anxiety is a global problem in pediatric surgical patients. Children often experience anxiety before outpatient surgical procedures during parental separation and at mask induction (De Querioz Siqueira et al., 2014; Kerimoglu, Neuman, Paul, Stefanov, & Twersky, 2013; Seiden et al., 2014). Currently, the most common treatment for pediatric preoperative anxiety is administration of oral midazolam, a benzodiazepine with undesired side effects of prolonged sedation, behavioral changes, and emergence delirium (Wetzel, 2016). The use of interactive distraction has not been sufficiently investigated in its effectiveness to minimize preoperative anxiety. Frontline perioperative nurses identified needs to: (1) evaluate non-pharmacological preoperative interventions, (2) enhance patient and family satisfaction, and, (3) promote patient safety during their outpatient surgical experiences. This is the first research study conducted by frontline nurses as previous studies have been conducted by anesthesiologists (De Querioz Siqueira et al., 2014; Seiden et al., 2014).

Methods: Single-blinded prospective comparative study design was used with randomized assignment to experimental iPad™ group and control oral midazolam group. The study was conducted at 403-bed urban pediatric medical center in the southwestern United States; Institutional Review Board approval was received. Research personnel in the Post-Anesthesia Care Unit (PACU) were blinded to study intervention. A total of 102 pediatric patients with 102 primary caregivers were recruited: 51 patients (mean age 6.8 years, 51% male) with 51 primary caregivers (mean age 35.7 years, 84% females) for iPad experimental group and 51 patients (mean age 6.9 years, 65% male) and 51 primary caregivers (mean age 35.3 years, 75% females) for oral midazolam control group. When the child participant picked the “dinosaur” card, the child received the control intervention of oral midazolam 15 to 45 minutes prior to parental separation. When the “robot” card was selected, the child was given an iPad™ mini with an age-appropriate gaming application one minute prior to parental separation to be continued through mask induction. Outcome measures included: (1) psychometrically established, modified Yale Preoperative Anxiety Scale (mYPAS; Jenkins, Fortier, Kaplan, Mayes, & Kain, 2014; Kain et al., 1997) at admission, parental separation, and mask induction, scored from nurse observations on activity, vocal, emotional expression, and arousal; (2) Pediatric Anesthesia Emergence Delirium (PAED; Bajwa, Costi, & Cyna, 2010; Sikich & Lerman, 2004) Scale upon awakening and 15 minutes post-awakening, scored from nurse observations in PACU; (3) parent’s perception of child’s anxiety at admission and separation, with Likert-style responses; (4) parent satisfaction with child separation, with Likert-style response; (5) time in minutes from PACU arrival to awakening, (6) time from PACU arrival to discharge home, and (7) assessment of post-hospitalization behavioral change in pediatric patients at 7 and 14 days postoperatively using Post Hospitalization Behavior Change Questionnaire for Ambulatory Surgery (PHBQ-AS; Jenkins et al., 2015). Data was analyzed using descriptive and inferential or non-parametric statistics (based on level of data) such as: Repeated Measures Analysis of Variance (RMANOVA) or Friedman Two-Way Analysis of Variance by Ranks or paired-sample *t*-tests for measurements within groups and multifactorial Analysis of Variance (ANOVA) or independent-samples Mann-Whitney U Test or independent-sample *t*-tests between groups.

Results: Children in the interactive distraction group demonstrated significantly lower mYPAS scores at times of parental separation and mask induction compared to oral midazolam group on activity, vocal, and arousal. On PAED scores at 15 minutes post-emergence, the iPad™ mini group had significantly lower scores (oral midazolam: 6.65 versus iPad™ mini: 3.3; $p=0.001$). Within groups, there were statistically significant differences on caregiver ratings of their child's anxiety from admission to separation; all rated their child's anxiety lower at time of separation. There were no statistically significant findings between groups on overall parent satisfaction. Times from PACU arrival to awakening were significantly lower ($p = 0.007$) in the distraction group. Times from PACU arrival to discharge home were statistically significant between groups (oral midazolam: 2.07 hours versus iPad™ mini: 1.66 hours; $p < 0.0001$). On 7-day PHBQ-AS responses, caregivers of children who received oral midazolam ($n=12$) reported higher percentages of poor appetite (25%) and temper tantrums (17%) while caregivers of children ($n=9$) in the distraction group reported more bad dreams (11%). By 14 days, the majority of PHBQ-AS responses returned to baseline except for continued temper tantrums (11%) and poor appetite (11%) in the oral midazolam group ($n=9$) and caregivers of the distraction group ($n=9$) said their children had more trouble getting to sleep (22%).

Conclusion: Use of interactive distraction was more effective in reducing preoperative anxiety and post-emergence delirium in pediatric outpatient surgery patients, 4 to 12 years old, when compared to the administration of oral midazolam preoperatively. Participants who used the iPad™ mini were extubated earlier and were discharged in less time than the oral midazolam group. Use of less sedative medications translates to decreased length of stay in the PACU which could result in increased productivity and financial savings for the medical center. Due to low response rates at 7 and 14 days on the PHBQ-AS, these findings cannot be generalized but can guide discharge teaching of caregivers on potential post-hospital behaviors. Interactive distraction was shown to be an effective alternative to oral midazolam in reducing preoperative anxiety and post-emergence delirium in pediatric surgical patients. Nurses worldwide can utilize this evidence to: (1) incorporate the age-appropriate and evidence-based use of interactive electronic distraction into their practice, (2) promote empowerment of families and patients through education on available options for reduction of preoperative anxiety, and (3) collaborate with various disciplines (i.e. anesthesiologists and child life specialists) to decide treatment options for preoperative anxiety. Frontline nurses are equipped with the skills and knowledge to identify needs for practice change and, with mentoring, can engage in the successful conduct of clinical research positively impacting patient outcomes.

B 13 - Care of Minority Populations

Clinicians and Bicultural Workers' Views on Coassessment to Improve Mental Health Assessments in Multicultural Clients

Saras Henderson, PhD, MEd, RN, FRCN, Australia

Abstract

Purpose: In Australia, multicultural people are overrepresented in mental health inpatient facilities and are more likely to be on involuntary orders (Australian Bureau of Statistics, 2012; Warnock-Parks et al., 2010). This is partly attributable to the many cultural and language barriers limiting access to and effective utilisation of services (Queensland Health, 2012). In Australia, mental health services use a service delivery model that provides clinicians such as mental health nurses, psychologist, psychiatrist, social workers with interpreters to overcome language barriers which is important in producing accurate assessments and diagnosis but do not address cultural barriers (Scala, 2012). Overcoming cultural barriers is more complicated but understanding how culture impacts on mental health and help seeking behaviour can improve mental health outcomes for multicultural communities (Owiti et al. 2014; Scala, 2012). Typically an ethnic matching model of matching the ethnicity of the mental health professional and client has been used with some success (Cabral & Smith, 2011). One Australian study using ethnic matching reported reductions in crisis presentations and hospital admissions and an increase in contact with community mental health services (Ziguras et al., 2003). However, ethnic matching has limitations; in particular it is difficult to find a range of ethnically diverse mental health professionals to respond to the broad cultural diversity of clients/patients. Ethnic matching is particularly difficult in Australia when there is an increasing number of new and emerging communities, in which there are only a few or no mental health professionals within the population. To overcome this problem and to ensure mental health assessments are culturally appropriate, the co-assessment model which pairs a mental health clinician with a bicultural worker to jointly assess multicultural clients was used in an Australian mental health facility. It was envisaged that the use of the co-assessed model would help clinicians to better understand how cultural factors impact on clients' understanding of mental health. The purpose of our study was to explore clinicians and bicultural workers' views on using the co-assessment model.

Methods: Qualitative design was used with a purposeful sample of nine clinicians and nine bicultural workers drawn from a transcultural mental health facility. Using semi-structured open-ended questions, two focus group interviews, one with the clinicians and one with the bicultural workers were conducted. Information was sought from participants on the co-assessment process, perceived benefits and challenges, and how the model differed from the use of interpreters. Data were transcribed verbatim, coded and analysed using content analysis

Results: The findings indicate the model is effective in increasing cultural understanding and sensitivity in mental health assessments. Clinicians found bicultural workers provided the cultural lens to better assess and diagnose clients. Bi-cultural workers stated their cultural and personal experience in the assessment process facilitated a holistic approach. A common challenge for participants was time constraints and the blurring of role boundaries.

Conclusion: Our findings suggest the co-assessment model has applicability to mental health nurses and health professionals to enhance optimum assessment outcomes for multicultural communities.

B 13 - Care of Minority Populations

Beliefs, Attitudes, and Perceptions of Spirituality: A Case Study of Homeless Women in Nevada

Jene' M. Hurlbut, PhD, RN, CNE, USA

Marcia M. Ditmyer, PhD, MBA, MS, MCHES, USA

Abstract

Purpose: The purpose of this qualitative case study was to assess the beliefs, attitudes, and perceptions of the meaning of spirituality in a cohort of sheltered homeless women in an urban area in southeast Nevada.

Methods: Fourteen (14) personal interviews were conducted at a homeless shelter located in the southwest of the United States. Open-ended questions were used to allow respondents to answer questions in their own terms or in a manner that reflects their own attitudes, beliefs, and/or perceptions rather than those of the researcher. A process for categorization the data collected was used. Respondents agreed to be tape recorded for the purpose of data collection. Only aggregate data was used for purposes of reporting. The data was subsequently transcribed, and grouped in an effort to synthesize the data into identified patterns/themes. Once identified, the themes were then looked at to better determine the beliefs, attitudes and perceptions of respondents.

Results: The convenience sample of women meeting the inclusion criteria interviewed ranged in age from 20-68 (M=46). A majority of the women in this sample had experienced homelessness 1-2 times and had been homeless for approximately 0-3 months. From the interviews five overarching themes emerged: 1) a belief in God or a higher power, 2) a distinction between religious beliefs and spirituality, 3) a belief that there is a plan for their life, 4) spirituality and beliefs provides guidance for what is "right" and what is "wrong", and 5) a belief that their life will improve. In their descriptions of spirituality the women often shared stories and life experiences to illustrate their understanding of this concept.

Conclusion: The findings of this study support the fundamental importance of spirituality in the lives of homeless women. Spirituality was acknowledged as providing hope and support and the ability to improve health and well-being. Implications from this study can help healthcare professionals to design interventions that support spiritual practices and perhaps lessen the negative impact of homelessness for these women. Moreover, healthcare professionals need to become comfortable in addressing the spiritual needs of clients, in doing so this will improve the holistic care that is provided to this marginalized and vulnerable population. During a time when rates of homeless for women have increased, further research is needed to explicate the meaning of spirituality and how this impacts their overall resiliency and health.

B 14 - Promoting Clinical Outcomes

Nurse-Led Diabetic Retinopathy Screening: A Revolutionary Approach to Vision Care for Canadian Aboriginal Peoples

Shelley Spurr, PhD, MBA, BSN, RN, Canada

Jill Bally, PhD, RN, Canada

Carol Bullin, PhD, RN, Canada

Abstract

Purpose: Aboriginal people living in Canada are among the highest risk populations for diabetes and related complications, including retinopathy (Harris, Bhattacharyya, Dyck, Hayward, & Toth, 2013). Diabetic retinopathy is the most common cause of new cases of blindness in adults ages 20-74. Nearly two thirds (60%) of the population living with type 2 diabetes for 20 years or more suffer from retinopathy, and many individuals (21%) will have symptoms of retinopathy at the time their diabetes was diagnosed (Boyd, Advani, Altomare, & Stockl, 2013). The increasing prevalence of diabetes and the associated complications in Aboriginal peoples illustrate the pressing need to understand the impact of this chronic disease.

To date, visual health has been largely ignored, which has resulted in significant numbers of Aboriginal Canadians suffering from serious ocular and visual health problems. Only a few ocular health programs have evolved targeting Aboriginal communities (Venne, 2011). As such, the **purpose** of this study was to investigate the risk factors for type 2 diabetes and the possibility of using a portable fundus camera (Optovue) as a novel approach for convenient, earlier, and more accessible vision screening and referral for Aboriginal peoples living with type 2 diabetes in northern and remote Canadian communities. This mobile state-of-the-art technology allows for quick vision screening and can be used by registered nurses to screen for visual changes related to diabetes. The data can be saved and any images of concern can be securely emailed to the off-site ophthalmologist for further investigation.

Methods: Study Design: This two stage quantitative pilot study screened participants for identification of risk factors of type 2 diabetes with anthropometrical measurements, blood pressure, and a A1C point of care blood glucose test (Stage 1), followed by vision exams to screen for signs of retinopathy in participants diagnosed with type 2 diabetes using fundus photography (Stage 2).

Population: A purposeful sample of adults living in northern and remote Canadian communities were invited to participate in this pilot study. Participants were recruited from an ophthalmology clinic (n=33) and criteria for the study included a diagnosis of type 2 diabetes.

Stage 1 - Risk Measurements: As recommended by the Canadian Diabetic Association (CDA), weight, height, Body Mass Index (BMI), blood pressure, and an A1C were measured to screen for risk of type 2 diabetes. Descriptive statistics were computed using the Statistical Package for Social Sciences (SPSS v.22.0). **Stage 2 - Vision Exams:** The first vision exam involved the nurse screening for retinopathy using a portable fundus camera. The second eye exam involved fundus photography completed by the ophthalmologist. The nurse led vision exam results were compared to those of the ophthalmologist to determine sensitivity of the portable fundal camera as a screening tool for detection of diabetic retinopathy. A Cohen's Kappa was used to evaluate the inter-rater agreement between the nurses and ophthalmologist.

Results: Stage 1-BMI: The participant's BMI measurements ranged 18.75 and 48.63 with a mean of 32.22 (SD = 6.88). The percentage of obesity (≥ 30) = 54.5%. **A1C:** The A1C levels ranged from 5.50 to 13.00 with a mean of 8.30 (SD = 1.64). The percentage of elevated BMI (7.1 or higher) = 78.8%. **Blood Pressure:** The percentage of prehypertension (systolic = 120-130 OR diastolic = 80-89) and hypertension (systolic = 140-159 OR diastolic = 90-99) = 69.6%. **Stage 2-** Interrater reliability was calculated using Cohen's Kappa with results demonstrating a moderate agreement between the health professionals' judgments ($k = .67$).

Conclusion: Nurse-led vision screening in remote or northern communities can improve the standard of care by extending access to health services, lower the costs to families by reducing travel expenses, and prevent loss of vision for Aboriginal peoples. This research is being used as a foundation to advocate for expanded primary health services to improve the health outcomes for Aboriginal people living with type 2 diabetes in northern and remote Canadian communities. Future research with a larger sample is indicated to validate these results.

B 14 - Promoting Clinical Outcomes

Symptom Management in Adults With Knee Osteoarthritis Using Transcranial Direct Current Stimulation: A Pilot Study

Hyochol Ahn, PhD, MSN, MS-ECE, MS-CTS, RN, APRN, ANP-BC, USA
Roger Fillingim, PhD, USA

Abstract

Purpose: Osteoarthritis is a leading cause of pain and functional impairments in people 45 years and older (Lakkireddy, Bedarakota, Vidyasagar, Rapur, & Karra, 2015). Noninvasive brain stimulation, such as Transcranial Direct Current Stimulation (tDCS), has received significant attention for the treatment of pain in chronic conditions owing to its neuromodulatory effect (Ayache et al., 2016; Woods et al., 2016). tDCS involves the application of weak direct electric current to the head in a noninvasive and painless manner, leading to the modulation of the brain activity involved in pain processing (DaSilva et al., 2016; O'Connell & Wand, 2015). Therefore, we assessed the preliminary efficacy and safety of tDCS on pain symptoms in adults with knee osteoarthritis.

Methods: We conducted a double-blind, randomized, sham-controlled pilot clinical study in 40 community-dwelling participants with knee OA who were 50–70 years old. The participants were randomly assigned to receive either five daily sessions of 2mA tDCS for 20 minutes or sham tDCS (1:1 for two groups). Randomization was performed by a statistician with no clinical involvement in this trial. The anode electrode was placed over the primary motor cortex of the hemisphere contralateral to the affected knee, and the cathode electrode was placed over the supraorbital region ipsilateral to the affected knee. Osteoarthritis-related pain symptoms were measured at baseline and after tDCS via the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). The WOMAC consisted of 3 subscales relating to pain during activities (5 items), stiffness during the day (2 items), and impairments of physical function (17 items), with higher scores indicating worse pain, stiffness, and impairments of physical function. Also, we monitored possible side effects of tDCS by asking whether participants experienced the symptoms of tingling, itching sensation, burning sensation, pain, fatigue, nervousness, headache, difficulty concentrating, mood changes, or changes in vision or visual perception (Bikson et al., 2016). All the side effects were recorded, and their severity was graded from 0 (not at all) to 10 (highest degree). The safety questionnaire was administered after each stimulation session.

Results: The mean age was 59 years (Standard deviation = 8 years), and 53% were female. After five daily sessions, the tDCS group had a greater reduction than the sham group in pain during activities (active tDCS: 1.25 ± 3.13 , sham: 0.60 ± 2.11), stiffness during the day (active tDCS: 0.55 ± 1.36 , sham: 0.20 ± 0.83), and impairments of physical function (active tDCS: 2.40 ± 10.44 , sham: 0.10 ± 7.33). Effect sizes (Cohen's d) ranged from $d=0.24$ for reducing pain during activities ($t=0.77$, $df=38$, $p=0.44$), $d=0.31$ for reducing stiffness during the day ($t=0.98$, $df=38$, $p=0.33$), and $d = 0.27$ for reducing impairments of physical function ($t=0.88$, $df=38$, $p=0.39$). Also, all participants tolerated tDCS well without experiencing any significant adverse effects. No participants complained about fatigue, nervousness, headache, difficulty concentrating, mood changes, or vision changes during tDCS sessions. A few adverse events occurred during tDCS session, such as tingling, itching sensation, burning sensation, pain, and change in visual perception. However, these symptoms were mild (less than or equal to 2 out of 10) and transient, and the symptoms had resolved at the completion of the stimulation session.

Conclusion: Although our primary results were nonsignificant, there is a preliminary suggestion that tDCS targeting primary motor cortex may reduce osteoarthritis-related pain symptoms in adults with knee OA without any significant adverse effects. Future studies are needed to refine this novel approach for pain neuromodulation.

B 15 - Quality of Life in Cardiac Patients

Comparisons of Cardiometabolic Risk Between African American and Caucasian Women in a Worksite Wellness Program

Barbara Ann Graves, PhD, RN, USA

Susan J. Appel, PhD, RN, APRN-BC, CCRN, FAHA, USA

Abstract

Purpose: Cardiovascular disease (CVD) is the leading cause of death and chronic illness in the US. The burden of CVD is substantial in terms of mortality, disability, and cost. More than 82 million Americans have some type of CVD.¹ Total direct medical costs are projected to triple, from \$273 to \$818 billion, between 2010 and 2030.² More women die from CVD than men, but still represent an under-researched population.³⁻⁵ African-American women experience some of the highest age-adjusted prevalence rates for heart attack, stroke, hypertension, and diabetes. The purpose of the research study was to compare CMR or the interplay of risk for diabetes leading to heart disease, between African-American and Caucasian women.

Methods: A cross-sectional design was used to compare CMR variables in 50 women (25 African-American and 25 Caucasian) participants in a worksite wellness program. CMR profile data was obtained that included: 1) blood levels of fasting insulin and glucose (blood sugar), hemoglobin A1c (risk for diabetes), C-reactive protein (inflammation), 2) acanthosis nigricans scoring (darkened skin on the neck as risk for diabetes) and 3) Measures of body habitus (weight, height and waist circumference). A multivariate analysis of covariance (MANCOVA) was used to compare African American and Caucasian participants on the CMR variables while controlling for age and BMI. A regression analysis using a stepwise procedure was also used to determine which CMR measures were the best predictors of insulin resistance.

Results: There was a significant multivariate main effect of race, Wilks' $\Lambda = .58$, $F(10, 32) = 2.28$, $p = .04$, suggesting that there were significant differences between African American and Caucasian participants on measures of CMR. Stepwise regression analysis further revealed that the overall model was significant, $R^2 = .57$, $F(6, 38) = 8.36$, $p < .001$ for predicting insulin resistance. The analysis further indicating that BMI, fasting triglycerides, fasting HDL, and fasting hemoglobin A1c were significant predictors of insulin resistance.

Conclusion: Findings from this study provide valuable insights to guide the development of specific interventions to reduce CMR among understudied women in general. More specifically, findings inform how to tailor interventions among African-American women, as risks for heart disease and stroke have been found to differ by both gender and race.

Cardiac Rehabilitation Improves Health-Related Quality of Life for Patients With Atrial Fibrillation: A Pilot Study

Lynn C. Macken, PhD, RN, USA

Charles Morrison Carpenter, MD, FACC, USA

Caitlin R. Coppenrath, MS, RCEP, USA

Gail Alison Crocker, BS, RN, USA

Karen Kurkjian, MD, FACC, USA

Aimee Chapman, BS, RN, CHFN, USA

Kristiina Hyrkas, PhD, LicNSc, MNSc, RN, USA

Abstract

Purpose: The prevalence of atrial fibrillation (AF) has reached epidemic proportions world-wide and in the U.S. (Abed et al., 2013). Patients with AF are at high risk for stroke, functional impairment, depression, symptom recurrence and poor quality of life (Alli et al., 2013). Medical treatment for AF has focused on controlling the arrhythmia and preventing stroke. Pharmacological or electrical cardioversion and ablation have shown limited success over time (Ganesan et al., 2013). Recurrent symptoms of fast, irregular heart rate, breathlessness and other troublesome symptoms foster profound psychological distress and limit patients' capacities to make important lifestyle changes. A recent study (Abed et al., 2013) investigating intensive cardiometabolic risk factor management showed a significant improvement in AF symptom burden, symptom severity, number of episodes and duration of episodes compared to usual care in overweight/obese patients with symptomatic AF. While cardiometabolic risk factor modification shows promise, strategies for improving health-related quality of life (HRQOL) in these patients are not clear (McCabe, Schumacher, & Barnason, 2011). Cardiac rehabilitation is an established, underutilized and low cost, evidence-based intervention that has been shown to improve physical function, reduce cardiometabolic risk factors and improve HRQOL in patients with known heart disease such as myocardial infarction and coronary artery bypass surgery (American Association of Cardiovascular and Pulmonary Rehabilitation [AACVPR], 2013). However, in the U.S., patients served by community-based cardiac rehabilitation programs rarely have AF as a primary diagnosis, often due to a lack of insurance coverage for this outpatient service. In the U.S., nurses provide the majority of patient-centered care in cardiac rehabilitation programs in collaboration with physicians, exercise therapists, dietitians and other rehabilitation specialists. This pilot study aims to examine cardiac rehabilitation as an innovative approach for improving the HRQOL of patients with symptomatic AF.

The purpose of this study was to describe and compare the six-month trajectory of HRQOL outcomes of patients with symptomatic AF who participate in cardiac rehabilitation or receive usual care.

Methods: A prospective, observational, longitudinal design was used for this IRB approved, one-year pilot study. Subjects were recruited from a convenience sample of patients with symptomatic paroxysmal or persistent AF who were referred by their physicians to the community-based cardiac rehabilitation program of a large, tertiary care hospital in the northeastern U.S. For study inclusion, patients were required to have rate-controlled cardiac rhythm, at least one cardiometabolic risk factor, and be medically cleared for moderate exercise. A potential pool of 10 patients per month was estimated from the number of patients with AF treated in the institution's cardiology-electrophysiology clinics. Cardiac rehabilitation staff contacted the referred patients by phone and described the program. After patients accepted or declined cardiac rehabilitation, staff invited them to participate in the research study. The intervention group received an intake interview to develop an individualized exercise and cardiometabolic risk modification care plan. They participated in 2-3 supervised, non-EKG monitored exercise sessions weekly for 12 weeks and attended educational classes for risk factor modification. Subjects who chose not to participate in cardiac rehabilitation but agreed to participate in the study were followed by their usual care providers and received risk factor modification advice and education at routine office visits.

HRQOL outcomes included AF symptoms and disease-specific quality of life. Questionnaires were collected at three time points: entry into the study/cardiac rehabilitation (T1), 3-months or completion of

cardiac rehabilitation (T2), and 6-months after study entry (T3). Symptoms related to AF were assessed with the University of Toronto Atrial Fibrillation Severity Scale (AFSS) (Dorian et al., 2013). HRQOL life was assessed with the Atrial Fibrillation Effect on Quality of Life (AFEQT) instrument (Spertus et al., 2011). Permission to use the AFSS and AFEQT was obtained from the authors. Subjects received a small stipend (\$25 U.S.) upon completion of the questionnaires at each time point. The modest cost of the cardiac rehabilitation program (\$60 U.S. per month) was paid by an internal grant for intervention subjects.

Results: Data were analyzed with descriptive and non-parametric statistics using SPSS, version 17. Thirty-four eligible patients were referred to cardiac rehabilitation between October 2015 and March 2016. Eighty-eight percent (30/34) agreed to study participation, with 23 (77%) selecting the intervention and 7 (23%) choosing usual care. Intervention subjects were significantly younger (66 vs. 73 years, $p=.017$) and were more likely to present with paroxysmal versus sustained AF ($p=.044$) compared to the usual care group. The majority of subjects reported a history of hypertension, hyperlipidemia, central obesity, orthopedic limitations, and no regular exercise at baseline. Intervention subjects were significantly more likely to have been treated with cardioversion (15/23, 65%) than the usual care group (1/6, 17%) ($p=.033$).

The AFSS symptom score (range 0-35) indicates how bothered subjects are by palpitations, shortness of breath at rest and during physical activity, exercise intolerance, fatigue at rest, lightheadedness and chest pain/pressure. The AFSS burden subscale (range 3 to 30) is the sum of frequency, duration and severity of AF episodes. Higher scores on both scales indicate worse symptoms or burden. AFSS global well-being was assessed with a visual analog scale rating how the subject feels about his/her life (1=worst possible; 10=best possible). The symptom trajectory for the intervention group showed significantly improved ratings of AF symptoms ($M=11.3$ vs. 5.8 , $p=.005$) and global well-being ($M=6.5$ vs. 7.6 , $p=.003$) between baseline and three months. There were no significant changes in AF burden, symptoms, severity or global well-being in the usual care group over time. Group comparisons showed that the intervention subjects had significantly worse AF burden scores at baseline ($M=18.8$ vs. 12.4 , $p=.030$) and six months ($M=15.1$ vs. 9.5 , $p=.011$); and worse AF severity at six months ($M=5.8$ vs. 2.8 , $p=.003$) than usual care subjects. No significant differences between groups were found for health care utilization by number of emergency room visits, hospitalizations and specialist visits in the year prior to study enrollment.

AF-specific quality of life was measured with the AFEQT overall and subscale scores (range 0 to 100; extreme to minimal disability/difficulty). For the intervention group, the HRQOL trajectory showed improvement in overall AFEQT scores ($M=60.8$ vs. 80.1 ; $p=.001$) and three of the four subscales for daily activities, treatment concerns and treatment satisfaction between T1 and T2. No significant changes in AFEQT scores were found for the usual care group at any time point. AFEQT meaningful important improvement scores were examined as described by Dorian et al. (2013), in which a 19-point or greater change indicates a substantial improvement in quality of life ($p=.385$). Between baseline and 3-months, 61% (11/18) of intervention subjects were found to have a meaningful improvement. No meaningful improvements in quality of life were found for usual care subjects between time periods. Group comparisons showed that the intervention subjects reported significantly worse treatment concern scores than the control group at baseline ($M=59.5$ vs. 85.3 , $p=.029$). Treatment concern items rate how worried or anxious the subject feels about their AF starting at any time, worsening other medical conditions and worry about medication and treatment side effects. Except for the treatment concern subscale, no statistically significant differences for overall AFEQT, AF symptoms, daily activities and treatment satisfaction were found between groups at any time period.

Limitations: One important limitation was the small sample size, especially in the usual care group. However, referral and participation rates were consistent with the anticipated number of eligible patients at this site. No sample size calculation had been planned for the pilot study.

Conclusion: The results of this study confirmed that many patients with a primary diagnosis of symptomatic AF often present with multiple cardiometabolic risk factors. While usual care providers are aware of the need to address lifestyle modifications, office time is limited and typically focuses on medical management issues. Referring appropriate patients to a community-based cardiac rehabilitation program significantly improved AF symptoms, symptom burden, daily activities, treatment concerns, treatment

satisfaction, global well-being and AF-related quality of life for the intervention group. A recent study by Dorian and colleagues (2013) found a meaningful important improvement in overall HRQOL in 35% of patients after three months of usual care treatment. With the addition of the cardiac rehabilitation intervention in our study, 61% of subjects with similar baseline characteristics reported a meaningful improvement in HRQOL over the same time period. The advantages for patients to participate in cardiac rehabilitation include the repetitive interaction with and coaching by skilled nurses and clinicians who specialize in exercise therapy, dietary modification, stress management and self-care strategies (AACVPR, 2013).

These results also suggest that patients with AF who voluntarily participate in a 12-week cardiac rehabilitation program may present with unique characteristics such as being relatively younger, experienced cardioversion, had worse treatment concerns and reported greater disease burden related to frequency, duration and severity of AF episodes. Future research aimed at identifying patients with symptomatic AF who may benefit the most from cardiac rehabilitation would be useful to nurses and other clinicians who regularly care for these patients. This pilot study also suggests that strategies to sustain improvement in HRQOL beyond the cardiac rehabilitation intervention are still needed.

B 16 - Adolescent Sexual Health

Using Youth-Participatory Research to Address Health Disparities in Sexually Transmitted Infections Among Homeless Youth

Michelle Dang, PhD, RN, APHN-BC, USA

Abstract

Purpose: Sexually transmitted infections (STIs), including HIV, among homeless youth are a significant public health issue with STI rates among homeless youth being more than twice that of nonhomeless youth. Despite known risk factors, effective interventions for STI prevention and treatment for this population remain elusive. Evidence-based STI interventions targeted at adolescents typically encompass community or school-based, behavioral approaches; such approaches are a poor fit with a highly mobile population and do not address underlying social conditions that contribute to unsafe sexual behaviors such as survival needs, social norms, and access to health education.

This project is an exploratory study using a youth-participatory approach to determine the most effective methods in STI research with homeless youth as well as identifying key social and structural characteristics that will inform programs that target this population in developing culturally-specific interventions that will increase protective sexual behavior and improve access to care. Four current and former homeless youth (2 males, 2 females, ages 19-21) were recruited as co-researchers and cultural informants and co-designed the study's methodologies and instruments.

Methods: The PI and youth researchers, hereafter team, determined that focus groups with homeless youth would be the appropriate first step design to gather data about the overall health care access for STI-related issues and the general perceptions of youth about STIs. After completing IRB training, the youth researchers collaborated with the PI to develop focus group questions and recruited other homeless youth to participate in the focus groups through word of mouth and in-person invitations. The PI trained the youth researchers in how to facilitate focus groups, and the team conducted mock focus groups prior to actual data collection. A total of three focus groups were completed, and one youth researcher facilitated each focus group along with the PI, who was present at all the focus groups.

Results: The team analyzed the data together using thematic analysis. Data from the focus groups revealed four main themes: 1) mistrust of the healthcare system; 2) stigma and shame related to STIs; 3) concerns about confidentiality; and 4) lack of knowledge about insurance coverage. These findings support the need for more in-depth qualitative interviews with homeless youth to illuminate processes related to these concerns (2nd phase). As a youth-participatory project, the research team also identified systems issues that posed challenges to a full academic-youth partnership.

To gain more in-depth information about the issues identified in the focus groups, the team collaborated in developing interview questions and identified brief standardized questionnaires about STI knowledge and stigma to include in the study. Twenty homeless youth were recruited for one-on-one interviews conducted by the PI. Data analysis indicated that participants had good knowledge about STIs with the vast majority being able to identify all of the correct answers on a brief quiz about STIs. Sample questions included, "A person can have a sexually transmitted disease or STD and not know it," "STDs that aren't cured early can cause sterility in women." Participants also reported that access to STI testing and treatment was not a barrier to them getting tested, and that they advocated for testing for themselves and their partners. Two main themes arose regarding concerns about getting tested: 1) fear of the unknown and how their friends will perceive them; and 2) fear of getting STDs that non-curable such as herpes and HIV. In terms of the decision making process as to whether they would use condoms during sex, several themes emerged: 1) condoms reduce pleasure associated with sex; 2) condoms are not necessary if you know someone well; and 3) not using condoms when they are "in the moment".

Conclusion: Findings from both the focus groups and semi-structured interviews indicate that homeless youth have adequate understanding about STIs and access to testing and treatment as well as free condoms. Interventions to prevent STIs often focus on education alone. The narratives provided by the

youth in this study support a need to provide developmentally appropriate interventions. The youth in this study have a clear understanding about how STIs are spread and prevented; and access to testing and treatment does not pose a barrier as would be expected for this population. They also reported feeling comfortable talking with health care providers about getting tested for STIs. Findings suggest that interventions should not focus only on education and access to care. An emphasis should be placed on normalizing routine STI testing and reducing stigma and fear. Nurses and other health care providers are trusted by youth and can serve as an important catalyst in changing young people's perceptions about getting tested for STIs.

B 16 - Adolescent Sexual Health

Understanding the Intersection of Adolescent Girls' Motives for Sex and Risk Profiles

Dianne Morrison-Beedy, PhD, MSN, BSN, RN, WHNP-BC, FNAP, FAANP, FAAN, USA

Linsey Grove, MPH, CPH, CHES, USA

Ming Ji, PhD, USA

Elizabeth Baker, PhD, MPH, CPH, USA

Abstract

Purpose: Sexual risk behaviors resulting in HIV, STIs and unplanned pregnancy continue to pose a significant health risk to adolescent girls globally. Tested in a randomized controlled trial, the Health Improvement Project Teens (*HIPTeens*) is recognized by the Department of Health and Human Services (DHHS) and the Centers for Disease Control (CDC) as an HIV/STI and teen pregnancy prevention evidence-based intervention (EBI) (Morrison-Beedy, Jones, et al., 2013). Understanding what motivates girls to participate in safe and risky sex is important to developing and tailoring behavioral interventions to increase their utility across the globe. The purpose of this study was to examine the baseline sex motives of *HIPTeen* participants and the intersection of these motives with demographic, sexual and mental health risk profiles. These findings can be used to identify vulnerable subgroups for future health promotion interventions.

Background/Literature: In 2015, The CDC estimate that approximately 25% of adolescents have acquired an STI (Prevention, 2015). Although U.S. teen pregnancy rates have fallen in the past decade, disparities in STIs and unintended pregnancies continue among minority groups and those with a history of risk behaviors (CDC, 2015). Young women of color accounted for the highest number of estimated new HIV diagnoses compared to all other racial groups (CDC, 2016). Reproductive history and demographic variables have been linked with sexual risk behaviors as well; for example, younger sexually active females experience higher rates of unprotected sex and multiple sexual partners (Vasilenko, Kugler, & Rice, 2016) and face sexual coercion from older partners (Morrison-Beedy, Xia, & Passmore, 2013; Volpe, Hardie, Cerulli, Sommers, & Morrison-Beedy, 2013). A history of pregnancy, especially repeat pregnancy, is associated with negative long-term health implications (Meade & Ickovics, 2005) as well as having other negative impacts as teen moms are less likely to graduate high school and find stable employment (Hoffman & Maynard, 2008; Seth, Wingood, DiClemente, & Robinson, 2011; Shrier, Walls, Lops, Kendall, & Blood, 2012).

For most teens, adolescence is a time of great biological and psychosocial change. Unfortunately for some, this can mean facing mental health and substance abuse challenges. A recent study found that over the course of a year 12-17 year old girls experienced nearly three times more major depressive events than their male peers (Substance Abuse and Mental Health Services Administration, 2012). Adolescent girls were more likely to feel sad or hopeless almost every day for two weeks or more, drink at least one alcoholic beverage, and smoke marijuana in the past month (Kann et al., 2015). Struggling with mental health and substance abuse issues can increase sexual risk as well as compound it (Mazzaferro et al., 2006; Jackson, Seth, DiClemente, & Lin, 2015). Substance use and depression have been linked with sexual risk behaviors including decreased condom use and substance use co-occurrence with sexual activities (Shrier et al., 2012). Studies have shown that varying motives for having sex influence risk behavior among adolescents. The relationship between motives for sex and condom use was examined in a study by 277 females; intimacy motives were associated with a reduction in condom use (Gebhardt, Kuyper, & Greunsven, 2003). Conversely, participants with low scores on the motive "to express love" (intimacy) with steady partners were more likely to have protected sex (Gebhardt et al., 2003; Gebhardt, Kuyper, & Dusseldorp, 2006). In another study, inexperienced and sexually active adolescent girls motivations to have sex were driven differently by personal values and religious influence (Paradise, Cote, Minsky, Lourenco, & Howland, 2001). Cooper, Shapiro and Powers, investigated motivations for sex categorized into four areas: self-focused or socially-focused interactions with positive or negative reinforcement (1998) identifying differences among subsets of respondents across genders. Still, limited information exists on the motivations of why vulnerable or disenfranchised adolescent girls

have sex. Understanding their motives to participate in sexual risk behaviors taking into account their risk profiles can help us tailor interventions to at-risk subgroups.

Methods: Sexually-active girls, ages 15-19 ($n=738$) were recruited from urban community-based settings and provided a gender-specific intervention in small group sessions. This intervention was theoretically-driven from the Information-Motivation-Behavioral Skills model which highlights these three constructs in successful behavioral approaches (Fisher & Fisher, 1992). Data were collected via audio computer-assisted self-interview surveys (ACASI) including a 17-item sex motives 5-point scale encompassing six domains: intimacy, enhancement, self-affirmation, coping, peer pressure, and partner approval (Morrison-Beedy, Carey, & Tu, 2006). Descriptive and inferential statistics and cluster analyses were used to describe the baseline distribution of sex motives in various subgroups defined by demographics and other risk factors and t-tests to determine differences between these subgroups.

Results: Participants were predominantly African American, impoverished, and exhibited multiple sexual risk factors. The principal sex motives identified were enhanced ($M=4.95$, $SD=3.09$) and intimacy ($M=7.69$, $SD=3.38$) while partner approval, peer pressure, and self-affirmation were reported infrequently. Statistically significant motive differences across domains were identified among mental health risk profiles (depression, marijuana use, binge drinking) at baseline. Girls who reported high depressive symptoms had significantly higher peer pressure ($M=0.30$, $SD=0.95$), partner approval ($M=2.06$, $SD=3.40$), coping ($M=2.15$, $SD=2.72$), and self-affirmation ($M=2.00$, $SD=3.07$) motives mean scores. Coping ($M=1.38$, $SD=2.18$), self-affirmation ($M=1.17$, $SD=2.28$), and enhanced ($M=5.43$, $SD=3.10$) motives mean scores were significantly higher among participants that had ever used drugs. Sex motives also differed significantly among demographic and reproductive health characteristics including race, age, and parental status. No history of pregnancy ($M=0.19$, $SD=0.68$) or children ($M=0.17$, $SD=0.65$) were associated with significantly higher peer pressure motives mean scores. Significantly higher mean intimacy motive scores (protective factor) were found among girls who were older ($M=8.01$, $SD=3.19$), black ($M=7.85$, $SD=3.36$), had never been treated for an STI ($M=8.00$, $SD=3.23$), and were not depressed ($M=7.87$, $SD=3.30$).

Conclusion: Understanding sex motives in girls and their relationship to modifiable and unmodifiable factors can improve tailoring of evidence-based risk reduction interventions to target specific subgroups. Opportunities to address modifiable variables during pre-intervention may augment intervention efficacy. *HIPTeensis* a scientifically tested intervention translated to inform evidence-based practice (EBP) in at-risk communities and settings. Understanding the motivational context of decision-making in adolescent girls regarding sexual choices and the intersection with their risk profiles is an important next step in translational science.

Relevance to Conference Themes & Objectives: Furthering research on sex motives in adolescent girls and their interaction with different profiles of risk is a critical step in promoting the transformation of sexual risk knowledge and evidence-based practice to advance global health and nursing. Utilizing interprofessional environments and partnerships like Sigma Theta Tau International to disseminate evidence-based interventions can fuel meaningful discussion on implementation strategies, provide opportunities for interdisciplinary learning, and promote the exchange of ideas on how to integrate technology which accelerates the translation of research into evidence-based practice.

C 04 - Challenges in Substance Abuse

A Retrospective Descriptive Study of Chemically Impaired Nurses in Texas

Mercy N. Mumba, PhD, RN, CMSRN, USA

Abstract

Purpose: The purpose of this study was to describe the population of nurses with impaired practice in the state of Texas going through a peer assistance program between 2013 and 2016.

The lack of education and screening for substance abuse, negative attitudes towards substance abuse, and the stigma associated with mental illness have further exacerbated this problem (Darbro & Malliarakis, 2012). Furthermore, very few interventional studies have been conducted on nurses with impaired practice. This is partly due to the complexities involved with studying nurses with impaired practice, specifically when considering confidentiality problems and maintaining anonymity of these nurses.

Consequently, very little is known concerning the characteristics of nurses with impaired practice, especially those going through peer assistance programs. Few recent studies have aimed at comprehensively describing this population, including their recent prevalence, demographic characteristics, and interventions specific to nurses in order to promote recovery and reduce relapse rates. In Texas, no studies were found in the literature that addressed the aforementioned concerns. Before any specific interventions can be recommended, a clear picture of who these nurses with impaired practice are is needed

Methods: This study was a retrospective analysis of secondary data of nurses who are chemically impaired collected by TPAPN between January 2010 and October 2016. It included both associational and comparative designs. Associational design was used to examine the strengths of relationships among variables, as well as to predict the behavior of one variable based on how another variable was acting. A comparative design was also used to answer research questions that examined differences between groups but lacked an active independent variable.

Results: Currently, 348 nurses in TPAPN are actively participating in the program for substance abuse related offenses. Many nurses are also referred to the program are for dual diagnoses. Of all the nurses that were referred to TPAPN over the last six years, 1553 were specifically for substance abuse related problems. These represent two percent of the population of nurses in Texas. The average age of participants in this study was 40.1 years, and approximately half of them were under the age of 40. Females represented 75% of participants and 76% were registered nurses. About 32% relapsed while they were in the program, and about 41% successfully completed the program. Nurses with impaired practice abuse variety of substances including prescription drugs and illegal drugs. Opioids were the most frequently abuse class of drugs, followed by alcohol, and then stimulants. The majority of nurses obtained their drugs by diverting from patients. Contrary to what is in the literature, nurses working in long-term care, medical-surgical units, and home health care had the highest prevalence of impaired practice. In this study, psychiatric comorbidity was not significantly associated with relapse. Self-report status was significantly associated with gender, age category, license type, relapse, and drug of choice. There was a significant inverse relationship between time it takes to enroll and number of days abstinent. Men were also more likely to be employed while in the program compared to their female counterparts. Of the twelve-predictor variables used in Cox Regression analysis, only two were significant predictors of relapse among nurses with impaired practice in TPAPN. These two predictors were (a) having substance use disorder as the referral type and (b) having alcohol as the primary drug of choice

Conclusion: A significant number of nurses still suffer from substance use disorders. From the results of this study, it is evident that the prevalence of substance abuse among nurses is higher than what is traditionally reported. Also, only a small percentage of nurses report themselves to the peer assistance programs. This who report themselves see to have better outcomes and thus, self-report should be encouraged.

C 04 - Challenges in Substance Abuse

A Redemption Story: A Case Study of a Faith-Based Addiction Recovery Process

Chitra Paul Victor, PhD, RN, RM, CNE, USA

Abstract

Purpose: The purpose of this study is to acquire an in-depth descriptive explanation regarding the role of the faith-based recovery program and the influence of this program on the healing of body, mind, and spirit and the restoration of hope for women recovering from substance addiction.

Methods: The researcher used a single embedded interpretive case study design based on the social process theory: Understanding God as Sponsor. Data was collected through observations, in-depth interviews, and the analysis of artifacts. The researcher used purposive sampling to recruit female drug addicts recovered in a faith-based recovery program and their care providers. The researcher used interpretivist approach to explore the perception and the real-world experiences of the faith-based recovery process. The interpretivist approach of case study draws a conclusion of individuals, units, or cases within specific contexts and involves description and exploration (Yin, 2013). The interpretivist approach allowed the researcher to explore *how* faith is understood and implemented in the reality of day-to-day recovery from addiction and *why* questions about whether faith-based recovery process are occurring or not. The interpretivist paradigm in nursing research helped the nurse researcher to explore the process, meaning, and qualities of a faith-based recovery process from substance addiction that is not subject to measurement or experiment.

Results: Within the boundaries of the single case of the selected faith-based program, fifteen female participants who underwent the faith-based recovery process and five of their caregivers were interviewed. Rich description of the interview data and the program interventions revealed the case. The data analysis using inductive strategy and coding process revealed five major themes, twelve subthemes, and eight outliers. The major themes include (1) I was Battling with Addiction (2) In You, I Found a Love Unconditional and Divine (3) I know I have a Future (4) New Hope, New Dreams, and New Life (5) I'm a New Person: God created Me to be. The themes revealed participants were subjected to drug addiction because of abuse, low self-esteem, rejection, depression, and hopelessness. Therefore, addiction was perceived as a symptom, and alienation from God was considered to be the root of the problem. However, the findings revealed that the faith-based interventions restored addicts' relationship with God, which promoted self-esteem. The themes also revealed developing a relationship with God is one's free will and cannot be forced by discipline or rules. The faith-based program interventions help the recovering addict to complete one step at a time to reach a complete recovery and the healing of body, mind, and spirit. These five steps include (1) Hopelessness, (2) Surrender, (3) Future, (4) Hope, and (5) Healing. Recovery from addiction and the healing of body, mind, and spirit began when the women realized God's unconditional love and believed God wants to help them to be free from the addiction. When the participants experienced holistic healing through the faith-based recovery process, they developed hope for the future.

Conclusion: Substance Use Disorders (SUD) and addiction lead to significant socio-economic costs due to crime, increased health care, and loss of productivity (Giardano, 2014). The epidemic of SUD is costly and costs the nation hundreds of billions of dollars each year. In the United States, \$700 billion is spent on health care and productivity losses related to SUD each year. Many individuals with Substance Use Disorders (SUD) are living without hope because of their repetitive and uncontrolled behavior to use drugs (NIDA, 2014). These individuals need hope for recovery and social acceptance (Timmons, 2012). Holistic healing, the healing of body, mind, and spirit can promote this hope and quality of life. Instilling hope through spiritual faith reconnects the addicts to their recovery and healing. Faith is the powerful factor for promoting hope and is a key concept in holistic nursing (Benefiel, Fry, Geigle, 2014; Miller, & Ewest, 2013).

From the data analysis of this single embedded interpretive case study, five main themes emerged reflecting the success of the program and the process of the faith-based recovery. The influence of the

faith-based recovery program on the recovery process was explained by identifying various faith-based interventions. Nursing is a caring profession founded in spirituality and in a religious background that involves a holistic perspective of caring for the mind, body, and spirit of the patient (O'Brien, 2013). In a rapidly changing health care environment, it is imperative to implement cost-effective and holistic interventions to help addicts recover and abstain from Substance Use Disorders.

Relieving Pain and Anxiety via Sensory Modification

Christi M. Turnage, ADN, RN, USA

Abstract

Purpose: The purpose of this review was to evaluate literature related to the efficacy of sensory modification in relieving pain and anxiety and promoting comfort during medical procedures and hospital stays as an alternative to pharmacological management.

Methods: A single researcher conducted individual searches using OVID, CINAHL/EBSCO, and PubMed. Several keyword combinations were used, but those yielding usable results were procedure, noise, ICU, light, surgery, pain, and anxiety reduction. Inclusion criteria included English language, human subjects, free full text, clinical trial, and date range including only those articles published within the last five years. After application of criteria, 15 topic relevant studies were located. All studies reviewed were randomized controlled trials (RCTs). All but eight studies were rejected as they involved sample populations that were either children or undergoing dental procedures. These eight RCTs were retained for this review.

Results: Of the seven RCTs examined, six reported significant reduction in pain and anxiety with sensory modifications of mixed modality. These included earplugs, eye masks, music intervention, and therapeutic touch. Two RCTs examined the addition of earplugs and eye masks to care routines in intensive care and postoperative units during nights following surgery in order to reduce anxiety and physiological stress for patients during their stay. The study by Hu et al was a prospective single-center randomized controlled parallel-group clinical trial. Using the closed envelope method, 45 patients were randomly assigned to either an intervention group or control group. Earplugs and eye masks were provided to the experimental group for three days prior to surgery. Control group received usual care. Subjective sleep perception was evaluated by self report. Nocturnal melatonin and cortisol levels were measured one day prior to surgery and for two days following surgery. Nocturnal noise and light levels were measured in the ICU beginning when patients arrived on the unit following surgery. Mean \pm standard deviation were used to express measurement data and ratios were used to express count data. An independent samples t test was used for comparison of the intervention and control groups. The chi square was used to compare count data. One way ANOVA was used to express differences in cortisol and 6 SMT over time. Cronbach's alpha of 0.05 was significant. This study indicated that eye masks and earplugs are effective in reducing disturbance in sleep that can lead to anxiety. In the study by Le Guen et al, 41 patients were randomized into an intervention group receiving earplugs and eye masks on the first night after surgery or a control group receiving routine care. Sleep quality was evaluated by self report, actigraph placed on nondominant wrist, and external assessment by a nurse. For this study, all data are expressed in terms of mean, median, or percentage. MANOVA with $P < 0.05$ considered significant was used to compare each night's data while in unit. This study suggests that eye masks and earplugs preserve sleep quality and may reduce anxiety.

Another three studies looked at the effect of music therapy via headphones and either CD or MP3 players on perceived anxiety of patients undergoing medical treatment. The study by Eckhouse et al was a pretest/posttest study in which 112 patients were randomized into three groups. One group received usual care before during and after treatment. The remaining groups received either music focused relaxation via headphones and compact disc (CD) during treatment or viewed a 20 minute music video during treatment. One way ANOVA and paired t tests were used to compare patient characteristics and pre and posttest scores. $P = 0.05$ was considered significant. There were no statistical differences between scores of each group to suggest that audio or visual intervention was more effective in reducing anxiety. In the study by Chlan et al, 373 ICU patients were randomized into a control group receiving usual care, a group receiving noise abating headphones, or a group receiving self directed music therapy. Anxiety was measured using daily anxiety assessment and measures of sedative intensity and frequency. Repeated measures ANCOVA was used to measure anxiety and sedative exposure. Significance level was set at $p < 0.05$. Results showed that anxiety and sedative exposure was most reduced by self directed music

therapy. In the study by Palmer et al, 207 patients undergoing breast surgery were randomly assigned to receive patient directed live music preoperatively with therapist directed recorded music intraoperatively, recorded music selected by patient preoperatively and selected by therapist intraoperatively, or usual care preoperatively with noise blocking earmuffs intraoperatively. Anxiety was measured by self report and propofol required during surgery. With a significance level of $p < .001$, one way ANOVA showed a greater reduction in anxiety scores, but not in the amount of propofol required for anesthesia.

The remaining studies explored the impact of preoperative physical conditioning prior to surgery or therapeutic massage prior to surgery on pain and anxiety of patients undergoing surgery. The study by Rosenfeldt et al randomized 117 cardiovascular surgery patients in two groups. The first group received usual care while the second received what was termed holistic care involving physical conditioning for two weeks prior to surgery and mental stress reduction. Outcomes were measured via self report using the Short Form 36 item Health Survey Questionnaire and medical records to assess length of stay. Chi square and Fischer's exact tests were used for continuous variables and parametric data were analyzed with the student's t-test. Two way repeated ANOVA was used to compare variables with repeated measures. Results were not statistically conclusive, but further research was warranted. The study by Braun et al examined the effect of massage therapy on anxiety and pain levels in cardiac surgery patients. A total of 152 patients were randomized into two groups that received wither massage or rest after surgery. Visual analog scales (VAS) were employed to assess levels of pain and anxiety both before and after each intervention. Fischer's exact test was used to examine proportional differences between groups. Repeated measures ANOVA was used to assess changes in VAS scores. Massage significantly relieved pain and anxiety when performed on day 3 or 4 postoperatively ($P < .0001$). The study by Peng et al also looked at the effect of massage on anxiety in patients receiving percutaneous coronary intervention. A total of 117 participants were randomized into two groups receiving either massage of head, neck, shoulders, and back for 20 minutes before surgery or usual care. Blood pressure, heart rate, and anxiety levels were assessed and compared. Anxiety levels were measured via the State Trait Anxiety Inventory (STAI). The groups were compared using the t-test for independent samples. Comparisons within groups were obtained using a paired t-test. Comparisons of indicators of pain and anxiety were compared between groups using repeated measures ANOVA. Results showed significant reduction in anxiety levels in those patients receiving massage therapy. Self reported anxiety, heart rate, and blood pressure were notably lower in the experimental group. Significance level was $p < 0.05$.

Conclusion: According to studies, compared with groups of patients receiving no environmental sensory modifications, patients undergoing medical procedure in sensory controlled environments experienced more positive outcomes. These outcomes include reduction in anxiety, decreased perception of pain, and improved sleep quality. Addition of complementary therapies to usual care for those patients who are hospitalized or undergoing treatment offer an easy, inexpensive way to reduce anxiety and pain without the side effects of pharmacological management.

Anxiety-Reducing Efficacy of Inhaled Essential Oils: A Case Study and Literature Review

Dawn L. Langley-Brady, MSN, RN, AHN-BC, CHPN, CCAP, USA

Abstract

Purpose: Anxiety disorders impact approximately 40 million adults, are the most prevalent mental health-related diagnosis, and cost the United States healthcare system over 42 billion dollars annually. Additionally, anxiety can mimic many other health problems (e.g., shortness of breath, chest pain, nausea and vomiting), thus adding to the burden on patients and healthcare systems. Current anxiety treatment consists of pharmacotherapy, cognitive behavioral therapy, and some complementary therapies, but not aromatherapy. Pharmacological approaches to reduce anxiety primarily include the administration of benzodiazepines, but may also include SSRIs, and beta-blockers. These pharmacological approaches come with a myriad of potential side effects including dry mouth, confusion, constipation, fatigue, headaches, nausea, weight gain, and sexual dysfunction. Aromatherapy is understood as aroma from essential oils eliciting psychological or physiological responses via the limbic system in the brain. The following essential oils were reviewed: *Angelica archangelica* (Angelica Root), *Citrus x aurantium* (Bergamot), *Elettaria cardamomum* (Cardamom), *Lavandula angustifolia* (Lavender), *Citrus aurantium* (Petitgrain), and *Origanum marjorana* (Sweet Marjoram). The purpose of this project was to present a clinical aromatherapy case study and review the literature as a foundation for future research investigating the effectiveness of clinical aromatherapy in reducing adult anxiety instead of or in addition to standard treatment.

Methods: The adult anxiety case study was conducted over a three week period, following guidelines of the National Association for Holistic Aromatherapy, by a registered nurse and certified clinical aromatherapy practitioner. CINAHL, Medline (via Ovid and PubMed), ProQuest, and TRIP databases were searched for peer-reviewed journal articles in English with the following keywords: angelica, bergamot, cardamom, generalized anxiety disorder, lavender, marjoram, and petitgrain. **Results** were further filtered by inhalation, and human studies. No publication date limitations were used.

Results: The case study demonstrated efficacy of the aromatherapy blend in reducing generalized anxiety with nausea and vomiting after both the initial, and each subsequent use. The literature review found significant evidence-based knowledge of the use of lavender essential oil for reduction in generalized anxiety via oral administration and inhalation. One animal study was found that demonstrated bergamot essential oil efficacy compared to diazepam in a rat model. No information was found regarding the use of angelica, cardamom, marjoram, or petitgrain for anxiety, despite their use in clinical aromatherapy. No studies were found assessing the effect of these essential oils' chemical constituents for anxiety either.

Conclusion: The anxiety-reducing efficacy of essential oils in humans has yet to be explored beyond clinical aromatherapy case studies with the exception of lavender which recently completed clinical trials and is now available as an over-the-counter product. Aromatherapy has the potential to reduce generalized anxiety without the adverse effects of prescription medications. Other essential oils may also reduce generalized anxiety, but warrant further research.

C 07 - Factors in Suicide

Suicide Risk Assessments: A Mixed-Methods Study of Nurses' and Patients' Experiences With Evidence-Based Practice

Elaine E. Santa Mina, PhD, RN, Canada

Elizabeth McCay, PhD, RN, Canada

Donald N. Rose, PhD, MN, BScN, RN, Canada

Beth Hamer, MSc, RN, Canada

Abstract

Background: Suicide remains a serious safety concern. In 2012, suicide was the 15th leading cause of death as the global rates remain persistently high despite the focus on prevention (http://www.who.int/mental_health/prevention/suicide/suicideprevent/en/retrieveddec 2 2016). Suicide risk assessments are fundamental to prevent suicidal behaviours and death by suicide (Boudreaux et al, 2016). Nurses, as front-line clinicians, are pivotal in the accurate diagnosis and the delivery of care to prevent suicide through the identification and documentation of risk, in the clinical record, as per evidence-based best practice (Canadian Federation of Psychiatric and Mental Health Nurses, 2014). A Centre for Mental Health Care developed and implemented a policy for suicide risk assessment and documentation, in response to jurisdictional accreditation requirements and to meet the needs of their patient population. The policy was informed by evidence-based practice guidelines. Nursing leaders implemented the policy within the institution over the subsequent 1.5 years. This study provides a unique opportunity to explore nurse and patient perspectives of suicide risk nursing assessments. Patient narratives may sensitize nurses to important aspects of the nurse-patient relationship during this critical interaction and may enhance nursing assessment skills. The research questions were: 1) What is the evidence that suicide risk assessments, as measured by proxy via nursing documentation, adhere to best practice recommendations? 2) What are nurses' perspectives of their knowledge of suicide risk assessment and practice? 3) What are the patients' experiences of the assessments of their suicide risk by nurses?

Purpose: This study investigated evidence of nurses' congruence with and patients' experience of suicide risk assessment post implementation of evidence-based practice education.

Methods : This study used a cross sectional, mixed-method, post-intervention (guideline implementation and education) design in which the qualitative and quantitative methods were conceptualized, designed, and implemented within the pragmatist paradigm. This mixed-method design with a complementarity purpose sought elaboration, enhancement, illustration, and clarification of the results from one method with the results from the other approach. Interpretation and meaning was enhanced by via the inherent strengths of each method (quantitative: patient record / documentation audit and qualitative: focus group with RNs and RPNs plus individual interviews with patients), while counteracting the respective inherent methodological biases. Quantitative and qualitative methods were used to measure overlapping but also different facets of the phenomenon, yielding an enriched, elaborate understanding. The expansion purpose was used to measure different and distinct phenomena (i.e. nurses' and patients' perceptions of the nursing assessments of patient suicide risk versus documentation of assessment and response to suicidal ideation). This extended the breadth and range of inquiry through different methods for different inquiry components. The triangulation purpose was based on the logic of convergence. This logic required that the quantitative and qualitative methods be different from one another with respect to their inherent strengths and limitations (biases) and that both method types be used to assess the same phenomenon. Data was collected from one acute care and one long term care unit plus the outpatient department. Quantitative Methods: The researchers collected key nurse and patient demographic data to describe the sample. The Principal Investigator and the Co-Principal Investigators conducted patient record audits of nurses' notes to measure nurses' suicide risk assessment documentation. The researchers used the audit data from the patient record nurses' notes instrument, created by the investigators for this study, to measure congruence with the guideline recommendations, via compliance indicators as measured on a 3-point likert scale. The quantitative data was analyzed with SPSS version 20. Qualitative Methods: The Investigators conducted three (3) – 30 minute nurse focus groups (5-7

persons per group) in order to provide adequate time for all participants to contribute and discuss their perceptions of their assessment and documentation of patients' suicidal ideation and/or behavior. The investigators conducted nine (9) individual out-patient interviews to assess patients' perceptions of nurses' assessment of their suicidal feelings and behaviours. Each individual interview required approximately one-half (1/2) hour of each patient's time. The qualitative data was analyzed using methods consistent with constructivism. Ethics approval was granted from the University and the Health Care Centre.

Results : Thirty-four patient records (long term care n = 15, acute care = 19) were audited for evidence of congruence and/or divergence of suicide risk assessment according to guideline recommendations. Fourteen nurses (female n = 10, male = 4) participated in three focus groups. Nine patients (female n = 6, male n = 3) participated in individual interviews. Data triangulation revealed practice congruence with and divergence from recommendations specific to suicide risk assessment constructs. Descriptive analyses demonstrated that all patient records had at least some dimension of suicide risk assessment documented by nurses. However, nurses more frequently documented patients' future plans to attempt suicide (100 %) than the suicide plan that prompted admission to hospital (46%), or previous history of suicide attempts (57%). Documentation of suicidal ideation, suicidal behaviour, and suicide attempt method were also less frequent (66%, 78%, 44%, respectively). Documentation of other risk factors for suicide attempts and protective factors against suicide was also less frequently documented (85% and 76% respectively). Thematic analysis of narratives complemented the quantitative results and supported the quantitative evidence that suicide risk was assessed by nurses. However, both patients and nurses described 'the dance-who will invite whom?' between them that may facilitate or hinder assessment. This theme may indicate that nurses and patients may be reluctant to approach the other to engage in a conversation about suicidality and timing of that approach was described as similar to the timing involved in an invitation to 'dance'.

Conclusion: Study findings demonstrate the richness of triangulation of nurse-patient data to evaluate implementation outcomes and understanding of the phenomenon: suicide risk assessment. Although there is substantive evidence from suicide risk assessment documentation as well as nurse and patient experience of such assessments, some crucial dimensions of assessment may not be as fully assessed and documented as appropriate to patient needs. If both patients and nurses experience a tentative approach to each other to discuss this risk dimensions, then critical intervention opportunities to provide safe care may be missed. Issues around this 'dance' may be grounded in the foundations of the nurse-patient therapeutic relationship. Therefore, the study highlights the limitations of a linear approach to application of recommendations from one guideline without integration with, reference to, and education of other related guidelines. It also highlights the limits of a purely positivist approach to understanding and applying evidence in practice; and that a more holistic, intuitive approach may be appropriate to complex nursing care (Welsh & Lyons, 2001). This presentation highlights the importance of including the patients' voices in addition to the nurses' perspectives to expand upon the traditional, objective metrics in evaluation of evidence-based practices to inform clinicians, educators, and researchers.

Implications: Findings provide direction for guideline education for nurses. Related guidelines, such as a guideline for the nurse-patient therapeutic relationship, need to be considered and included in nursing education of suicide risk assessment. Suicide risk assessment guidelines are not linear per se and need to be taught simultaneously, within the context of holistic patient care. Nursing education and practice need to focus on areas of risk that are less likely to be assessed and documented. Nursing research on evaluation of evidence-based practice needs to include the nurse and patient narratives to more fully understand dimensions of practice. Larger multi-site studies would be beneficial to explore potential, broader similarities and differences across practice settings and demonstrate a global reach to improve risk assessment and suicide prevention.

C 07 - Factors in Suicide

The Association Between School-Related Victimization, Depressive Symptoms, and Suicidality Among U.S. High School Students

Nancy Pontes, PhD, RN, FNP-BC, USA

Cynthia Ayres, PhD, RN, FNAP, USA

Manuel C. F. Pontes, PhD, USA

Abstract

Purpose: Research has shown that victimization during adolescence is associated with numerous adverse health outcomes (Bauman, Toomey & Walker, 2013; Bowes, Johnson, Wolke & Lewis, 2016; Cole et al., 2014; Messias, Kindrick & Castro, 2014; and Sibold, Edwards, Close & Hudziak, 2015). The primary purpose of this research is to use data from the Youth Risk Behavior Survey (YRBS) to examine the relationships between two types of school-related victimization, 1) bullying and 2) threats or injuries with a weapon, and depressive symptoms and suicidality, including suicidal ideation and suicide attempts among US high school students.

Methods: This research is a secondary analysis of YRBS data, which are collected biennially from a nationally representative 3-stage cluster sample design of US high school students. The binary (Yes/No) dependent variables for this study are depressive symptoms, suicidal ideation, and suicide attempts. The independent variables of primary interest are school-related bullying and threats or injuries with a weapon. Covariates are gender, race/ethnicity, survey year, and grade level. Four waves of YRBS data (2009, 2011, 2013, and 2015) were pooled for analyses. Data were analyzed using multivariate logistic regression with SPSS 24 Complex Samples™, which correctly incorporates the multi-stage sampling design and sampling weights and enables nationally-representative estimates with associated standard errors and confidence intervals. Analyses were performed for three samples, 1) all students, 2) male students, and 3) females students.

Results: Among all students, there were significant relationships between school bullying victimization and depressive symptoms (OR=2.79, 95% CI=2.63-2.97), suicidal ideation (3.03, 95% CI=2.85-3.23), and suicide attempts (OR=2.86, 95% CI=2.57-3.18). Results also showed that there were significant relationships between school-related threats or injuries with a weapon and depressive symptoms (OR=2.57, 95% CI=2.34-2.83), suicidal ideation (2.80, 95% CI=2.51-3.12), and suicide attempts (OR=4.76, 95% CI=4.14-5.48). The association between weapon related victimization and suicide attempts was more positive (OR=4.76) than the association between bullying victimization and suicide attempts (OR=2.80). Separate analyses by gender showed that the relationship between weapon-related victimization and suicidal ideation was significantly greater among male students (OR=3.10, 95% CI=2.71-3.55) than among female students (OR=2.46, 95% CI=2.11-2.87). Results also showed that the relationship between weapon-related victimization and suicide attempts was significantly greater among male students (OR=6.45, 95% CI=5.29-7.85) than among female students (OR=3.56, 95% CI=3.01-4.21). There were also significant effects of race/ethnicity and depressive symptoms and suicidality. Notably Hispanic students were significantly more likely than non-Hispanic White students to report depressive symptoms, suicidal ideation, and suicide attempts. All minority student groups were significantly more likely to attempt suicide than non-Hispanic White students.

Conclusion: School-related bullying victimization and threats or injuries with a weapon have very large effects on depressive symptoms and suicidality among US high school students. Future efforts are imperative using evidence-based interventions to prevent all forms of bullying and weapon-related victimization and reduce the health-harming effects of school-related victimization.

C 08 - Global Midwifery Practices

Psychosocial Knowledge for Future Nursing and Midwifery Practice in Community Placement in Vietnam and Australia

Yvonne Karen Parry, PhD, MHSM, GradCertEdu, BA, RN, Australia
Pauline Hill, ME (St), BN (Ed), DipApp (Sc), RN, RN, Australia

Abstract

Purpose statement: The two research projects illustrate the students learning gained from community placements in two different settings and the applications of the psychosocial knowledge gained to future nursing and midwifery practice.

Abstract Description: The oral presentation will report on two completed research projects which compare the levels of staff and student learning across two community based placements, one in the Vietnam highlands and one in a homelessness service in South Australia. Both community based placements provided health care to vulnerable and disadvantaged population groups. Community placements with vulnerable population groups provide nursing and midwifery students with the confidence needed to care for people with complex health and social issues in acute care settings. These placements enhanced the student's clinical skills and linkages to psychosocial theories of human development. The Australian research project mixed methods research design allowed for in-depth interviews and correlational analysis to explore the levels of knowledge gained and application to future practice. The findings outline the impact of these community based placements on the student's future clinical practice. The Vietnam community placement used in-depth, pre and post interviews, with the staff and students providing health clinic services in the rural Vietnam highlands. Both research projects found that the use of community based placements provides important experiences and learning outcomes for students that enhance their future nursing and midwifery practice.

Abstract summary: This research and community placement provide nursing and midwifery students with a broader understanding and practical application of psychosocial theories and the social determinants of health through innovative placement experiences. The Australian and Vietnam community placements are compared to determine the benefits or otherwise, of local or international experiences.

The Australian homelessness and student nurse community placement research.

In Australia at least one in 30 children under the age of 5 years are homeless. Further 26% of attendees at homelessness services are children under 10 years accompanied by an adult, with 44% of these children under 5 years. Homelessness is a time of great risk for children. Homeless children and their families have poorer health and educational outcomes. The purpose of this community based participatory research project aimed to provide services to match the identified gaps in service delivery for homeless children and their families. The placement of second year nursing students in a community based setting with vulnerable families had two main aims. Firstly, previous research by Parry and Grant (2015) found a lack of access to health services amongst homeless families leading to poor health in their children. Secondly, the homelessness service staff had limited knowledge and skills about child development, assessment, psychological and mental health issues. Consequently, they were unable to identify homeless families' health needs and potential issues requiring intervention. The addition of nursing students on placement in the service was recognised as adding value while also contributing significantly to the students learning. The research project of Parry and Hill (2106) demonstrated that the use of community placements provide expanded knowledge on the application of psychosocial theories and advanced skills in working with vulnerable populations groups.

Method: This mixed methods community based participatory research project used qualitative interviews and surveys with the managers, staff and nursing students regarding the inclusion of nursing students in home visiting service to families in emergency and short term housing. The interviews were thematically analysed and the quantitative data provided before and after views of the students and staff regarding the

student's knowledge of factors leading to homelessness and the impact of the nursing students on the care, health information and referral services provided.

Results: Previous research found themes from the staff and parent's interviews identified the need for greater links with health services. A lack of engagement with health services often resulted in no immunization and children missing developmental milestones. This result for children often occurred due to the homelessness service staff's lack of health knowledge and the parents coping with the homelessness crisis were unable to connect their child with the appropriate health service. There is a need for expanded community health nursing, and collaborative health/homelessness practice to provide support for homelessness children and their families, in order to decrease children's exposure to poorer health outcomes. Community health nursing is ideally placed to address this dire need.

This research investigated student nurses and homelessness staff regarding their knowledge, skills and perceptions of the value of community based placements. This oral presentation reports on these findings and compares the results indicating student's recognition of the skills to be learned in a non-acute setting "are relevant and useful in traditional nursing roles". The staff in the homelessness service espouse the enhancement provided by the expertise of the nursing students working with vulnerable populations. This research highlights the benefits as perceived by students on often undervalued community based placements. The Australian research findings are compared to the knowledge and skills learned for an international community placement in Vietnam.

Conclusions: Teaching students of nursing about the broader population through community based placements with disadvantaged groups increases the student's confidence in dealing with the variety of people they will encounter in the acute care setting. The psychosocial assessment of a patient is an extremely important part of nursing care but often under prioritised in preference to immediate physical care requirements.

The Vietnam highlands student nurse/midwife community placement research.

As above community placements are important to student learning and future professional practice. This research project explored the students' experiences of this 3 week community health placement. The research provided an insight into how this placement will inform their future practice as health professionals. The results have assisted administrators and academics on the needs of students on overseas placements, cultural safety, interprofessional learning.

The research promoted students and staff understanding of the relationship between different social phenomena and the process of OS community health placement. Additionally, the OS community placement provided an understanding the needs of interdisciplinary health students, their education and the nature of work integrated education.

Methods: A thematic analysis of student interviews and journal entries revealed the environment, communication, culture, resources, education, group dynamics, politics and personal development were important key experiences. This paper provides insight into student learning outcomes from an overseas community health placement and extends our knowledge about WIL with an international partner.

A qualitative study design was used to describe the student experiences and reflections relating to an inter-professional community health placement in Vietnam. Ethics approval was received from the Flinders University Social and Behavioural Research Ethics Committee.

A semi-structured face to face interview with 14 students was facilitated prior to the placement to enable the researchers to ascertain the expectations of the students and their previous travel experience. After the placement seven participants were interviewed face to face or by phone and asked to compare and contrast their reflections having completed their trip. An additional source of in-depth data was obtained from reflective journals kept by seven of the participants. The journals afforded an insight into their experiences providing a significant component of the research data. The interview transcripts and reflective journals were read and analysed for emergent themes, words or ideas which described the community placement experience.

Results: This study is important as it provides insight into the student perspectives about their learning experiences when undertaking an international, inter-professional work integrated placement. A review of the literature has identified that, while there has been research on work integrated learning, inter-professional education and study abroad programs, there appears to be limited research on bringing these concepts together. By investigating the synergistic effect of combining these three concepts in one experience, universities will be better positioned to provide more high quality international learning opportunities to supplement local placements.

Overall conclusion: The application of developmental psychosocial theories to clinical practice, and assessment techniques, can be difficult to achieve in traditional acute care placements. In the current BN/BM curriculum community based experiences are provided in each year level to develop student's understandings about the psychosocial aspects of people in their care. While there are differences between the two community placements overall there is an intrinsic value in community based placement in enhancing students learning of, psychosocial theories, and the social determinants of health, and these impacts on health care for vulnerable population groups. Additionally, these research projects support previous findings that the nursing and midwifery students gain confidence in dealing with vulnerable population groups for their future practice.

C 08 - Global Midwifery Practices

Evidence-Based Research and Delayed Cord Clamping: Implications for Cross-Cultural Education, Research, and Policy

Mary Ann Faucher, PhD, MPH, MS, BS, RN, CNM, FACNM, USA

Abstract

Purpose: Conduct an educational capacity building research initiative for nurse midwives in India to improve iron status of newborns by delaying the clamping of the umbilical cord at birth. In India, iron deficiency affects nearly 80% of reproductive aged women and their offspring (Viveki 2012). Compared to immediate cord clamping, delayed cord clamping is a physiologic practice that also results in significantly enhanced serum levels of iron in newborns up to 6 months after birth (McDonald et al., 2013).

Methods: A two-part research design was implemented. Part 1 was quantitative utilizing a single group pre and post-test research design incorporating lecture and simulation. In Part 2, ten months after completion of Part 1, focus groups were conducted with the same group of nurse midwives about the benefits and barriers to implementation of delayed cord clamping.

Results: Significant improvement in knowledge, beliefs and the practice of delayed cord clamping were found comparing pre-test to post-test results both immediately after the intervention and at a 10-month follow-up visit. Simulation revealed important nuances of midwifery practice pertinent to the uptake of delayed cord clamping. Results from the focus groups illuminate perceived factors that affect midwife decision-making, areas of concern related to practice and perceived benefits of delayed cord clamping expressed by the nurse midwives.

Conclusions: One consequence of the medicalization of childbirth is immediate clamping of the umbilical cord at birth resulting in the newborn not receiving a significant amount of blood from the placenta that provides a substantial source of iron (McDonald et al., 2013). The upscaling of midwifery practice and education has been recommended as a strategy to improve maternal and infant outcomes around the world including in India, to address both the qualifications of midwives and the escalating rates of cesarean birth (Renfrew et al., 2014). Findings from this study have implications for cross cultural education with nurse midwives, research design, policy, , and keys to sustainability of evidence base-practice in this setting.

C 09 - Health Promotion for Clinicians

A Learning Collaboration to Deliver Onsite Health Promotion for Hospital Staff

Mary Val Palumbo, DNP, MSN, BS, APRN, GNP-BC, USA

Abstract

Background: Using metrics including unscheduled absenteeism, workman's compensation claims, patient handling injuries, staff participation in biometric screening and participant satisfaction, an employee wellness program was evaluated in 2011. Based on the success of this program, the nurse practitioner students and an employee wellness team have continued to adjust this evidence based program over the past five years by tracking participation and introducing new social media methods of reach to the target population with health promotion messaging.

Methods: One unit at an academic health center was selected by the Employee Wellness team for delivery of the "Stepping Stones to Wellness program" over a six-month period. The unit management and staff was given a selection of weekly wellness topics to choose from and the Employee Wellness Team added other important topics. The nurse practitioner students were responsible for presenting the weekly health topics on a bulletin board, Facebook postings, Twitter messages and personal interactions. Biometric screening was made available on the unit and management worked to free up staff to attend these sessions. Health coaching was provided by the nurse practitioner students and S.M.A.R.T. (specific, measureable, attainable, realistic and timely) goal setting was encouraged. Nurse practitioner students received training in Motivational Interviewing and were instructed to use this during the health coaching session.

Results: In the fifth year of offering the unit based Stepping Stones to Wellness program, the goal for biometric screening of 60 employees was exceeded (n=68). Participant satisfaction with the program was high: 100% surveyed report they feel this offering made a positive difference and 100% surveyed hope to have this program replicated and offered again. Open ended questions indicated an appreciation for the NP students' help in the area of goal setting and visits to the night shift. The Facebook posting reached 475 (eating disorders) to 3428 (substance abuse) people depending on the topic; blogs views ranged from 35 for seasonal affective disorder to 589 for anxiety. The educational bulletin board was evaluated by a range of participants -10 for seasonal affective disorder to 22 for anxiety. All evaluation data from this evidence based program will be presented.

Discussion: Wellness offering must show a return on investment in order to be sustained. This unit-based wellness program was a 6-month comprehensive and integrated program with a primary focus on self-care and health education. The program initially paid for itself and may have contributed to a return on investment of \$3,745.17 by not paying unscheduled time off in comparison period. This unit-based wellness program using incentives, has continued to yield high participation and satisfaction over the past five years. This project found that bringing health promotion activities directly onto a hospital unit has been cost effective and satisfactory to the participants, as well as, nurse practitioner students.

Further research: This quality assurance project lacks the rigor and controls necessary for a research study and since it was conducted in one academic medical center, replication is recommended. Further research utilizing larger samples, testing unit-based nurse health promotion activities, is indicated.

C 09 - Health Promotion for Clinicians

Nurses With Activity Limitations: Implications for an Aging Nurse Workforce

Barbara Wilson, PhD, RNC-OB, USA

Abstract

Purpose: Though previous studies have examined the causes of work-related illness and injuries among nurses, little is known about labor market disparities between nurses with and without long-term activity difficulties, e.g., some sort of physical or psychological impairment. Because nursing is a profession where physical or psychological difficulties increase sharply over the course of one's career as s/he ages (Matt, Fleming, & Maheady, 2015; Wray, Asplin, Gibson, Stimpson, & Watson, 2009), the issue of potential labor market disparities for nurses with activity limitations is an important one.

Dissimilar outcomes for nurses with activity limitations does not necessarily indicate any market *discrimination* against such nurses, where 'discrimination' means *disparate treatment where productivity is equivalent*. A nurse with an activity limitation may simply choose to work fewer hours so his/her total annual wage and salary may be less. But whether nurses with activity limitations are truly discriminated against is not clear. Hence, the purpose of this study was to understand the extent to which annual total wage and salary disparities were due to discriminatory treatment, and the extent to which wage and salary disparities were due to voluntary choice, by decomposing annual wages into work participation, hours, and hourly wage components.

Methods: The American Community Survey (ACS, 2014) is an ongoing, extensive governmental survey of the population which includes basic demographic information, wages, hours of work, and employment status, with consistently defined variables key to our analysis. A representative sample of about 30,000 registered nurses (RNs) is contained in each year's sample of the ACS. Moreover, these data also contain "difficulties with daily activities" measures, which we employ as our variable of principal interest, used to measure the impact of dressing difficulties, uncorrectable vision or hearing problems, difficulties with physical activities, difficulties with memory, and difficulties with independent living. Our sample, from 2006 to 2014, is limited to those whose occupation is self-identified as a registered nurse (RN) in their current or most recent job, and whose ages are between 25 and 70 years old.

To sort out the effect 'difficulties with daily activities' measures of annual wages, wage rate, and employment probability, we take advantage of the following relationships: since $\log(\text{annual wages}) = \log(\text{hourly wage rate} * \text{number of annual hours}) = \log(\text{hourly wage rate}) + \log(\text{annual hours})$, if we know the regression of $\log(\text{annual wages})$ and $\log(\text{hourly wage rate})$ on our independent variables, then we automatically know the coefficients of the regression of $\log(\text{annual hours})$ on the independent variables (since regressions are linear mathematical operators). For example, if the coefficient of males in the $\log(\text{annual wages})$ regression is .2 (males make 20 percent more than females with similar sociodemographic status), and the coefficient of males in the $\log(\text{hourly wage rate})$ were .05 (the male nurse wage rate is percent higher than the female nurse wage rate), then the male coefficient in the hours regression is .15 (.05 + .15 = .2). Hence, using multiple regressions we examined evidence on annual wages, hourly wages (so we can infer the regression on annual hours), and the likelihood of employment.

Results: As seen in virtually all other studies of the North American labor markets, some groups made more than others: male nurses had higher wages (17 percent more than female nurses), blacks had lower wage rates (black nurses made 5% less than white nurses per hour, but they worked more hours so that total annual wages were not significantly different from white annual earnings), and Hispanic nurses made 7.5 percent less than non-Hispanic whites per hour.

Wage income increased with age (up to about age 55 in the 2013 sample), while employment was highest in the mid-forties. This is consistent with data from the US Census Bureau (2010) who reported that nurses aged 45-54 years replaced those aged 35 to 44 years as the largest age group of RNs in the U.S., reflected by the median RN age in 2000 of 42.4 and 45.4 in 2009 (Juraschek, Zhang, Ranganathan, & Lin, 2012). The effect of educational attainment, given that one is a RN, and of a certain age, shows no particular trend.

As suggested by the regression results, there was relatively little disparity in the hourly wages between the abled and disabled nurses. But there was enormous disparity in the disabled's employment and hours of work opportunities, and hence a moderate amount of disparity in annual wages. For example, a nurse who reported some sort of physical or mental impairment or disability in 2009 made, on average, 33.6 percent less and had nearly 64 percentage lower likelihood of being employed relative to nurses without physical impairments or activity limitations.

Conclusion: Nearly 40% of the RNs currently working in the U.S. are over the age of 50 (Auerbach, Buerhaus, & Staiger, 2015). Baby boomer RNs are continuing to work into their late 50s and 60s, and there are currently more workers in the US over age 55 years of age than ever before (Phillips & Miltner, 2015). This significantly increases the probability that nurses with activity limitations will be a substantial portion of the nursing workforce moving forward. In addition, employment among healthcare practitioner occupations is expected to increase by 21.4% and will result in almost 1.6 million new jobs, driven by an increasing demand for healthcare services. Registered Nurses will account for more than one-third of the growth in this occupational group (Bureau of Labor Statistics, 2010).

Labor market discrimination is an important problem for persons with activity limitations across many occupations. Labor market discrimination for disabled persons, coupled with gender inequality in the U. S. labor market, may pose additional challenges for nurses, who are predominantly female. Whatever the cause, jobs dominated by females pay less on average than jobs dominated by males, and women's occupations pay less than male dominated occupations in many countries (Olson, 2013).

Nurses with a broad range of activity limitations are currently employed in the hospital setting (Wood & Marshall, 2010), although persons with activity limitations have historically been under-represented in the nursing workforce. Approximately 154,000 of the 2.2 million nurses surveyed in 2000 indicated they were employed in positions other than nursing because of disability or illness (Matt, 2008). For those nurses that do work with a disability, significant barriers can exist in getting and keeping jobs (Guillett, Neal-Boyland, & Lathrop, 2007), including acceptance by co-workers, supportive environment, organizational policies related to accommodations, and an understanding of how these physical limitations affect the nurse and the nurses' job performance (Job Accommodation Network, 2011; Guillett et al., 2007; Matt, 2008 & 2011). Given the current data presented here, there is evidence that the issue of practicing nurses with physical or mental impairments or activity limitations will continue to grow in importance to the nursing workforce.

Global implications: As noted by Sherman, Chiang-Hanisko & Koszalinski (2013), the aging nursing workforce is a global challenge. On a recent RN4CAST project funded by the European commission, a nursing shortage of over 600,000 nurses was projected across Europe by 2020 (Sherman et al., 2013). Falling fertility rates and the aging population with increased life expectancies have created a declining ratio of young and working adults to the number of retirees. In fact, the Organization for Economic Co-operation and Development estimated that by 2015, the number of retirees would outnumber those entering the workforce (Warmuth, 2008). Indeed, the aging of the nursing workforce is anticipated to lead to projected nursing shortages in many countries (Buchan, Twigg, Dussault, Duffield, & Stone, 2015).

Because a substantial number of nurses who, as they continue to age, will experience increasing activity difficulties, it is imperative that employers provide job accommodations and resources for nurses developing activity limitations. As examples, employers can promote flexible schedules and alternative work assignments; create environments that foster acceptance and support of disabled nurses (e.g., use of flexible access computer stations with different types of chairs at the nurses' station); and conduct a careful review of job descriptions to ensure essential job functions are accurately reflected and describe the professional nursing role (Guillett et al., 2007; Matt, 2011; Matt et al., 2015). Employers must also ensure all possible resources are being used to provide work accommodations including consultation with the disabled nurse (JAN, 2011), and education of co-workers regarding how to interact with their peers with physical limitations (Matt, 2008). In so doing, the "caring" profession will best care for their own.

C 10 - Interprofessional Education in Nursing Programs

Webinars and Weaving: An Innovative Model of Interprofessional Education in an Online DNP Program

Linda A. Lewandowski, PhD, RN, FAAN, USA

Raeann Genevieve LeBlanc, DNP, AGPCNP-BC, CHPN, USA

Pamela Aselton, PhD, FNP-BC, USA

Gabrielle P. Abelard, DNP, MS, BS, RN, PMHNP, PMHCNS- BC, USA

Christine Callahan, MS, RN, USA

Clare Lamontagne, PhD, RN, USA

Abstract

Purpose: Educating future nurse practitioners in meeting the essentials of advanced nursing practice includes advanced competency in the core competencies of interprofessional collaborative practice--IPCP (The National Organization of Nurse Practitioner Faculties, 2012). Teaching in an all-online learning environment in which students are geographically scattered presents some challenges, especially in promoting some concepts such as collaboration. Distance learning technologies can be used to design opportunities that promote collaborative educational learning and advance quality, evidence-based practice. This presentation focuses on two strategies: live interprofessional case-based webinars with course-based facilitated discussions and curriculum “weaving” of IPCP content throughout the NP curriculum.

Methods: The Core Competencies for Interprofessional Collaborative Practice (Interprofessional Education Collaborative Expert Panel, 2012) served as the basis for the didactic content that was woven across the online Doctorate of Nursing Practice Nurse Practitioner curricula. Innovative, live streaming webinars were created and delivered case-based content from interprofessional collaborative practitioners as role models while inviting inter-professional exchanges from participating students. Professionals from different disciplines were identified by a community practice liaison in developing the webinar teams. Webinar topics central to primary care and practice improvement included topics on patient and family centered care, evidence- based practice quality improvement projects (e.g., identifying and managing sepsis), and collaborative biopsychosocial management of complex health problems (e.g. headaches, CHF, PTSD, nutrition in children and adolescents). Online evaluations of the webinars followed each presentation. The cases and interprofessional collaboration exemplars were then followed with a facilitated discussion in relevant clinical courses. In evaluating these curriculum enhancements, students rated their ability level on collaborative practice through completing the 42-item self-assessment, IPEC Competency Self-Assessment Tool – Version 1 (Dow, DiazGranados, Mazmanian & Retchins, 2012; 2014) in a pre-post, repeated measures design (on entry into the program and at designated evaluation points). This measurement tool is based on the competencies defined by the Interprofessional Education Collaborative expert panel (2012). Weaving interprofessional collaborative practice content throughout the program was assessed via a process of curriculum mapping.

Results: Live interprofessional webinars were identified as an effective approach to delivering and role modelling interprofessional collaboration. Active student participation can be promoted via the live question and answer/discussion session following the interprofessional panel and case discussion and course-based facilitated discussions. Specialists in diverse areas of primary care enriched the clinical education of the nurse practitioner students and other health professionals through the webinar series. Evaluating the core competencies of interprofessional collaborative learning in an online program is successfully measurable and reflects the areas of learning needs and competency attainment. Assessment of the development of the core competencies can be better understood when delivered at time series points throughout the Doctorate of Nursing Practice/Nurse Practitioner plan of study. This model can also be applied to other types of online educational programs.

Conclusion: Live case-based webinars that role model the process of inter-professional collaboration combined with facilitated discussions and curriculum weaving of the core competencies of

interprofessional collaboration are effective strategies to teach interprofessional collaboration in an online learning environment.

C 10 - Interprofessional Education in Nursing Programs

An Interprofessional Collaborative Educational Experience With Nurse Practitioner Students and Community-Based Pharmacists

Judy K. Anderson, PhD, CNE, USA

Abstract

Purpose: Terms such as interprofessional and collaborative education have become a frequent encounter in nursing education literature. The movement for interdisciplinary / team-based education started with the Institute of Medicine's (IOM) report "Educating the Health Team" (1972). Since that time, numerous organizations, both national and international groups focusing on healthcare, education or a specific profession, have published statements advocating the importance of shared education experiences and collaborative relationships in the practice setting. In 2011, representatives from six diverse health-related professional organizations formed the Interprofessional Education Collaboration identifying recommended competencies for interprofessional education. These competency domains included: (a) values /ethics for interprofessional practice, (b) roles / responsibilities, (c) interprofessional communication, and (d) teams and teamwork. Together, competency in these domains through interprofessional education is thought to improve collaborative practice and ultimately result in the "triple arm" identified by the Institute for Healthcare Improvement (2015). These included an (a) improved patient experience, identified both subjectively through satisfaction, and objectively through improved safety; (b) enhanced population health; and (c) improved cost effectiveness and efficiency of the healthcare system.

True interprofessional education (IPE) can be defined as happening when students from two or more disciplines share a learning experience, learning with and about the other (World Health Organization, 2010). However, a challenge exists for smaller or rural schools of nursing that are not affiliated with schools of medicine, pharmacy, or dentistry, where students of two disciplines may be located. Finding opportunities for collaborative education requires creativity and looking outside of the educational institution for these experiences. Writing prescriptions is one aspect of the role of an advanced practice nurse. The collaborative aspect of writing prescriptions also involves a consumer, who will be taking the medication and the pharmacist who will dispense the medication. Nurses in nurse practitioner programs have minimal experience working with pharmacists who fill prescriptions in the community setting. The importance of interprofessional education is well-documented, but there is a paucity of literature detailing experiences of collaborative educational experiences between nurse practitioner students and community-based pharmacists. This study involved one approach to providing a collaborative experience to facilitate development of the interprofessional competencies in a setting individuals from two specific disciplines have the ability to learn about and with each other. The purpose of the study was to identify nurse practitioner student perceptions of an experience focused on a short-term immersion with pharmacists working on "the other side of their prescription."

Methods: After university IRB approval, a convenience sample of second-year students ($n = 26$) taking a pharmacotherapeutics course co-taught with a hospital-based pharmacist and adult nurse practitioner completed an observation experience with a community-based pharmacist. Observations were completed within a three-state area and lasted three to four hours. Students then completed a reflective journal that served as the basis for a qualitative analysis for themes and patterns. The primary research question was: What are the most important insights gained from the collaborative experience with a pharmacist? A second question asked: How did the experience of working with a pharmacist influence their perspectives about the prescribing role on an advanced practice nurse?

Results: Seeing through new lenses was the overarching theme that emerged from the data. Patterns of: Seeing the: (a) rainbow of roles, (b) dark clouds of challenges, (c) winding road of technology, and (d) gears of collaboration were identified.

Conclusion: Correlation to how this activity paralleled the interprofessional education domains are examined along with recommendations for strengthening interprofessional education and further research. Resources for developing interprofessional curricular activities are offered.

C 11 - Care of Dementia Patients

Resilience and Dementia Caregiving: An Integrative Review

Barbara E. Harrison, PhD, APRN, GNP-BC, FGSA, USA

Abstract

Purpose: To review the literature for evidence related to resilience in family caregivers of person with dementia. Families caring for a person with dementia can experience physical, psychological, emotional, financial, and social burdens. Family caregivers who report resilience have experienced less burden, fewer depressive symptoms, and better health outcomes. Resilience is defined as “positive behavioral patterns and functional competences” (McCubbin & McCubbin, 1996).

Methods: Review of research and non research papers published between 2003 and 2016 that answered the following question “What evidence based factors and practices support resilience in family caregiver of persons with dementia ? ” Databases of Cochrane, Cumulative Index to Nursing and Allied Health literature (CINAHL), PubMed, and PsycInfo were searched for key words of resilience and dementia caregivers. Inclusion criteria were quantitative and qualitative studies published in peer reviewed journals, written in English. Other keywords associated with the literature were “hardiness” and “stress”.

Results: Twenty two unique studies were identified. Samples, representing a global perspective were from Australia, Canada, England, Scotland, South Africa, South Korea, and United States. Caregivers included spouses, children, siblings with age range from 25 to 90 years. Although many samples were primarily Caucasian, others were from ethnically diverse populations. Evidence on descriptive factors and interventions were found for relationships between resilience and the following concepts: appraisal, burden, environment, marital satisfaction, personality, religious coping, resources, stress, and suicide ideation. Resilient caregivers were characterized as those who maintained positive attitudes, continued to learn and adapt as dementia progressed, had positive coping strategies, and utilized social and environmental resources to achieve goals for self and person with dementia. Non – resilience was associated with pre-existing physical and mental health conditions and family conflicts. Interventions that support resilience are usually multi-factorial programs that include dementia education, exercise, and techniques for managing behavioral symptoms.

Conclusion: Dementia prevalence is increasing worldwide and there is a dramatic need for family members to be prepared for the caregiver role. This review synthesizes the evidence on caregiver resilience and its related concepts to supports family caregivers of persons with dementia. Recommendations for practice (assessment and supportive interventions) that enhance resilience are identified. Gaps in the literature and future recommendations are described. The evidence from this review has potential to improve knowledge and practice that advances global health and nursing.

C 11 - Care of Dementia Patients

Proxy Decision-Making and Dementia Care: Exploring Decision-Makers' Thinking Using Construal Level Theory

Helen M. Convey, MA, RN, United Kingdom

Janet Holt, PhD, RGN, RM, United Kingdom

Barbara Summers, PhD, United Kingdom

Abstract

Purpose: Dementia is a syndrome which affects the individual's ability to make decisions and to undertake everyday activities (ADI, 2015; WHO, 2012). A range of neurodegenerative diseases (including Alzheimer's disease) cause progressive or chronic symptoms which persist until death and these symptoms include loss of; memory and insight, the ability to make judgements, the ability to communicate and the ability to carry out complex tasks. Symptoms also cause changes in behaviour (ADI, 2015; WHO, 2012).

When the person who is living with dementia does not have decisional capacity another person, the proxy decision maker, will need to make the decision. WHO (2012) report that the ethical issues occurring in everyday decision making are often neglected in research and that such issues can occur because of the need to balance an individual's past values and views with current values and views. When the contemporary interests and desires of an individual who is living with dementia conflict with their past interests and desires proxy decision makers must choose which interests and desires take precedence (Stonestreet, 2014; Nys, 2013).

The empirical research outlines the responsibility of decision making. It is challenging (Givens et al., 2012) and the process is difficult (Hummel, 2015). Decision making is an emotional experience (Hummel, 2015; Ducharme et al., 2012; Manthorpe et al., 2012) and Wolfs et al. (2012) find that emotions may influence decisions. Decision makers experience stress (Lopez et al., 2013; Givens et al., 2012; Wolfs et al., 2012), guilt (Caldwell et al., 2014) and uncertainty (Givens et al., 2012; Manthorpe et al., 2012). Nurses and other healthcare professionals may therefore be required to support decision makers.

The aim of this study was to explore the potential for Construal Level Theory to be used as a basis for analysing the conceptual thinking of proxy decision makers when they are making a decision where the past and present interests of the person who is living with dementia are in conflict. Construal Level Theory (Liberman and Trope, 2014 for a review puts forward that individuals can surmise about or remember the past and imagine reactions and make predictions about the future by traversing psychological distance. When individuals think about distant events or objects which are discrete from their direct experiences they have to traverse psychological distance. Dimensions of psychological distance may be in time, in space, in social distance or in considering hypothetical situations. When we think of things beyond our direct experience across psychological distance, we think of them more abstractly. Abstract thinking (high level construal) entails consideration of the central features and the desirability of an event or object; the end result is given importance. When making decisions abstraction gives meaning and allows for the clarification of goals. In contrast, when individuals think concretely (low level construal) details and practical concerns are taken into account; feasibility is considered. Construal Level Theory has been applied in the health domain (Choi et al., 2012) but there is no evidence in the literature of its application to proxy decision making.

Methods: This project focused on individuals' responses to a progressing scenario about a person who could no longer decide for themselves. The aim of the research was to test the applicability of Construal Level Theory.

A qualitative design was selected because the research aimed to explore influences and associations in decision making (Ritchie and Ormston, 2014). Sequences can be identified and theory can be tested (Bryman, 2016). Invitations to participate and information for participants were placed on a Virtual Learning Environment for students and emailed to staff in a department within a large University. Given

the exploratory nature of the work a convenience sample of seven participants was used (Ritchie et al., 2014).

Face to face semi-structured interviews including the presentation of a scenario were used for data collection. Participants gave their informed consent before the interviews commenced and these were audio-recorded and transcribed verbatim. This approach provided structure and encouraged the participant to deliberate and talk aloud. Generating data through a specific interaction provides an opportunity to find out what participants are thinking about (Lewis and McNaughton Nicholls, 2014) and interviews allow for direct exploration and clarification of perspectives (Lewis and McNaughton Nicholls, 2014), therefore they are a useful way to gain understanding (Rowley, 2012). Scenarios provide consistency and a focus for discussion (Arthur et al., 2014). The scenario featured Alan, an individual who is living with dementia. He has expressed a preference to sleep in his wheelchair at night with a blanket over his head, he is a bilateral amputee, but he is no longer competent to make his own decisions and questions regarding putting him into bed at night are asked of participants. The scenario is in three parts, two parts involving progressions from the base scenario, and in each part different information is given relating to the question about putting Alan into bed at night. Progressions were included to explore how participants reacted to new information. Participants were led through each part of the scenario and were asked what they were thinking and feeling about it. "How" and "why" questions were not asked as this can induce abstract thinking which may influence participant responses (Burgoon et al., 2013). A Likert scale was used to measure familiarity and similarity with this type of scenario because this may also influence construal (Burgoon et al., 2013).

All three members of the research team analysed the same two transcripts for themes. Thematic analysis is a flexible way to discover patterns and meaning (Spencer et al., 2014). Analysis was inductive and deductive as themes emerged from knowledge of decision research and from the data itself. The team met to agree on themes and saturation was reached with the seven participants. After this part of the analysis was complete, responses within the themes were analysed for abstractness of language using the Linguistic Category Method. The distinction between low-level and high-level construal can be found in the use of concrete or abstract action verbs and adjectives. Concrete action verbs indicate low-level construal as they describe how an action is performed and its feasibility whereas abstract action verbs and adjectives indicate high-level construal as they describe why an action is performed and its desirability (Liberman and Trope, 2014).

Results: Participants in this study were found to travel across psychological distance to think abstractly about individual in the scenario. Participants also thought concretely when considering pragmatic concerns. We find that Construal Level Theory can be used to analyse the conceptual thinking of proxy decision makers, providing insight into concerns and ways to address them (e.g. by identifying principles for decision making). This understanding can inform the support that nurses and other healthcare professionals give to decision makers.

Conclusion: The next stage of the research is to develop the following projects:

1. Decisions which have real links to an individual who is living with dementia, where there might be emotional and social elements, will be explored using Construal Level Theory
2. A framework with which to reflect on and structure decision making will be developed and evaluated. This could be used by lay people, nurses and other healthcare professionals

C 12 - Pediatric Safety

Identifying Child Physical Abuse: Who Is Reporting, and How Accurate Are Their Reports?

Grace W. K. Ho, PhD, RN, Hong Kong
Deborah Gross, DNSc, RN, FAAN, USA
Amie Bettencourt, PhD, USA

Abstract

Purpose: Child physical abuse (CPA) is one of the most lethal forms of child maltreatment; being reported for suspected CPA alone substantially heightens the child's risk for sustaining future fatal injuries (Putnam-Hornstein, Cleves, Licht, & Needell, 2013). Therefore, early and accurate identification of CPA is imperative to the protection and timely provision of services to children in need. In the U.S., professionals who are mandated to report suspected child maltreatment initiate the majority of child maltreatment reports (62%; U.S. Department of Health and Human Services, 2015). However, few studies have been conducted to describe the distribution of report source for CPA or how report sources may associate with the outcomes of these reports. Further, these relationships have only been investigated using reports made for children under age five (King, Lawson, & Putnam-Hornstein, 2013). This study addressed these gaps by (1) describing the distribution of report sources for CPA reports investigated by Child Protective Services; (2) examining the likelihood of CPA report substantiation by reporter type (i.e. professionals and nonprofessionals) and report source (i.e. occupation of the professional reporter); and (3) fully investigating the impact of the child's age on the relationships between report outcomes and report source.

Methods: In a national sample of 204,414 children birth to age 17 years who were reported and investigated for suspected CPA in 2013, the distribution of reporter type and report source were described. Multilevel logistic regression was used to predict report outcome (i.e. substantiated or unsubstantiated) based on the reporter type or report source, controlling for child, caregiver, and state-level characteristics. A report source x child age interaction term was added to assess the differential impact of child age on report outcome by source of report. Marginal effects using mean predicted probabilities were calculated to predict the probabilities of report substantiation based on reporter type and occupation.

Results: Approximately 13% of children reported for CPA were later confirmed to be victims of abuse. Professional reporters initiated 84% of all CPA reports, of which 20% were made by a healthcare provider or mental health professional. The odds of report substantiation were 1.6 times higher when initiated by a professional versus a nonprofessional. Compared to nonprofessionals, reports made by healthcare providers and legal/law enforcement personnel have a 2.6 and 3.3 times higher odds of being substantiated, respectively. However, reports made by even the best reporters (i.e. legal/law enforcement) only have a 26% chance of substantiation. Moreover, mental health professionals appeared to be less accurate reporters than nonprofessionals (OR=0.67; 95%CI=0.62, 0.73). Overall, the difference in likelihood of CPA report substantiation among professional and nonprofessional reporters diminish as the age of the reported child increases.

Conclusion: In 2013, fewer than 1 in 7 children reported for CPA were found to be victims of abuse. Although there are many reasons for an unsubstantiated report, reports that cannot be confirmed due to weak or insufficient evidence may add undue stress onto a child protection system that is already stretched thin. Importantly, reports made without sufficient cause may threaten family well-being and further endanger families that are already vulnerable. Because professional reporters initiate the vast majority of CPA reports, strategies that promote accurate reporting among professionals are warranted. Some of these strategies that are pertinent to the nursing profession will be described.

C 12 - Pediatric Safety

Measuring Harm in Hospitalized Children via a Trigger Tool

Lya Michele Stroupe, DNP, APRN, CPNP, NEA-BC, USA

Abstract

Purpose: To use the Global Assessment of Pediatric Patient Safety (GAPPS) tool to detect adverse events in a pediatric inpatient setting of an academic medical center children's hospital and compare to internal incident reporting methods.

Methods: Nurse reviewers used the GAPPS tool during a retrospective chart review of 100 patients discharged from the children's hospital. Among the total 100 cases, 20 adverse events were discovered with the tool. Adverse events were validated by physician reviewers and the severity of harm and preventability were assigned. The number of adverse events were then compared to internal incident reporting for the same time frame.

Results: The detection rate is 4.87% within 411 patient-days. In contrast, the hospital had only 1.22% incident reports.

Characteristics of patients include medical records from 100 patients discharged from a children's hospital on a general pediatrics floor. Out of the 100 cases reviewed, 20 adverse events were discovered with the GAPPS tool. A total of 45 triggers were identified in the 100 patients. The mean rate of triggers per patient is 0.45. Ten patients had one adverse event and 4 patients had two or three adverse events during their hospitalization period. The detection rate is 4.87% within 411 patient-days. In contrast, the hospital had only 1.22% incident reports (147 cases in 12005 patient-days) in 2014. Patients experienced adverse events had significantly longer average length of stay in hospital and higher mortality rate ($p < 0.01$). In addition, the distribution of hospital service at admission is significantly different in the two groups ($p = 0.05$): patients who had adverse events were less likely to be admitted as general medicine (21.43% vs. 45.35%) but more likely in intensive care (14.29% vs. 4.65%), compared to patients who didn't have adverse events. The distribution of discharge disposition of the patients with adverse events was that 78.57% of them were discharged to home and one of them was deceased.

Characteristics of the adverse events shows that there is a significant difference between the two (triggers by the GAPPS tool and adverse events by hospital incidence reports) ($p < 0.01$): the triggers detected by GAPPS tool were distributed almost evenly in medications/fluids, hospital care environment, hospital acquired infections and hospital transfers/outcomes; while nearly half of the adverse events reported by the hospital were concentrated in medications/fluids, and more than a third of them were not related to the six categories.

Among the 20 adverse events, 9 (45%) of them are not preventable, while 11 (55%) of them are preventable. Because there are 4 patients who had multiple adverse events, a total number of 74 triggers were identified among all adverse events.

Conclusion: This is the first study that compares two methods for detecting adverse events in hospitalized children. The GAPPS tool can detect 4 times more adverse events than the hospital incident reporting system. The results are likely to be replicated for other children's hospitals to increase identification of adverse events and harm to patients. In our study we found 20 AEs (Adverse Events) per 100 patient and 48.66 AEs per 1000 patient-days. This is about 2-3 times higher than some of the trigger tools methods, where an ADE-only trigger tool was used.

Implementing the GAPPS triggers in EHRs will improve the usability and would also help concurrent detection of adverse events and preventing harm occurrences. The GAPPS study developed an automated version of 30 trigger tools. Future research will help in the refinement of the use of triggers in EHRs and to expand their use to include complex triggers to make it more usable and sustainable.

Differentials in Health-Related Quality of Life of Employed and Unemployed Women With Normal Vaginal Delivery

Anthonia U. Chinweuba, PhD, MSC, RN, RM, RPHNE, FWACN, Nigeria

Ijeoma L. Okoronkwo, PhD, MSC, RN, RM, RNE, FWACN, Nigeria

Agnes N. Anarado, PhD, MSC, RN, RM, RNE, FWACN, Nigeria

Noreen E. Agbapuonwu, PhD, MSC, RN, RM, RNE, FWACN, Nigeria

Abstract

Purpose: This study investigated the differences in health-related quality-of-life of employed and unemployed women in Enugu, Nigeria, with normal vaginal delivery at 6, 12 and 18 weeks postpartum in the light of their mother-worker dyad. Childbirth is an important event affecting the health of women. The arrival of new baby to a family in an African society where women do most of the unpaid household tasks and subsistence food production (Team & Doss, 2011) automatically increases the woman's workload. This, in turn, can affect her health-related quality-of-life, that is, self-report of her perceived feeling of comfort, ability to realize her life potentials and satisfaction with life as expressed in her physical, emotional and social functions of life. Extreme situations may result to all-cause morbidity and mortality. Available literatures on health-related quality-of-life such as Plugge, Douglas and Fitzpatrick (2011) and Bhagat, Baviskar, Mudey and Goyal (2014) view health-related quality-of-life as a framework for examining disease and its impact on a patient. There has been a paradigm shift from emphasis on curative to preventive healthcare. However, there is paucity of studies that compared quality-of-life of newly delivered women who have paid job and the unemployed. **Results** from studies like this will provide valid quality-of-life indicators for measuring maternity outcomes and promoting health of women of child bearing age in this era when women's roles have expanded exposing them to more physical, mental and socio-economic health risks (Bar & Jarus, 2015). Sprangers and Schwartz's Response Shift Theory underpinned the study.

Methods: Longitudinal, prospective descriptive design was used for the study. A sample of 234 newly delivered mothers were drawn from an estimated population of 363 women that used six selected hospitals in Enugu, Nigeria, through proportionate stratified and convenience sampling techniques. Subjects were identified through hospital records and self-revelation. Data were collected at 6, 12 and 18 weeks post-delivery by using a researcher-modified form of the standardized Iranian version SF-36v2™ health-related quality-of-life instrument – a generic short form of health-related quality-of-life survey instrument developed by Ware and Sherbourne in 1992 with 36-item self-rated health status profile that measures eight health-related concepts: physical functioning, role limitation due to physical problems, bodily pain, general health perceptions, vitality, social functioning, role limitation due to emotional problems, and perceived mental health – and five personal-profile items as interview guide. Data collection was through personal contacts at the hospital initially, and visits to home/workplace or cell-phone interview at subsequent times. Women were requested to respond to each interview item as applied to them at each of the three post-partum contact periods. Data collection continued until sample size was reached and lasted for six calendar months and seventeen days. Data were analysed descriptively using frequencies, percentages, mean and standard deviations. T-test was used for group comparison of dimensions of health-related quality-of-life of the women while two-way Repeated Measure ANOVA with time/group effects was used to establish statistical significant difference in mean scores on the eight SF-36v2™ subscales over time.

Results: There was significant difference in the women's health-related quality-of-life over time ($F = 4,58$; $Df_n = 2$; $p = 0.0268$). Both groups had better health-related quality-of-life at 6 and 12 weeks. Employed women reported bodily pains ($\bar{x} = 51.0$) and problems with role physical ($\bar{x} = 51.2$) and social functioning ($\bar{x} = 52.9$) more frequently. However, employed women that did not resume work after 18 weeks had better health-related quality-of-life than those who resumed work. Health-related quality-of-life scores of the women increased as their age, educational level and personal income increased ($p < 0.05$). However, working-class women with increased education had higher health-related quality-of-life than the unemployed.

Conclusion: Findings strongly suggest that quality-of-life improves as a woman's level of education and personal income increase. On the other hand, increased responsibility combined with increasing age negatively affect their reported health-related quality-of-life. Based on the findings, researchers recommend that paid six months maternity leave should be adopted by governments of all countries particularly the developing countries. The role of social supports for domestic chores is highly implicated. To this effect, special allowance should be paid to all employed women with under-one year old baby to enable them hire a paid care-giver. Also, paternity leave should be granted to fathers, on request, to have time at home to assist their spouse as may be necessary. Gender sensitive employment opportunities should be created to empowered more women economically

C 13 - Maternal Mental Health

Factors Influencing the Grief, Depression, and Quality of Life in Taiwanese Women With Perinatal Loss

Ya-Ling Yang, PhD, RN, Taiwan

Abstract

Purpose: Chinese culturally bound taboos against talking about perinatal loss related issues. The experience of pregnancy loss can be devastating and potentially traumatizing for women emotional and psychological health regardless of what kind indications for the perinatal loss and selective termination. However, maternal postpartum care still less concerning provide supportive bereaved care for parents. How to solve this clinical dilemma and to establish an appropriate compassionate bereavement support challenges care-givers in perinatal medicine.

The main purpose of this study were to explore the experience in Taiwanese women with perinatal loss due to non-elective indications (such as IUFD, spontaneous abortion and preterm premature rupture of membrane.) or elective termination due to fetal gene or chromosome defect. Thus, we examined (1) the trend changing in grieving adaptation, emotional depression and quality of life during six months after who had perinatal loss. (2) to compare the difference between the non-elective indication and elective indications two subgroups in grieving adaptation, emotional depression and quality of life. (3) to identify the influencing factors (maternal age, the indication of perinatal loss, gestational age), maternal self-efficacy and self-esteem, are related with the perinatal grieving, depression and quality of life.

Methods: This study is a retrospective with cross-sectional research design. Data were collected at the Outpatient Department of a medical center in North Taiwan by consecutive samplings method. All participations were assessed by a trained interviewer with structure interview using several measurement scales, including (1) Background information form, (2) The perinatal grief scales (3) Becker depression scale (4) Self-esteem scale (5) self-efficacy scale and (6) Short form 12 health survey (SF-12).

Results: Total forty seven participations were recruited and divided into non-elective perinatal loss subgroup (53.2%) and elective termination subgroup (46.8%). Additionally, all participants were divided into three subgroups depended on the time since their experience perinatal loss/termination after hospital discharge with range from 6-8 months (40.4%), 3-4 months (38.3%) and 2 months (21.3%). The results presented that (1) both the time range and the indication in perinatal loss were not significant influencing factors of all of our measuring. But between the non-elective and elective subgroups there were significance differences existed in the perinatal grief subscale and Becker's subscales. (2) The average total scores of mental component (MCN) in SF-12 of the non-elective and elective two subgroups were far below the norm. MCN score had significant positive association with the participant's self-esteem and self-efficacy, but with significant negative association with perinatal grief score and Becker depression score. (3) No matter the participants had held their deceased infants /fetus or not, there were no statistic difference in the measuring tools.

Conclusion: Although its grief reactions over time will gradually calm down, the participant still need medical professional assistance to provide continued support for identification the value of their deceased infants /fetus exist and to obtain export emotions. We anticipate these results will be benefit to construct the clinical educational programme for caregivers and practice care model for bereaved parents. Eventually, to promote the quality of care and to encourage the related health policy making in both gender friendly medical environment.

C 14 - Promoting Outcomes in the Clinical Setting

Misconceptions About Peripheral Intravenous Catheter Complications Rate Based on Insertion Settings: A Comprehensive Literature Review

Ani Kaziu, USA

Liam Mcneil, CPHT, USA

Laura Lee Robishaw, MA/EMT, ACLS, PALS, BLS, USA

Erica Marie Luke, CST, USA

Elisha Son, BLS, USA

Abstract

Purpose: With more than 300 million IV catheters sold and 60% to 90% of hospitalized patients requiring PIVC access in the United States, this intervention is the most common, invasive, patient procedure performed worldwide (Helm et al., 2015). Current guidelines for PIVC care suggest that complication rates may be increased when access is obtained in pre-hospital or emergency department settings over those placed in the inpatient care units. The 2011 CDC published guidelines state there is no need to replace PIVC more frequently than 72 to 96 hours in order to decrease the risk of complications in adult patients (CDC, 2011). However, the CDC does not offer any further recommendations in regards to the removal and replacement of PIVC's when clinical indications of complications are not present – this is an issue the CDC acknowledges requires further attention (CDC, 2011). Through this literature review, the published original research reports were appraised through studies in order to determine if adult patients in the United States who required PIVC access in the pre-hospital and emergency department settings were at an increased risk for PIVC complications, in comparison to patients who had PIVC's initiated in the inpatient units.

Methods: This literature review was performed through systematic research of professional databases such as Ovid, CINAHL, and PubMed with access from MCPHS University with select keywords. To be eligible for inclusive research, the research needed to be conducted in the United States and include primary data within the last 10 years (2006-2016). The keywords included combinations of "intravenous therapy and equipment," "peripheral intravenous therapy," "infection," "phlebitis," "infiltration," "prehospital," "emergency care" and "peripheral catheterization". The articles utilized in this review are primary quantitative research reports, with the infection and complications of peripheral IV's as the dependent variable.

Results: Results suggest that the area of patient care with the highest incidents of PIVC complication rates are inpatient care units, with the fewest incidents of complications being the emergency department. Peripheral intravenous catheters (PIVC) placement guidelines, particularly those published by the CDC, suggest that the area of patient care in which initial IV access is obtained may be directly correlated to the development of complications from IV access. Studies showed that complication rates are relatively low for PIVC's inserted in the pre-hospital setting, with phlebitis as the most often noted complication. There were less complications correlated with emergency department PIVC insertion in comparison to PIVC's initiated in the pre-hospital setting. While in the inpatient units, patients often have the same PIVC in place for several days. Due to the increase in time with the same PIVC, complications such as phlebitis are common.

Conclusion: The information compiled through this literature review revealed the rates of PIVC complications only varied slightly between all the areas of care evaluated. Clinical manifestations of a complication, patient complaints of pain/discomfort, and nurses' clinical judgment should be considered the determining criteria for removal or replacement of peripheral IV's. Although the CDC based much of their recommendations on dwell time for determining PIVC replacement or removal, there is more evidence that indicates clinical manifestation of a complication should be used to make that determination to fully decrease any risks posed to the patient. The Infusion Nursing Society's 2016 recommendations point to a standard of care for PIVC's and all things pertaining to infusion, which includes standards pertaining to education, implementation, and risk reduction which is based on relevant, recent evidence collected throughout varying patient care settings. If professionals adhered to the INS recommendations

and guidelines and those like it, perhaps many of the complications discussed in this literature review could be decreased further, leading to the improvement of patient care and satisfaction.

C 14 - Promoting Outcomes in the Clinical Setting

A Comparison of EMLA and LMX4 for Managing Pain During Sharp-Wound Debridement

Wendy M. Woith, PhD, RN, FAAN, USA

Jennifer Perry, BSN, CHRN, USA

Jessica Lee, BSN, CHRN, USA

Abstract

Purpose: The purpose of this study was to compare the efficacy of eutectic mixture of local anesthetics (EMLA) cream to 4% liposomal lidocaine cream (LMX4) for managing pain during sharp debridement of wounds.

Sharp debridement involves the use of a scalpel or scissors to assist with removal of infected or necrotic tissue; this method is preferred for deep wounds, when there is a large amount of tissue to be removed, or when significant infection is present with risk of sepsis, and has been found to decrease time to healing over other forms of debridement. However, sharp wound debridement has been associated with pain, and minimizing pain is essential, as undertreated pain causes distress.

Eutectic mixture of local anesthetics (EMLA) is an emulsion of 2.5% lidocaine and 2.5% prilocaine. EMLA is effective in providing dermal anesthesia for IV cannulation in adults and children, lumbar puncture, sharp debridement of leg ulcers and decubitus ulcers, among other wound types. Lidocaine is an effective agent for providing anesthesia in a variety of procedures such as intravenous cannulation procedures of the oral cavity, prostate biopsy, episiotomy, and wound debridement. Lidocaine comes in different preparations and strengths. 4% liposomal lidocaine is a newer lidocaine preparation which facilitates a more rapid onset of anesthesia. Both EMLA and LMX4 have been available for several years, and much of the research on efficacy was conducted as these agents were released.

Few studies were found that compared EMLA to 4% lidocaine or 4% liposomal lidocaine. Of those studies found, EMLA cream was superior to 5%, 4%, and 2% lidocaine in studies of topical anesthesia for oral and nasal mucosa. Other studies found no significant difference between EMLA and 4% lidocaine gel; or between 4% liposomal lidocaine and EMLA when used for laser procedures and skin micro-needling. In addition, EMLA cream was reported to be more expensive than some of the lidocaine preparations. No studies were found comparing EMLA cream to 4% liposomal lidocaine cream for managing pain during sharp debridement.

Methods: This study was a randomized, controlled, double-blinded, cross-over trial of EMLA cream compared to 4% liposomal lidocaine (LMX4) for the management of pain during sharp wound debridement. It was approved by the facility's Institutional Review Board.

Forty patients referred to the wound center for sharp debridement of a venous, arterial, or lymphedemic wound, or pressure ulcer that required more than one debriding were recruited for this study. People with diabetes were included if there was no neuropathy. People who were taking analgesics were considered if they had not used an analgesic in the 24 hours prior to their appointment.

Each participant was randomly assigned to treatment order. An RN applied the anesthetic agent to the wound using the method prescribed by the manufacturer, and covered the site with an occlusive dressing. Lidocaine remained covered for 15 minutes and EMLA for 30 minutes prior to debridement. Debriding was performed according to wound type and location, and the wound was dressed as per standard care.

Participants were asked at both appointments to rate their wound pain using a visual analog scale with a range of 0 to 10 at four points during the procedure: prior to topical anesthetic application, before debridement started, during debridement, and following debridement. They were also assessed for any complications from the cream or the procedure. Following the second debridement, they were asked if the

anesthetic applied at the first debridement (T1) or the second debridement (T2) provided better pain relief.

Results: Thirty-two participants completed the study. Forty-one percent believed LMX4 provided better pain relief than EMLA (28%). Repeated measures MANOVA revealed a significant effect of time ($\lambda = .369$, $F(3,28) = 15.964$, $p = < .001$). Mean pain rating was higher at T1 than at T2 for corresponding assessment points. Pain during debridement at T1 was statistically significantly higher than pain at any other point except during T1 admission and T2 debridement. There was also a significant effect of drug by drug order (LMX4 applied at Time 1 or EMLA applied at Time 1) ($\lambda = .796$, $F(1,30) = 7.677$, $p = .010$); those who had EMLA at T1 reported less pain at T2 with LMX4, but there was no difference for those who had LMX4 at T1.

Conclusion: This was the first known study to compare EMLA to LMX4 for sharp debridement. We found no statistically significant difference between EMLA and LMX4 in managing pain associated with sharp wound debridement. There were, however, significant differences in pain ratings for the four points in time at which pain was assessed for both topical anesthetics, and for the topical anesthetics by the order in which they were given. Participants believed that LMX4 provided better pain relief than EMLA. Five participants experienced burning on application of EMLA, a common complication associated with this agent (Claeys et al., 2010; Evans & Gray, 2005).

An unexpected finding was that participants who received EMLA first reported significantly lower pain during the second treatment when they were given LMX4. One possible explanation is that participants who received EMLA first, as a result of having more intense pain initially, experienced the decrease more acutely. It is also possible that the burning sensation experienced by some of the participants on application of EMLA may explain the difference.

C 15 - Research in Academia

Assessment and Curricular Framework Development of Undergraduate Research in the School of Nursing

Flor A. Culpa-Bondal, PhD, RN, USA

Debbie Greene, PhD, RN, USA

Josie Doss, MSN, RN, USA

Abstract

Purpose: The purpose of this presentation is to discuss assessment results of undergraduate nursing students' evidence-based practice (EBP) competencies and faculty's EBP teaching practices in the undergraduate nursing courses in one southern United States school of nursing (SON). The consequent development of a curricular framework for infusing EBP in an undergraduate BSN program as a result of the assessment will also be presented. The audience will be engaged in discussing the barriers, challenges and opportunities in the development and planned implementation of the model.

Methods: During the 2015-16 academic year, a thorough assessment of the integration of evidence-based practice throughout the undergraduate curriculum was conducted. The assessment included faculty interviews and student surveys. The interviews included what courses in the undergraduate program are using EBP, and what SON resources and capacities are available for EBP integration. The assessment showed several gaps and opportunities for improvement. One issue with the current curriculum is an inability to identify where evidence-based practice (EBP) is introduced to students, despite the identification of EBP as a core concept for the program. According to the current curriculum, introduction of EBP occurs during the third semester research course. However, scattered projects during the first two semesters utilize EBP skills, without focused content on EBP at an introductory level to inform these assignments. The SON also lacks a clear vehicle to mentor and guide faculty in course designs that infuse EBP and to actively engage students in it.

Results: Guided by the AACN accreditation guidelines and evidence-based practice framework by Flood, Gasiewicz and Delpier (2010) that describes progression of evidence-based practice from novice to advanced levels, a curricular framework emerged.

Conclusion: Findings from the assessments and implementation recommendations based on the new framework were presented to SON in March 2016. A multi-phase implementation of revisions to the undergraduate nursing curriculum to improve student outcomes related to undergraduate EBP was proposed and scheduled to commence Fall 2016.

C 15 - Research in Academia

Research Capacity Development in a Nursing Education Context

Nelouise Geyer, PhD, MCur, BCur, RN, RM, RPsyc, South Africa

Gisela H. Van Rensburg, DLittetPhil, MACur, BACur (Hons), BACur, RN, RM, RCN, RPN, RNE, RNM, RON, South Africa

Susan Jennifer Armstrong, DCur, RN, RM, FANSA, South Africa

Abstract

Purpose: Research capacity development is essential for quality, cost-effective care and well-prepared healthcare professionals. Although various institutions have invested in a number of projects to build the capacity of professionals, research capacity remains fragmented and to a large extent limited to postgraduate research activities. The United Nations Educational Scientific and Cultural Organization (UNESCO) describes capacity building as being focused mainly on skills building that would enable the attainment of development goals through education (Edwards et al., 2016). Research capacity development varies in focus.

Following an annual nursing education conference, the absence of presentations on research done by nurse educators from nursing education institutions (NEIs) not attached to universities was noted with concern. Taking into consideration that nursing programs are migrating to higher education, research and public presentation skills are essential for all nurse educators. To bridge this gap, the novice researcher program was developed. Under the supervision of the authors, the successful applicants undertake a small research project to expose them to the full research process. The research project is written up, presented at the annual nursing education conference and published as an article. The candidates undertake this work in a group thus strengthening their ability to work in a team over a period of nine to twelve months.

The purpose of the presentation is to assess the novice researcher program outcomes against Cooke's integrated framework as described by Edwards et al. (2016).

Methods: An exploratory case study design was used (Crowe et al., 2011; Thomas, 2016) to gain insight into the contributions that a novice researcher program makes towards research capacity development. The case was formed from the annual reports, reflective activities and conference presentations. The 'global' nature of the case was then examined holistically, as described by Polit and Beck (2012). Trustworthiness was ensured by providing a dense description drawn from the case. Credibility was achieved through prolonged engagement over a six-year period. As the case study was constructed from various units of analysis submitted to the executive committee of the professional organization and a research ethics committee, it could be transferable to other contexts. Should the study be repeated, the evidence provided in the study would be similar in that the data analysis was based on a well-researched conceptual framework to evaluate research capacity building in healthcare. Confirmability was assured in the audit trail of the individual sub-units that were used to create the case. The researchers upheld scientific integrity in all phases of the research to prevent or minimize bias. Permission to use data from the novice researcher program was obtained from the Research Ethics Committee, the professional organization who is the custodian of the program as well as the participants. The names of the organization and its chapters are not mentioned to ensure confidentiality and anonymity.

The case was deductively analyzed using the literature on research capacity development as the point of departure. The Cooke's integrated framework for research capacity building in healthcare was used to evaluate the development that took place.

Results: The findings of the analysis are described and discussed according to the eight dimensions of the Cooke's integrated framework indicating that this novice program fulfilled all the dimensions of the framework, namely skills and confidence; research applicability; linkages, partnerships and collaborations; dissemination and knowledge translation; continuity and sustainability; infrastructure; leadership; and empowerment.

Conclusion: The success of the program lies in the skills and confidence gained by the participants and the contribution they could make to address and resolve their education practice problems. In this process, they developed strong partnerships through sharing responsibilities in the execution of the project. Under the leadership of the program leaders, their work delivered results that could be implemented in their workplaces and were shared at conferences and in publications. Continuity and sustainability of the program remain a challenge and was partially promoted by using the premises of the professional organization or university participating in the project, devolving the program to chapter level and partnership with universities.

It could be argued that a Hawthorne effect is possible due to the small number of participants and the researchers reviewing their own program. The authors also recognize that the participants are so grateful for the opportunity to participate in the program that it could affect their views making them extremely positive in their reviews of the program. This was overcome through using different units of analysis, keeping the reflections anonymous and using a framework for analysis of data.

Selection and recruitment should be given careful attention. The confidence of the participants and cohesion of the group improves with interaction, therefore an ice breaker/introductory workshop could assist in getting to know each other and identifying where power differentials lie. Institutions where the research is conducted should be supported through knowledge translation to implement the recommendations of the completed projects. Involvement of more universities would assist sustainability and could serve as preparation for postgraduate studies as well as providing library access for program participants.

Sustainability is further promoted through mentorship of the presenters of the project and fundraising initiatives. Dependent on funding, the program would ideally have a dedicated person to drive this program.

C 16 - Doctoral Nursing Education

Doctoral Nursing Students' Use of Evidence-Based Knowledge, Skills, and Attitudes of Scholarly Writing

Diane F. Hunker, PhD, MBA, RN, USA
Teresa Shellenbarger, PhD, RN, CNE, ANEF, USA
Elizabeth A. Gazza, PhD, RN, FACCE, LCCE, USA

Abstract

Purpose: Scholarly writing is required for doctoral program graduates who plan to disseminate their work and advance the discipline of nursing. However, nurses enter doctoral programs with varying ability and experience with scholarly writing (Gazza, Shellenbarger, & Hunker, 2013). Further compounding this issue are the curricular differences noted amongst programs. Additionally, there may be differences in students, their educational and experiential backgrounds, and whether they are enrolled in a PhD or a Doctor of Nursing Practice program (AACN, 2014).

Nursing faculty may expect that doctoral students have advanced scholarly writing ability due to the knowledge, skills, and attitudes developed at the baccalaureate and masters level. Doctoral nursing students often face challenges with writing and may struggle to write proficiently at the expected level (Ryan, Walker, Scaia, & Smith, 2014). This causes frustration for both the student and the faculty. Prior studies have suggested that scholarly writing develops throughout nursing education and requires that students learn the requisite knowledge, skills, and attitudes related to writing at each level of nursing education (Gazza, Shellenbarger, & Hunker, 2013). Limited information is available that can guide faculty and students to develop their writing. Most of the information available is not evidence based (Hawks et al, 2015).

The purpose of this study was to assess doctoral nursing students' use of an evidence-based set of knowledge, skills, and attitudes specific for scholarly writing.

Methods: After obtaining IRB approval, an email invitation was sent to nursing program administrators of doctoral programs in the United States that were listed on the Discover Nursing website. Administrators were asked to distribute the email invitation along with an electronic link to a self-assessment to all enrolled doctoral nursing students. Consenting students completed a 35- item tool using a 5- point Likert scale assessing evidence-based knowledge, skills, and attitudes (KSA) of scholarly writing (Hunker, Gazza & Shellenbarger, 2014). Respondents used ratings from 1- Never, 2-Rarely, 3-Sometimes, 4- Usually, to 5-Always. Data was analyzed using descriptive and inferential statistics.

Results: Seventy-three doctoral students enrolled in PhD and DNP programs responded to the self-assessment. Seventeen PhD students from six different states completed the tool. They were primarily female, Caucasian, and enrolled part-time in their doctoral program. PhD respondents had a mean age of 44. PhD program delivery was diverse with traditional, hybrid, and online program represented in the sample. Using Fisher's Exact test, data analysis revealed no associations between self-assessment of KSAs and gender, age, enrollment status, GPA, or mode of delivery. While students responding to the self-assessment were at different points of completion of their PhD program, all were at least half way through their program. Analysis of the mean for each item on the electronic self-assessment revealed that PhD students either "sometimes" or "usually" used all of the KSAs.

Fifty-six DNP students representing 11 states also responded to the self-assessment. They were primarily female, Caucasian, and enrolled full-time in their doctoral program. They had a mean age of 37. Program delivery was primarily a hybrid format. Using Fisher's exact test, there was a positive association between age and item response ($P=.0378$) suggesting that students who were older in age tended to rate the items higher on the self- assessment. The investigators were unable to determine where the DNP students were in terms of program completion.

Analysis of the mean for each item from the electronic self-assessment revealed that DNP students, like PhD students either “sometimes” or “usually” used the KSAs. However, within the DNP student sample, there were two items that had a mean score less than 3, indicating they “rarely” used the KSA. Those items were: “I create abstracts and written summaries of written material that has already been published”, and “I serve as a mentor and role model for undergraduate and master’s students, and colleagues about scholarly writing”. The two items identified are both “skills” typically acquired at the BS level; therefore, it appears that the DNP students have the knowledge and attitudes but lack some of the skills identified at the beginning level.

Conclusion: All of the evidence-based KSAs for the PhD students and all but two of the KSAs for the DNP students were at least “sometimes” used. This suggests that most doctoral students at least recognize scholarly writing KSAs from their earlier programs. Often times student success in a doctoral program hinges on the ability to write well. Strategies are needed for purposeful learning activities that will help to promote scholarly writing development and further enhance student writing. More specifically, recommendations for faculty at the doctoral level include assessing KSAs at the time of entry into the program, and tailoring writing assignments, guidelines and rubrics to help support and develop writing at the doctoral level. Nursing programs should plan to provide general writing support and build curricula that offer sequential writing assignments that work to develop the students’ scholarly writing development over time.

Based on the study results, it can be inferred that DNP students are rarely creating abstracts or written summaries of written material. As expert clinicians, they may need to provide those written summaries to share with others. Nurse educators should be encouraged to consider assignments and learning activities that allow DNP students to develop abstract writing and summarize work. Data also suggests that DNP students are not role modeling scholarly writing for others. As emerging leaders, they may be expected to use those role modeling skills to lead others during writing activities. Nurse educators need to further explore this issue and provide opportunities for DNP students to develop this essential skill.

This small convenience sample of doctoral students provides beginning information about scholarly writing knowledge, skills, and attitudes; however, further study with a larger more diverse sample is needed. By effective development of doctoral student writing, faculty can support and promote the transformation of knowledge and practice to advance global health and nursing.

C 16 - Doctoral Nursing Education

Impressions of Uses for Visual Thinking Strategies Among Doctorate of Nursing Practice Leadership Students

Meg Moorman, PhD, RN, WHNP-BC, USA

Desiree Hensel, PhD, RN, PCNS-BC, CNE, USA

Abstract

Purpose: Visual Thinking Strategies (VTS) is a structured art viewing technique that can help students develop aesthetic understanding and critical thinking skills (Housen, 2002). VTS integrates many techniques to build cognition including fact-finding, questioning, speculating, and personal association (Yenawine, 1997). Originally used with children, there is now a growing recognition that VTS holds value in higher education (Moorman, & Hensel, 2016). In the field of Nursing, undergraduate students have reported that VTS helps create a safe learning environment and helps them see things differently. (Moorman, 2015). Other undergraduate students have reported that VTS helped them gain observational, cognitive, interpersonal, and intrapersonal skills (Moorman, Hensel, Decker, & Busby, 2016). Very little is known about how VTS might be used among nurses in leadership and administrative positions. The purpose of this project was to explore perceptions of how nurses enrolled in a Doctorate of Nursing Practice (DNP) program thought they might use VTS in their practice.

Methods: Fourteen DNP students, enrolled in a leadership DNP, participated in a standard VTS session lead by a trained facilitator. The group viewed three works of art and then were asked three open ended questions: 1. *What is going on in this picture?* 2. *What are you seeing that makes you say that?* and 3. *What more can you find?* Following the session the participants provided written feedback to open ended questions: 1. *What was your impression of Visual Thinking Strategies?* and 2. *How might you use Visual Thinking Strategies in your Nursing or leadership?* All participants gave written consent to use de-identified data for research purposes. Data were analyzed using the qualitative descriptive approach described by Sandelowski (2000) with Dedoose Version 7.5 software.

Results: The VTS session was well received as being enjoyable and having applications for practice. Three themes emerged about how participants might use VTS: as a teaching tool (N=13), changing thinking in practice (N=7), and facilitating interpersonal relations (N=14).

Conclusion: Thinking “out of the box” is becoming increasingly important for nurses to deal with complexity in today’s health care environment. This study found DNP students felt VTS could be used as a tool to improve communication and critical thinking in practice and education. Future research should address how skills learned in VTS improve nursing practice.

C 17 - Defining the Nurse Faculty Role

An Integrated Model of Learning and Role Development in Nursing Education

Monika Schuler, PhD, RN, CNE, USA

Abstract

Purpose: With a view towards understanding how students develop new knowledge and practices that facilitate role development in the clinical and simulation settings, the purpose of this project was to examine the process by which new knowledge is absorbed and processed leading to perspective transformations and ultimately role development.

In considering how students learn, constructivist pedagogy involves active learning where students have an opportunity to challenge previous thoughts on content and try out different aspects of their future role with guidance (Handwerker, 2012). This active learning helps a student develop metacognition and an ability to transfer knowledge and skills to new situations ultimately resulting in the development of clinical reasoning and a sense of relevance. The clinical and simulation environment is an ideal place for active learning. Recent work by Arreciado Maranon and Ilsa Pera (2015) reinforce the value of clinical education in forming student identities particularly as they are given an opportunity to examine this education in light of what was learned in the classroom. Students often come into clinical experiences with preconceived notions of what they will see and do, though there are numerous occasions when something unexpected occurs (Palese, Petean, & Cerne, 2013). Furthermore, many nursing students experience an incongruity between what they are taught in the classroom and what they experience in the practice settings (Chappy, Jambunathan, & Marnocha, 2010). Understanding how students process, reconcile, and learn from what is studied in the classroom compared to what is experienced in the clinical setting and how this facilitates learning and role development was examined.

Methods: Influenced by Mezirow's (1978) Transformative Learning Theory, Tanner's (2006) Clinical Judgement Model, and Benner, Sutphen, Leonard, and Day's (2010) landmark work on *Educating Nurses* a constructivist approach was adapted in the development of a new model for describing the process of learning and role development in the clinical and simulation setting. This approach involved reviewing the literature, re-analyzing themes, development of multiple schematics, continual review, personal observations of students in the clinical and simulation settings, and feedback from peer educators. The resulting Reflection, Feedback, and Restructuring Model was developed.

Results: The Reflection, Feedback, and Restructuring Model describes an inductive, iterative process strongly influenced by feedback. The first component of the model depicts a new experience encountered by the student. The second component focuses on the student's reflection of the event where an attempt is made to interpret the event in the context of what is known or has been learned in the classroom. Within this reflection component is an inductive response in terms of identification of gaps in knowledge (if any) and formulating a plan for responding should this event occur again. The next step in the process draws on the literature related to the value of formative feedback which has been described as an essential component of student learning and improves performance and skills, motivation, personal development, and confidence (Koharchik, 2016; Motley & Dolansky, 2015; Plakht, Shiyovich, Nusbaum, & Raizer, 2013). The final step in the process of student learning and role development involves restructuring. In this phase, the student responds to the feedback and adopts a new perspective of what is appropriate given what was experienced. The student may recognize he or she may need to restructure preconceived notions or ways of doing things. Finally the student emerges with a new sense of what is normal and expected nursing actions. This new normal serves as foundation for future nursing action and role development.

Conclusion: A key component of nursing education is the integration of knowledge and practice for the development of critical thinking skills that inform subsequent action in the practice setting when providing patient care. For many students, a component of the learning involves reformulating and re-conceptualizing what is learned in the classroom with what is seen and experienced in the clinical setting. The model was used as a conceptual framework to guide the development of reflective questions used by

Schuler (2016) examining professional role conceptions following a shadowing experience. The Reflection, Feedback, and Restructuring conceptual model may be a useful tool to guide nurse educators facilitating the transition from the classroom to the clinical setting and facilitating knowledge and role development for the nursing student.

C 17 - Defining the Nurse Faculty Role

Description and Meaning of Clinical Competency: Perceptions of Nurse Managers and Baccalaureate Nurse Faculty

Carolyn D. Meehan, PhD, RN, RN, USA

Abstract

Purpose: Clinical competency is a significant concept for nursing as it relates directly to the quality of patient care that nurses provide in the healthcare setting. Despite the vital nature of this concept, in the literature, there is currently no widely accepted understanding of the term between the academic and clinical groups in nursing. Consequently, there is a continuous struggle to set standards to measure clinical competency in undergraduate nursing students. This imprecise understanding of clinical competency widens the gap between education and practice. When acute care nurse managers and prelicensure baccalaureate nurse faculty share expectations of what constitutes clinical competency in nursing students, that gap may be bridged. The focus of this interpretive description study was to describe and gain an understanding of the concept of clinical competency from the perspective of acute care nurse managers and baccalaureate nurse faculty.

Methods: A purposive sample was recruited through the snowballing method. Participants included eight acute care nurse managers and nine prelicensure baccalaureate nurse faculty. Data were collected through semi-structured interviews with the participants, and analyzed through a constant comparative analysis until the data reached saturation.

Results: Four themes emerged from the data of this interpretive description study when acute care managers and baccalaureate nurse faculty described the meaning of clinical competency and what expectations managers have of the new graduate nurse in regards to clinical competency. The themes are *applying metacognitive judgment*, *getting the big picture*, *providing safe care*, and *developing professional nursing behaviors*. This study presents Transitions Theory as a theoretical framework to support its findings, as student nurses transition to the role of the new graduate nurse in the acute care setting. The application of the four themes described in this study to Transitions Theory assists in further understanding the meaning of clinical competency in nursing.

Conclusion: Implications of this study from the perspective of nursing science and research offered for the first time a shared view of the concept of clinical competency from the perception of the managers in practice and the faculty educating undergraduate nursing students in the clinical area. Implications for nursing education included providing faculty a means to structure the clinical experience so that students may be better prepared to practice in the acute care setting as a new graduate nurse. In nursing practice, the benefits for the managers are an understanding of the level of clinical competency and preparation of the new graduate nurse, which enables them to further support their transition to clinical practice. Future research may include a tool for the objective measurement of clinical competency.

D 12 - Nursing Governance

Evaluation and Revision of a Nursing Professional Practice Model Using Focus Group Research Methodology

Susan C. Cobb, PhD, RN-BC, USA

Anne E. Jadwin, MSN, RN, AOCN, NE-BC, USA

Kathleen M. Wolf, MBA, BSN, RN, NEA-BC, USA

Abstract

Purpose: The purpose of this presentation is to describe how focus group methodology can be successfully used to engage nurses in the evaluation and revision of a Nursing Professional Practice Model in a healthcare setting.

A nursing professional practice model (NPPM) is a conceptual representation of nursing within an institution which serves as a framework for nursing practice and interprofessional collaboration. Magnet®-designated organizations must show evidence of on-going evaluation of their nursing professional practice model with involvement of clinical nurses (American Nurses Credentialing Center, 2014).

NPPMs have been evaluated through several approaches including quantitatively via surveys and questionnaires. Since each NPPM is unique to an institution, the validity of using existing instruments to evaluate can be limited. Focus groups are another method to evaluate NPPMs which can provide rich data that can be used to validate the components of the model and inform any need for modifications. Focus groups may also contribute to development of a specific tool (Basol, et al., 2015) or be part of a mixed-methods evaluation approach (Harwood, Downing & Ridley, 2013). Our institution is seeking its fifth Magnet® designation and chose this approach which could be useful to other organizations seeking to evaluate their NPPM utilizing a qualitative research methodology. The purpose of this study was to evaluate nursing staff understanding and perceptions of the NPPM. The aims of the study were to obtain increased knowledge of how the NPPM is understood and used by nurses and how its relevance to current practice can be enhanced.

Methods: The study design was qualitative using focus groups. Participants were Registered Nurses from all levels, settings and shifts. Four focus groups were held and structured interview questions were used by the moderator. Two clinical nurses were sub-investigators on the study and assisted with field notes during the focus groups. Data analysis consisted of review of the audiotapes, transcripts and field notes with identification of major and minor themes to reach saturation. Data and thematic concordance were verified by an experienced qualitative researcher consultant.

Results: Major and minor themes were identified. Major themes included that the NPPM is multifaceted and empowers nurses. Themes and values articulated include caring and compassion, evidence-based practice, quality patient care, education and certification, nursing voice, visible leadership, and holistic and complementary care.

Conclusion: The focus group research approach was effective in evaluation of the NPPM. The NPPM was found to be relevant and reflective of nursing practice. Study participants indicated that the NPPM needs to be more visible throughout the organization and offered several suggestions for this. It was felt that the NPPM needs to be diligently communicated to nurses new to the organization as representative of the nursing culture and expectations. The evaluation revealed that a few minor revisions to the NPPM were indicated. A follow up group was convened and accomplished a minor redesign of the NPPM based on the focus group results.

Use of a focus group research study design is an innovative way for nursing leadership to promote the development of research skills of clinical nurses and to engage them in evaluating NPPMs relevance to current nursing practice and the interprofessional environment.

D 12 - Nursing Governance

Measuring Nurses' Perceptions of Collaborative Governance as a Method of Assessing Transformation of Organizational Culture

Jaynelle Stichler, DNS, MSN, BSN, RN, NEA-BC, EDAC, FACHE, FAAN, USA

Maria del Carmen Colombo, PhD, MBA, RN, NEA-BC, USA

Debra Milbert Poeltler, PhD, MPH, RN, CCRC, USA

Abstract

Purpose: This completed study describes the measurement of nurses' perceptions of collaborative governance (CG) over 5 years after implementation of a CG structure developed to transform culture and empower nurses to be more involved in decision making. The study is important since few evidence-based studies regarding CG exist in the literature.

Transformation leaders inspire others to achieve more than they thought possible for themselves (Porter-O'Grady & Malloch, 2015). The Magnet culture requires transforming the organization culture and facilitating leadership growth and empowerment of all nurses in the organization (Dearmon, 2015). CG is a structure and process used to change organizational culture by empowering and engaging clinical nurses in interprofessional decision-making as compared to the traditional hierarchical decision-making model (Ansell & Gash, 2008; Barden, Griffin, Donahue & Fitzpatrick, 2011; Hood, 2016). Benefits of CG have been described as advancing the scholarly work of clinical nurses, improved patient outcomes, and improvements in clinical nurse job satisfaction (Burkoski & Yoon, 2013; Myers, et al., 2013; Parkosewich, 2013). CG facilitates the transformation of the organization and is a developmental process that can be measured over time (Larkin, Cierpial, Stack, Morrison, Griffith, 2008).

After a review of the literature exploring best practices in collaborative governance (Burkman, 2012; Dearmon, 2015; Franklin, Murphy & Cook, 2014), the nurse leaders and clinical nurses at the study site designed, implemented, and evaluated a CG organizational structure with a conceptual model (Bretschneider, Eckhardt, Glenn-West, Green-Smolenski & Richardson, 2010). This study surveyed clinical nurse perceptions of the CG structure annually to measure growth and enculturation.

Intervention: Recognizing that leadership was the key to transforming organizational culture (Hood, 2016; Slatyer, Coventry, Twigg & Davis, 2016), the first step forming the Magnet Steering Leadership Council (MSLC) comprised of clinical nurses and nurse leaders who began the work of designing the CG structure for the hospital. Once the CG councils were identified (Professional Development Council, Research & Innovation, Healthy Work Environment, Quality & Patient Safety, Professional Practice), clinical nurses were invited to participate on hospital-wide councils and/or unit practice councils (UPCs). The clinical nurse members and nurse leaders developed charters to outline responsibilities, deliverables, and terms of membership complete with annual SMART goals. Communication systems were developed to facilitate information exchange among the UPCs and house-wide councils. Magnet Factoids disseminated electronically familiarized all employees with the work of the councils and Magnet components. Council accomplishments were reported yearly at professional development workshops and featured in the Nursing Annual Report. CG councils were evaluated by clinical nurses and interprofessional participants to identify opportunities for growth.

Methods: After Institutional Review Board approval, the study was conducted in a large metropolitan hospital located in the Southwestern region of the United States. The study used a time series quantitative survey design to test perception changes of CG over 5 years. The hypotheses were: (1) nurses will improve their perceptions of CG over time as a result of their involvement with the CG process in UPCs and hospital-wide councils; and (2) nurses will perceive that CG enhances their professionalism as the CG structure and process matures. The CG Survey was used to measure the nurses' perceptions of CG. The 39-item instrument has a reported Cronbach's alpha of .97 and is rated on a 4-point Likert scale from 4 (strongly agree) to 1 (strongly disagree). The instrument has three subscales – understanding CG; Commitment of the organization to CG; and personal perceptions of CG. Data was collected each May-June since 2012 and analyzed with SPSSv23.

Results: A total of 562 nurses responded over the 5 years (Y) (n = 131, Y1; n = 181, 2; n = 121, Y3; n = 84, Y4; and n = 45, Y5). While mean (M) ages differed slightly over the 5 years, there were no significant differences in mean ages (M = 42 years combined), years employed at the hospital (M = 12 years), work status, ethnicity or highest degree earned. There were significant differences ($p = .000$) in nurses' perceptions for the total CG scale score (Y1 M = 2.82 to Y5 M = 3.96) and the three subscales – perception (Y1 M = 2.91 to Y5 M = 3.86); knowledge (Y1 M = 2.79 to Y5 M = 3.98), and commitment (Y1 M = 2.80 to Y5 M = 3.99) from year to year (only Y1 and Y5 reported here). Nurses reported that CG enhanced the level of professionalism among nurses (M = 3.97) and among all staff (M = 3.8).

Conclusions: Although the generalizability of the study is limited since it is a single site study, the results indicate a CG structure and process does enhance nurses' perceptions of CG over time as the structure matures and contributes to nurses' perceptions of enhanced levels of professionalism. This study provides new knowledge about the importance of measuring the effect of CG structures over time on nurses' perceptions, knowledge and commitment to CG. The study has global implications for nursing, since collaborative structures and processes that facilitate nurses' decision making at the point of care have promise to improve patient outcomes and contribute to job satisfaction and retention among nurses.

D 12 - Nursing Governance

The Theory of Psychological Ownership: Measurement and Uses in Nurse Work Environment Research

Lori M. Schirle, PhD, CRNA, USA

Abstract

Purpose: Research suggests nurse work environment is a critical component of good nursing care leading to better job satisfaction, lower burnout, less turnover, and improved patient morbidity and mortality (Kutney-Lee et al., 2015). Work structures and processes that increase control, empowerment, autonomy, decision making, good working relations, and supportive leadership are identified as crucial to these outcomes (Aiken et al., 2012). As pervasive as these concepts are in nursing research, recent systematic reviews find inconclusive effects of nurse work environment on both patient and nurse outcomes (Bae, 2011; Dariel, Petit, & Regnaud, 2015; Lu, Barriball, Zhang, & While, 2012). Critical analysis suggests that a bivariate approach to such a complex situation may be too simplistic, and causal mechanisms such as moderators that play a key role in the relationship should be considered (Bae, 2011; Norman, 2013).

Psychological Ownership is a concept that describes how work environment psychologically influences the worker, and may provide a mechanism for this connection. The Theory of Psychological Ownership identifies three routes to the development of feelings of psychological ownership: Control, Intimate Knowledge, and Investment of Self (Pierce & Jussila, 2011). Only one route is needed to develop feelings of ownership for a target. Organizations provide opportunities for job ownership through the way work is structured and the degree to which employees control their work. Psychological ownership links the employee to the organization or job, leading to a heightened sense of responsibility for work outputs. Positive effects of psychological ownership include increased commitment, job satisfaction, organization-based self-esteem, work engagement, lower burnout, and increased intent to stay (Dawkins, Tian, Newman, & Martin, 2015)

Although related concepts have been researched in the context of work environment such as organizational commitment, job satisfaction, and organizational identification, psychological ownership is the *only* construct focused on the sense of ownership (Pierce & Jussila, 2011). Ownership is a primitive concept that may influence behavior and reasoning in many domains (Friedman & Ross, 2011). Employees with heightened psychological ownership exhibit an enhanced sense of responsibility for the target of the ownership (Dawkins et al., 2015). Accordingly, facilitating nurse psychological ownership through work environment manipulation could translate into improved care delivery and a heightened sense of responsibility for patient outcomes, providing the missing link between improved nurse work environments and desired outcomes.

Since its inception in the 1990s, the Theory of Psychological Ownership has been employed to study many types of organizations and their employees. Critical constructs in good nursing work environments and those central to the concept of psychological ownership overlap, yet, only two published nursing studies have utilized a tool based on psychological ownership, (Kaur, Sambasivan, & Kumar, 2013; Yoo, Yoo, & Kim, 2012), and none have applied the Theory of Psychological Ownership. Several tools exist to measure psychological ownership, the most-used a 6-item tool that measures the degree of psychological ownership, but not the three routes (Pierce & Jussila, 2011). Recently, a tool was introduced which expanded the original 6-item tool, adding three subscales to include the routes to psychological ownership (Brown, Pierce, & Crossley, 2013). The purposes of this presentation are to 1) introduce The Theory of Psychological Ownership as a tool for nurse work environment research, and 2) describe the use of the expanded measure in a hospital nursing sample.

Methods: A convenience sample of 542 Florida APRNs from 126 different hospital settings responded to an online survey. APRNs were recruited through a public Board of Nursing database, or through their Chief Nursing Officers. APRNs who self-identified as working in hospitals were eligible for participation. The expanded Psychological Ownership questionnaire was a measure included in the survey. This

measure is composed of 21-items and 4 subscales of Control, Intimate Knowledge, Investment of Self, and Psychological Ownership. Items are scored on a 4-point Likert-type scale (*strongly agree, agree, disagree, and strongly disagree*). Reliability and validity tests were performed, and confirmatory factor analysis (CFA) was employed to ascertain the measures' functionality in this sample.

Results: Analyses reveal good measure and subscale reliability with subscale Cronbach α s ranging from .77-.91. CFA model results reveal good fit of the model to the data ($X^2 [393] = 403.185, p=.351, RMSEA = .007$, and $CFI=.998$). Subscale factor loadings were significant and high, with standardized estimates ranging .65 to .94. Eighty-four percent of APRNs reported favorable responses (*strongly agree or agree*) the psychological ownership subscale indicating a strong sense of psychological ownership. Subscale analyses revealed the highest favorable scores on Intimate Knowledge (94%), and Investment of Self (93%), and the lowest favorable scores on Control (59%).

Conclusion: The expanded psychological ownership measure performed well in an advanced practice nursing population indicating the subscales of the measure functioned as intended. This is not surprising given the overlapping fundamental constructs in psychological ownership and good nursing practice environments. Percentage of favorable responses in the control subscale were low in comparison with other subscales, suggesting that although overall perceptions of psychological ownership are high in this population, it primarily develops through intimate knowledge of and investment of self into one's job, rather than through control. This is in contrast to findings in other professions studied (Pierce & Jussila, 2011). Hospitals are organizations known for bureaucratic, hierarchical power structures with less favorable practice environments for APRNs (Poghosyan et al., 2015). Control, empowerment, and decision making are interwoven organizational structures that impact the development of psychological ownership (Pierce & Jussila, 2011), therefore it is predictable that the route of control may be less consequential to hospital APRNs' overall psychological ownership scores.

The Theory of Psychological Ownership is a contemporary idea with substantive applications for nursing work environment research. Experts recognize the importance of nurse work environment, but are calling for targeted research that can lead to interventions to improve patient and nurse outcomes. Evidence suggests fostering psychological ownership for one's job improves employee/organizational performance and outcomes in other fields. Exploration of Psychological Ownership as a mechanism for improved outcomes, and organizational interventions to increase psychological ownership of nurses has great potential to meet the global goal of improved healthcare quality.

Preventing Heart Failure Readmissions By Using a Risk-Stratification Tool

Anna Dermenchyan, MSN, RN, CCRN-K, USA

Abstract

Purpose: To implement strategies to improve care and patients' experience and reduce readmissions for heart failure (HF) patients, Ronald Reagan UCLA Medical Center accepted an invitation from the American College of Cardiology (ACC) to join the Patient Navigator Program (PNP). The goal for the program is for hospitals to establish a patient-centered focus that involves making hospitalization less stressful for patients by providing evidence-based quality improvement strategies. At the initiation of the program (Spring 2014), UCLA utilized a validated risk model, LACE index, to identify patients who are at high risk of readmissions before discharge. This tool has been used to predict the risk of unplanned readmissions as well as mortality within 30 days of hospital discharge in both medical and surgical patients.

Methods: The LACE Index tool is used to identify patients who would benefit from specific interventions. The score is calculated in the electronic health record (EHR) for each patient from 0 to 19 on the basis of all the following parameters: length of stay (L), acuity of admission (A), comorbidity (C), and emergency department visits in the preceding 6 months (E). Based on the LACE criteria, a low (0–6), medium (7–10) or high (≥ 11), each score has an identified bundled intervention for each level of risk (Table 1). For example, a HF patient with a low risk score of 6 would receive medication reconciliation from the pharmacist, an updated medication list from the nurse, and a standardized discharge summary from the discharging physician, as well as a follow-up appointment within 5 days. In contrast, a HF patient with a high risk score of 14 would receive the same interventions plus consultations by a physical therapist, a social worker, a case manager, and a dietician; one-to-one medication teaching by the pharmacist; and a follow-up appointment within 3 days.

Results: The LACE Index score is now calculated in the EHR for all patients. Currently, HF patients receive bundled interventions 80% of the time on the cardiac wards. Since the initiation of the risk score, 30-day unadjusted readmission rates for HF patients at UCLA have decreased from 19% (baseline) to 16.7% (2016, Q2) as compared to the Navigator hospitals 19.2% (baseline) to 17.9% (2016, Q2). In the area of patient experience related to patients' understanding of medications, UCLA is consistently higher than other Navigator hospitals (100% vs. 72.2%) and has identified and shared best practices during the monthly webinars. In addition, UCLA has increased the number of HF patients consistently receiving a follow-up appointment within 7 days after discharge: baseline of 76.6% to 87.5% (2016, Q2).

Conclusion: There are numerous factors that cause hospital readmissions. By using a risk model, UCLA is able to identify patients who would benefit from specific evidence-based interventions. This has improved outcomes in 30-day unadjusted readmission rates and patient experience.

Table 1. LACE Risk Stratification Score and Bundled Interventions at Ronald Reagan UCLA Medical Center

Intervention Needed and Responsible Provider	LACE Risk Stratification Score & Bundled Interventions		
	Low (0–6)	Med (7–10)	High (≥ 11)
Standardized D/C summary (after-visit summary)	X	X	X
Medication reconciliation (MD/pharmacist)	X	X	X
Update medication list (RN)	X	X	X
Physical therapy consultation		X	X
Pharmacy 1:1 teaching		X	X
Social work (psychosocial issues/complex cases)			X

Care coordination: home health, community-based care transition program (case management)				X
Nutrition 1:1 teaching (dietician)				X
Post hospital follow-up visit with physician (Department of Medicine staff)	≤ 5 days	≤ 5 days	≤ 3	days/Home Health RN

Palliative care (PRN)

Abbreviations: D/C, discharge; LACE, length of stay, acuity of admission, comorbid conditions, and emergency department visits; MD, physician; PRN, as needed; RN, registered nurse.

Demoralization Syndrome Affects Health-Related Quality of Life (HRQOL) in Patients With Heart Failure

Hsing-Mei Chen, PhD, RN, Taiwan

Liang-Miin Tsai, MD, Taiwan

Yun-Han Shie, MSN, RN, Taiwan

Abstract

Purpose: Health-related quality of life (HRQOL) is an important outcome measure for guiding appropriate and effective therapeutic interventions for patients with heart failure (HF). Demoralization syndrome consists of a cluster of emotional symptoms including loss of meaning, dysphoria, disheartenment, helplessness, and sense of failure. Patients with demoralization syndrome may have poor quality of life. To date, information about the relationship between demoralization syndrome and HRQOL in patients with HF, however, is still lacking. Therefore, the purpose of this study was to examine the relationship between demoralization syndrome and HRQOL in patients with HF.

Methods: A cross-sectional correlational research design was employed, and a convenience sample of 120 heart failure participants was recruited from a medical center located in southern Taiwan. Measurements included Demoralization Scale, and Left Ventricular Dysfunction questionnaire. Bivariate analysis and hierarchical multiple regression analysis were carried out to test the relationship between demoralization syndrome and HRQOL.

Results: The mean age was 64.95 (SD 13.67) years with a majority of male (71%), married (80%), unemployed (68%), sufficient financial status (84%), and New York Heart Association (NYHA) Class II (74%). The bivariate analyses showed that HRQOL was significantly associated with age ($r = 0.22, p < 0.05$), education ($F = 3.08, p < 0.05$), employment status ($F=6.08, p<0.001$), NYHA Class ($t = -3.80, p < 0.001$), and all demoralization domains and total score ($r = 0.26, p < 0.01$ to $r = 0.53, p < 0.001$). A two-step hierarchical multiple regression analysis showed that the significant determinants of HRQOL were age ($\beta = 0.24, CI = 0.04-0.22$), financial status ($\beta = -0.29, CI = -8.62- -2.05$), NYHA Class ($0.17, CI = 0.13- 5.44$), demoralization-disheartenment ($\beta = 0.40, CI = 0.33-1.16$), and demoralization-sense of failure ($\beta = 0.21, CI = 0.06-0.41$). The total model explained 40.2% of the variance in HRQOL, with demoralization domains accounting for 12.1% of the variance.

Conclusion: HF participants who were elderly, had poor financial status, identified as NYHA Class III and IV, reported higher disheartenment, and perceived greater sense of failure experienced poor HRQOL. The study suggests demoralization syndrome is common in patients with HF and should be early identified to maintain HRQOL of the patients.

Partnering With Community Health Workers and Faith-Based Organizations to Provide Hypertension Management in Haiti

Cynthia G. Cortes, DrPH, MSN, RN, CPNP-PC, COI, USA

Abstract

Purpose: The purpose of the program was for U.S. based healthcare providers to manage Haitian patients' hypertension through bimonthly clinics and community health workers to monitor blood pressures weekly. Approximately 27% of Haitian adults have raised blood pressures; cardiovascular diseases account for 24% of the total deaths in Haiti and stroke is the leading cause of death (WHO,2012). Community health workers (CHW) have been effective globally in multiple education activities. In Haiti, CHW have been instrumental in providing education on cholera prevention and control (CDC, n.d.) as well as education and preventive services to people with HIV.

Methods: Potential health promoters were recruited from churches to receive training in general health promotion and disease prevention, basic anatomy and physiology of the circulatory system, proper techniques for assessing blood pressure, documentation of blood pressure, and when to refer those with elevated blood pressure for additional assessment and hypertension management. Stethoscopes and blood pressure cuffs were provided to the health promoters who passed their blood pressure validation. The education was provided by a nurse practitioner with vast experience in delivering health care in developing countries.

A general medical clinic was conducted in the West Region of Haiti by U.S. healthcare providers and persons with systolic blood pressures over 140 mm/Hg and diastolic blood pressures over 90 mm/Hg were eligible to participate in an ongoing hypertension management clinic. Patients were given a sufficient quantity of medication to last until their scheduled appointment at the hypertension management clinic approximately 2 months from the initial date of service. Guidelines for prescribing anti-hypertensive medication were evidenced based and developed in collaboration with a nephrologist based on drug effectiveness in the Haitian population and not requiring electrolyte monitoring (Roehm, 2010; Weber et al., 2014).

Results: At the general medical clinic 115 patients were started on medication to treat hypertension. At the first follow-up clinic 22 patients returned; 10 of the 22 returned for the second follow-up; and 7 of the 10 patients were also seen at the third follow-up clinic. Amlodipine and hydrochlorothiazide were the primary medications prescribed. Of the 31 patients seen at least twice, blood pressures were controlled for 10 patients.

Conclusion: Additional strategies need to be developed to promote lifestyle modifications to decrease the risk for hypertension, increase adequate blood pressure monitoring, and increase medication adherence in the Haitian population. Nurse practitioners are prepared to provide both training for CHW and hypertension management for patients.

D 15 - Clinical Competency Progression Evolution of Expertise Among Critical Care Nurses

Teresa Welch, EdD, NEA-BC, USA

Abstract

Purpose: Nurses are highly skilled educated professionals who are called upon every day to incorporate accurate clinical assessment skills; decisive critical thinking and judgment skills in a dynamic, oftentimes emotionally charged situation to effectively manage multiple patients with complex emotional and medical conditions. The nurses' role is highly complex and demanding as they maintain a constant vigil at the patient's bedside twenty-four hours a day, seven days a week to ensure optimal healthcare outcomes. Through this vigil, those patient outcomes will be directly impacted by the expertise and care of the bedside nurse. According to the literature, development of expertise is directly correlated with three fundamental requirements: a) a tremendous amount of dedicated work, b) time, and c) relevant experience. Experts in most domains attain their highest level of performance after 10,000 hours of dedicated practice (Weiss & Shanteau, 2014). This is equivalent to ten years of dedicated and relevant experience within the expert's respective domain. Within the domain of critical care nursing the skill level of the bedside nurse has been directly correlated with quality patient outcomes, greater reimbursements, and decreased operational costs. This presentation represents a study that was designed to explore the emic perspective of the critical care nurse as it relates to expertise, expert performance and the critical care nurses journey in the achievement of expert performance.

Methods: This study used a grounded theory qualitative methodology. Data was collected through in-depth participant interviews with open-ended questions. Benner's (1982, 2011) seminal model of skill acquisition, Novice to Expert, provided the theoretical structure and framework guiding the development of participant inclusion/ exclusion criteria and data collection. However, as expertise was considered within the dynamic critical care environment, Ericsson and Smith's (1991, 2010) expert performance approach was used to strengthen Benner's Novice to Expert Model providing valuable structure and insight into the concept of expertise (Causar, Barach & Williams, 2014). As themes were identified the expert performance approach provided valuable evaluative strategies to facilitate understanding of expert nuances and processes within critical care practice.

The purpose of this study was to examine and explore the critical care nurse's personal perceptions of expertise, expert performance and the transition from novice to expert in clinical practice. The study addressed the following questions:

- a) How would you define the expert nurse in clinical practice in critical care?
- b) What criteria or characteristics would you use to define expert performance in clinical practice in the critical care unit?
- c) How does one become an expert in critical care?
- d) In your experience what factors have supported or hindered your professional development?

Results: Study findings supported three major themes: a) experience with sub-themes diversity and intensity; b) knowledge with the sub-theme critical reasoning; and c) self-actualization with sub-themes personal presence, and life-long learning. Furthermore, data findings supported the researcher's assertion that "tacit" knowledge is a more appropriate term to represent the requisite knowledge base and diversity of experience demonstrated by nurses in actual clinical practice rather than the term "intuitive grasp" as found in current literature.

Conclusion: The research findings of this study hold significance for nurse educators and professional nurse leaders alike who are in a position to foster professional development and clinical expertise for young nurses entering the nursing profession. Future implications for research would need to focus on understanding and adding to the body of knowledge as it relates to the influence of the individual, personal presence and further refinement of the understanding of the expert and expert thinking on the unconscious or automatic plan.

D 15 - Clinical Competency Progression

State of the Science on Clinical Evaluation of Competence in Nursing Education

Elizabeth Van Horn, PhD, RN, CNE, USA

Lynne Porter Lewallen, PhD, RN, CNE, ANEF, USA

Abstract

Purpose: This presentation will describe the state of the science on clinical evaluation of competence in nursing education and address issues related to instrumentation and methods used in clinical evaluation globally.

Methods: A NLN-funded research synthesis was conducted to identify published research and dissertations on clinical evaluation of nursing students. Cooper's (2010) method of conducting a research synthesis was used to guide the study. Search methods included literature searches of nursing, educational, and health sciences databases; dissertation abstracts; review of table of contents of 7 leading nursing education journals from 2005-2015; and review of the reference lists of 6 review articles on clinical evaluation (e.g. Cant, McKenna, & Cooper, 2013). The full search resulted in 177 articles, of which 77 met the study criteria related to research on clinical evaluation of nursing students. From these, a total of 30 studies focused on clinical evaluation of competence, which was defined as the measurement or evaluation of competence in general or in a specific area. Data analyses included creation of a matrix for comparison of study data and narrative synthesis of study data.

Results: The 30 studies were published between the years 1988-2015 and used quantitative (n = 26), qualitative (n = 1), and mixed methods (n = 3). The studies were conducted in eight different countries including Australia, Finland, Ireland, Sweden, Taiwan, Turkey, the United Kingdom, and the United States, providing information useful for evaluating diverse populations of students in various clinical settings including international venues.

The majority of the studies aimed to measure global competence at the end of a nursing program. Studies frequently measured student progress over time with pre and post-measures administered before and after an entire program, semester, clinical rotation, or specific event, such as a summer precepted experience. Seven studies focused on competence in a specific area including medication calculation (Macdonald, Weeks, & Mosely, 2013), vaccinations (Nikula, Puukka, & Leino-Kilpi, 2012), critical thinking (Pitt, Powis, Levett-Jones, & Hunter, 2015), psychiatric nursing skills (Glass & Ward, 2008), culturally specific care (Jeffreys & Dogan, 2013), and interpersonal communication (Klakovich & Cruz, 2006).

Most of the studies (n = 21) used researcher-developed instruments, and some also conducted psychometric testing of the study instrument (e.g. Hsu & Hsieh, 2013). Data for analyses included student-self reports (Kajander-Unkuri et al., 2014), faculty or preceptor evaluations of student performance (Cassidy et al., 2012). Many studies examined comparisons among these types of evaluations, while others compared either specific exam scores or grades in didactic courses with the clinical measures. A majority of the studies used descriptive, correlational, or comparative methods, and were classified as levels 4 or 6 according to Melnyk and Fineout-Overhalt's (2011) levels of evidence.

Conclusion: Clinical evaluation in nursing education has been an ongoing area of educational research for decades and includes evaluation of competence in specific skills or nursing practice specialty areas, and in general competence. Despite the use of standardized licensing exams for entry into practice in many countries globally, a review of the research literature reveals clinical evaluation of competence lacks standardization of measures or methods, and a lack of replication of studies and instrument testing to build the science of nursing education related to evaluation of clinical competence. The common use of student self-evaluation and researcher-created measures is problematic for determining reliability and validity of instruments and comparison of findings across studies. The use of predominately descriptive research decreases the ability to use the research findings as evidence to guide nursing faculty in clinical evaluation methods. Imperative areas for future research and practice are the need to accurately and efficiently measure competence in the clinical area, the need for reliable and valid instruments, and the

elevation of nursing research rigor in clinical evaluation of competence to include quasi-experimental and experimental research methods.

D 15 - Clinical Competency Progression Rochester Nursing Competence (RNC) Theory

Yu-Ching Chuang, MS, RN, USA
Marie A. Flannery, PhD, RN, AOCN, USA
Mary G. Carey, PhD, RN, FAHA, FAAN, USA

Abstract

Purpose: Nursing competence is a critical factor that is directly related to improved and positive patient outcomes. A major proposition in Benner's from novice to expert model (Benner, 2001), competence is a continuous process of acquiring knowledge, skills, and experience. Although Benner's model has made many significant contributions, it's time to advance the model to a new theory. One major challenge is that nursing competence does not always increase in a linear fashion. Building on the work of Benner, this abstract describes a new theory, Rochester Nursing Competence (RNC) that examines the relationship between nursing competence during the course of a career and patient outcomes.

Methods: The RNC theory, adapted from Raymond Vernon's product life cycle theory (1966), as derived using Walker & Avant's theory derivation strategies. Five steps were followed for the development of theory: 1) To become familiar with the topics related to nursing competence and patient outcome in the nursing literature by critically appraising studies published in the English language between 1980 to 2016; 2) To study widely in nursing and economic disciplines to determine the appropriateness of the derivation; 3) To select the product life cycle theory as a parent theory for derivation and exam similarity, and discrepancy between the parent and new theory, RNC; 4) To identify and modify the structure and statements of parent theory in the development of RNC theory; Finally, 5) to redefine new concepts and statements in forming RNC theory.

Results: RNC theory presents a dynamic trajectory plotting a relationship between the two concepts of nursing competence and patient outcomes. Patient outcomes, on the y-axis ranging from low to high, reflect the effect of clinical nursing care and are driven by nursing competence. A higher level of patient outcomes refers to the patient with a higher quality of care and vice versa. Nursing competence, on the x-axis, refers to an increasing clinical capability over time in coping with various clinical situations by integrating knowledge, skills, and experience. Four stages of nursing competence reflect in a nurse's lifelong career: the beginning, growth, maturation, and declination. Theoretically, increased nursing competence contributes to better patient outcomes in clinical practice and vice versa. In RNC theory, nursing competence, which is varied over the course of an individual's career, enhances over time but may also plateau or decline after reaching the maturation stage. The plateau or decline results in a stagnant or decreasing effect on patient outcomes. RNC includes three proposed strategies, which are at three levels: individual, hospital system, and environment. These three strategies act as moderators to prevent or minimize any decline in nursing competence. In addition, three strategies are layered from inner to outer influencing each other.

Conclusion: Understanding the trajectory of nursing competence is important for examining patient outcomes in clinical care. RNC theory proposes a pragmatic relation between nursing competence and patient outcomes and includes a career-long trajectory of nursing. RNC theory offers a practical framework for future studies of nursing competence as it evolves over time in clinical practice.

E 06 - Factors Influencing Patient Care for the Advanced Practice Registered Nurse

Development Trajectory of a Fall Detection Device Involving Community-Dwelling Older People

Friederike J. S. Thilo, MScN, RN, Switzerland
Jos M. G. A. Schols, PhD, MD, Netherlands
Ruud J. G. Halfens, PhD, Netherlands
Sabine Hahn, PhD, MSNc, RN, CNS, Switzerland

Abstract

Purpose: The aim of the study was to explore and consider the needs, requirements, feasibility and usability aspects of daily life from the perspective of community-dwelling older people, by involving them interactively in the development of a wearable fall detection sensor, including its smartphone application.

Methods: A qualitative descriptive study was chosen. Community-dwelling older people, 75 years and older, were involved in two stages of device development using the theoretical framework of Shah et al. (2009). They were involved in the device design and mock-up evaluation stage and in the real field prototype testing stage of the fall detection device. In the first stage, the needs and requirements of the participants regarding the mock-up (not functional prototype) were explored using focus group interviews. Based on those findings the fall detection prototype was developed. One year later, participants tested its feasibility and usability for nine days in daily life, and participated in a focus group interview. Data was analysed using content analysis with the application of deductive coding.

Results: 22 participants took part in the device design and mock-up evaluation, and 15 participants tested the fall detection prototype for nine days in their daily life. The average age was 80.7 years.

The 24 hour wearing comfort of the lightweight, waterproof, body-worn sensor was high. The automatic alerting process in case of a fall met the needs of the participants. The manual alerting option was useful, as other emergency situations might occur. It was recommended that blinking lights be added in order to locate the sensor more easily. However, the smartphone did not adequately meet the needs of the participants due to: high battery consumption; difficulties using the touch-screen; and limited range between smartphone and sensor of eight to ten meters which was considered as limiting activities in daily life. In general, the smartphone application satisfied the requirements of participants as it was easy to manipulate, false alerts could be manually stopped and the design and acoustics were pleasant.

Having several contact persons in case of an alert was required by the participants. It was emphasized that at least one health professional should be included in order to verify a reply in case of an alert, which would increase the feeling of security. Utilizing relatives, friends or neighbours as contacts may lead to the feeling of being a bother, which may be a barrier for use of a fall detection device. Additionally, the participants highlighted that they would prefer more coaching and training in using this fall detection device.

The added value of user involvement was amongst others that it enabled the focus to remain on the most needed aspects from the perspective of users, instead of focusing solely on the technological aspects. The challenges of user involvement were the establishment of a shared language with engineers and financial and time resources.

Conclusion: The study demonstrated that older people contribute in a «needs-driven» way, to the development of a fall detection device. Involving users is valuable because it enables researchers to go beyond factors related to the technology itself, by identifying barriers and facilitators in the daily use of fall detection devices. It is important that nurses are aware of and familiar with new technologies, since they have a key role in instructing and supporting patients in their use.

E 07 - Global Health Equity

Half the Sky: Use of Literature to Teach Undergraduate Nursing Students About Global Health Equity

Jane Greene-Ryan, PhD, CNM, USA

Jane Donovan, MSN, USA

Abstract

Purpose: This presentation describes qualitative findings from a global health assignment which we have used with undergraduate maternal child nursing students for the past ten years. We developed this assignment as a way to encourage students to reflect upon literature as well as current evidence when considering the needs of vulnerable populations of migrant women whom they are likely to encounter in their clinical practice. Our university is situated with a distinctly urban setting in the northeastern United States. Our diverse but inherently financially privileged student body is situated within an inner city where many residents live far below the poverty line. Upon graduation our students are expected to be able to provide care which takes into consideration a patient and family's psychosocial needs including how those factors influence health-related decisions. One example is the strong likelihood of encountering migrant women who are being trafficked when they seek care in our local emergency rooms. Thus, this assignment grew out of a desire to expose our students to experiences which are vastly different from those typically experienced in their own lives in a way which was compelling, relevant and safe.

For this assignment students are required to read two chapters from *Half the Sky: Turning Oppression into Opportunity for Women Worldwide* (Kristoff & WuDonn, 2009) and write a two page reflective essay describing what they felt what they learned about maternal child health as well as the assignment. They are asked to identify one compelling aspect of global women's health, review an evidence-based article addressing that health concern and synthesize the reading from *Half the Sky* with current nursing science.

Methods: Qualitative data analysis of ten years of student reflective journals.

Results: Three themes emerged from the students reflective journals:

Overcoming Resistance: Students discussed their reluctance to take the time to read *Half the Sky* which they felt wasn't relevant to this clinical course. They expressed feeling overwhelmed with the requirements of this high-stakes clinical course which they are taking in conjunction with other similarly challenging clinical courses and were thus unsure how this assignment would help them study for and pass their exams. In short, they didn't feel that it was relevant.

Growth of Compassion: Students expressed deep sadness at the situations endured by women in other parts of the world. Realizing that these same women could easily be part of patients for whom they would soon be assuming care was frightening particularly as they came to realize that the women might well be presenting to the emergency rooms with other related symptoms such as sexually transmitted illnesses or symptoms of physical and sexual assault.

Call to Commitment: Being asked to find and review an article describing the current nursing science of care for this vulnerable population reinforced their understanding of the prevalence of this population. They reported feeling a renewed commitment to provide compassionate, evidence-based care when encountering women (and children) who were at increased risk.

Conclusion: Students completing this assignment reported increased understanding of the needs of vulnerable populations of women. Some students expressed interest in working in global health, others told of increased understanding that this population of patients can be encountered wherever care is provided.

E 07 - Global Health Equity

Human Trafficking: A Call for Inclusion in Nurse Practitioner (NP) Education

Rebecca M. Lutz, MSN, ARNP, FNP-BC, PPCNP-BC, USA

Abstract

Purpose: Human trafficking has increased worldwide. Nurse practitioners practice in a variety of clinical settings and may encounter trafficking victims within their clinical practice. Therefore, it is essential nurse practitioners have the ability to identify and assist trafficking victims. However, human trafficking is not fully integrated into nurse practitioner curriculum. In addition, a lack of evidence exists regarding best practice for curriculum content to increase knowledge of trafficking. This project assessed family and pediatric nurse practitioner knowledge of human trafficking in six primary areas: (1) definitions, (2) laws, (3) prevalence, (4) identification, (5) treatment, and (6) community resources.

Methods: A one-hour educational intervention focused on each of the six primary areas. The intervention was designed for family and pediatric nurse practitioner students enrolled at a large university. The intervention included a lecture driven by the use of power points, videos, and discussion. Measurement of student knowledge of trafficking was assessed through the use of pre- and post-surveys. Each survey consisted of six Likert-style items measured on a 6-24 point scale. Demographic data collected on all participants included age, gender, years of experience, and previous exposure to trafficking education.

Results: Student participants (n=73) completed the demographic and pre-survey. Post-survey tool completion fell slightly (n=69). Demographic data revealed participants included more female students (n=64, 87.7%) compared to male students (n=7, 9.6%). A small number of participants did not identify gender preference (n=2, 2.7%). Participants ranged in age between 20 and 59 years of age. Years of nursing experience ranged between 0 and 25 years. Overwhelmingly, most students reported they had never received formalized education on human trafficking (n=69, 94.5%) or education on the treatment of human trafficking victims (n=73, 100%).

Following the intervention, a t-test analysis provided insight into increases in knowledge. All survey questions demonstrated increases in knowledge with t-test outcomes ranging from 11.85 to 20.78 with $p < .05$. Three survey questions demonstrated the greatest increase in participants' knowledge: (1) knowledge of laws regarding human trafficking; (2) ability to identifying victims of human trafficking; and (3) knowledge of community and social service resources for victims of human trafficking.

Conclusion: A gap was identified in family and pediatric nurse practitioner students' knowledge of human trafficking. An educational intervention increased student's knowledge of human trafficking. Inclusion of trafficking into nurse practitioner curricula increases the number of providers with knowledge to positively impact health outcomes of the victims.

E 08 - Cancer Screening Practices

Addressing Breast, Cervical, and Colorectal Cancer Screening-Related Health Disparities and Practices in Asian-Indio Women

Sharon K. Byrne, DrNP, APN, NP-C, AOCNP, CNE, USA
Evelyn Robles-Rodriguez, MSN, RN, APN, AOCN, USA
Yogini Patel, BA, USA

Abstract

Purpose: This retrospective research project reviews outcomes resultant from the delivery of cancer screening services to women living in the U. S. from an Asian-Indio background within a clinic setting.

According to the National Action Plan for Cancer Survivorship, culturally competent patient education and care is a priority (2015). The Cancer Outreach Project at MD Anderson Cancer Center Cooper provides culturally and linguistically appropriate cancer education and screening to underserved Asian-Indio women through the use of a dedicated outreach worker and Nurse Practitioner run clinic. A collaborative relationship was established in 2007 between the Cancer Outreach Project and National Indio Cooperative Enterprises, Inc. (NICE), a non-profit organization dedicated to service of the Indian community in Southern New Jersey, U.S. The Cancer Outreach Project provides health promotion and disease prevention activities that specifically focus on cancer education and screening to women rarely or never before seen for women's healthcare due to their culturally diverse health beliefs and practices. Specifically, within the Asian-Indio population, these beliefs and practices have been influenced by both the Ayurveda medical system and the Hindu religion (Gordon, Bernadett, Evans, Sharpiro and Patel, 2016).

In order to reach women that were not getting screened for cancer, a dedicated clinic within a suburban medical oncology out-patient setting was established. A Nurse Practitioner (NP) and Outreach Worker/Lay Navigator have worked in tandem one day a month in the clinic setting providing screening and follow-up over a 9 year time frame to Asian-Indio women. Clinical breast examination (CBE), screening and or diagnostic mammography based on the result of the CBE, Pap smear and pelvic exam, immunochemical fecal occult blood testing and referral for colonoscopy as per American Cancer Society (ACS) guidelines related to patient age and risk factors are provided (ACS, 2016). Those with abnormal findings were referred for diagnostic services at no cost through grants from the New Jersey Cancer Early Education and Diagnosis Program (NJCEED) or Susan G. Komen for the Cure. The Program also made referrals to the New Jersey Charity Care Program, MD Anderson at Cooper's Comprehensive Breast Center, Cooper's Women's Care Center and/or Department of Gastroenterology.

Methods: IRB approval was obtained to conduct a retrospective chart review so that outcome of the program could be compiled and reviewed. Data analysis consisted of descriptive statistics and regression analysis.

Results: From its inception in 2007 through June 30, 2016, slightly over 750 Indian women with a mean age of 47.5 years have been educated through the programs outreach activities at Temples and through home health parties (Byrne & Robles-Rodriguez, 2009) provided by a dedicated Outreach Worker/Lay Navigator with close ties to the community. Approximately one-third of this population (n= 249) with a median age of 53 years has participated in both initial and continued cancer screening clinics. Outcomes included six cancers have been diagnosed through the program; (1) DCIS, (1) LICIS, (1) Stage I breast cancer, (1) Stage III breast cancer, (1) cervical cancer and (1) endometrial cancer. Further data will be discussed in detail.

Conclusion: Identification of facilitators and barriers related to participation in cancer screening within the Asian Indio female population has implications for practice. Strategies such as identification of and collaboration with key stakeholders in the Asian-Indio community, obtaining funding for a lay navigator and coordination of a dedicated clinic and culturally tailored program are noted to influence initial and on-going early detection behaviors. The sharing of lessons learned from this research may benefit other

healthcare providers interested in developing sustainable cancer screening services for this select population.

E 08 - Cancer Screening Practices

Knowledge, Attitude, and Practice of Men Towards Colorectal Cancer (CRC) and Its Prevention in Tobago

Esther Shirley Daniel, PhD, RN, RM, Trinidad and Tobago

Annette Dick, MSc (Nsg), RN, Trinidad and Tobago

Gloria Ramdeen Mootoo, MSc (ClinPsy), RN, RM, Trinidad and Tobago

Abstract

Purpose: In Trinidad and Tobago, colorectal cancer is the second leading cause of death from cancer; therefore attempts must be made to decrease this rate with the use of prevention and screening which is still the best methods according to research done to fight this disease. The purpose of the study was to explore the knowledge, attitudes, and practice of men towards CRC and its prevention in Tobago.

Methods: A descriptive, quantitative and cross-sectional study. Colorectal is a prevalent condition that can be identified and definitively treated during an asymptomatic phase, thereby preventing the morbidity and mortality associated with the unscreened clinical course of the disease (Taha et al; 2015; Rogers et al; 2014; Tam et al; 2011;). Varied literature on colorectal cancer and its effects was reviewed. Limited knowledge about the importance of colorectal screening and the methods used which includes colonoscopy and faecal occult blood test (FOBT) was identified as major issues as it relates to the person accessing CRC screening (Mullira et al; 2016; Ghahramani et al; 2015; Şahin et al; 2015; Andriole et al; 2012; Salimzadeh et al; 2012;) there was no relationship between gender, health insurance status, family history of individuals and their knowledge about CRC (Bidouei et al; 2014; this was a similarity also found in the present study. Fear as it relates to a positive screening test result, failure of physicians to recommend screening, scheduling difficulties, cost, lack of insurance coverage, gaps in knowledge, embarrassment, pain, aversion, lack of symptoms, and perceived low risk was identified as a reason for the limited uptake (Gordon et al; 2015; McClellan et al., (2015), Vrinten et al; 2014; Wong et al; 2013;).

Person perception about the need for screening was also identified the most cited reasons for not having screening tests was "did not have any symptoms or problem" and "did not think it was needed" "never think of the test," "doctor did not recommend the test," (Bidouei et al; 2014; Salimzadeh et al; 2012 ;).

It was found that there is a common thread throughout the literature: that colorectal cancer is a preventable disease and there are screening options, which if accessed, can help to drastically reduce the number of persons affected by this disease (Tsai; 2015; Lasser et al; 2011; Winterich et al; 2011;). Each individual is responsible for his or her health and wellbeing and CRC can be prevented by the modification of one's lifestyle. This includes changes in diet: increase in fibre intake; decrease in consumption of fatty and processed food; cessation of smoking and alcohol use; and early screening for persons who are at increased risk due to family history(Wutayd et al; 2015 ; Wong et al; 2013;)

Education and teaching initiatives developed with the target audience in mind both individual and healthcare professionals, that focuses on educating the public about how to reduce their risk of contracting this non-communicable disease, in my opinion, is the way forward and was also recommended in a study done by (Barros et al; 2014; Souza et al 2012; Ravichandran et al; 2011).

Target Population for the study included men aged between 19-45 years of age, who are residing in Tobago. An estimated sample of 200 men residing in Tobago was the sample size. The subject was chosen by non-random sampling method called convenient sampling or volunteer sampling. The subjects in the convenient sample were volunteers who were readily accessible to the nurse researcher. A cross-sectional study was conducted in Tobago with 200 male participants ranging from ages 19-45 years old, males who visit the mall/ shopping centre and residents of Tobago. Data was collected using an in-depth self-administered KAP questionnaire. Participants' demographic characteristics assessed in Section A.

Section B of the questionnaire consisted of 30 items, which identified the knowledge and practice of colorectal cancer among the respondent. With response option and points given for UNSURE =3 points,

TRUE= 2 points, FALSE = 1 point. This was then divided into four subsection (i) knowledge of colorectal cancer questions, (ii) Colorectal symptoms, (iii) Colorectal risk factors and (iv) Colorectal Screening tests.

Section C had ten statements on attitude towards detection of CRC. It is a 5 point Likert scale ranging from strongly disagree to strongly agree. Strongly agree has a score of 5, agree a score of 4, undecided a score of 3, disagree a score of 2 and strongly disagree a score of 1.

Ethical approval was obtained from UWI Campus Ethics Committee as well as the Public administrative body/ administration of the malls of Tobago to conduct the study and from the study respondents who were willing to participate in the study. Scoring and Interpretation of reliability & validity of the tool was established through test retest method. Data were analyzed using SPSS.

Multivariable statistical methods were applied to identify independent predictors for CRC screening among participants.

Limitations of the study is that it focused on the geographical region of Tobago which may not necessarily be applicable to other Caribbean territories.

Results: Majority of the respondents 185(92.5%) are employed, only 15(7.5%) retired or unemployed. And maximum respondents 179(89.5%) do not have a family history of colorectal cancer. When respondents were asked about whether they participated in any cancer screening in past 2 years, most of them 162(81%) replied that they didn't participated in any such study, only 58(19%) said that they did participated. When they were asked about whether they had colonoscopy in the past, 185(92.5%) said no or they don't know, only 15(7.5%) replied as yes. When respondents were asked about whether they ever done FOBT or bowel cancer screening test, 190(95%) of them responded as no or they don't know, only 10(5%) answered as Yes. When they were asked about whether they know someone in the family has cancer, 135(67.5 %) replied as no and 65(32.5%) replied as yes.

T-values were found significant in the means of knowledge and practice towards colorectal cancer (58.17+26.68) and its symptoms (47.50+26.46) and risk factors (53.50+26.60) and but reinforcement needed on colorectal screening tests, which were much below 50% (21.78+11.57).

Attitude of respondents towards CRC screening among the study respondents revealed the following. When people were asked whether they understand the severity of colorectal cancer, 133(66.5%) said that they understand its severity. Nearly, 128(64%) people replied that they will get themselves tested for colorectal cancer. While 91(45.5 %) said that doctor did not recommended the test for them, while 95(47.5%) respondents thought that the test was not needed for them. Nearly, 116(58%) respondents said that they never thought of the test and 113(56.5%) people think that they do not have any symptoms or problems as of now. Almost half of the respondents 98(49%) have a fear of developing the colorectal cancer. And half of the respondents 61(51.5%) are not sure about the cost of the test. Almost 100(50%) respondents thought if they get colorectal cancer then their career or life will not be over. Majority, 149(74.5%) respondents agreed that screening tests would decrease their chances of dying with colorectal cancer. Hence it can be concluded that respondents had an understand about the severity of colorectal cancer and they had a positive attitude towards the screening test.

Conclusion: Colorectal cancer almost always develops from precancerous polyps (abnormal growths) in the colon or rectum. Screening tests can find precancerous polyps so that they can be removed before they turn into cancer. Screening tests also can find colorectal cancer early, when treatment works best.

As such, the findings of the study are crucial to policy makers and educators, particularly in efforts geared towards holding preventive campaigns highlighting the main cancer risk factors (tobacco, alcohol, diet, physical inactivity, obesity); key socio-demographic factors; and health sector plans, policies and services for cancer. The findings demonstrate that the participants had good attitudes about CRC screening, but their experiences and knowledge regarding CRC screening as it relates to colonoscopy and Faecal occult blood test (FOBT) was inadequate. Culturally sensitive health education messages should be tailored to fulfil the knowledge gap among all population strata.

E 09 - Improving Clinical Outcomes Through Physical Activity Evaluation of an Email-Mediated County Extension-Delivered Walking Intervention

Elizabeth A. Richards, PhD, RN, CHES, USA
Stephanie Woodcox, MPH, CHES, USA

Abstract

Purpose: Even though promotion of physical activity (PA) has been a public health priority for decades, key U.S. public health agencies, such as the Centers for Disease Control and Prevention (CDC), routinely collect data indicating that most Americans are not meeting PA guidelines (Centers for Disease Control and Prevention, 2012a). Physical inactivity is directly related to the prevalence of obesity and the development of many chronic diseases (Centers for Disease Control and Prevention, 2014). Walking is an excellent way for most people to increase their PA and has been declared by the Surgeon General as a powerful public health strategy (U.S. Department of Health and Human Services, 2015). Walking is an easy way to start and maintain a physically active lifestyle because walking is accessible to almost anyone, does not require specific skills or abilities to perform, can be performed alone or with others, and is adaptable (i.e., can be performed at any chosen intensity and is inexpensive) (U.S. Department of Health and Human Services, 2015). Intervention strategies are needed to increase walking across populations.

Internet-mediated PA interventions have the potential to reach a large number of people with lower costs compared to in-person intervention delivery (van den Berg, Schoones, & Vliet Vlieland, 2007). By using e-mail, intervention participants can have flexibility with when and where they choose to interact and receive intervention information (Napolitano & Marcus, 2002). Previous reviews on the effectiveness of internet-mediated PA interventions have indicated e-mail as a promising intervention delivery mode (Marcus, Ciccolo, & Sciamanna, 2009; Marcus, Nigg, Riebe, & Forsyth, 2000; van den Berg et al., 2007).

As one of the nation's largest providers of scientific research-based information and education, the Cooperative Extension System is another established delivery method for health behavior change programs. Traditionally, Extension education programs are offered in group settings. In our region (state?), the current intervention was the first health promotion program to be delivered solely via e-mail. By delivering the intervention through county-based Purdue Extension Educators, it is important to evaluate the program not only in terms of outcomes, but also from the perspective of educators as well as community residents who participated. The purpose of this study is to evaluate the feasibility of delivering this intervention through county-based Extension Educators.

Methods: The Get WalkIN' intervention was primarily based on a previously tested e-mail mediated social cognitive theory-based intervention which demonstrated effectiveness in a small, controlled sample (Richards et al., 2016). Based on this previous success, a team of Extension Educators and the lead researcher tailored the intervention to create Get WalkIN' with the goal of making the intervention suitable for the various populations Extension serves.

In spring 2016, 300 participants were recruited from 12 counties across the state, each of which is served by county-based staff of Purdue Extension. Recruitment methods included newsletters, flyers, and social media. As this is a community-based program, there were no inclusion or exclusion criteria for participation. Intuitional review board approval was granted.

Get WalkIN' consists of a total of 16 e-mails designed to increase walking. Program e-mails to participants by Extension Educators were sent bi-weekly for the first four weeks and then weekly for the next eight weeks. These e-mails targeted principles of self-efficacy, social support, goal-setting, and benefits/barriers to walking.

To assess the perceptions of acceptability of the intervention, participants were asked eight 5-point Likert scale questions (1=strongly disagree; 5=strongly agree). Questions included: the e-mails were easy to

read; the frequency of the e-mails was adequate; and the advice appeared to be credible. Participants were also asked how often he/she read the e-mails and open-ended questions to determine what aspects of the intervention e-mails were helpful, seemed unnecessary, and if they would recommend this intervention to a friend.

The theoretical constructs of self-efficacy and social support were measured using existing measures with demonstrated reliability and validity and adapted to be specific to walking (Sallis, Grossman, Pinski, Patterson, & Nader, 1987; Sallis, Pinski, Grossman, Patterson, & Nader, 1988). Mean scores were computed across all items in each subscale. Self-reported PA was assessed using the Godin Leisure Time PA Questionnaire. Individuals reporting moderate-to-strenuous activity scores ≥ 24 were classified as active and individuals reporting moderate-to-strenuous activity scores ≤ 23 were classified as insufficiently active (Godin & Shephard, 1985).

Descriptive statistics were used to summarize participant characteristics and analyze the feasibility and usability data. Means and standard errors were calculated for continuous variables and frequencies and percentages for categorical variables. Chi-square and two-sample t-tests were used to assess differences between baseline and post-intervention assessments. Data were analyzed using SAS 9.3 (SAS Institute Inc., 2009). Statistical significance was set at $p < 0.05$.

Results: Most participants were non-Hispanic white females with an average age of 54.0 ± 12.7 . On average, participants were classified as obese (average BMI 30.9 ± 8.2) and insufficiently active (52%). Additionally, participants agreed that the intervention e-mails were easy to read (mean=4.3), easy to understand (mean=4.3), frequency of e-mails was adequate (mean=4.3), and that the e-mails helped to increase walking (mean=4.0). Eighty-eight percent of participants reported reading the e-mails quite often or always, while 11% reported sometimes, and 2% reported rarely. While the theoretical constructions of self-efficacy and social support increased post-intervention, mean scores were not significantly different from baseline. Post-intervention, 82% of respondents were classified as sufficiently active compared to 48% pre-intervention ($p < 0.05$).

Conclusion: The novelty of this study is the partnership formed with Purdue Extension for the delivery of this intervention. Leveraging the strong infrastructure that Extension has statewide, it was possible to train county-based Extension Educators for intervention recruitment and delivery. Extension Educators live and work in the counties they serve, thus having strong community relationships, being a familiar face in their county, and trust established. In addition to discussing program evaluation, this presentation will discuss research implications for strengthening ties with and partnering with Cooperative Extension for community-based interventions and health promotion programming.

E 09 - Improving Clinical Outcomes Through Physical Activity

Improving Clinical Outcomes and Physical Activity in Older Adults With Comorbidity: A Randomized Controlled Trial

Elizabeth A. Schlenk, PhD, RN, USA
Susan M. Sereika, PhD, MPH, USA
Joan Rogers, PhD, OTR/L, FAOTA, USA
G. Kelley Fitzgerald, PhD, PT, FAPTA, USA
C. Kent Kwoh, MD, USA

Abstract

Purpose: Over 9 million Americans have osteoarthritis (OA) of the knee, a chronic disorder associated with frequent knee pain and functional limitations that intrude upon everyday life. About half of those with OA of the knee have hypertension (HBP), one of the most prevalent risk factors for cardiovascular disease (Eymard et al., 2015). Persons with OA of the knee experience reductions in blood pressure (BP) when they participate in regular physical activity. Yet, only 13% of persons with OA of the knee (Wallis et al., 2013) and 28% with HBP (Healthy People 2020) meet recommended guidelines for physical activity. Although physical activity is recommended for OA of the knee (Hochberg et al., 2012) and HBP (Eckel et al., 2014), the knee pain and functional limitations associated with OA hinder physical activity and prevent adoption and maintenance of a regular physical activity program. Physical activity interventions can reduce pain and improve physical function in those with OA of the knee (Fransen et al., 2015), but to date no interventions have been tailored to those with OA of the knee and comorbid HBP. Staying Active with Arthritis (STAR) is a randomized controlled trial of an individually delivered, home-based, 6-month lower extremity exercise and fitness walking intervention based on self-efficacy theory with older adults with OA of the knee and HBP. The purposes were to evaluate the effect of the STAR intervention compared to attention control on knee pain, physical function, participation in fitness walking, performance of lower extremity exercise, and BP at immediate post-intervention and at six months after the end of the intervention.

Methods: The STAR group received usual care; 6 weekly individual face-to-face sessions with the physical therapist for evaluation, graduated therapeutic exercises, and progressive fitness walking; 9 bi-weekly telephone sessions with the nurse for ongoing counseling; and daily physical activity e-diary during intervention for self-monitoring. The attention control group received usual care, and 6 weekly and 9 bi-weekly telephone sessions with the nurse on senior health topics. Knee pain and physical function were measured by the Western Ontario and McMaster Universities (WOMAC) Osteoarthritis Index. Self-reported daily minutes of participation in fitness walking and daily minutes of performance of lower extremity exercise (repetitions \times sets/week) were collected by the e-diary with participation in fitness walking also objectively assessed by daily activity minutes from ActiGraph accelerometers [none to very low (0-99 counts), light (100-2,019 counts), and moderate-to-vigorous (\geq 2,020 counts)] (Dunlop et al., 2011). Systolic and diastolic BP were measured by OMRON BP Monitor. Linear mixed modeling was performed to examine the effect of the STAR intervention vs. attention control on these outcomes over time. Standardized mean differences between the treatment groups (d[*between*]) for the change from baseline to immediate post-intervention and to six months after the end of the intervention were computed to summarize the observed treatment effects. As changes within the attention control group over time were negligible, standardized mean differences within the STAR group (d[*within*]) from baseline to immediate post-intervention and to six months after the end of the STAR intervention were also computed.

Results: Participants ($N= 182$) were on average 65 ($SD= 8$, range 50-90) years old, 73% ($n= 133$) female, and 73% ($n= 133$) white. Significant group by time interactions were found for knee pain ($p= 0.015$; d[*between*]= -0.214 at immediate post-intervention; d[*between*]= -0.183 at six months after the end of the intervention) and physical function ($p= 0.016$; d[*between*]= -0.242 at immediate post-intervention; d[*between*]= -0.208 at six months after the end of the intervention). The STAR group reported having significantly less knee pain and better physical function at immediate post-intervention (d[*within*]= -0.265 for knee pain; d[*within*]= -0.293 for physical function) and six months after the end of the intervention

($d_{\text{within}} = -0.194$ for knee pain; $d_{\text{within}} = -0.309$ for physical function) compared to baseline. Significant group by time interactions were also found by the e-diary for mean daily minutes of fitness walking, mean daily minutes of lower extremity exercise, and mean performance of lower extremity exercise (all $p < .0001$). Compared to the attention control group, the STAR group had significantly greater improvement at immediate post-intervention and at six months after the end of the intervention in mean daily minutes of fitness walking ($d_{\text{between}} = 0.737$ at immediate post-intervention; $d_{\text{between}} = 0.467$ at six months after the end of the intervention), mean daily minutes of lower extremity exercise ($d_{\text{between}} = 1.198$ at immediate post-intervention; $d_{\text{between}} = 0.819$ at six months after the end of the intervention), and mean performance of lower extremity exercise ($d_{\text{between}} = 1.732$ at immediate post-intervention; $d_{\text{between}} = 0.812$ at six months after the end of the intervention). Compared to baseline, the STAR group reported significantly more mean daily minutes of fitness walking ($d_{\text{within}} = 1.030$ at immediate post-intervention; $d_{\text{within}} = 0.621$ at six months after the end of the intervention), mean daily minutes of lower extremity exercises ($d_{\text{within}} = 1.110$ at immediate post-intervention; $d_{\text{within}} = 0.788$ at six months after the end of the intervention), and mean performance of lower extremity exercises ($d_{\text{within}} = 1.592$ at immediate post-intervention; $d_{\text{within}} = 0.746$ at six months after the end of the intervention). No significant group by time interactions were found by ActiGraph for the three intensity levels (none to very low, light, and moderate-to-vigorous). No significant group by time interactions were found for systolic and diastolic BP.

Conclusion: The STAR intervention had small effects on improvements in self-reported knee pain and physical function at immediate post-intervention that were maintained at six months after the end of the intervention. The treatment effects on pain and physical function were lower than those reported by Fransen et al. (2015) at immediate post-intervention, but similar to those reported by Fransen et al. (2015) at six months after the end of the intervention. Further, the STAR intervention had large effects on improvements in self-reported participation in fitness walking and performance of lower extremity exercise at immediate post-intervention with slight declines at six months after the end of the intervention. However, improvements in objectively assessed fitness walking and BP were not found. Lack of significant group differences in intensity levels by ActiGraph may be due to the slight increase from 3 to 12 mean daily minutes of fitness walking in the STAR group. Mean daily minutes of lower extremity exercise increased from 1 to 9 in the STAR group, but is not detectable by ActiGraph. While fitness walking reportedly increased, the mean fell short of the goal of 21 mean daily minutes (150 minutes/week), which may have contributed to lack of difference in BP. Enhancements to the STAR intervention, such as addition of significant other support, may further improve outcomes.

E 10 - Care of Moms and Babies

Suctioning of the Neonate on Nasal Continuous Positive Airway Pressure (NCPAP): Building the Evidence

Esther M. Chipps, PhD, MS, BSN, NEA-BC, USA

Michele Ann Sweet, MS, RN, CNS-Neo, USA

Debra Lanton Armbruster, PhD, RN, NNP-BC, CPNP-BC, USA

Alai Tan, PhD, MS, MD, USA

Abstract

Background: Nasal continuous positive airway pressure (NCPAP) has become a first line treatment for infants with respiratory distress in the Neonatal Intensive Care Unit (NICU) (Gupta & Donn, 2016). Nasal continuous positive airway pressure (NCPAP) was first introduced as a modality to improve oxygenation in neonates in 1971 (Gregory, 1971). Since its development, different NCPAP systems have become available with Bubble NCPAP reported to be the most widely used system (Mann, Sweet, Knupp, Buck, & Chipps, 2013). NCPAP has gained support as an alternative method of respiratory support in selected neonates and has been demonstrated to reduce the need for intubation and the incidence of bronchopulmonary dysplasia. However, the successful use of NCPAP is not without risks including nasal injury, and nasal breakdown. Similar risks to endotracheal suctioning are evident as well, including increased risk of infection, bradycardia, laryngospasms, cardiac dysthymias and even cardiac arrest. Registered Nurses (RNs) and Respiratory Therapists (RTs) who care for these neonates require extensive knowledge about the equipment set-up, maintenance and operation of the system.

Guidelines for endotracheal suctioning in neonates requiring mechanical ventilation (MV) are published in the literature but lack strong empirical support. No evidence-based guidelines for safe suctioning in neonates while on NCPAP have been published. Preliminary research shows that nurses' decision-making regarding the frequency of and techniques for suctioning of neonates is quite variable (Mann et al., 2013), and is concerning because practice variation is often associated with less favorable outcomes.

Suctioning while on NCPAP is a very frequent nursing practice in NICUs across the world. This study represents the next steps toward the development of an evidence-based practice guideline for this nursing practice.

1. **Purpose:** To describe the clinical/behavioral responses of neonates on Bubble NCPAP in a Level III NICU following routine suctioning.
2. To characterize variability in suctioning response among neonates by gestational age and birth age.

Methods: This pilot study has a one sample within-subject repeated measures design in which neonates served as their own control. This study took place at a level III-49 bed NICU in a large academic medical center in the Midwestern USA.

A convenience sample (n=16) neonates who met the inclusion criteria was recruited from the NICU. We included neonates who were (1) on Bubble NCPAP (Respiroinics Bubble NCPAP™) (2) 27-32 weeks gestation, (3) older than 3 days of life but less than 7 days of life; (4.) have a legally authorized representative; and (5) are clinically stable as defined by the NICU healthcare team. Exclusion criteria included: (1) any facial/cranial deformities, (2) chromosomal/genetic abnormalities, (3) congenital heart disease, (4) chest tube placement, (5) persistent pulmonary hypertension, (6) receipt of any medications that alter responses to pain such as paralytics, narcotics or other sedatives.

The suctioning procedure tested was based on the expert opinion from a focus group of our clinical experts of our NICU since no empirically based guidelines exist. Two experienced RNs served as the study RNs and they established interrater reliability on the suctioning procedure prior to data collection. Data on an infant's physiological and behavior measures (heart rate, respiratory rate, O2 saturation, and Premature Infant Pain Profile (PIPP score)) were collected repeatedly: 5 minutes prior to suctioning

(baseline), during suctioning (right nare, left nare, mouth), immediately upon completion of suctioning sequence and 10 minutes after suctioning OR the return to within 10% of baseline physiological parameters.

Results: A total of 16 neonates were enrolled with mean gestation age of 29.76 weeks (SD=1.49) and an average day of life of 3.4 (SD=1.15). Overall, the infants' heart rates did not differ significantly ($p=.51$) across the suctioning sequence. Eight neonates required a second pass of either the nares or mouth and 2 neonates required a third pass of pass of the mouth. The average heart rate across the suctioning sequence ranged from 155 to 167 on the first pass. The largest change in heart rate occurred between after the second and third suctioning passes of the mouth. Respiratory rate dropped but only slightly during the suctioning sequence ($p=.79$). Oxygen saturation demonstrated a noted drop between baseline and the first pass of suctioning in the right nares as well a considerable drop from the first pass to second pass of the right nares in one infant ($p=.0001$). PIPP scores clearly demonstrated a precipitous increase in pain during the first suctioning pass and remained high throughout the procedure. ($p=.0001$). When controlling for gestational age and days of life, oxygen saturation had significant reduction of 3.0-4.4% ($\leq .01$) and pain (PIPP) scores had significant increase of 3.0-3.7 points ($\leq .001$) across the first passes of the entire suctioning sequence.

Conclusion: Our results suggest that the procedure tested is tolerated by infants and no adverse events were observed; however the neonates did experience a mild to moderate amount of pain. Oxygen saturation remained within acceptable ranges and no clinically significant concerns were raised with respiration, and heart rate. Neonatal response to suctioning while on NCPAP was not highly sensitive to days of life or gestational age. Repeating this study and evaluating the use of "oral suckers" during suctioning and other pain management strategies will further support an evidence-based guideline for this frequent procedure.

E 11 - Nursing Student Interprofessional Collaboration

Preparing Students for Interprofessional Collaboration: A Grounded Theory Study

Monica Bianchi, PhD, EMBA, MSc, RN, Italy
Annamaria Bagnasco, PhD, MSN, RN, Italy
Giuseppe Aleo, PhD, Italy
Loredana Sasso, MSc, RN, FAAN, Italy

Abstract

Purpose: Explore and understand the process of preparation to the IPC put in place by clinical tutors and students, of the various professions involved in experiences of IPE, in order to encourage the recruitment of the professional role and to become a member of a team.

Methods: To answer to the question "What processes are used by students and clinical mentors to develop interprofessional collaboration?" it has been used a constructivist grounded theory approach.. This approach has enabled the researcher to enter into the research setting, to observe it from the inside, to collect the data that were analyzed to define a theoretical explanation of the process studied.

In a university of applied sciences and arts of outhern Switzerland, ten students of the bachelors in nursing, physiotherapy, occupational therapy and the clinical tutors who followed them in the last stage of the bachelor course (sixth semester) were involved in the study. In the participants' selection, we have respected the criteria of theoretical sampling. This, in proceeding, allowed us to develop and confirm the characteristics of the emerging categories. The data collection process took place in a first step through semi- structured interviews with participants and university documentation consultation; in the second phase through focused interviews, participant observations and consultation of documentation produced by the participants. The total number of interviews, initially estimated in a total of 21, was 17 in the first phase and 6 in the second (total 23); the two additional interviews have been inserted in order to reach the theoretical saturation. The participating observations conducted were 3 for a total of 13 hours. The analysis was conducted through a coding process: initial, focused and theoretical (Charmaz 2014). Data were analyzed and coded using constant comparative analysis and the software Nvivo 10 In the initial coding 35 nodes were derived; During focused analysis they were grouped in 15 categories and 55 sub-categories; in the theoretical analysis they were defined 8 categories.

Results: A substantive theory "Practicing contextual models of interprofessional care" was generated. It explains how the whole process is played, the interaction between tutor and student and how they proceed together to the creation of models of interprofessional care, linked to the context in which they find themselves in, and to patients / families who are part of it. These models of care will be applied at the end of the whole process by the new professional (who was a student at the beginning of the path). The theory has been described as a journey: to think of this process as a journey and as students and tutor as companions of this trip helps to understand the intensity of relationships, communication and exchanges that the two travellers live through and build together. The relationship between student and tutor is the innovative aspect of this theory. This relationship, which develops between student and tutor and that consolidates and transforms, is structured differently from dyad to dyad but has constant support through the different types of communication (verbal and nonverbal) and through different modes of structuring (individualized) is the core around which it develops and is expressed throughout the process.

Conclusion: This theory allows us to understand the complex process engaged by students and tutors in order to build the student's professional identity and to prepare him for the collaboration with other professionals. The fundamental concepts that derived concern: the way in which the professional identity is built and the role of the student in the team, the relationship that, throughout the process, develops and consolidates between student and tutor, the relationship with patients and families as well as with other professionals; all concepts that are integrated for building models of interprofessional care in that specific context.

E 12 - Postpartum Health

Social Determinants of Rural Hispanic Women at Risk for Postpartum Depression

Younglee Kim, PhD, RN, PHN, USA
Vivien Dee, PhD, RN, NEA-BC, FAAN, USA

Abstract

Purpose: Postpartum depression is generally accepted as one of the common phenomena among childbearing women regardless of countries or culture. It is a critical and major problem for rural health. The Hispanic population is the largest and fastest growing minority in the United States. The growth of the Hispanic population is a profound factor to maintain and improve public health. Guided by the Orem's Self-Care Deficit Theory as a theoretical framework, the purpose of this study was to identify the social determinants of rural Hispanic women at risk for postpartum depression. The specific aims for this study were twofold: (1) examine the relationships between the social factors (maternal age, infant gender, marital status, education, annual household income, job, delivery type, number of children, and religion) and women at risk for postpartum depression, and (2) determine which of the social factors were predictors that contribute to increased risk for postpartum depression in Hispanic women in the rural areas.

Methods: This study was a descriptive cross-sectional design. The sample for the study included Hispanic women who lived in Mecca, Thermal, and North Shore in Southern California. The women were in their postpartum period beginning right after childbirth and extending to 12 months post-delivery. A convenience sample of 223 Hispanic women ranging in age from 18 to 47 years old without medical diagnosis or treatments for mental health issues participated. They spoke either English or Spanish during the data collection. An interview-survey was utilized to collect the data. Based on the results of the Edinburgh Postnatal Depression Scale (EPDS) the study participants were divided into two groups: (1) women not at risk for postpartum depression ($n = 128$) and (2) women at risk for postpartum depression ($n = 95$). Descriptive statistics were used to describe the basic features of the data in this study. Chi-square was used to determine the relationships between the social factors (maternal age, infant gender, marital status, education, annual household income, job, delivery type, number of children, and religion) and the EPDS scores. Multiple logistic regression was also performed to determine the significant predictors for postpartum depression among the rural Hispanic women.

Results: The prevalence for Postpartum Depression (PPD) in this sample was about 43%. The average age of the 223 Hispanic women was 28.49 (SD = 6.01). Chi-square statistical test reported the significance in EPDS scores among social characteristics such as education level, delivery type, job condition, and number of children, $p < .05$. Multiple logistic regression analysis also indicated that four of the predictors were significantly related to the likelihood of having postpartum depression: delivery type (OR = 0.513, 95% CI = .290 - .905, $p = .021$); number of children (OR = .417, 95% CI = .203 - .858, $p = .017$); education levels (OR = 2.38, 95% CI = 1.023 - 5.570, $p = .044$), and job condition (OR = 1.86, 95% CI = 1.017 - 3.432, $p = .044$).

Conclusion: The study findings provided the empirical data for determining the associations among the social determinants for postpartum depression among Hispanic women in rural communities. These findings can provide health care professionals with a better knowledge and understanding in the development of tailored preventive health care interventions or education for rural Hispanic women with postpartum depression, including approaches for self-care. Furthermore, these findings also provide the essential evidence to assist in the development of health policy for rural Hispanic women to enhance public health

E 12 - Postpartum Health

A Randomized Trial Evaluating Connective Tissue Massage on Pain in Post-Cesarean Section Primiparous Women

Mary Colleen Simonelli, PhD, RN, USA

Louise T. Doyle, BSN, RNC-OB, HNB-BC, LMT, USA

Abstract

Purpose: Pain creates physiological responses that can prolong the body's recovery after surgery including cesarean surgery which may impact a woman's ability to establish a maternal-newborn bond and effective breastfeeding. In the United States 77% of current heroin users claim to have used opioid pain medications prior to their heroin initiation (Jones, 2013). With today's opioid crisis, it is imperative that nurses find alternative strategies to the current administration of opioids to manage postoperative pain. The purpose of this study was to evaluate the efficacy of connective tissue massage on reducing postoperative pain in primiparous patients on their first postoperative day after cesarean section.

Methods: In this research sixty women were randomized into three groups; Massage, Standard Care and Birth Story. The study sample was comprised of primiparous women aged 17-44 who underwent an unplanned cesarean birth in the previous 24-48-hour time period. A retrospective chart review was conducted to gather data on pain score, opioid and NSAID use for entire postoperative hospitalization.

Results: Data were analyzed using analysis of variance and post hoc Tukey tests. One-way ANOVA revealed a significant difference between groups for Pain, Stress and Relaxation scores at time 2 ($p=.017$, $.004$, $.000$ respectively). Additionally, opioid and NSAID use day 2 were significantly different ($p=.032$, $.022$ respectively). Post hoc Tukey's evaluating the interaction between Massage and Standard Care groups were approaching significance for Total opioid use/BMI and Total NSAID use/BMI during the hospitalization ($p=.09$, $.06$ respectively).

Conclusion: Using massage therapy during postoperative hospitalization decreased pain, stress and improved relaxation and had the potential to decrease overall pain medication use in this sample of childbearing women. Nurses using massage therapy for post-surgical patients can decrease the pain, stress, and increase relaxation associated with unplanned cesarean birth and impact their overall opioid use. Further research is needed to determine the "dose" of alternative therapies that would sustain this impact.

E 13 - Declining Functional Status in the Aging Adult

Association Between Age-Related Hearing Loss and Disability in Older Adults: A Systematic Review

Tzu-Chia Lin, MS, Taiwan

Miaofen Yen, PhD, RN, FAAN, Taiwan

Abstract

Purpose: Age-related hearing loss (ARHL) is the loss of hearing or proportional to the degree of hearing impairment that gradually occurs as we grow older. ARHL management also consumes an increasing portion of healthcare expenditures given the rising mean age of people. Previous studies have investigated the association of ARHL and disability in older adults, but the results are inconsistent. However, identifying potentially modifiable risk factors such as hearing loss would provide a substantial public health benefit. Therefore, the aim of the study was to comprehensively evaluate the evidence connecting ARHL to disability in older adults.

Methods: Studies were identified through systematic searches of the electronic databases of Medline, Pubmed, CINAHL, Cochrane library, Airiti library. Bibliographic of retrieved articles were also searched. The following Mesh subject terms and keywords were used: hearing impairment, hearing loss, presbycusis, hearing handicap, deafness, disability, activities of daily living, older adults, elderly, aged, aging, senior. Two reviewers independently reviewed the abstract and selected studies that met the inclusion and exclusion criteria. Inclusion criteria were: (1) the study population involved individuals with age-related hearing loss/hearing impairment/presbycusis; (2) there was a predetermined definition of hearing loss/hearing impairment/presbycusis and reported disability outcome assessment; (3) cohort study. Exclusion criteria were: (1) non-English nor Chinese publication; (2) not primary research; (3) outcome not of interest. Retrieved articles were independently assessed by two raters for reporting quality using Newcastle Ottawa quality assessment scale (NOS).

Results: Ten eligible studies were identified. Only one of the 10 studies used gold-standard audiometric testing (inability to hear a tone of 40 dB or greater at 2,000 Hz frequency in the better ear is regarded as having ARHL) to evaluate hearing loss, whereas the other nine studies relied on self-report hearing problems with various questionnaires. The ARHL prevalence was from 15.7% to 28.0%. 8.6% to 57.1% participants with ARHL at baseline became disability. Compare to those without ARHL at baseline, the percentage of becoming disability is higher in participants with ARHL. The odds of disability were 0.80-7.93 times greater among older adults with hearing loss than older adults with normal hearing. However, most studies reveals that ARHL was not associated with increased odds of disability among participants with ARHL at baseline, after adjusting the covariates.

Conclusion: In the published literature, ARHL was not associated with a significantly increased odds of disability in older adults. However, HL is a gradual condition, and the limit between normal and not normal must be defined along a continuous scale.

E 13 - Declining Functional Status in the Aging Adult

Hospital-Associated Functional Status Decline in Older Adults With Chronic Obstructive Pulmonary Disease (COPD)

Amy C. Shay, MS, RN, CNS, USA

Janet S. Fulton, PhD, RN, ACNS-BC, ANEF, FAAN, USA

Abstract

Purpose: The purpose of this study was to identify activity factors that contribute to hospital associated functional status decline in older adults with chronic obstructive pulmonary disease (COPD) by promoting functioning during hospitalization.

Background/Significance: COPD is a significant worldwide cause of chronic illness and mortality. The World Health Organization predicts that COPD will become the fourth leading cause of death globally and rank seventh in burden of disease by the year 2030 (Cruz, et al., 2007). COPD is one of the most common admitting diagnoses in the United States, carrying a fifty billion dollar economic burden with the majority of expenses related to hospitalization (HCUP, 2011).

Persons with COPD are at increased risk for deconditioning during hospitalization, which can lead to decreased functional status at discharge (Boltz, et al., 2012). Despite the prevalence of COPD, there are very few studies examining this population for whom mobility is uniquely problematic (Reid et al., 2012). Older adults with COPD are most vulnerable to hospital associated functional status decline (Greening et al., 2014; Liao et al., 2015; Nguyen et al., 2015). To help alleviate the secondary effects of immobility, a clinical nurse specialist-led mobility protocol was developed; however, specific elements of the protocol have not been examined for associated outcomes.

Methods: *Design:* This predictive correlational study is a secondary analysis of a pre-existing dataset. The parent study arose from a hospital unit quality improvement initiative for physical activity and patient outcomes. The parent study measured correlations between an Activity Progression Protocol and hospital length of stay, discharge disposition, falls, pressure ulcer prevalence, oxygen requirements, perceived dyspnea, and maximum activity level. The current study analysis explored the number, type, and timing of activity events in relation to the selected functional status outcomes of discharge disposition, length of hospital stay, and 30 day readmission rates for hospitalized older adults with COPD.

Ethics: This study was approved by the authors' university's human subject review board.

Sample/Setting: For the parent study, data were collected over a ten month period from patients on a pulmonary unit in a large, tertiary care hospital. The parent study sample included 358 patients admitted during the peak winter months of COPD exacerbation for the northern hemisphere (Donaldson & Wedzicha, 2014). For this secondary analysis, 137 patients with COPD diagnoses were pulled from the larger sample for comparison with non-COPD patients. The subjects with COPD were patients admitted to a pulmonary unit and received a care intervention protocol designed to address mobility barriers related to COPD and hospitalization.

Procedure: The activity protocol was a unit based protocol enacted for all patients admitted to the study unit (Nurse-Administered Pulmonary Protocol Increases Out-of-Bed Activity, Shortens Length of Stay, and Reduces Readmissions, 2009). Mobility was initiated per protocol during the first 24 hours of admission once hemodynamic, neurological, and respiratory stability were achieved. The protocol included screening for readiness, progressive levels of activity, oxygen titration, and use of a rollator for walking support. The nurse-driven protocol for early mobilization was based upon principles of cardiac and pulmonary rehabilitation (Spruit, et al., 2013) and prior study of hospitalized community acquired pneumonia patients (Mundy, et al., 2003).

Analysis: Logistic regression analysis was used to assess the relationship between the number of out of bed activity events, and timing of first out of bed activity and the dichotomous dependent variables of

discharge disposition to home versus ECF, and 30 day readmission status. The out of bed activity event data were combined by category as weight bearing (bathroom, up in room, ambulation) and non-weight bearing (bedside commode, dangle, chair) for analysis. Multiple regression was used to assess the relationship between the number, type, and timing of individual out of bed activity events and hospital length of stay. Chi square and ANOVA analyses were used to compare the COPD related diagnoses patient group and patients with non-COPD related diagnoses.

Results: Preliminary results show weight bearing activities (ambulation, up to bathroom, up in room) have a significant effect on discharge disposition to home ($p=0.012$). The probability of discharge to home increases for each additional weight bearing activity per day ($p<0.001$). Activities with the greatest effect upon discharge to home are ambulation ($p=0.0003$), up to the bathroom ($p=0.021$), and bedside commode ($p=0.031$), in that order. Getting up to the bathroom, however, is nearly seven times more likely to affect discharge to home than bedside commode activity. For each additional weight bearing activity (bathroom, up in room, ambulation) per day, we expect to see the length of stay decrease by 1.69 days. For each additional ambulation per day, we expect to see the length of stay decrease by 3.8 days. For each additional day to the first out of bed activity, we expect the length of stay to increase by 1.07 days. For each additional day to first out of bed activity, we expect the odds of discharge to home to decrease by 14 to 36.2 percent on average.

No activities were found to have a significant effect on 30 day readmission (individually or categorized). The number of days to first out of bed activity was not significant for 30 day readmission.

Preliminary results of group differences in outcomes show COPD patients are less likely to be readmitted within 30 days as compared to non-COPD patients and more likely to be discharged to home as compared to non-COPD patients in this sample. Advancing age affects non-COPD patients to a greater degree than COPD patients with regard to effect upon likelihood of discharge to home. Group differences with regard to specific activities, time to first out of bed activity, and comorbidity influence are still being analysed and results may shed light upon the differences in outcomes of these two groups.

Conclusion: The preliminary findings of this study demonstrated that out of bed physical activities are associated with shortened hospital length of stay and improved patients' likelihood of discharge to home for older adults with COPD.

Implications for Practice: Nurses should place emphasis on and direct resources toward *daily* weight bearing activities (ambulation, up to bathroom) to improve outcomes and preserve functional status during hospitalization. Nurses are in a unique position to drive efforts to prevent such decline given their continual presence at the bedside and primary responsibility for physical activity while the patient is hospitalized.

E 14 - Promoting Outcomes in the Infectious Patient

A Collaborative, Systemwide Approach to Reducing Healthcare Onset Clostridium Difficile (HOC-diff)

Renecha Abrams, MSN, BSN, RN, APRN, ACCNS-AG, CCRN, USA
Angeleta Zipporah Robinson, MSN, CNL, GBLSS, USA

Abstract

Purpose: Healthcare Onset Clostridium Difficile (HOC-diff) is one of the most common healthcare associated infections (HAIs), within the United States. It has a negative impact on patients by increasing their hospital length of stay by 2.7 days, has an associated mortality rate of 10%, and negatively impacts the citizens in our community (Dubberke et al., 2014). Healthcare onset C-diff also increases the cost to the organization by \$15,000 per episode (Dubberke et al., 2014).

In reviewing our processes and knowledge base across the system, a team of subject matter experts (SMEs) identified several areas for improvement. Variations within clinical practice and lack of evidence-based policies and procedures were found to be top contributors to the increase in HOC-diff rates within the system. A review of antibiotic usage revealed the need to implement antimicrobial stewardship programs at each facility. Major differences in practices were identified in the cleaning of the environment and equipment between facilities by environmental services (EVS). A knowledge deficit, a lack of standardized tools and workflow across the system, and communication between nursing staff and EVS regarding daily cleaning were also discovered. A lack of standardization in EVS cleaning, compliance in cleaning between c-diff patients, and insufficient validation of hand hygiene compliance among the clinical staff was revealed in the outpatient setting.

The hospital system failed to meet its fiscal year 2016 C-diff goal rate of 6.89 per 10,000 patient days, ending with a rate of 8.86. This unachieved outcome prompted a new goal of reducing the HOC-diff rates for FY17 by 20%, with a target rate of 7.09. The purpose of this multidisciplinary team approach was to standardize our clinical practices across the system, implement evidence-based policies and procedures related to c-diff, identify and correct practices that contribute to HOC-diff cases. All actions were aimed at decreasing the rate of HOC-diff cases, decreasing patient's length of stay, decreasing organizational expenses associated with HOC-diff, reducing mortality, and decreasing the impact on our community.

Methods: The Health System consists of 5 legacy hospitals and 6 new facilities as of April 1, 2016. The C-diff taskforce consisted of multidisciplinary teams brought together to reduce HOC-diff. The teams were antimicrobial stewardship, education, EVS, Clinical Inpatient, Clinical Ambulatory, Clinical Community, Information Technology (IT), and Communication/Marketing. A project manager, executive sponsors, operational leaders, and executive leaders led the taskforce and helped to facilitate the removal of barriers by creating a more cohesive group with clear cut goals.

The Antimicrobial Stewardship (AMS) team conducted a retrospective review of HOC-diff cases that revealed an overuse of agents shown to be associated with HOC-diff and delays in microbiological identification of pathogen, which caused prolonged empiric antimicrobial therapy. The team worked with IT to implement best practice advisories (BPAs) for additional diarrhea-inducing medication and these target agents which prompted providers to consider other antibiotics.

The Education team stratified a teaching plan based upon the needs of each employee type to address infection prevention and isolation precautions. A computer based learning module and competency check off was created and finalized to validate competency amongst new and current employees.

EVS discovered there was a lack of standardization in cleaning of the environment and equipment. Standardized competencies were developed and reviewed by EVS leads with the support of Infection Prevention (IP) and organizational learning. The result was standardized education and simulation lab for all new and existing team members. An equipment cleaning policy was developed and piloted at one of the legacy facilities, in an effort to formulate a plan for system implementation.

The Clinical Inpatient team finalized a system wide c-diff nurse driven protocol. They collaborated with the Professional Practice department and/or leaders at each facility and Organizational Learning to roll out education on the Nurse Driven Protocol and strategies to prevent the spread of infections, respectively. Several tools were implemented as job aides to assist in hardwiring the process changes. Communication tools were also implemented to provide clarification on proper high touch cleaning and accessing reports that would provide needed information when evaluating whether or not to test.

The Clinical Ambulatory team reviewed their practices and identified patients' risks of transmitting c-diff through surface areas within the examine rooms to their staff, patients, and vendors. They also discovered multiple EVS contracts in place at various locations, along with an unclear knowledge of their cleaning practices or insight of healthcare cleaning protocols.

The Clinical Community team focused their attention on the skilled nursing facilities, home health agencies, retail pharmacies, clinics and affiliated detention center as patients are routinely received and transferred to and from these areas, creating a high risk for transmission. Their goal was to create a communication tool to utilize during patient transitioning, therefore, allowing them to share information in a timely manner.

The information technology team found opportunities to enhance the electronic medical record to support communication between the RN and care partners (CPs) by providing CPs with the ability to document stool consistency as well. They also improved the ease of documenting when labs and/or specimens had been collected and sent to lab.

The Communication and Marketing team identified a lack of infection prevention education and communication for the staff when interacting with families and patients. This included c-diff and the basic isolation policy, all of which are crucial in preventing the spread of infections. The teams worked to develop scripting for hospital staff when interacting with compliant and noncompliant visitors of patients in isolation. They created new color-coded infection prevention "contact precaution" room signage to differentiate between c-diff contact and all other contact isolations. They also created system communications, developed PPE educational brochures, and standardized the check-in process for visitors on isolation patients.

The six new facilities reported their contributing factors to HOC-diff cases as a lack of hand hygiene, a lack of compliance with the c-diff Nurse Driven Protocol, lack of understanding regarding terminal cleaning, timing and collection of stool specimens for c-diff orders, lack of antimicrobial stewardship, and poor compliance with PPE in contact precaution rooms. The countermeasures included establishing a transdisciplinary c-diff team, adopting, education, and implementing the nurse driven protocol, educating the staff on stool samples, implementing secret shoppers to observe contact precaution compliance, training on terminal cleaning for the EVS staff, and educating the providers.

Results: The FY17 YTD rate for the legacy facilities is 6.97, so far achieving our target rate of 7.09 per 10,000 patient days.

AMS was unable to meet their initial goal reduction with the identified target agents. However, the number of interventions submitted doubled when compared to data from the previous year. Meanwhile, AMS continues to monitor antibiotic consumption, HOC-diff rates, along with implementing new BPAs.

The Education and Clinical inpatient teams successfully completed the education roll out of all new initiatives. However, after the initial roll out, it was discovered not all employees were captured. A second education roll out plan was initiated with better success. Through staff interviews, a better understanding of the appropriateness of when and how to test was discovered.

The EVS team has completed the system policies and procedures roll out for legacy and newly added facilities. A three day training and simulation lab was instituted and completed for new hires and existing employees. Leader orientation was implemented, along with the use of Oxycide in all clinical areas. The

team has had 100% completion of environmental services training and simulations with 3 out of the 5 legacy facilities and 50-100% completion in 3 out of 6 of the new facilities.

Standardized cleaning between patients was implemented at all facilities. C-diff CBL training and the process of handling c-diff patients within the outpatient clinical setting was not extended to employees of the newer facilities. However, current and new employees at all facilities receive this training during new hire orientation. Hand hygiene observations are currently in the works in the legacy practices. Plans for the newer practices are still in the decision phase. AMS will be incorporated at both legacy and newly acquired outpatient practices. EVS standardization still needs to be assessed at the newer practices.

Conclusion: An evaluation of our c-diff initiatives was conducted using a lean value stream methodology. Several of the positive tests were found to be that of carriers or previously positive patients who were retested, instead of new HOC-diff cases. The double check process yielded significant lower rates in September 2016, verifying staff competency and compliance to the protocol. The taskforce meets biweekly to evaluate their progress and develop action plans to address new or current issues. They continue to conduct root-cause analyses on all positive tests, evaluate compliance with the testing protocol, monitor cleaning, and hand hygiene compliance. Antimicrobial stewardship continues to aim at decreasing the excessive use of broad-spectrum antibiotics and will transition consumption monitoring to days of therapy to benchmark with other organizations. The taskforce is evaluating the best utilization of adjunct cleaning technology, piloting the use of probiotics, improve hand hygiene compliance, and fully incorporate the newer facilities into the system wide strategic plan to reducing HOC-diff.

E 14 - Promoting Outcomes in the Infectious Patient

Predictors of Survival for Patients With a Diagnosis of Sepsis

Kim Reina Failla, PhD, RN, NE-BC, USA
Cynthia D. Connelly, PhD, RN, FAAN, USA

Abstract

Purpose: Sepsis is a major public health priority. Sepsis-related diagnoses are life-threatening global health care conditions that may lead to organ failure, shock, and death. The rate of associated hospitalizations doubled from 2000 through 2008; sepsis was the leading cause of death in the United States in 2010 and was noted to be the single most expensive condition treated in hospitals in 2011 (Walkey, Lagu, & Lindenauer, 2015). Despite advances in the recognition and treatment of sepsis, mortality remains at 30%. By 2020, an estimated additional one million cases annually are projected to occur due to the aging population, increased invasive procedures, and comorbidities (Leedahl, Personett, Gajic, Kashyap, & Schramm, 2014). Predictors of survival for those with sepsis are inconclusive. Notably, clinical sepsis studies evaluating the influence of gender on survival are not clear (Jacobson, Liedgren, Johnsson, Ferm, & Winso, 2012; Madsen et al., 2014; Nachtigall et al., 2011). Contributors to disparities have been attributed to differences in clinical presentation and health care delivery (Soto et al., 2013). The purpose of this completed study was to identify factors including gender that affect survival for patients with a diagnosis of severe sepsis or septic shock.

Methods: After Institutional Review Board approval, the study was conducted in a large metropolitan, non-profit, Magnet recognized, acute care hospital located in the Southwestern region of the United States. This study used a retrospective, descriptive correlational design. A sample of patients, 18 years or older presenting to the emergency department and who subsequently met the criteria for a discharge diagnosis of severe sepsis or septic shock as defined by the Surviving Sepsis Campaign provided data for this study (Society of Critical Care Medicine, 2015). Data on patient characteristics, clinical variables, care management processes, and outcomes were extracted from the electronic medical record and analyzed. Descriptive and inferential statistical analyses were performed using International Business Machines Statistical Package for the Social Sciences for Windows, Version 23.0.

Results: Data were reviewed for all patients with a diagnosis of severe sepsis or septic shock and 482 patients met inclusion criteria: Males (248, 51.5%); Females (234, 48.5%). Exclusion criteria included patients who had previously selected end-of-life or palliative care measures upon admission. The mean age for all patients was 67.9 years (SD 16.5). The majority of patients were White (51%), with 16.6% Hispanic, 14.9% Asian, 5.8% Black, and 11.6% other. The majority of the patients were diagnosed with septic shock (62.2%) compared to severe sepsis (37.8%).

Logistic regression with eight independent variables included: (1) discharge diagnosis, (2) age, (3) comorbidities, (4) length of hospital stay, (5) source of infection, (6) first lactate level, (7) recommended fluids administered, and (8) gender. All independent variables reliably predicted which patients would survive $\chi^2(12, 423) = 118.39, p < .001$ and correctly classified 77.3% of cases. All independent variables significantly contributed to the model, but the model revealed females had a higher likelihood of hospital mortality than males (OR = 1.68; 95% CI, 1.01-2.79; $p < .05$). Limitations of the study included potential selection bias since the study was observational and lacked a random sample of patients with severe sepsis or septic shock. Additionally, because all data were extracted from the electronic medical record, providers' undocumented impressions of diagnosis, source of infection, and/or severity of illness may have affected care processes.

Conclusion: The Surviving Sepsis Campaign has provided a clear path for patients with sepsis-related diagnoses including the need for early recognition and treatment interventions (Society of Critical Care Medicine, 2015). Previous studies have identified more rapid identification of patients at risk for sepsis through electronic medical record enhancements, sepsis response teams, and interprofessional education and simulation (Palleschi, Sirianni, O'Connor, Dunn, & Hasenau, 2014; Schramm, Kashyap, Mullan, Ognjen, & Afessa, 2011). Therapeutic strategies are needed to address gender differences and

there are opportunities to address decision-making with regard to potential bias. New or revised policies may be established to safeguard against disparity between genders and educational efforts may be employed to build awareness surrounding the different illness presentations exhibited by females versus males. Aggressive applications of evidence-based interventions may result in better patient outcomes. The study findings have global implications for future studies in addressing if gender disparities exist in the use of validated sepsis therapies.

E 15 - Retention Strategies for Entry-Level Nurses

Next Steps Program: Utilization of Multifaceted Retention Strategies to Retain American Indian Student Nurses

Loretta Heuer, PhD, RN, FAAN, USA

Abstract

Purpose: To gain a deeper knowledge of staff, mentors and student nurses' perceptions and experiences with multifaceted support services and retention strategies and to contribute to the scant literature on retention of American Indian student nurses.

Background: The growing shortage in healthcare professionals across the nation has been an increasing problem which is attributed to an aging workforce as well as an aging population with increased health needs.¹ This issue is compounded in rural communities because of the limited resources. Smaller populations of rural areas do not typically attract healthcare professionals and the loss of these individuals in rural communities can greatly impact the surrounding area; especially where people travel greater distances for healthcare.^{2,3} Although there is a shortage of healthcare professionals throughout the entire country, North Dakota (ND) has an uneven distribution in cultural diversity of health professionals, which can be a shortfall when caring for patients in Tribal communities or surrounding rural areas. In 2015, there were 13,933 employed licensed nurses, including all ethnicities. Of this population, there were 195 or 1% employed self-reported American Indian nurses.⁴ Per the Institute of Medicine Report, a culturally diverse nursing workforce is essential to meeting the health care needs of the nation and reducing the health disparities that exist with minority populations.⁵ In recognition of the severe underrepresentation of American Indians in the health care workforce,

Cankdeska Cikana Community College partnered with the Recruitment and Retention of American Indians in Nursing (RAIN) Program, University of North Dakota to implement the "Next Steps Program." This program provided opportunities for American Indians to access an "educational pathway" leading to careers in the nursing profession. Services provided to students enrolled in the Next Steps Program include financial support for tuition fees and books for participation in healthcare education and training, support services to meet childcare and transportation needs and intensive mentoring services.

Methods: A qualitative descriptive design was used to obtain detailed descriptions of the program, services provided and impact on the students' success.⁶ Participants involved with the Next Steps Program were recruited by purposeful sampling (N=27). The data were collected through a semi structured interviews from November – March 2014. Validity and reliability was confirmed when recurrent themes were identified by researchers through independent coding. All interviews were analyzed using qualitative inductive content analysis to identify key themes.

Results: The Next Steps staff and mentors were enrolled members of a North Dakota Tribal Nation. One of the two Next Steps staff and three of the four mentors were female. Three mentors were 50-59 years old while one was in the 30-39 age group. Educational level of the mentors included one with a Bachelor's degree, two with master degrees and one doctoral prepared. Sixteen students were enrolled in one of the North Dakota Tribal Nations. Three resided in North Dakota but were enrolled members of Tribal Nations in other states. The student nurses were all female, older than average students and the majority were single with children. Thirteen were enrolled practical nursing programs in one of the three North Dakota Tribal Colleges while one attended a State College. Four were enrolled in university Baccalaureate Programs. The perceptions and experiences of the twenty-seven participants were classified into six major themes: 1) Next Steps Support Services, 2) Mentoring Experiences, 3) Challenges in higher education, and 4) Future educational and/or employment plans. These four main themes occurred repeatedly and affected the life experience of the participants.

Conclusion: The Next Steps Program staff and mentors provided support and services to older than average Native American students with children. These services allowed them to obtain their dream of

becoming nurses. While personal commitment is an important factor, the Next Steps staff, mentors, and peers played an important role in the success of the student nurses. All the student nurses clearly valued the financial assistance for living expenses including child care, tuition, and gas cards so they could travel to their clinical sites. The majority of the nursing students believed that without the support and services of the Next Steps Program, they would not have been successful in the enrollment process or completion of their nursing programs.

E 15 - Retention Strategies for Entry-Level Nurses

Measuring the Effect of a Nurse Residency Program on Person-Organizational Enculturation

Laurie Ecoff, PhD, RN, NEA-BC, USA

Kim Reina Failla, PhD, RN, NE-BC, USA

Jaynelle Stichler, DNS, MSN, BSN, RN, NEA-BC, EDAC, FACHE, FAAN, USA

Abstract

Purpose: This completed study describes the effects of a structured Nurse Residency Program featuring reflective learning on nurses' organizational enculturation from Year 1 (Y1) to Year 2 (Y2).

It has been reported that 6% of new graduate nurses leave the profession within their first year of practice because of job dissatisfaction, poor transition from the student role to the work environment, poor social integration within the work unit, concerns about their competency levels, and poor coping and self-efficacy (Kramer, Halfer, Maguire & Schmalenberg, 2012). Nurse Residency Programs (NRPs) have been viewed as an effective way to prepare and new nurse graduates for work in the complex healthcare environment (Al-Dossary, Kitsantas & Maddox, 2016; Bratt, 2013; Bratt & Felzer, 2012; Green, Warren, & Perkins, 2016). While NRPs are discussed in the literature, specific attributes of NRPs facilitating nurses' integration into the organization and the work unit have not actually been measured for their effectiveness in facilitating the enculturation and retention of the new graduate nurse. The NRP in this study uses an evidence-based curriculum (Anderson, Hair & Todero, 2012) with Knowles adult learning theory (Knowles, Holton & Swanson, 2015) and Kirkpatrick's Four Stage Model of Evaluation (Kirkpatrick & Kirkpatrick, 2006) and features a dedicated Nurse Manager (NM) for oversight of the program, reflective learning where the nurse residents (NRs) discuss their feelings in a structured group experience related to clinical interactions and experiences and looping where the NRs are rotated through specific clinical and support departments exposing them to care delivery in different settings. The study measured changes in nurse residents' perceptions of person-organizational enculturation defined by **person-organizational fit (POF)**, **social support (SS)**, **coping self-efficacy (CSE)**, **knowledge and skills (K&S)**, **organizational commitment (Org Com)**, **organizational citizenship behaviors (OCB)**, **civility norms (CIV)**, **occupational commitment (Occ Com)**, and **burnout (BO)** over a two-year period. These variables were used to measure the effectiveness of the NRP featuring the reflective learning component.

Methods: After Institutional Review Board approval, the study was conducted in a large metropolitan hospital located in the Southwestern region of the United States. New graduate nurses were interviewed by the NRP Nurse Manager and hired directly into the NRP rather than an assigned clinical area. All NRs were invited to participate in the study and their completion of study surveys at Y1 and Y2 indicated their consent to participate. The questionnaire consisted of 82 items with a 5-point response set (5 = strongly agree to 1 = strongly disagree) measuring the variables of interest. Eleven demographic items were used to describe the samples in Y1 and 2, and an additional 14 items provided more information about the NRs at Year 2. **Sample:** There were 105 respondents in Y1 and 24 respondents in Y2 from a population of 129 new graduate nurses for a response rate of 82% in Y1 and 19% in Y2. There were 16 nurses whose responses could be matched from Y1 to Y2. The data was analyzed using SPSS v 23 to analyze the data for the matched pairs sample ($n = 16$) and independent samples ($n = 105, 24$) for differences in study variables from Y1 and 2. The entire sample was analyzed to determine correlations among variables in Y1 and 2.

Results: All of the scales in the questionnaire had reliabilities greater than $\alpha = .70$ in both Y1 and Y2 with the exception of the **Org Com** scale ($\alpha = .67$) in Y2. The total survey with all items had a reliability of Cronbach's α of $.80$. The matched pairs sample included 81% female and 19% male. The majority of the respondents were White (66%), with 14% Asian, 10% Hispanic/Latino, 4% Black, 4% Pacific Islander, and 2% other. NRs reported their job titles as 70% Associate Nurse and Clinical Nurse 30% in Y1 and 18% Associate Nurse and 73% Clinical Nurse in Y2. This change occurred because the progression in job title from Associate Nurse to Clinical Nurse is expected from Y1 to Y2. The majority of the matched

NRs had Baccalaureate degrees (64%), Master's degrees (16%), and only 11% reporting Associate Degrees. Some of the NRs had prior employment with the organization (39%), but 61% did not. Significance level was set at $p < .10$ because of the small sample size nested within the larger non-matched sample. There were no significant differences in the following variables from Y1 to Y2: **Org Com**, **OCB**, **CIV**, **Occ Com**, and **BO**. Significant improvements in mean scores were noted between Y1 to Y2 in NRs' perceptions of **CSE** ($M1 = 3.60, M2 = 3.87; p < .015$) and **K&S** ($M1 = 3.13, M2 = 3.30; p < .060$), but significant declines in mean scores were noted in **POF** ($M1 = 4.31, M2 = 4.02; p < .038$) and **SS** ($M1 = 3.31, M2 = 3.09; p < .041$).

With the data analyzed as two independent samples in Y1 ($n = 105$) and Y2 ($n = 24$), there were no significant differences in age, gender, job title (Associate Nurse or Clinical Nurse), nursing degree, or assigned shift. With the significance level set at $.05$, three significant differences were noted in the study variables between Y1 and Y2 (assuming unequal variances related to unequal group sizes). The mean scores for **Org Com** decreased from Y1 ($M = 4.45$) to Y2 ($M = 4.10, p = .003$); **POF** (Y1, $M = 4.44$; Y2, $M = 4.15, p = .05$); and **SS** (Y1, $M = 3.45$; Y2, $M = 3.23, p = .04$). Associate nurses rated **CIV** significantly higher ($M = 4.18$) than clinical nurses ($M = 3.89$) at Y1 ($p < .05$), but that difference was not observed in Y2. NRs working the day shift reported higher **SS** ($M = 3.57$) than those working evenings/nights ($M = 4.36$) at Y1 ($p < .01$), but that difference was also not observed in Y2. NRs who had prior experience at the employing hospital reported higher **Org Com** ($M = 4.71$) than those who did not have prior employment ($M = 4.39$) at Y1 ($p < .05$), but that difference was not observed in Y2. Similarly, NRs with prior experience at the employing hospital reported higher perceived **POF** ($M = 4.67$) at Y1 as compared to those who did not have prior experience ($M = 4.34, p < .05$), but that difference was not observed in Y2.

For the independent samples, significant correlations were noted between **Org Com** and **Occ Com** (Y1, $r = .632, p < .01$ and Y2, $r = .632, p < .01$); **POF** and **Org Com** (Y1, $r = .613, p < .01$ but not significant in Y2); **SS** and **Org Com** (Y1, $r = .487, p < .01$; Y2, $r = .766, p < .01$); and **SS** and **CSE** (Y1, $r = .236, p < .01$; Y2, $r = .50, p < .01$). Negative correlations between **SS** and **BO** were noted in Y1 ($r = -.345, p < .01$) and Y2 ($r = -.602, p < .01$). All of the correlations between **SS** and the other study variables were higher in Y2 as compared to Y1 with the exception of the correlation between **SS** and **POF** which was not significant in Y2.

A regression analysis was done using **Org Com** as the dependent variable and all other variables as IVs, and the model was significant ($R^2 = .587, p = .000$) with **Occ Com** ($B = .315, p = .000$) and **POF** ($B = .394, p = .000$) as the strongest predictors of **Org Com**.

Conclusions: The results indicate the NRP with the reflective learning was effective in improving matched NRs' perceptions of **CSE** and **K&S** in Year 2, but unfortunately, mean scores declined for **POF** and **SS** in Year 2, which is a critical time when nurse residents decide to continue employment at the organization or leave the organization and/or profession. The strong, significant correlations between **SS**, **CSE**, and **Org Com** indicate the importance of reflective learning in a NRP as a means of providing structured social support for the NRs. The negative relationship between **SS** and **BO** indicate the strong need for program elements like reflective learning to enhance social support, diminish burnout and the potential to leave the organization. The strong relationship between **Org Com** and **Occ Com** reinforce the importance of reflective learning with discussion of professionalism in nursing (occupational commitment) and other forms of social support to prevent new graduate nurses from leaving the professional all together. This notion is supported by **Occ Com** and **POF** significant predictors of **Org Com**. This study supports findings from other studies on the effect of nurse residency programs on retention and enculturation into the organization (Rosenfeld & Glassman, 2016).

This study provides new knowledge about attributes of a successful NRP featuring reflective learning and the effectiveness of the program in enhancing **CSE** and **K&S** from Year 1 and Year 2. The study has global implications since the transition of new nurses into practice and the retention of nurses are important issues to nursing.

E 16 - Student Nurse Success Strategies

Evaluation of Students' Perceptions Compared With Baccalaureate Program Objectives of a Peer-Tutoring Program

Catherine S. Thomas, DNP, MSN, RN, CNE, USA
Nancy E. Peer, PhD, RN, CNE, USA

Abstract

Purpose: The purpose of this research was to compare and contrast any differences between students' perception of and actual performance related to program objectives of a pilot peer tutoring program in an undergraduate nursing program. This pilot peer tutoring program was implemented based on both ongoing program assessment and a program needs survey in which students identified the need for additional academic services and resources. This pilot program was implemented to improve student performance on standardized assessments, student self-confidence, and student understanding of nursing content and concepts through the use of newly available resources and peer to peer learning.

Methods: This quantitative research study compared and contrasted students' perception, as measured by a Likert scale online survey, that focused on student experiences and their satisfaction with various aspects of the tutoring program and resources. Those results were compared with student performance on a standardized assessment that they completed twice during the academic semester (HESI Exit Exam 1 and 2). The peer tutors were selected by faculty, based on their previous performance on both standardized assessments and faculty generated assessments. Their acceptance of the compensated position was voluntary, and they completed an orientation to their role, and were given a job description and program guidelines. The faculty coordinators interacted with the peer tutors frequently, both in person and via email to provide oversight and guidance. The students were referred to the tutoring program, based on their performance on previous standardized assessments and faculty generated assessments, as well as any presence of test anxiety and need for improvement in understanding nursing content and concepts. The students were expected to attend the tutoring program regularly throughout the semester, and their hours and use of resources were tracked.

Results: Students' perceptions of the peer tutoring program did not match the achievement of program objectives. The students rated their perception of the program as marginally positive. However, their rating of the newly available resources was high. Their perception of the experience may have been influenced by the peer tutoring room, as it was not a dedicated space. While it was located in the same building as the nursing department and lab, as well as one of their nursing classes for the semester, it had limited seating around a small table, the temperature of the room was frequently unpredictable, and the space was occasionally shared with graduate student workers who were completing data entry for another university program. Several times the tutors and students took advantage of seating located in the hallway. Student performance on the standardized assessment increased an overall net of thirty-two percent, which had not been demonstrated by previous senior classes in the program. Limitations for the study included a small sample size, lack of demographic data collection with the survey, the use of a non-voluntary referral process, and the inability to have a control group.

Conclusion: This study contributes to the limited body of evidence on academic focused peer tutoring in nursing education. Students' perceptions and achievement of program objectives did not match. The various resources available were rated high and the assigned space was not perceived as meeting their needs. The relevance to nursing education is the evaluation of this pilot program as a cost-effective pilot program that addressed and supported the learning needs of diverse learners through the availability of resources and peer tutors. This study may provide guidance and knowledge for nursing faculty and programs that may be considering implementing peer tutoring to support student success.

E 16 - Student Nurse Success Strategies

Nursing Students' Evaluation of Support Offered by Preceptors

Lizemari Hugo, MSocSc (Nsg), RN, PHC, NE, South Africa

Abstract

Purpose: Nursing students are being placed in a complex and challenging clinical environment as part of their educational training program. During their placement they are expected to integrate theory with practice in order to become competent nurse practitioners. Students need support to develop cognitively and professionally in order to become part of a sustainable workforce that are able to address the healthcare needs of the population of South Africa. Preceptors are the perfect entity to provide the necessary support and maximize transfer of learning. Good working relationships between the preceptor and clinical staff contribute to a positive clinical learning environment that is conducive for transfer of learning. The types of support that preceptors should provide to students include system, tangible, cognitive and emotional support. Nursing education institutions should ensure that preceptors provide comprehensive support to students enrolled in their program.

The purpose of this study is to describe the support offered by preceptors to undergraduate nursing students at a school of nursing in South Africa.

Methods: A quantitative survey was done. Second to fourth year undergraduate nursing students completed the questionnaire. Respondents had to indicate on a four-point Likert scale whether they strongly agree to strongly disagree with the latter having the lowest score. Students completed the questionnaire at the end of their clinical placement over two consecutive months. Descriptive statistical analysis was done.

Results: Results showed that preceptors provided students with the four types of support. Students rated emotional support as the highest type of support offered by preceptors. The mean value of each type of support varied between 3.21519 and 2.01321 and showed that there is still a lot of room for improvement on the support that preceptors offer to students.

Conclusion: The use of this instrument can provide nursing education institutions with a clear indication on the quality of support that the preceptors provide to their students.

E 17 - Use of Antibiotics

Reducing Antibiotic Use in the Management of Upper Respiratory Infections in the Urgent Care Setting

Melissa Jones Holley, DNP, MSN, BSN, APRN, FNP-c, USA

Abstract

Purpose: Upper Respiratory Infections (URIs) are the most common presenting complaint to urgent care centers across the United States. Regardless of etiology or provider specialty, antibiotics are prescribed 60% of the time for the treatment of URIs, contributing to drug resistant respiratory organisms which often provide clinical management challenges for patients and their providers. These practices impact patient outcomes, quality of care, antimicrobial resistance, and economics in community and hospital settings. Chart reviews at a local urgent care company revealed similar practices among providers. Differences in provider type, knowledge base, confidence, practice experiences, and the lack of company adopted treatment guidelines were noted to be probable contributors. As a result, a quality improvement project was implemented to promote quality, evidenced based care in the management of patients with upper respiratory infections.

Methods: A multimodal intervention combining provider consensus meetings, clinical guideline review and development, use of clinical pathways, prescriber feedback and audit, and patient education was implemented at two urgent care centers to reduce the rate of antibiotic prescribing for URIs. Antibiotic prescribing rates for the baseline and intervention periods were obtained through the review of 273 patient charts with diagnoses of URI, nasopharyngitis, bronchitis, and sinusitis for each respective period and compared. Clinical guideline adherence rates were also captured and analyzed for this intervention.

Results: Evaluation of 273 patient encounters with diagnoses of URI, sinusitis and bronchitis during the intervention period demonstrated a 56.8% reduction in the prescribing rate of antibiotics (CI 95%, $p < 0.00$) and an 87.2% rate of compliance with the adopted clinical guidelines (CI 95%, $p < 0.00$).

Conclusion: Antibiotic prescribing for common URI diagnoses was significantly reduced at two urgent care centers through the implementation of multimodal strategies targeting providers and patients. Such an approach could enhance compliance with URI evidence-based practice guidelines in the outpatient setting resulting in the judicious use of antibiotics.

E 17 - Use of Antibiotics

Advance Practice Registered Nurses' (APRNs') Clinical Practice Strategies to Deter Antibiotic Overuse

Pamela Willson, PhD, APRN, FNP-BC, CNE, FAANP, USA

Susan K. Lee, PhD, RN, USA

Marcia Poole, EdD, APRN, FNP-C, USA

Abstract

Purpose: Despite evidence that unnecessary antibiotic therapy for acute respiratory tract infections (ARTIs) increases risk of adverse drug events, increases antibiotic-resistant bacteria and healthcare costs, while not providing clinical improvement, prescription use is common. While there are reports of physician clinical practice strategies to deter antibiotic overuse, no studies specific to Advanced Practice Nurses' (APNs) practice behaviors were found. The provider's communication of positive and negative treatment recommendations leans to support for deterring antibiotic misuse. The primary aim of this study was to describe APNs clinical strategies to reduce antibiotic overuse for ARTIs in pediatric patients.

Methods: The conceptual model of evidence-based guideline adherence framed the Case Scenario Questionnaire. A random sample (N=3,000) of Family and Pediatric APN members of the Texas Nurse Practitioner professional organization were invited to participate. Two hundred and sixty-eight (N=268) APNs responded to the electronic 35-item survey and free-text Case Scenario Questionnaire. The Case Scenario Questionnaire was developed and field-tested prior to the project and contained a color image of the case study patient's oropharynx. The questionnaire content addressed: 1) recognition of ARTI guidelines, 2) use of point-of-care testing, 3) identification of communication strategies, and 4) determination of clinical practice comfort care alternative and complementary management recommendations.

Thirteen participants were not currently practicing and, therefore, did not meet inclusion criteria. Most respondents' specialty practice was primary care [i.e., family (n=155, 62%), adult/gerontology (n= 26, 10%), pediatrics (n=19, 8%)], followed by 16 (6%) in acute care. Neonatal, woman's health, psych/mental health, and emergency room APNs comprised the remaining 34 (14%) respondents. Most APNs practiced in urban areas (n=189, 75%) for 1 to 37 years.

Results: Point of care rapid strep testing was performed by 60% (n=135) of the APNs, 35% (n=78) of clinics did not have testing, and 6% reported the test unnecessary to diagnose ARTI. Of those who use rapid tests, a negative result lead to 43% (n=56) proceeding to throat culture prior to prescribing antibiotic. Fifteen percent (n=19) did not prescribe an antibiotic, but educated the patient and family on home remedies for symptom management. Antibiotic contingency plans were utilized by 71% (n=151) APNs and primarily consisted of calling the patient in 48-72 hours to verify the patient's condition. If no improvement was reported, antibiotics were prescribed. Fifty-nine percent (n=112) of patients'/parents' expectations to receive antibiotics affected the decision to prescribe antibiotics. The most common reason for not prescribing antibiotics was that the illness was viral. Recommended symptomatic care strategies included: fluids and rest (n=147, 82%) and over-the-counter acetaminophen, decongestants, or cough medicine (n=113, 63%). Alternative therapies recommended were: saline nasal irrigation twice a day (n=72, 40%), Vitamin C 500 to 1000 mg three times a day for first 3-4 days (n=38, 21%) and zinc gluconate or acetate every 2 hours while awake (n=33, 19%). Comparison rates for guideline adherence, as well as types and rates of comfort care strategies used, were reported.

Conclusion: Patient/parents expect antibiotics for symptoms that are of viral etiology. Texas APNs must stay abreast of national guidelines of care for ARTIs and are implementing patient/parent education and clinical strategies to decrease the overuse of antibiotics for patients. Since contingency plans and patient-centered education are methods to avoid antibiotic overuse, challenges exist to address system approaches for APNs' unique practice settings.

F 13 - Promoting Outcomes in Obese Patients

Effectiveness of Weight Control Program on Nutritional Status and Knee Pain in Overweight Older Adults

Noppawan Piaseu, PhD, RN, APN/NP, Thailand
Pawena Narasri, BNS, RN, Thailand

Abstract

Purpose: A common health problem in older adults is knee pain, particularly those with overweight. Weight control is an appropriate approach for overweight older adults suffering from knee pain. This study aimed to examine the effects of weight control program using community and group support on nutritional status and knee pain in overweight older adults with knee pain. The specific research purposes were to: 1) compare mean scores of nutritional status (body mass index and waist circumference) and knee pain in the experimental group before and after the program, and 2) compare mean differences of nutritional status (body mass index and waist circumference) and knee pain between the experimental and the control groups.

Methods: This study employed quasi-experimental research with 2-group pre-post design. Through convenience sampling with inclusion criteria, the sample included 60 overweight older adults with knee pain who lived in two communities in Bangkok, Thailand. The 30 subjects in the experimental group in a community participated in the 12-week weight control program including four stages: Raising community awareness, Aiming at target health outcome, Mobilizing change, and Assuring synergy through group activities. The program consisted of 14 activities addressing food exchange and behavioral modification for food consumption, arm swing exercise, knee exercise, modification of postures in daily living and arrangement of the surrounding environment in the community as well as monitor of body mass index and waist circumference. The control group received only leaflets and booklets. Data were analyzed using descriptive and inferential statistics including Chi-square test, Paired t-test, Independent t-test, and Wilcoxon Signed Ranks test.

Results: Results revealed that the mean age of the subjects was 70.8 (SD 5.8) years, ranging from 60-84 years. There were no significant differences in demographic characteristics between the control and the experimental groups. At baseline, the mean body mass index, waist circumference, and knee pain in the control group were 27.2 kg/m² (SD 3.5), 94.6 cm (SD 9.5), 5.4 (SD 1.6), respectively and those in the experimental group were 27.9 kg/m² (SD 3.5), 95.3 cm (SD 8.8), 6.7 (SD 1.9), respectively. There were no significant differences in body mass index and waist circumference between the control and the experimental groups at baseline, except for knee pain. After the program, the experimental group had body mass index (27.2: SD 3.1), waist circumference (93.6: SD 8.7) and knee pain (4.4: SD 1.9) less than before the program with statistical significance ($t = 2.128, p = .042$; $t = 6.599, p < .001$; $Z = -4.745, p < .001$, respectively). Mean differences in body mass index (-.69), waist circumference (-1.74), and knee pain (-2.4) in the experimental group were more than differences in body mass index (.01), waist circumference (.44), and knee pain (.13) in the control group with statistical significance ($t = 2.124, p = .038$; $t = 7.209, p < .001$; $t = 7.447, p < .001$, respectively).

Conclusion: The weight control program was effective. The results suggested approaches to behavioral modification on food consumption behaviors and group support for arm swing exercise and knee exercise as appropriate for the overweight older adults with knee pain.

F 13 - Promoting Outcomes in Obese Patients

Evaluating Nursing Home Resident Monitoring Technology Use in Pressure Ulcer Prevention: A Mixed-Methods Approach

Tracey L. Yap, PhD, RN, WCC, CNE, FAAN, USA

Jill Flanagan, MS, BS, USA

Kao Ly, MSN, RN, USA

Susan M. Kennerly, PhD, RN, WCC, CNE, USA

Abstract

Purpose: Standard practice for pressure ulcer (PrU) prevention care in U.S. nursing homes (NH) is to reposition residents every 2 hours to minimize pressure exposure; however, on-time repositioning compliance is low (~30%). This study examined the adaptive and technical challenges nursing staff face in using new technology to facilitate on-time repositioning of NH residents.

Methods: A 21-day trial with a convergent mixed methods pre/post-test design compared resident and staff outcomes at a southeastern U.S. NH. The Leaf Patient Monitoring System is a wireless movement tracking system that monitors resident position and movement 24-hours a day, cues staff when repositioning is required; captures position and repositioning frequency, and enables calculation of the percentage of on-time compliance. Web-based surveys completed by staff (RNs, LPNs, CNAs) pre/post intervention were the Nursing Culture Assessment Tool (NCAT), Perceived Organizational Support (POS), and Affective Organizational Commitment (AOC). During post-intervention staff focus groups (2, n=13), perspectives of adaptive and technical challenges were gathered via semi-structured questions. Quantitative analyses were performed for NH staff data and Leaf monitoring data. Qualitative analyses using transcribed focus group sessions identified core concepts, applied satisfaction-based apriori codes, and allowed emergence of new themes.

Results: Staff on-time repositioning compliance improved from 59.8 to 77.3%. Staff responded positively to repositioning cues and described an enhanced sense of teamwork in order to achieve on-time repositioning, believing that usual care was provided faster. Adaptive and technical challenges focused on accessibility to system monitors, difficulties repositioning residents in reclining chairs, and uniformity in using system pause functions. Nursing culture's normative ranking percentage increased and communication, satisfaction, and professional commitment item scores positively corresponded with focus groups. Also, POS and AOC scale scores improved.

Conclusions: Triangulated findings support the effectiveness of nursing staff strategies for managing the adaptive and technical challenges experienced in using new technology. Clinical and research insights will be discussed in relation to implications for adaptive leadership to aid translation of findings to PrU prevention practice.

F 13 - Promoting Outcomes in Obese Patients

Comparison of Braden Nutritional Risk Screening to Dietary and Weight Outcomes: Clinical and Research Insights

Susan M. Kennerly, PhD, RN, WCC, CNE, USA
Tracey L. Yap, PhD, RN, WCC, CNE, FAAN, USA
Melissa K. Batchelor-Murphy, PhD, RN-BC, FNP-BC, USA
Lisa Boss, PhD, MSN, BSN, RN, CEN, USA
Susan D. Horn, PhD, MS, USA
Ryan Barrett, MS, BS, USA
Nancy Bergstrom, PhD, RN, FAAN, USA

Abstract

Purpose: The Braden Scale for Pressure Sore Risk[®] is a screening tool used to determine overall risk of pressure ulcer (PrU) development and estimate severity of individual resident risk factors, such as nutrition. Nurses often use the Braden nutrition subscale to screen nursing home (NH) residents for nutritional risk, and recommend a complete nutritional assessment as needed. Clinical and research insights gained in comparing initial Braden Nutrition subscale (hereafter nutrition subscale) scores to dietary intake and resident outcomes (e.g., BMI and body weight change) will be highlighted and a researcher-developed nutritional risk evaluation and PrU prevention care planning framework introduced.

Methods: Secondary data from the TURN study's investigation of U.S. and Canadian NH residents (n= 690) who scored at moderate or high PrU risk were used to evaluate the nutrition subscale's utility for identifying nutritional intake risk factors. Associations were studied between the nutrition subscale screening score, dietary intake (mean percent meal intake and by meal type, mean number of protein servings, and type of protein source(s), and percent intake of supplements and snacks), weight outcomes, and new PrU incidence.

Results: The majority (61.9%) of residents who were at moderate risk for PrU development and 59.2% of those at high risk consumed a mean meal intake of <75%. Less than 18% of residents consumed <50% of meals or refused meals. No significant differences were observed in body weight variances by nutrition subscale risk or in mean number protein servings/meal [1.4 (+ SD=0.58) versus 1.3 (+ SD=0.53)] for moderate versus high risk residents. Nutrition subscale estimates approximated subsequent estimated dietary intake.

Conclusion: Nutrition subscale scores can offer insight into meal intake patterns for those at PrU risk. Findings support use of the Braden Scale's nutrition subscale as a preliminary screening method to identify focused areas for potential intervention. Dietary intake monitoring in conjunction with weight loss or gain as indicators of dietary adequacy helped further document connections between nutrition risk category, intake, and weight sustainability. Clinical and research insights will be discussed in relation to nutritional risk evaluation and care planning framework to aid translation of findings to PrU prevention practice.

H 05 - Transitions in Care of the Older Adult

Effects of Care Arrangements on Chinese Older Adults' Relocation to Long-Term Care Facilities

Jing Wang, MSN, USA

Bei Wu, PhD, FGSA, FAGHE, USA

Wei Pan, PhD, USA

Qing Yang, PhD, USA

Abstract

Purpose: By the end of 2013, the number of China's older adults aged 60 and above reached 202 million, accounting for 14.8% of its total population (Chinese Academy of Social Sciences, 2014). It is estimated that more than 100 million older adults are diagnosed with one or more chronic diseases and 37.5 million of them are living with functional disabilities. Although the rate of institutionalization of Chinese older adults in long-term care (LTC) facilities has increased rapidly from 0.86% to 1.51% between 2005 and 2012 (Ministry of Civil Affairs of the People's Republic of China, 2013), China's long-term care facilities are in a preliminary developmental stage (Peng & Wu, 2015). Placing older parents in LTC facilities is still stigmatized by Chinese society to some extent (Gu, Dupre, & Liu, 2007).

Most Chinese older adults still rely primarily on family support, particularly after they become functionally dependent (Wang, Zheng, Kurosawa, Inaba, & Kato, 2009). However, the traditional familial care for older adults has been decreased by fewer children, smaller family size, out-migration of adult children from rural to urban areas for employment opportunities, and increased women employment. Older adults in empty nest families surpassed 50 million by the end of 2013 (Chinese Academy of Social Sciences, 2014). Under this circumstance, elder care in China has become a public concern.

As a developing country with widened urban and rural divide and limited social and economic resources, early and unnecessary institutionalization of older adults can be a heavy burden on the country and taxpayers. It is crucial to understand factors impacting on institutionalization of older adults in China. In a study based on national survey data, Gu et al. (2007) identified poor health status at baseline (ADL disability, cognitive impairment, and having one or more chronic diseases), as risk factors for institutionalization. However, no study so far in China investigated the effects of different care arrangements on institutionalization of older adults although care arrangement is a key point to understand China's elder care development.

The objective of this study was to examine care arrangement in China and to explore effects of care arrangements on Chinese older adults' age to relocate to long-term care facilities (institutionalization) after taking their ability to perform activities of daily living, self-rated health, residence, and other demographic variables into account. We hypothesized that different types of care arrangements will have significant impacts on older adults' age to institutionalization.

Methods: This study is a secondary data analysis using a true longitudinal dataset of Chinese Longitudinal Healthy Longevity Survey (CLHLS). Data collection was cosponsored by the US National Institute on Aging, the United Nations Fund for Population Activities, and the China National Foundation for Social Sciences. Its study sample was randomly selected from half of the counties and cities in the 22 provinces of China, representing 85% of the total population of the country.

The 2002-2011 longitudinal dataset composed of 15475 older adults who were surveyed in 2002 and then followed up in 2005, 2008 and 2011. Event is coded as 1 or 0. Event =1 is defined as "residing in nursing home (institutionalization)" at the time of follow-up interview and event=0 is defined as "living alone in the community" or "living with household members in the community" till 2011. The missing data of the included variables of our samples is less than 5%. After deleting missing data, I have a sample of 2628 older adults with 233 of them moving to nursing home in 2005, 2008, or 2011 (event=1) and 2395 of them still live in the community in 2011(event=0). In China, those who reside in nursing home have less than 0.2% chance of going back to the community (Gu, Dupre, & Liu, 2007), so that we regard

institutionalization as a fixed event that will not change once happened. The time variable in the current study is defined as older adults' age when they were first institutionalized in the study.

Eight different care arrangements for older adults are independent variables included in this study: spouses, son and daughter-in-law, daughter and son-in-law, son and daughter, grandchildren and their spouses, other informal caregivers, domestic helpers, and nobody. Covariates in this analysis included gender, place of current residency, self-rated health, ability of performing activities of daily living, financial independence. Except gender as a fixed variable, other four covariates are time-varying variables. Thus, in the current study, we only use participants' report of the other four covariates at the time of the follow-up interview when they moved to nursing homes.

The significance level was set at 0.01. Multivariate cox regression model was applied to investigate how different caregiving arrangements impact on community-dwelling older adults' age to move to nursing homes in China after controlling for covariates included in this study. We also plotted adjusted Kaplan-Meier survival curves, which allows the comparison of curves of different caregiving arrangements that are balanced for other variables in the model. SAS9.3 was used to data analyses.

Results: The total rate of institutionalization between the 2002 and 2005 waves was 0.5%, compared with a rate of 0.8% between the 2005 and 2008, and 1.2% between the 2008 to 2011 waves. Nearly half (47.87%) of the older participants are still primarily cared for by son and daughter-in-laws. Spouses also play important roles in taking care of older adults included in this study (23.78%). Hiring domestic helpers as primary caregivers for older adults is more common in the city (4.16%) compared to rural areas (1.17%).

Care arrangements are a predictor of older adults' age of institutionalization after adjusting for covariates included in this study. In terms of the covariates, current place of residence and their needs for ADL assistance were found to have a significant impact on the outcome variable. The hazard rate of different care arrangements from low to high are son and daughter-in-law, grandchildren, spouses, daughter and son-in-law, son and daughter, other informal caregivers, domestic helpers, and cared for by nobody. Compared to older adults primarily cared for by their spouses, those who are taken care of by both sons and daughters tend to have a 91% increase (Hazard Ratio=2.49, $P=0.002$) in the hazard rate; those who are cared for by other informal caregivers (relatives and friends) and domestic helpers tend to have 2.39 times (Hazard Ratio = 4.03, $P<0.0001$) and 2.53 times (Hazard Ratio = 4.64, $P<0.0001$) the hazard rate of those cared for by spouses respectively. Those who have nobody to take care of them tend to have a 172% increase in the hazard rate (Hazard Ratio = 5.59, $P<0.0001$) compared to those who are cared for by their spouses. Those who need ADL help tend to have a 67% decrease in hazard rate (Hazard Ratio = 0.50, $P<0.0001$) compared to their counterparts who do not need ADL assistance (See table 2).

Conclusion: Nearly half of the older participants are still primarily cared for by son and daughter-in-laws. This is in line with the Confucian concept of filial piety or "xiao" in Chinese has long been valued in China. The notion of filial piety covers a broad spectrum of attributes. It encompasses "Children's respect, obedience, loyalty, material provision, and physical care to older parents" (Zhan, Feng, & Luo, 2008, p.545).

It is interesting to see that compared to older adults primarily cared for by their spouses, those who are taken care of by both sons and daughters tend to have a higher hazard rate. This can be reflected from increasing reports of family disputes on elder care and older adults' right protection in recent years. When elder care responsibilities are shared by sons and daughters, there are more possibilities that none of them would like to take the leading roles of caring for their older parents. Instead, they are more likely to avoid or shift elder care responsibilities to their siblings.

In contrary to the status in Hong Kong, China, hiring domestic helpers as older adults' primary caregivers in Mainland China increases their hazard rate of institutionalization in the current study. Significant differences between Chinese domestic helpers and foreign domestic helpers in Hong Kong concerning their age, educational background, income level, training, and access to social welfare can be potential reasons for this difference. By and large, Hong Kong has long been attracting thousands of foreign

domestic helpers with its preferential policies and legal protection and support. For Chinese domestic helpers in mainland China, low income, lack of protective regulation, and ineffective supervision and law enforcement all contribute to the serious shortage of competent and qualified elder care workers and their high turnover.

It is interesting that those with no need of ADL assistance have significantly higher hazard ratio compared to those with ADL assistance needs. This is related to the status quo of China's formal long-term care development. Unlike most developed countries, where the predominant objective of nursing homes is to provide care for persons who are physically or cognitively impaired, most elder care institutions in China tend to preferentially accept younger, healthier, or non-disabled older adults.

H 05 - Transitions in Care of the Older Adult

Participatory Approach to Build Capacity: Nurse-Led Research to Overcome Insufficient Mobility in Hospitalized Older Adults

Gordana Dermody, PhD, RN, CNL, USA
Ruth A. Bryant, PhD, RN, CWOCN, USA

Abstract

Purpose: The objectives of this presentation are to: 1) Describe the participatory approach used to involve bedside nurses, and other disciplines in the conduct of nurse-led research to overcome insufficient older adult mobilization. 2) Discuss how this participatory approach served as a spring-board to build capacity for additional nurse-led research at the bedside.

Background: It is well-known that hospitalized older adults do not receive the mobility they need (Barber et al., 2015; Fisher, Graham, Ottenbacher, Deer, & Ostir, 2016). Due to musculoskeletal changes that accompany aging, this population is at increased risk for accelerated muscle loss and weakness which contributes to functional decline, and other adverse health outcomes (Cruz-Jentoft et al., 2010). Studies conducted in a variety of developed countries, including Australia, Canada, England, Ireland, Israel and the United States, show that concerns about the insufficient promotion of mobility in hospitalized older adults exist on an international scale. The urgency to address the mobility needs of older adults is heightened by the demographic shift that is occurring due to our aging population. A recent international research study reported that the growth of older adults 65 years and older is accelerating in multiple developed as well as developing nations (He, Goodkind, & Kowal, 2016).

Busy inpatient units have been described as chaotic settings (Catchpole, 2013). In addition, within this environment, nurses encounter a variety of barriers to promoting mobility in older adults (Hoyer, Brotman, Chan, & Needham, 2015). The literature suggests that there is a convergence of knowledge, attitude and external barriers that contributes to the vexing problem of insufficient mobility (Hoyer et al., 2015). While the incongruence between mobility needed and the mobility promoted in hospitalized older adults has been studied for decades—and literature has pointed a critical finger at nurses for failing to promote mobility—little is known about whether the barriers that nurses encounter could explain nurses' mobility-promoting behavior. The accelerated rise in the number of older adults necessitates that clinical and academic nurses work collaboratively to take the lead to overcome potential barriers to nurse-promoted mobility for this vulnerable population by becoming involved in the design and conduct clinical research.

Two key principles to participatory research are to engage partners in all phases of research and to build on existing goals of the clinical setting (Schmittiel, Brumbach & Selby, 2010). The initial project stemmed from a staff identified need, which was substantiated by the Nurse Manager as a priority and then the study was designed and conducted by the nurse researcher with the participation of bedside nurses. Subsequent projects were based on findings from the initial study and designed collaboratively with the staff and the nurse researcher.

Methods: A participatory approach was used to engage nursing staff in the research process. A team of hospital nurses were involved in discussions addressing all phases of research including data collection methods. To recruit nurse participants for the initial study, informational group discussion sessions were conducted which served to foster an awareness and enthusiasm among the nursing staff. Several additional strategies were employed to nurture and sustain engagement of the nursing staff (Roll et al, 2013). Regular communications were maintained with the nursing staff through informal (i.e., being present on the unit) and formal methods (i.e., unit-based newsletter or email, unit-based council meetings). Study procedures were integrated into daily patient care such as using the informational patient "white board" for communicating mobility goal setting. Nursing staff co-investigators were encouraged and supported to submit abstracts at local, regional and national professional meetings to disseminate findings.

Results: Numerous research-based activities have been generated stemming from the original study purpose to identify and then minimize barriers, and increase nurse-led patient mobilization. Between June 2015 and December of 2016 three research projects were conducted, and two other studies are currently in progress. In addition, 3 manuscripts are under review. Furthermore, findings have been disseminated through posters and podium presentations in a variety of venues including hospital-based symposia, national research conferences and professional nursing organizations. Contributing authors of these research activities are interdisciplinary and include bedside nurses, nurse managers, physical therapists, volunteers, nurse-researchers, and data analysts. Using a participatory approach is useful to build capacity for nurses and other disciplines to collaboratively address clinical issues and to facilitate nurse-led research at the bedside. In addition, using this approach has stimulated an ongoing dialogue about research findings and has fostered a curiosity about next steps. This has served as a springboard for future nurse-led research to overcome insufficient older adult mobilization.

Conclusion: A participatory approach to clinical research capitalizes on the strengths and knowledge of the bedside nurse and the researcher to design and conduct clinically relevant research. This partnership fosters a culture of curiosity and serves as a springboard to generate additional researchable clinical questions. In addition, this approach provides numerous opportunities for the nursing staff to develop their presentation skills.

H 06 - Chronic Illness Management

American Lymphedema Framework Project: An Overview of 8 Years in Moving the Lymphedema Field Forward

Jane Armer, PhD, RN, CLT, FAAN, USA

Nathan C. Armer, MEd, USA

Joseph L. Feldman, MD, CLT-LANA, USA

Abstract

Purpose: To inform nurses and other health professionals in the U.S. and around the world about the founding of the American Lymphedema Framework Project (ALFP) in 2008 as the first invited national framework of the International Lymphoedema Framework (ILF) and the ALFP progress in achieving its mission to improve the management of lymphedema and related disorders in the United States, while contributing to global international advancement.

Methods: In 2008, lymphedema clinical experts, researchers, educators, patients, advocates, and other stakeholders began the process of developing the American Lymphedema Framework Project (ALFP) at the invitation of the ILF. At the American Cancer Society-sponsored Stakeholders Conference in 2009, the collaboration of healthcare providers, researchers, patients, educators, advocates, third-party payers, and industry representatives established the mission and initial goals of the ALFP. Using the 'open-space meeting' approach, consisting of 'self-managed work groups where leadership is shared, diversity is encouraged and personal empowerment is achieved,' the initial group of 72 experts explored the issues involved in the management of lymphedema and lymphatic system disorders in the United States. To ensure that the work of the ALFP remained current, subsequent 'open-space meetings' were held in 2011 (Columbus, OH) and 2014 (Columbia, MO, and Atlanta, GA). In 2015, the first international 'open space' stakeholder meeting was held in Cape Town, Republic of South Africa, in support of the formation of the Lymphedema Association of South Africa (LAOSA), modeled after the ALFP.

Results: Seven major issues in the management of lymphedema were identified at the first stakeholder meeting: (1) Establish the credibility of the ALFP; (2) Create awareness of lymphedema and related lymphatic system disorders; (3) Develop research to refine diagnostic standards and provide evidence for effective treatments; (4) Enhance patient education, support, and self-management; (5) Establish criteria for health provider education; (6) Promote evidence-based practice for lymphedema management; and (7) Improve reimbursement. The stakeholder meetings in 2011 and 2014 confirmed the same issues as a priority, with awareness/education as the highest priority. International issues in a lower-resource country (2015) mirror those in a higher resource country, such as the U.S.

Two of the established goals of the ALFP are to: (1) Define best practices of lymphedema management; and (2) Develop a minimum data set to support research to improve lymphedema outcomes. Progress in meeting these goals is summarized here.

As part of working toward promotion of evidence-based best practices, teams comprised of ALFP steering committee members and other lymphedema experts conducted systematic reviews of the current literature on management of lymphedema (N=10). A research librarian assisted with searches of 11 major medical databases. From almost 6000 screened articles, articles were selected based on defined eligibility criteria for final review (n=1303) and categorization (n=659) by topic experts. The following reviews have been completed and published in peer-reviewed journals, with complete references and links available at the ALFP website (ALFP.org):

1. The surgical treatment of lymphedema: A systematic review of the contemporary literature (2004-2010)
2. Exercise in patients with lymphedema: A systematic review of the contemporary literature
3. A systematic review of the evidence for complete decongestive therapy in the treatment of lymphedema from 2004 to 2011
4. Psychosocial impact of lymphedema: A systematic review of literature from 2004-2011

5. Complementary, alternative, and other non-complete decongestive therapy treatment methods in the management of lymphedema: A systematic search and review
6. Palliative care for cancer-related lymphedema: A systematic review
7. Intermittent pneumatic compression therapy: A systematic review
8. Self-management of lymphedema: A systematic review of the literature from 2004-2011
9. Exploring the usefulness of botanicals as an adjunctive treatment for lymphedema: A systematic search and review.
10. A systematic review of care delivery models and economic analyses in lymphedema: Health policy impact (2004-2011)

Another resource developed to promote best practices in lymphedema management is the ALFP Therapist Directory. Look4LE is a mobile app developed by the ALFP to help find therapists trained to assess and treat lymphedema. Look4LE is a searchable online database with demographic information (geographical location, telephone, email, and geospatial linkages) of certified lymphedema therapists. The app currently features almost 1,200 Lymphology Association of North America (LANA)-certified therapists, with plans to steadily add 135-hour-trained therapists worldwide. Therapists may be found by using the directory, or by accessing the app's built-in map feature to search by location name, zip code, or current location. Each therapist has a contact page where phone, street, web, and email addresses can be found; a map viewed; directions obtained; and the therapist contact information added to system contacts. An individual (health care professional or patient) seeking a therapist can search by geographical location or discipline with assurance that the therapist is certified as a lymphedema therapist with the required 135 hours of specialized study. There are also a number of resources listed in the app with links to webpages and organizations relevant to lymphedema.

Working toward achievement of the second goal, the lymphedema minimum data set (MDS) has been created by the ALFP to collect and analyze clinical and self-reported data related to lymphedema. The data set contains longitudinal visit information, volume measurements, symptoms, and treatment data. The MDS currently contains approximately 1300 patients across over 8000 clinical visits. The MDS has been tested to ensure the elimination of data duplicates and inconsistency. Each site's data export into the MDS has been developed and tested. A suite of data mining tools has been developed to identify clinically significant patterns and to support more sophisticated analytic approaches to understanding lymphedema risk, emergence, diagnosis, treatment, management, and long-term impact. The ALFP team has collaborated with experts in engineering to develop a 3D mobile imaging platform for remote measurement of limb volume to be transferred to the MDS for surveillance and clinical management.

Conclusion: Through a continued partnership of patients, healthcare professionals, researchers, industry representatives, third-party payers, and advocates, the ALFP has established a leadership role in risk reduction, treatment, education, and research of lymphedema management. Based on the systematic reviews, it is evident that there is a paucity of rigorously-conducted research studies. There is a critical need for well-designed, randomized trials to examine the available range of treatment modalities to determine which ones may be the best for managing LE. It is imperative that we design and test strategies using relevant patient-reported outcomes and bring the scientific findings to the understanding of and application by therapists, clinicians, patients, families and others involved in the management of lymphedema. Aggregation of clinical and research data through informatics infrastructures such as the ALFP minimum data set support development of practice-based evidence to guide best practices for lymphedema. Innovations such as development and refinement of mobile devices for limb volume measurement and resource retrieval promise to improve management for persons with and at risk of lymphedema. The American Lymphedema Framework Project has made a major contribution toward addressing the prioritized issues identified by stakeholders in 2008 and moving the field forward.

Insomnia and Health-Related Quality of Life in Adults With Type 2 Diabetes

Susan Sereika, PhD, USA

Eileen R. Chasens, PhD, RN, FAAN, USA

Letitia Y. Graves, MSN, RN-BC, USA

Abstract

Purpose: Previous research that suggests that obstructive sleep apnea (OSA) is associated with an increased risk for T2DM (Aronsohn, Whitmore, Van Cauter, & Tasali, 2010) as well as decreased health-related quality of life (HRQoL) in persons with diabetes (Chasens, Sereika, Burke, Strollo, & Korytkowski, 2014). Diabetes increases the risk for another sleep disorder, insomnia, in a dose-related fashion (Budhiraja, Roth, Hudgel, Budhiraja, P. & Drake, 2011). The purpose of this study is to evaluate if insomnia is associated with worse HRQoL in adults with T2DM.

Methods: This study is a secondary analysis of baseline data from participants in a randomized clinical trial (1R01DK096028). The parent study evaluates if persons with treatment of OSA + diabetes education have better glucose control and self-management behavior compared to those on a sham (placebo) device + diabetes education. Inclusion criteria for the baseline assessment include age > 18 years; self-report of T2DM, CPAP naïve, and willing to be randomized to CPAP if found to have OSA (apnea + hypopnea index [AHI] ≥ 10). Measures included demographics (sex, age, race, education), sleep quality (Pittsburgh Sleep Quality Index [PSQI] Buysse, Reynolds, Monk, Berman, Kupfer, 1989), (scores > 5 = poor sleep quality), insomnia (Insomnia Severity Index [ISI] Morin, Belleville, Belanger, Ivers, 2011); scores 0-14 = "no insomnia" to "mild insomnia" and scores ≥ 15 = "moderate insomnia" to "severe insomnia", diabetes related distress (Problem Areas in Diabetes [PAID], Welch, Jacobson, Polonsky, 1997) with higher scores = more distress, and mental and physical HRQoL component scores (SF-12v2 MCS, PCS, Ware, Kosinski, Keller, Ware, Kosinski, Keller, 1996.) with higher scores = better mental or physical HRQoL. The clinical evaluation included A1C for glycemic control; height and weight were measured to calculate BMI. Descriptive statistics include mean (SD) for continuous variables and percent and frequency for categorical variables. Inferential statistics included independent Students t-tests, and Pearson correlations. Linear multiple regression models were conducted to see if age, race, college education, BMI, diabetes related distress, or insomnia predicted mental and physical HRQoL (MCS, PCS). The level of statistical significance was set at $p < .05$.

Results: The sample ($N=194$) was primarily middle age (mean age = 56.8 years ± 10.7 [range 26-88 years], overweight (mean BMI = 34.7 ± 6.8), had suboptimal glucose control (mean A1c = 7.9% ± 1.8), and moderate-to-severe insomnia (41%). Participants were well distributed by sex (male 46%; $n=90$), race (white 54%, $n=105$), and college graduate (31%, $n=60$). No differences were observed in mental or physical HRQoL (MCS, PCS) by sex, race, marital status; participants with a college education had significantly ($p < .01$) increased physical HRQoL. Age was significantly associated with improved mental HRQoL ($r = .25$, $p < .01$). Participants with moderate-severe insomnia had significantly worse diabetes related distress [PAID], lower mental and physical HRQoL (MCS, PCS) than those who reported no insomnia/mild insomnia (all p values < 0.5). Using the enter method it was found that age, BMI, diabetes related distress and insomnia explain a significant amount of the variance in mental HRQoL ($F = 12.564$, $p < .001$, $R^2 = .296$, R^2 adjusted = .273). The regression model for physical HRQoL found that age, college graduate, BMI, and insomnia explained a significant amount ($F = 7.575$, $p < .001$, $R^2 = .202$, R^2 adjusted = .176). Limitations to this study include the cross-sectional sample, secondary analysis design, relatively modest sample size, and that the sample might not be reflective of all persons with T2DM.

Conclusions: Insomnia was highly prevalent in the recruited sample; insomnia was found to have significant negative impact on mental and physical HRQoL after controlling for age, race, education, BMI and diabetes-related distress. Future research is needed to determine if insomnia is associated with worse glucose control or diabetes self-management behavior.

H 08 - Children in the Intensive Care Unit

Newly Licensed Nurses' Experiences With End-of-Life in the Pediatric Intensive Care Unit (PICU)

Maureen Hillier, DNP, RN, CCRN, USA

Abstract

Purpose: Nursing education has identified gaps in student knowledge and has admitted to a sub-optimal amount of student education on death and dying education in current curriculums (Beck, 1997; Delaney, 2003; Rush, Adamack, Gordon, Janke, & Ghement, 2013; Thompson, Austin, & Pomfretto-McGrath, 2010). There is a paucity of information on the newly licensed nurses' experience with death and dying in critical care and minimal information for this phenomenon when it occurs in the pediatric critical care setting. Therefore a gap existed in nursing knowledge on how to best understand the death and dying experiences of the newly licensed nurse in pediatric critical care. The purpose of this qualitative descriptive research study was to explore the newly licensed nurse's experience with death and dying in the Pediatric Intensive care Unit (PICU) setting.

Those in the discipline of nursing spend more time with dying patients than any other profession and this is particularly true in the field of critical care where mortality rates are the highest (Bloomer & O'Connor, 2012). In one study, thirty-seven percent of graduate nurses described feelings of discomfort when caring for patients who are dying (Casey, Fink, Krugman & Probst, 2004). Research has demonstrated that newly licensed nurses have reported feelings of being scared and stressed; others have mistakenly believed their fear and guilt somehow contributed to a child's death (Vanderspank-Wright, Fothergill-Bourbonnais, Malone-Tucker, Silvar, 2011). Current research supports the need for additional coping strategies for pediatric nurses such as colleague support and institutional resources when caring for a child who is dying (Cook, et. al., 2012). Job dissatisfaction with new graduate nurses has been examined and as many as 17.5% of new nurses will leave their first job within one year (Kovner, Brewer, Fatehhi & Jun, 2014). Nurse turnover continues to be an international concern and has been studied throughout the world (Chen, Chu, Wang, & Lin, 2008; Josephson, Lindberg, Voss, Alfredsson, & Vingard, 2008; Camerino, et al., 2008; Morrell, 2005; O'Brien-Pallas, et al., 2006).

Methods: A qualitative study design was selected to best inform the identified gap in the literature and to describe death and dying from the perspective of the newly licensed nurse in the PICU. An expedited IRB approval was obtained from a free standing quaternary care children's hospital in the northeastern United States. Newly licensed nurses were asked to privately share their experiences with death and dying in the PICU. Inclusion criteria was less than 3 years of experience as a nurse, employed in a PICU, and one who had cared for a child who was dying or had died. Thirty-five nurses met inclusion criteria and received an email invitation to participate in an audio-recorded 45-60 minute 1:1 interview about their experience. The interviewer was the instrument and the interview was the tool. The interviewer was a hospital based nurse scientist with expertise in qualitative research methodologies who had no supervisory or evaluative responsibility. Participants were not identified, and interviews were transcribed verbatim with all identifiers removed. All data was reported in aggregate. The data analysis followed Colaizzi's 7-step method (1979) to assure credibility, trustworthiness, reliability and potential replication.

Results: Expressive and poignant perspectives of the nurses were gained through in-depth interviews. The participants reflected on the first experiences of caring for a child who died. The participants were the experts and were asked to share their thoughts and remembrances which led to rich data. During data immersion, multiple impressive statements were extracted and contributed to the emergence of two central themes which were *The Journey* and *Recommendations*. The subthemes that supported the theme *The Journey* were *Doesn't Seem Real until You're There*, *Technology: A Blessing or a Curse*, *Response to Death*, *Timing of Death*, *Empathic Presence* and *Tasking Care of Self*. The subthemes that grew out of *Recommendations* were *Support* and *Additional Education*.

There still remains a paucity of research specific to newly licensed nurses' experiences with death and dying in the PICU. The participants reflected on what had become their journey upon the sea of life and

death. Life they understood and felt confident about with their skill set. Death however, was filled with dread and uncertainty. Experiences prior to employment were few and exposure and information to their role was minimal. They all agreed that the experience was one that doesn't seem real until you're there. Participants discussed technology as both a blessing and a curse and were not sure which was more significant and at times which was preferred. The timing of death influenced how they responded to the death. They were challenged about how to respond to various kinds of deaths, while simultaneously juggling the need to provide empathic presence to family members at all times. Taking care of self then emerged as an important realization after participating in many encounters of such overwhelming experiences. Ultimately, recommendations that included more support and additional education were provided by participants in an effort to make it better for themselves and the next generation of newly licensed PICU nurses.

Nursing practice is dynamic and does not hold one worldview for all. Our results helped us to understand what newly licensed nurses perceived to be helpful during the death and dying process in the PICU. To date, the nursing research literature has not addressed this unique topic. It is hoped that a better understanding of this phenomenon will guide curriculum changes at the undergraduate level as well as provide information for the new graduate staff nurse orientation class. Limitations include the sample which was small and purposive which may not be transferable to all newly licensed nurses outside of one institution and specialty.

Conclusion: This qualitative research study served to enlighten our understanding of the experiences of the newly licensed nurses with death and dying in the PICU. The final results from this study are critical as many newly licensed nurses now seek to start their career in the PICU setting. In addition, many newly licensed nurses are being given preference in employment as they are less expensive for an institution to hire than an experienced nurse. This research will help academic and clinical educators to understand the newly licensed nurses' experiences with end-of-life in the PICU. It may also transform how the discipline teaches and prepares nurses to work in this environment. Future implications for practice may include additional teaching, support and self-care for the newly licensed nurse. It has been stated that the ability to provide high quality end-of life care for the child and the family is the most intimate act of nursing care (Ronaldson, 2006). This research identifies the need for PICU nurses to be better prepared to provide high quality end-of-life care for the dying child while also honoring and supporting the family. The findings of this research study are just the beginning of a body of knowledge that aims to address the ongoing needs of the newly licensed nurses employed in pediatric critical care.

H 08 - Children in the Intensive Care Unit

Factors Affecting Time Nurses Spend With Fathers in the Neonatal Intensive Care Unit (NICU)

Gina Clarkson, PhD, ARNP, NNP-BC, USA

Mary Jo Gilmer, PhD, MBA, RN, USA

Abstract

Purpose: The aim of this exploratory study was to describe factors affecting the amount of time neonatal intensive care unit (NICU) nurses spend with fathers. Background and Rationale. Family-centered care (FCC) is considered an important standard of practice in NICUs worldwide and research has been conducted in many countries such as Japan, Sweden, Canada, Germany, Iran, United Kingdom, Czech Republic, Taiwan and Australia (Asai, 2011; Blomqvist, Rubertsson, Kylberg, Jöreskog, & Nyqvist, 2012; Feeley, Waitzer, Sherrard, Boisvert, & Zelkowitz, 2013; Garten, Nazary, Metze, & Bühner, 2013; Hadian Shirazi, Sharif, Rakhshan, Pishva, & Jahanpour, 2015; Hugill, 2014; Jakšová, Sikorová, & Hladík, 2016; Lee, Wang, Lin, & Kao, 2013; Trajkovski, Schmied, Vickers, & Jackson, 2012). Family-centered care has been shown to be important to outcomes of infants and families (Maria & Dasgupta, 2016; Williams, 2016). Although nursing practice related to FCC has been studied with both parents (Asai, 2011; Trajkovski et al., 2012), NICU nurses have not previously been asked about how they spend time specifically with fathers. Fathers report NICU staff to be a great source of support (Feeley et al., 2013; Garten et al., 2013) but evidence suggests paternal visitation declines over the length of hospital stay (Clarkson, 2016; Garten, Maass, Schmalisch, & Bühner, 2011) making less time available for nurses to provide FCC to fathers. Fathers desire to be involved and report increased comfort with their infants with increased involvement (Blomqvist et al., 2012) but also report reluctance to be involved without support (Feeley et al., 2013). Therefore, it is important to evaluate factors which affect the amount of time nurses are able to spend with fathers during their visits.

Methods: This study used a descriptive design and an investigator-designed survey with open-answered questions. The setting was a NICU in a large urban teaching facility at a children's hospital in the southeast United States which employed 274 nurses. **Results** presented here were part of a larger survey. A formal IRB exemption was obtained prior to data collection. Neonatal nurse practitioners (NNPs) were excluded due to their provider role. The data was collected anonymously using an online survey. Invitations to participate were sent to all the nurses via emails by the unit assistant manager.

Results: Overall, 94 nurses participated (34% response rate). Demographic information showed most were bedside nurses (N=75, 79.8%) who worked full-time (N= 84, 90.3%) day shift (N= 53, 57%). Most were Caucasian (94.5%) women (98.9%) with bachelor's degrees (63.8%) who were married (65.9%). Median years worked in a NICU were 8 (range of <1 to 40). Median years of nursing experience were 10 (range of < 1 to 52). Age ranged from 23 to 72 years (M=39.6, SD=12.89). Out of the 94 participants, 65% (N=61) provided data for qualitative analysis. Content analysis of the data was conducted by two researchers with expertise in FCC and care of neonates and demonstrated 91.7% overall interrater reliability. Theme categories included nurse factors, father factors, mother factors and infant factors. Subthemes for nurse factors included work flow, equal educator, focus on mother, focus on father, promotion of family bonding and nurse as gatekeeper. Subthemes for father factors included confidence, motivation, level of competence, beliefs, attitudes and availability. Subthemes for mother factors included culture and maternal gatekeeping and subthemes for infant factors were level of illness and tolerance to activity.

Conclusion: Results show that although nurses indicate spending time with fathers in the NICU is important, many factors reduce the quantity and quality of that time. These results help to identify factors which may be modified or moderated by nurses or administration and can be used to help improve nursing knowledge and practice of family-centered care in NICUs worldwide.

H 09 - Clinical Practice Initiatives

Advance Care Planning (ACP) Training: Your Role as a Nursing Leader

Jessica Tully, MSN, RN-BC, CMSRN, CNML, USA

Carol Boswell, EdD, RN, CNE, ANEF, FAAN, USA

Abstract

In today's society, people are living longer. Despite aging and health issues, many American adults do not have Advance Directives (ADs). Statistics show that only 18%-36% of the U.S. population has completed an AD (Pecanac, Repenshek, Tennenbaum, & Hammes, 2014). Although a growing need for advance care planning (ACP) is noted, it is found that healthcare teams lack the education needed to provide teaching on ACP and ADs (Kroning, 2014). It is imperative that healthcare teams stress the value of ACP in order to clarify patients' wishes for future care, ideally before hospitalization (Ke, Huang, O'Connor, & Lee, 2015). Kroning (2014) states that research indicates a critical need for education related to ACP. Education and training assists with instilling confidence to effectively educate and advocate for patients' end of life wishes (Kroning, 2014). Providing healthcare teams education about ACP has potential to increase the number of individuals with completed ADs. While the research is based in the U.S., the lack of ACP training has a global impact related to providing patients healthcare according to their wishes. Providing staff training can potentially impact other important aspects in regards to patient outcomes and healthcare costs.

A pilot study was done in a community hospital. IRB approval was deemed not required by the facilities IRB council. An instructor with training in ACP and ADs provided training sessions. The sessions were open to all healthcare team members to voluntarily attend. Classes were capped out at 15-20 attendees to allow for dialogue and questions. A performed power analysis showed that an N of at least 60 was needed to reach statistical significance.

Three different tools were used for evaluation of the program. The tools were a pretest, posttest, and an evaluation form. All instruments used also provided space for optional feedback and comments from attendees. The pretest and posttest went through an approval process from a panel of experts. The experts conducted a content validity index (CVI) and provided feedback for improvement. The panel included an ACP expert, research expert, and an adult education expert.

The pretest had a total of 6 questions. Two of the questions included Likert scale ratings on self perceived knowledge and comfort regarding ACP and ADs. The pretest also had three yes and no questions asking about previous training, if they had an AD, and if they could describe the difference between ACP and AD. The last question asked how often the individual encountered someone needing assistance with an AD. The answer choices for this question were daily, weekly, monthly, yearly, and rarely.

The posttest had a total of 4 questions. The attendee completed the posttest immediately after the training session. Questions on the posttest included: two different questions using Likert scale ratings of self perceived knowledge and comfort regarding ACP and ADs post training, a yes or no question regarding if they did not have a completed AD before the training session, did they plan on getting one, and the final question was yes or no if they could describe the difference between ACP and AD.

The evaluation tool was completed to provide feedback regarding the effectiveness of the teaching session. Questions asked on the evaluation tool were about effectiveness of the presenter, the tools, and meeting the objectives. Answers were given using a Likert scale. The final two questions on the evaluation asked yes or no if the attendee planned on making changes to their practice and a narrative format of how they planned on using the information to impact their practice. Each healthcare team member provided their pre test and posttest by putting the last 4 digits of their phone numbers in order to remain anonymous. Once completed, the instructor submitted the tools to the project manager for analysis. Answers from attendees were compared per participant to measure the change in knowledge and comfort level regarding ACP. Data is currently in the analysis process with a statistician. Data will be reported during the presentation.

This session will provide an overview of the process used to develop the ACP Training Program. Participants will be able to discuss strategies that leaders should use to ensure the healthcare team has the training needed to confidently perform ACP with patients and families. This session will offer ideas for the participants to engage with other leaders in their own settings regarding the importance of ACP training. Recommendations for assessing the environment will be provided. The presenters will provide suggestions to be used to develop a program in other settings.

H 10 - Culturally Diverse HIV Health Education

Sex Education in the Mosque: An Abstinence-Based Approach to Prevent HIV, STDs, and Pregnancy

Shaakira Lateefa Abdul Razzaq, DNP, RN, USA

Suzanne Willard, PhD, RN, APN-C, ANCC, FAAN, USA

Prudence Arthur, DNP, RN, USA

Radhika Patel, DNP, RN, USA

Abstract

Purpose: Premarital sex among adolescents is very common in today's society throughout the globe. Adolescents often lack the maturity and mental capacity to navigate through the potential physical, psychological, and emotional consequences of sex. In order to reduce teenage pregnancy rates and the spread of sexually transmitted disease, it is important to focus on adolescent sexual education. The Centers for Disease Control and Prevention (CDC) found that "about 1 in 4 (26%) of all new HIV infections occur among American youth ages 13 to 24 years" (CDC, 2013, p 1). There is unique and particular need for education in the adolescent Muslim community that is reflective of their faith.

Islamic teachings are heavily focused on the virtue of chastity and there are many in this community that consider even the word sex to be "dirty." Despite the stigma and taboo nature of sex, two thirds of Muslim youth residing in the US and Canada reported having sex before marriage. In the developing nation of Malaysia, a strong Islamic country, 75.2% out of 238 female Muslims aged 16 to 18 reported premarital sex (Ghani, Abdullah, Akil, & Nordin, 2014). Prior research attributes such sexual behaviors to Muslim youth having weakened Islamic identities related to current societal norms conflicting with Islamic beliefs and ongoing criticism against the Islamic religion (Ghani et al, 2014).

Muslim youth also reported that their greatest source of sexual education is from the media which is often unreliable. Muslim youth lack effective sexual education that coincides with their religious beliefs and thus are unaware of the risks of unintended pregnancy and STDs. (Ghani, Abdullah, Akil, & Nordin, 2014). This project aimed to understand the link between Islamic religiosity and sexual behavior.

Methods: The research project was adapted from Dr. Loretta S. Jemmott's evidenced based curriculum titled *Making a Difference* which utilizes social and behavior theories to educate participants about their sexuality, STDs, and HIV, while instilling high self-esteem and confidence in them to abstain from sex before marriage (Jemmott, Jemmott III, & Fong, 1998). The curriculum was adapted with input from Islamic scholars to incorporate Islamic beliefs to reinforce the importance of having a strong Islamic identity in order to further strengthen Muslim adolescents' sense of confidence allowing them to delay sex until marriage.

Twenty five single, female Muslim adolescents between the ages of 13-19 years old participated in this project. This teaching based intervention was held in a mosque located in Northern New Jersey, USA.

Initial support for this work was minimal from elders in the Muslim community, however the Islamic leaders, scholars, and adolescents strongly supported it and the overall community followed this lead.

Results: The results demonstrated an increase in mean scores on the "HIV/STD/Pregnancy knowledge items" which proved the project enhanced participant knowledge of such topics. There was also an increase in positive attitudes and intentions to abstain from sex before marriage in the posttests. Overall, there was an increase in subjects who did not have sex within three months post intervention which provides further proof of its effectiveness.

Conclusion: The authors were unable to find any evidence based curriculum that addressed sexual education in the Muslim community. This project has laid the groundwork for tailoring an effective curriculum that can address the unique needs of this population. Nurses and other health care professionals must be prepared to acknowledge diverse religious teachings and their impact on sexual

health education. This is most important in the maintenance of the safety of Muslim youth while upholding their religious principles and cultural values.

H 10 - Culturally Diverse HIV Health Education Knowledge of HIV/AIDS Among Women in Rural Ugandan Villages

Linda Johanson, EdD, MS(n), RN, CCNE, USA

Abstract

Purpose: Rates of HIV have been decreasing in Uganda, however these rates, attributed to behavior change through education, have slowed in recent years (Hearst, Kajubi, Hedges, Maganda, and Green, 2012). It is unclear how much education about this issue reaches remote rural villages in the country of Uganda, and how the condition is understood by the people who live there. Women in sub-Saharan Africa have a disproportionate risk for HIV infection (Harrison, 2014). Basic correct understanding of the transmission, risk, symptoms, and treatment for HIV/AIDS will impact prevention behaviors for women in this country. Ultimately control of HIV/AIDS impacts global health. Assessment of knowledge is the first step for health care professionals to implement strategies that might impact beliefs and behaviors.

Methods: Using a convenience sample of household women in two rural villages in Uganda, focus groups were assembled and interviewed. In Rutooma, a mountain village in the western mountains of Uganda, the focus group consisted of 25 women ranging in age from 20-58. The second focus group was assembled in the village of Nampungwe, which is located in the Central Region of Uganda. The group there consisted of 33 women ranging in age from 18-65. The women were asked through an interpreter about their perceptions of the risk factors for HIV/AIDS, the difference in HIV and AIDS, the symptoms, prevention, and treatment. Discussions were translated, recorded, and analyzed for the scope and accuracy of responses.

Results: Respondents were overall gregarious and seemed eager to participate in the focus groups. Both sessions lasted approximately 90 minutes, and most of the participants provided input to the discussion. The group appeared to concur with one another on most of the information shared. There were three overall themes extracted from the focus groups:

1. The women of these two rural villages had mostly accurate, but basic knowledge about HIV/AIDS. They were most aware of transmission and prevention, and had obtained this knowledge by word of mouth. They were less clear on the difference between HIV infection and AIDS and the exact nature of treatments.
2. The main concern expressed about HIV/AIDS was access to treatment (anti-retroviral therapies), testing, and prevention. They were aware of common strategies for prevention, however cultural barriers interfered with implementation. Their partners, for example, refused to wear condoms, and unfaithfulness of partners was a shared concern. Abstinence was not seen as an option.
3. More than the concern about HIV/AIDS was the concern for access to reliable and effective contraception, which they called "family planning". This theme infiltrated almost every effort to discover their knowledge about HIV/AIDS, and there were many questions and request for help surrounding this concern.

Conclusion: These results are important for HIV/AIDS prevention strategies in rural Uganda. Knowledge appears to be accurate, however limited access to treatment and testing as well as a cultural impediment to behaviors that would control transmission present challenges.

H 12 - Fall Prevention in the Aging Adult

Perceived Quality of Life Following Falls: Voices of Community-Dwelling Older Adults

Anthony A. Adeniran, DNP, MSN, RN, PCA,, USA

Abstract

Background: Physiological age-related changes affect the function of everybody system, resulting in many quality of life challenges for older adults (Makizako et al., 2010). One of the resultant effects of age-related changes for older adults is higher incident and prevalence of falls and fall-related injuries. Fall is as an event which results in a person coming to rest inadvertently on the ground or floor or other lower level (Morgan, McDonald, & McGinley, 2015). Low-level falls are considered innocent in the young, but have lasting consequence for older adults. In general, 33% of older adults in the United States fall annually. Particularly, community-dwelling older adults have higher risks for falls, as up to 50% of community-dwelling older adults fall annually (Soriano, DeCherrie, & Thomas, 2007). The consequences of falls for community-dwelling older adults are grave, with far-reaching implications on their quality of life, including possible loss of independence. Community-dwelling older adults who have fallen tend to avoid activities that they are capable of performing due to fear of falling (Schepens, Sen, Painter, & Murphy, 2012; Trujillo, Painter, & R, 2014).

Purpose : The purpose of the study was to document the voices of community-dwelling older adults' perceived quality of life following the experience of falls.

Methods: This qualitative study utilized semi-structured questionnaires with probes to explore the perceived quality of life of five community-dwelling older adults who have experienced a fall within the previous 12 months of the study. Braun and Clarkes (2006) six-phase process of thematic analysis (TA) was used to guide the data generation and analysis.

Results: Analysis yielded 13 codes that were collated into four themes described participants' perceived quality of life following their fall experiences. The four themes are: 1) Perceived threat to individual autonomy and personal dignity 2) Amplified limitations of inevitable philological decline from normal aging process 3) Heightened awareness of environmental hazards as additional source and constant reminder of fear of falling and 4) Psychological scar from a previous fall experience affected their self-confidence and interfered with their self-worth.

Conclusion: The study echoed the voices of participant's about fear of falling as a limiting factor that affected their perceived quality of life. Study participant's described how their fall experiences influenced their thought processes, compelling them to avoid certain activities that they used to enjoy, and a need to adjust their way of living to mitigate their fall risks.

Significance and Implications: The findings of this study underscored the impact and consequences of falling for community-dwelling older adults, a phenomenon discussed in the literature. Study findings echoed the unique voices of community-dwelling older adults perceived quality of life following a fall experience. It highlights community-dwelling older adults' views of perceived quality of life following the experience of fall.

Strength and Limitations: This study contributed to knowledge of the consequence and implications of the experience of falls for community-dwelling older adults. It accentuates the unique voices of community-dwelling older adult's perceived quality of life following fall experiences. The findings should be interpreted in light of the relative small sample size. Larger sample is necessary to amplify the results of this study and to gain deeper understanding of community-dwelling older adults' perceived quality of life following fall experiences.

H 13 - Global Influences on Cancer Screening

Understanding Patient-Level Variables That Influence Lung Cancer-Screening Behavior and the Nurse's Role

Lisa Carter-Harris, PhD, RN, ANP-C, USA
Susan M. Rawl, PhD, RN, FAAHB, FAAN, USA

Abstract

Purpose: Lung cancer kills more people in the U.S. than breast, colorectal, pancreatic, and prostate cancers combined (American Cancer Society, 2016). Most die because they are diagnosed at an advanced stage with limited treatment options and a 1% five-year relative survival rate (American Cancer Society, 2016). Until recently, an effective screening test to identify lung cancer at an earlier stage did not exist. However, lung cancer screening with low-dose computed tomography is a recent U.S. Preventive Services Task Force Grade B recommendation for long-term smokers (Aberle et al., 2011; USPSTF 2014). Understanding variables that may or may not influence screening participation at the individual level is essential (Carpenter, 2010; Jonnalagadda et al., 2012). However, lung cancer screening also has potential harms which must be balanced against its benefits and may be weighed differently by different individuals. Shared decision-making is particularly important within contexts where one best solution does not exist (Makoul & Clayman, 2006). This is the case in lung cancer screening – where benefits are present, but risk and uncertainty exists and is patient specific. Nursing is uniquely poised to foster shared decision-making in lung cancer screening decisions through patient education, but we must first understand knowledge, risk perception, and health beliefs in the screening-eligible patient population in order to develop effective patient-level interventions that enhance shared decision-making in lung cancer screening, and subsequent screening behavior, in those at greatest risk. Therefore, the **purposes** of this study were to: (1) describe long-term smokers' knowledge and perceptions of lung cancer, risk, and screening; and (2) examine relationships between individual health beliefs (risk, benefits, barriers, self-efficacy) and screening behavior.

Methods: Descriptive, cross-sectional two-phase design using qualitative and quantitative data. Phase I: 4 focus groups (N=26) were recruited; 2 groups who recently completed lung cancer screening (n=12) and 2 groups who had never been screened (n=14). Data was collected via audio recordings and analyzed using thematic content analysis. Phase II: Guided by the Conceptual Model on Lung Cancer Screening Participation (Carter-Harris, Davis, & Rawl, 2016), a national convenience sample of screening-eligible individuals was recruited to collect data using survey methods (N=497). Data measured multiple variables including sociodemographic, health status characteristics and individual health beliefs.

Results: Phase I revealed low knowledge levels and confusion about risk factors and screening, and variables such as risk, benefits, barriers, self-efficacy, stigma, mistrust, fatalism, fear, and worry may be uniquely relevant in lung cancer screening. Using logistic regression in Phase II, we found perceived benefits ($p<.001$; OR=1.08, 95%CI (1.04, 1.14) and self-efficacy ($p=.001$; OR=1.06, 95%CI (1.02, 1.09) statistically significant, while perceived barriers was moderately significant ($p=.054$; OR=0.98, 95% CI (0.96, 1.00) with lung cancer screening behavior. Perceived benefits ($p<.001$) and self-efficacy ($p=.019$) maintained statistical significance with similar odds ratios, and barriers remained borderline significant ($p=.081$) when adjusted for other variables using multivariable logistic regression.

Conclusion: Results from this study indicate individual health beliefs and other individual-level variables may be important in understanding lung cancer screening behavior in long-term smokers. Nursing is an integral component in the patient education process related to cancer screening and primary and secondary prevention. Nursing-delivered interventions tailored on salient variables and integrated into the primary care visit to support patient-provider discussions about, and decisions related to, lung cancer screening are needed to advance the science of this new screening option to support early detection of the world's deadliest cancer.

H 14 - Promoting Physical Activity in Women

Physical Activity in U.S. Asian Indian Women: Comparison of Acculturation Level and Immigrant Status

Nitha Mathew Joseph, PhD, RN, USA

Sandra K. Hanneman, PhD, RN, FAAN, USA

Sheryl L. Bishop, PhD, USA

Abstract

Purpose: Asian Indian women generally have low levels of physical activity, which may increase their risk for chronic diseases compared with Whites and other immigrant groups in the U.S. (Daniel, Wilber, Marquez & Farran, 2013; Mathew Joseph & Bishop, 2014). Acculturation has also been associated with an increased risk for obesity, metabolic syndrome, type 2 diabetes, and coronary artery disease among Asian Indians (Khan, Jackson & Momen, 2016; Venkatesh, Weatherspoon, Kaplowitz & Song, 2013). Additionally, acculturation and immigrant status have been implicated as contributors to low physical activity levels (Walker, Caperchione, Mummery & Chau, 2015). The purpose of the study was to determine differences in three different domains of physical activity (occupational physical activity, household physical activity, leisure time physical activity) and sedentary behavior by acculturation level and immigrant status in U.S. Asian Indian women. Moreover, physical functioning was assessed as a possible explanation of differences in physical activity, independent of acculturation and immigrant status.

Methods: A cross-sectional, descriptive, comparative design was used with a convenience sample of 261 immigrant and nonimmigrant Asian Indian women living in Houston, Texas, who completed the International Physical Activity Questionnaire long form, the Modified Suinn-Lew Asian Self-Identity Acculturation Scale, and the Physical Functioning subscale from the RAND 36-Item Health Survey. Based on the distribution of the data, chi-square, one-way analysis of variance, or the Kruskal-Wallis test was used to compare study variables among acculturation-immigrant groups. Because the study premise was that activity is affected by acculturation and immigrant status, participants were categorized into four groups according to their acculturation level and immigrant status: low acculturation-immigrant, high acculturation-immigrant, low acculturation-nonimmigrant, and high acculturation-nonimmigrant.

Results: The low acculturation-immigrant women had the highest metabolic equivalent of task (MET) scores for occupational (59.8 MET hrs/wk) and total physical activity (102.6 MET hrs/wk), even though they were older and had lower physical functioning scores (both, $p < .001$). The high acculturation-nonimmigrant group had the highest leisure physical activity (21.9 MET hrs/wk) and sedentary behavior (47.2 MET hrs/wk) scores. The two high-accultured groups (immigrant and nonimmigrant) did not differ significantly in occupational and total physical activity MET scores, suggesting that these two physical activity domains are more closely associated with acculturation level than with immigrant status. The high acculturation-nonimmigrant group had the highest leisure physical activity (21.9 MET hrs/wk) and sedentary (47.2 MET hrs/wk) scores. However, the high-acculturation groups had greater proportions of students than the low-accultured women ($X^2 = 23.55$, $df = 4$, $p = .0001$), and this may partly explain group differences in sedentary behavior.

Conclusion: Acculturation is inversely related to occupational and total physical activity and may have a direct relation to leisure physical activity and sedentary behavior, the latter of which may be confounded by employment versus student roles. The findings suggest that acculturation of Asian Indian women to the United States is associated with less physical activity, which may increase the risk for chronic diseases. This study is a significant first step on a continuum of research toward the development of effective public health nursing interventions to promote physically active lifestyles. Nurses and other health professionals can consider acculturation levels when developing community- and work-based interventions to promote physically active lifestyles in Asian Indian women.

H 14 - Promoting Physical Activity in Women

Midlife African American Women's Maintenance of Lifestyle Physical Activity

JoEllen Wilbur, PhD, RN, FAAN, USA
Lynne Braun, PhD, APN, FAAN, USA
Susan Buchholz, PhD, RN, ANP-BC, FAANP, USA
Arlene Miller, PhD, RN, FAAN, USA

Abstract

Purpose: Group interventions combining guidance, self-management, and ongoing support effectively increase physical activity in African-American women, but little is known about long-term maintenance. Maintenance of physical activity is commonly defined as participant achievement of a pre-prescribed level of physical activity at 2 points of time often at the end of the intervention and 6 months later (Kahlert, 2015). Examination of 14 physical activity interventions with African American women revealed only three examined maintenance after cessation of the intervention with all reporting a return toward baseline or low retention. The 48-week Women's Lifestyle Physical Activity program designed to increase adherence to physical activity included six nurse led group meetings guided by Social Cognitive Theory (Wilbur et al., 2016). They were held every five weeks at six community healthcare facilities. In addition, there were three accompanying telephone conditions delivered between group meetings (group meeting + 11 motivation interviewing calls, group meeting + 11 motivational automated calls, group meeting only). Personal calls were brief motivational interviews and automated calls provided motivation tips. Findings showed high retention during the intervention phase (90%) with significant improvement in physical activity measured at 48 weeks. These effects did not differ by condition. The purpose of this study is to determine midlife African American women's maintenance of physical activity one to three years after completion of the Women's Lifestyle Physical Activity program and to determine if maintenance differed by telephone condition.

Methods: A longitudinal design was used. During the 48-week intervention phase the three telephone conditions were delivered in groups of 13-17 midlife women (total 18 groups). Assessment of long-term maintenance of adherence to physical activity began 1 year after the first group completed the intervention. Over the following six months long-term assessment was completed for each group in the order in which each group completed the intervention. By doing this data were systematically collected with most women participating in long-term assessment from one to three years after completing the intervention. All 288 women who began the intervention received a follow-up survey that included the self-report Community Healthy Activity Model Program for Seniors (CHAMPS) questionnaire covering minutes per week of reported moderate-vigorous (MV) physical activity, M-V leisure time physical activity and walking. The survey was conducted by mail, phone or in person.

Results: 254 women (88.2%) completed the follow-up survey. Linear growth analyses showed that increases in self-reported physical activity were sustained at follow-up across all three measures: total moderate-vigorous physical activity (MV physical activity; $p < .001$), leisure MV physical activity ($p < .001$), and walking ($p < .001$). After a sharp increase between baseline and 24 weeks, level of physical activity remained stable through the remainder of the 48-week intervention as well as during long-term maintenance. Minutes of physical activity changed by less than ± 2 minutes per month during long-term maintenance. None of the effects varied by intervention condition.

Conclusion: Group meetings are a powerful component of physical activity interventions that have sustained physical activity into an extended maintenance phase. Although increases in physical activity during the intervention were confirmed by objective accelerometer measures, long-term follow outcomes were limited by reliance on self-report measures of physical activity. Future studies should verify these results using objective measures of physical activity.

H 15 - Use of Big Data to Influence Nursing Care Data Acquisition Collaboration for Nursing-Cost Study Using

Peggy A. Jenkins, PhD, RN, USA

Esther M. Chipps, PhD, MS, BSN, NEA-BC, USA

Abstract

Purpose: Use of big data to generate nursing science is sparking much discussion among nursing scholars (Harper & Parkerson, 2015; Clancy & Gelinias, 2016). Defining the value of nursing through analysis of big data is a contemporary area of focus (Pruinelli, Delaney, Garcia, Caspers, & Westra, 2016). Big data is a term coined by the media to describe vast amounts of data now available in huge electronic repositories of healthcare data (Clancy, 2016). Most nurses are novice at understanding the potential use of big data. The science of “big data” provides a great enhancement and new methodological approaches to understand the complex question of nursing costs associated with patient care and patient outcomes. The purpose of the primary study was to explore variability of nursing cost per acute care episode for patients with similar DRGs using patient level data and to investigate the relationships among nurse characteristics and patient characteristics on nursing cost. Some results of the primary original study have been previously reported (Jenkins & Welton, 2014). The purpose of this presentation is to provide an overview of the complexities of data acquisition/management and outline the extensive collaborations among multiple stakeholders.

Methods: The sources of data included three large databases; 1) patient assignment software, 2) medical management system, 3) human resources. The software company staff wrote a query so data could be extracted including multiple variables required for the study. Hospital information technology staff de-identified the data. Forty-nine total variables were extracted or constructed including patient characteristics such as DRG, length of stay, age; plus, nurse characteristics such as years in organization, actual wage, education level. Nursing intensity by shift was a key variable extracted from patient assignment software. The data acquisition process required multiple iterations between the PI, the hospital based nurse scientist and the software company.

A four step data management model was used (Long, 2009); 1) planning, 2) organizing, 3) computing, 4) documentation. A systematic plan was organized using Stata do-files to record all code written for data management and analysis, so the study is replicable. Seven excel spreadsheets were merged using a patient and nurse common identifier. The sample included 3111 patients and 150 nurses in 44,771 total shift observations. Stata v.12 software was used for data analysis (Cameron & Trivedi, 2010). Shift level nursing intensity multiplied by actual nursing wage was summed for all nurses caring for a given patient resulting in direct nursing cost per shift. Shift level data was aggregated to construct nursing cost per day and acute care episode (defined as admission to discharge on the study unit).

Results: The nursing cost model generated using secondary data from big data sources provided direct nursing cost per patient shift, day, and acute care episode (i.e. DRG 192, nursing cost per day range \$4.87-322.66, nursing cost per acute care episode range \$54-1570). Direct nursing cost per patient data is not available or viewed by nursing leaders today.

Conclusion: Data is available in current big data sources that can be extracted through collaborations between interprofessional healthcare and software company staff and used in scientific inquiry to answer patient level research questions and advance the science of nursing. Managing large amounts of data is a research skill nursing scientists can learn and use to generate knowledge to better understand nursing cost as well as quality patient outcomes. Big data acquisition and management is an exciting vista and the possibilities for evolving nursing science are vast.

H 15 - Use of Big Data to Influence Nursing Care

Analytical Challenges in the Era of Big Data

Alvin D. Jeffery, PhD, RN-BC, CCRN-K, FNP-BC, USA

Abstract

Purpose: The popularity of “big data” along with an increasing capacity for real-time predictive analytics holds significant promise for nurses and other clinicians to gain new insights and develop novel decision support tools from our large clinical datasets. Unfortunately, these large datasets are not the panacea that some big data proponents would taut. For nurses with vast subject matter expertise in a clinical area who desire to leverage big data for solving practical problems, road blocks quickly surface in the form of acquisition and management of data, missing data, meeting assumptions of statistical models, and model evaluation for statistical and clinical performance. This talk will engage the audience in addressing these issues using an exemplar of the development of a prediction model for in-hospital cardiopulmonary arrest.

Methods: The following 4 topics will be addressed:

Data Acquisition and Management: From ethics approval to ensuring individual patient privacy to preventing undesired user access, collecting and storing “big data” is no simple task. The presenter will provide: (a) an overview of key concepts, (b) an exemplar for constructing a data acquisition and management team, and (c) several resources for learning more independently.

Missing Data: Almost all large datasets contain some amount of missing data. Regardless of the amount, finding the cause of missingness is of paramount importance. Approaches to determining a cause will be introduced, and disadvantages of complete case analysis will be described. Advantages and disadvantages of median imputation, multiple imputation, and machine learning imputation will be compared.

Statistical Model Assumptions: There are a variety of statistical models available, and with recent advances in machine learning methods, more approaches to retrieve information from the data are available to a wide array of users. An overview of the purpose and requirements of traditional modeling (e.g., logistic and linear regression) and machine learning approaches (e.g., random forests and cluster analyses) will be provided.

Model Evaluation: Determining how well a model performs on the current data and how well it is expected to perform on future data is essential in determining whether or not the model is helpful for clinical care. Internal (e.g., bootstrapping and cross-validation) versus external validation (e.g., split sample and chronological validation) techniques will be presented along with their respective advantages and disadvantages.

Results: Our in-hospital cardiopulmonary arrest prediction model required a team-based approach to solving the aforementioned challenges, and the audience will hear not only how we chose to solve the problems but also other approaches we considered. From the perspective of data acquisition/management, we found the best approach to be the inclusion of database and informatics specialists who used structured query language to extract the relevant data and then store it on a secure, organizational server. Following a simulation study, we discovered the missing data problem was best resolved by creating a multiple imputation model that included the outcome variable. Statistical model assumptions were best met by not assuming linearity while not permitting too many spline knots. Model evaluation comprised internal bootstrap validation for the regression models and split-sample validation for the machine learning methods.

Conclusion: Arriving at clinically meaningful insights contained within large datasets requires multifaceted expertise and teamwork. Nurses and other clinicians are the best members of the team to identify a problem that “big data” can help solve. To ensure a clinically meaningful solution surfaces from big data efforts, nurses should be aware of common challenges in big data research. As nurses become

more knowledgeable, they position themselves to be leaders in these research teams and advocates for implementation of novel findings.

Association Between Household Resources and Child Mortality: Ghana as a Case Study

Jerry John Nutor, MSN, BSN, RN, USA

Jaime C. Slaughter-Acey, PhD, MPH, USA

Janice F. Bell, PhD, MN, MPH, RN, USA

Abstract

Purpose: Child mortality, defined as death of infants and children under age of five years (United Nations, 2010) is an important measure of child health as well as an indicator of the overall health status of a country or region (Avogo & Agadjanian, 2010). Child mortality is often used as one of the strongest indicators of a country's wellbeing, as it reflects social, economic and environmental conditions, as well as access to health care (Alderman & Behrman, 2004). Children are more vulnerable to all kinds of hazards than adults as they are dependent on parents or other care takers to provide what they need in order to survive. Furthermore, a child's chances of survival are greatly dependent on adequate nutrition, immunization and environmental hygiene (Andoh, Umezaki, Nakamura, Kizuki, & Takano, 2007; Skolnik, 2008). Several research studies conducted recently on the impact of social determinants of health and household resources on child mortality have found that economic status of the household defined by possession of certain assets such as electricity, toilet facilities, source of drinking water, type of fuel for cooking, roofing and flooring materials, were found to influence child mortality (Godson & Nnamdi, 2012; Gyimah, 2006; Kabubo-Mariara, Karienyeh, & Mwangi, 2010). In a study conducted by Rutaremwa to examine child mortality differentials in the capital cities of East Africa and to establish whether there are substantial differences in infant and child mortality estimates in Nairobi, Dares-Salaam and Kampala, the incidence was highest among children of mothers residing in households with no toilet facility compared to those with flush toilets; furthermore, pipe-borne water was associated with lower odds of child mortality compared to well water. From this study it is clear that more proximal social determinants than rural versus urban residence have important roles to play in child survival (Rutaremwa, 2013). The current study therefore examined associations between household resources and child mortality in Ghana. The study answered the following research questions: (1) What household resources are associated with child mortality in Ghana? (2) Does the availability of household resources contribute to child mortality over and above the influence of other measures of socioeconomic status?

Methods: This cross-sectional descriptive study analyzed the 2007 Ghana Maternal Health Survey (GMHS), the first and the only maternal health survey conducted in Ghana (Ghana Statistical Service, 2009). The primary data were collected in two-phases of fieldwork. In phase I, a nationally representative sample of 240,000 households was selected from the 10 administrative regions of Ghana across rural and urban areas, out of which 226,209 completed the household questionnaire. We analyzed the data using STATA version 13 (College Station, TX). Descriptive inferential statistics were used to summarize the means of continuous variables and proportions of categorical variables and to cross-tabulate each variable, including the household resources, by maternal report of child death in the full sample and in the sample stratified by rurality of residence. Means were compared statistically with t-tests and proportions with chi-square tests. We examined the household resources and other variables for their intra-class correlations and assessed whether variable reduction strategies (i.e. factor analysis) were required. Logistic regression analysis was used to examine the association between household resources and child mortality, controlling for the covariates. In all of the analyses, survey weights were applied to account for the complex survey design.

Results: Women who resided in the urban area were more likely to report access to all the household resources measured than those in rural area, except kerosene lantern for which more rural women reported possession. In unadjusted comparisons, a significantly lower proportion of women who reported possession of each of the household resources reported child mortality with one exception. There was no significant difference in the proportion of women reporting child mortality by the reported number of sleeping rooms. Women who had primary, middle school and secondary or tertiary education had lower odds of reporting child mortality as compared to those who had no education. The odds ratios ranged

from 0.78 [95% CI: 0.65, 0.94] for primary school to 0.55 [95% CI: 0.38, 0.78] for those who had secondary or tertiary education. In the model restricted to women living in rural areas, none of the household resources were associated with child mortality. In contrast, in the model restricted to women living in urban areas and towns, having refrigerator at the time of interview was associated with lower odds of reporting child mortality 0.63 [95% CI: 0.48, 0.83]; whereas, having a kerosene lantern [AOR=1.40; 95% CI: 1.06, 1.85] or flush toilet [AOR=1.84; 95% CI: 1.23, 2.75] was associated with higher odds of reporting child mortality.

Conclusion: Possession of a refrigerator may play a role in child mortality, particularly in urban areas. This finding may reflect unmeasured SES or the importance of access to refrigeration in preventing diarrheal disease or other proximal causes of child mortality in sub-Saharan Africa. Further studies should focus on understanding the association of household resources and child mortality in rural areas and the contribution of community socio-economic attributes to child mortality.

H 16 - Socioeconomic Effects in Pediatrics

Parenting Bedtime Behaviors and Sleep Among Toddlers Living With Socioeconomic Adversity

Monica Roosa Ordway, PhD, APRN, IBCLC, USA

Nancy Redeker, PhD, RN, FAHA, FAAN, USA

Craig Canapari, MD, USA

Sangchoon Jeon, PhD, USA

Lois Sadler, PhD, PNP-BC, FAAN, USA

Abstract

Purpose: Sleep problems are very prevalent during the first year of life with 20-30% of infants reported to have a sleep problem. Families most commonly seek support from pediatric health care clinicians regarding their infant and toddler's bedtime resistance and frequent and prolonged night waking. While much has been published describing sleep patterns and sleep interventions to assist parents in helping their children initiate and maintain sleep, the majority of this literature included children living with middle to high incomes. Consistent with other health disparities, sleep disparities occur in children living in socioeconomically disadvantaged homes and emerging literature suggests that this disparity begins at 12 months. Hence, there is a need to develop interventions to support families living with socioeconomic adversity. The first step, however, is to determine if the significant associations between parenting bedtime interactions and sleep patterns of infants and toddlers commonly reported among families living in families of middle to high incomes is also observed among families living with socioeconomic disadvantage. This presentation will report findings of a study conducted with toddlers (12-15 months old) and their parents living in socioeconomically disadvantaged homes. Because one of the most commonly reported sleep problems among toddlers is night waking, the focus of our presentation will be the relationships between parenting interactive bedtime behaviors and disrupted sleep and night waking.

Methods: The sample includes 33 healthy toddlers and a parent who live with socioeconomic adversity. Data was collected during two data collection visits. Demographic information collected from the caregiver included their own gender, age, race/ethnicity, marital status, family housing, family income, education level, federal and state assistance, and number and age of children. Data was also collected on the toddler's race/ethnicity, age, gender, birth and medical history. Data on sleep characteristics included subjective and objective measures of sleep duration and efficiency, obtained with questionnaires, diaries, and nine days/nights of actigraphy. In addition to caregiver education collected with the demographics, income to needs ratio was collected as a measure of adversity. Income-to-needs ratio is a standard measure of a family's economic situation. The self-report Parental Interactive Bedtime Behavior Scale (PIBBS) is a 19-item Likert-type parent questionnaire that measures the interactive behaviors caregivers use with their children at bedtime. Five subscales and a total score are calculated: 1. Active physical comforting, 2. Encourage autonomy, 3. Settle by movement, 4. Passive physical comforting, 5. Social comforting. Associations of parenting bedtime interactions and sleep characteristics were examined using Spearman correlation coefficient.

Results: Sleep duration among the toddlers was just over 8 hours – much below the 10-13 hours of sleep recommended for this age group by the United States based National Sleep Foundation. Disrupted sleep (sleep fragmentation) and waking after sleep onset (WASO) between the toddlers were not associated with any of the parenting bedtime interactive bedtime behavior. However, there were significant associations between total parenting interactive behaviors and passive physical comforting and WASO ($r=.37$, $p=.05$ and $r=.52$, $p=.002$, respectively) within toddlers over the course of their week-long monitored sleep. Similarly, a significant association was found between total parenting interactions and sleep disruption within toddlers ($r=.36$, $p=.05$).

Conclusion: As described in the extant literature, the findings of this study support the connection between parenting interactions and toddler sleep patterns based on the variability of sleep disruption and night waking within the toddlers week-long monitored sleep. While active physical comforting (e.g. rocking to sleep, patting or rubbing child's back, etc.) is most commonly associated with sleep patterns in

infancy and toddlerhood, findings from this study suggest that passive physical comforting (presence of the parent in the room to fall asleep) was the strongest association with individual variability of the toddler's disrupted sleep and night waking. Future directions for this work include adding biomarkers of stress response to determine how characteristics of sleep in toddlers are associated with their stress response system as well as additional parenting variables to identify the characteristics of parenting linked to toddler sleep patterns in this populations. These results will then be used to inform the development of future health promotion interventions focused on improving sleep early in life.

I 03 - Culturally Diverse Geriatric Health Practices

The Experiences of Elderly Immigrants of Mexican Origin With Life-Limiting Illness: A Critical Ethnography

Sandra Scott Lee, PhD, RN, CNE, USA

Abstract

Purpose: Although limited studies have explored the health care needs of elderly immigrants of Mexican origin, Mexican immigrants account for the largest immigrant group in the United States. As of 2014, 28% of the total immigrant population is of Mexican origin, with 8% of Mexican immigrants being age 65 years and older (Zong & Batalova, 2016). Furthermore, studies to-date do not make recommendations for nursing practice. The purpose of this qualitative study was to describe and explain the health care experiences of elderly immigrants of Mexican origin who face life-limiting illness in the United States. The study aimed to answer the following research question: What are the perceptions of elderly immigrants of Mexican origin with life-limiting illness about their experiences with the U.S. health care system?

Methods: The study was approved by the University of Texas Medical Branch Institutional Review Board (IRB), protocol 13-0427. Participants were recruited at churches, community centers, and clinics, places where IRB-approved flyers were posted. Sites were selected that primarily service the Hispanic community. Recruitment also occurred by word-of-mouth. A purposive, non-random sample of 13 participants was enrolled. Eligible participants were self-identified as first or second generation immigrants of Mexican origin; aged 65 years or older; with a diagnosis of heart disease, diabetes, cancer, respiratory disease, or previous stroke; and English speaking. Participants were interviewed face-to-face by the investigator in a private area of their choosing and convenience. Interview protocol followed a semi-structured technique. The researcher also asked demographic questions of participants and recorded the responses on an investigator-developed demographic form. Interviews were digitally recorded. The research employed a critical ethnography design to answer the research question (Carspecken, 2012, 2016). The semi-structured, audio-taped interviews were analyzed using Carspecken's five stages of critical qualitative research.

Results: Low and high level coding techniques identified the three large categories of *REACTING* to the diagnosis, *RESPONDING* to the illness, and *RELATING* to health care providers.

Large Category--*REACTING* to the Diagnosis, with sub-categories Feelings, and Family Experiences. The category *REACTING* to the diagnosis emerged from the data as participants described what it was like when they learned that they had one of the diagnoses and then how they felt as they adjusted to the news. *REACTING* also included previous observations and experiences with family members who had the same diagnosis, and how that shaped the participants' own reaction. The lower level categories of (a) feelings and (b) family experiences organized into the high level code of *REACTING* to the diagnosis. *REACTING* to the diagnosis encompassed feelings, the depth of emotions that individuals experienced when diagnosed with diabetes, stroke, heart disease, lung disease, or cancer. Participants who had diabetes were particularly descriptive about the feelings of devastation, fear, and uncertainty. Several participants described how they had watched or lived through the negative health experiences of close family members, and how they feared that for themselves. Based on experiences they had observed with family members, participants were afraid they would face the same kinds of health outcomes.

Large Category--*RESPONDING* to the Illness, with sub-categories Self-management, Self-advocacy, and Community Interaction.

RESPONDING to the illness related to the adjustments and life changes participants made for the new diagnosis. *RESPONDING* included lower level categories of (a) actions to self-manage the disease; (b) efforts at self-advocacy; and (c) interaction with the community in order to help other people. Participants discussed commitment and efforts to comply with physicians' instructions and what they called "the rules" to manage their conditions. Inherent in participants' self-management plans were their efforts to advocate for themselves. When participants felt like the communication from health care providers was poor or

dissatisfactory, participants decided to find another provider; some even requested they be discharged from the hospital. Participants described unique ways of reaching out to the community to share their own experiences and to help others with the same diagnosis, including suggestions for how they could be optimally supported.

Large Category--*RELATING* to the Health Care Providers, with a sub-category of Experiences with Physicians and Nurses.

RELATING to Health Care Providers encompassed the range of both positive and negative communications and experiences that participants had with their health care providers, which in turn affected participants' understanding of their condition and their experiences with health care. *RELATING* to the Health Care Providers had lower level categories of (a) communication with doctors and (b) communication with nurses. Participants were particularly sensitive to perceived lack of communication from their providers. This lack of attention and communication did not support their cultural norms, *simpatía* or *personalismo*, nor did the hurriedness align with their time orientation. Participants had varied and unpredictable experiences with nurses. Some described nurses in positive ways, but unfortunately most participants described negative experiences with nurses. *RELATING* to Health Care Providers meant the communications and experiences that participants had with their health care providers, specifically their doctors and nurses, which in turn affected participants' understanding of their condition and their experiences with health care.

Conclusion: The purpose of this qualitative study was to describe and explain the health care experiences of elderly immigrants of Mexican origin who face life-limiting illness in the United States. This critical ethnography, philosophically informed by Jürgen Habermas's critical social theory and guided by Bronfenbrenner's ecological model, answered the research question "What are the perceptions of elderly immigrants of Mexican origin with life-limiting illness about their experiences with the health care system in the United States?" Low and high level coding techniques identified high level categories of *REACTING* to the diagnosis, *RESPONDING* to the illness, and *RELATIONSHIPS* with health care providers. This qualitative, critically-oriented study of the life-limiting illness experiences of elderly immigrants to the United States offers increased understanding about elderly immigrants of Mexican origin and their health care needs to ultimately achieve cultural understanding, and health care and policy change. The research is important to nursing because of the likelihood that many nurses will care for elderly immigrants in a variety of different care settings. Nurses are on the front line of patient care in a health care system affected by a political, social, and economic environment that is often emotionally charged with the issue of immigration controversies. Thus, studies that give voice to the stories of elderly immigrant participants who are experiencing life limiting illnesses may guide recommendations that will improve the health of elderly immigrants of Mexican origin. Realities of disparities in health care, which have been well supported by the literature, confront everyday nursing practice. The project contribution is significant because it informs nursing practice, nursing education, and public policy through its consideration of the multiple influences of community, social, and political factors on delivery of care to elderly immigrants of Mexican origin from a critically-oriented perspective. Although the sample size limits generalizability, findings suggest more research is needed to improve health care delivery to this population. In particular, the immediate emotional needs when diagnosed, appropriate assistance while learning to self-manage, and the paramount role of physicians and nurses in the elders' health care decisions merit further inquiry.

I 03 - Culturally Diverse Geriatric Health Practices

"I Should Have Come Sooner": A Qualitative Study Describing Care Preferences of Elders with HF

Victoria Vaughan Dickson, PhD, MSN, BSN, RN, CRNP, USA

Saul Blecker, MD, MHS, USA

Corita Grudzen, MD, FACEP, USA

Stuart Katz, MD, MPH, USA

Billy A. Caceres, MSN, RN, AGPCNP-BC, AHNP, USA

Melissa Martelly, MSN, RN, USA

Tina Sadarangani, MSN, RN, USA

Caroline Blaum, MD, MS, USA

Abstract

Purpose: Heart failure (HF) remains the leading cause of hospitalization among adults over the age of 65. The majority of these hospitalizations originate in the emergency department (ED). Hospitalized HF patients are more likely to experience negative health outcomes than outpatients with HF. Experts have suggested that many patients with HF may be safely given treatment in the ED with discharge home and close follow up. Therefore, the purpose of this study was to describe the reasons that elder HF patients present to the ED and explore care preferences including barriers and facilitators to home discharge.

Methods: In this qualitative descriptive study, 13 clinically-stable elders with HF (≥ 65 years) were enrolled during an ED visit and participated in in-depth interviews about their reason for ED visit, including symptom experience and self-care at home, and HF care preferences. Qualitative data were analyzed using content thematic analysis.

Results: In this sample (70% male, 77% White, Mean age 81 ± 8 ; range 67-93 years), the most common reasons for ED visits were dyspnea and leg swelling. All reported ≥ 1 ED visits for similar symptoms in prior 6 months. Most ($n=12$) described symptoms that had been present or worsening for ≥ 2 days; all were admitted. Poor symptom awareness, inadequate resources and fragmented care contributed to delays in seeking treatment. In general, self-care at home was poor including medication nonadherence "*I stopped that pill because it gave me <pain>*" and failed symptom monitoring "*they used to monitor me <at home> and I did ok...but that stopped.*" Some ($n=4$) preferred home discharge from the ED "*just get the fluid out...let me go home*"; but most believed hospitalization was necessary for symptom management "*they have to fix it...change the medication or something*" and to improve functional status "*...help get strength back.*" Barriers to home discharge centered around lack of tangible support "*I need help with everything*" and general physical deconditioning.

Conclusion: Many elders with HF struggle with recognizing HF symptom and inadequate support that may delay treatment and lead to emergency situations. Interventions to address recurrent ED admissions in elders should focus on addressing their unique social support and care-coordination needs as well as deficits in self-care.

I 04 - Closing the Theory-Practice Gap

Using Competency Testing to Close the Practice Gap With Undergraduate Baccalaureate Nursing Students

Patricia A. Sharpnack, DNP, RN, CNE, NEA-BC, ANEF, USA

Kimberly Dillon-Bleich, MSN, RN, USA

Lauren Patton, MSN, RN, CCRN, CHSE, USA

Abstract

Background: Nurse educators are continually exploring innovative methods to evaluate transfer of course content to clinical application and competence. Assessment of clinical competence is a critical requisite of nursing professional education, yet research has shown that new graduates are not prepared for transition to practice. Systematic use of competency testing throughout the curriculum can facilitate clinical decision making skill development in undergraduate BSN students (Salem, Ramadan, El-Guenidy & Gaifer, 2012). Attempts to unify the definition of competency and link competency testing to safe practice have been initiated in Canada, the United Kingdom, and Australia; however, evidence of this work has not been broadly presented in the United States (McWilliam & Botwinski, 2012). The OSCE is defined as “an approach to the assessment of clinical competence in which the components of competence are assessed in a well-planned or structured way with attention being paid to objectivity” (Najja, Docherty & Miehl, 2016). An OSCE requires that each student demonstrate particular skills and behaviors in a simulated situation or with standardized patients.

Purpose: To explore the use of competency testing through objective structured clinical examinations (OSCE) in facilitating the transition to professional nursing practice.

Conceptual Framework: Ericsson’s Theory of Deliberate Practice was used to frame the study. The design demonstrates alignment with the statewide nurse competency model (USA).

Method: Exploratory study. Nurse educators designed a series of OSCE’s as a final semester summative assessment for students in a baccalaureate nursing program. Clinical practice partners provided input and guidance on station design and evaluated testing criteria and processes. Station design was aligned with the state action coalition’s nurse competency model designed by nurse leaders in education and practice. Clinical scenarios that provided students an opportunity to demonstrate competency at patient management skills and identification of quality and safety concerns were included. Students were required to make clinical judgments based on assessments, initiate interventions, and demonstrate a professional, therapeutic relationship with the patient and/or family. Faculty evaluated each student on achievement of competencies using an objective evaluation tool; inter-rater reliability was maintained through consistent trained evaluators and the use of Panopto technology to record all stations. Student demographics and data from competency scores, participant feedback and NCLEX –RN results from more than 65 students was obtained.

Results: A chi-square test was performed to assess the relationship between competency testing stations, the ATI Pharmacology standardized assessment and NCLEX passage. The results for the ATI standardized assessment (1, N=65, = 6.08, $p < .05$), the clinical decision making competency station (1, N=65, = 4.4, $p < .05$), and the quality and safety station (1, N=65, = 4.69, $p < .05$), were significant. No significance was found with the delegation, patient assessment, or medication administration stations. Student and faculty feedback indicate that the OSCE effectively and fairly evaluated clinical competencies and judgement skills. Students suggested that the use of OSCE’s be integrated early in the curriculum to reduce stress level and promote improved accountability for best practice and maintenance of clinical competency. The lack of a reliable and valid tool for competency assessment was a limitation of the project.

Conclusion: The association between preparedness for practice and competency development has implications for nursing. Including competency testing throughout the curriculum, specifically testing that requires clinical decision-making is vital for safe transition to practice. The use of OSCE’s at key points in

the educational process can assist in evaluating student performance, identifying the need for remediation opportunities prior to graduation, and preparing students for the transition to practice. The use of Panopto video recordings of student testing provided opportunity for student reflection and self-assessment. Evidenced-based strategies that promote the use of competency testing and the integration of technology are essential for transference of knowledge into professional practice. Further research to evaluate student outcomes and develop a valid and reliable tool is essential in this process.

I 05 - Enhancing the Inpatient Hospital Experience

Perception and Acceptance of Hospital Meals Among Inpatients in a Tertiary Hospital in Nigeria

Funmilola Adenike Faremi, MSc (Nsg), BNSc, RN, RM, RPHN, Nigeria

Omowumi R. Salau, MSc (Nsg), BNSc, RN, RM, RPHN, Nigeria

Adeyinka T. Ajayi, BNSc, RN, RM, Nigeria

Abstract

Purpose: Hospital food and nutrition services play an important role in patient recovery and well-being. It can also influence patients' satisfaction with their overall hospital experience. Previous studies showed that hospital food services remain to be a widespread problem all over the world. With literature search, there is dearth of studies on patients' satisfaction with food services in health care facilities in the country, hence the need to assess patients' perception and acceptance of hospital meals in order to provide insights on areas of focus for the achievement of quality improvement in hospital food and catering services from the perspective of the consumers, thus promoting their health.

Methods: A descriptive cross-sectional study was adopted for the study. A multistage sampling technique was employed to select 220 adult in-patients across five (5) sections or service areas in the hospital. Children and patients below the age of 18 years were excluded from the study. Also, due to the unstable nature and peculiarity of patients, the Adult and Children Accident and Emergency Units and the Mental Health ward were also excluded from this research study. A self-administered questionnaire pilot tested to ensure validity and reliability (Cronbach Alpha = 0.798) was used to collect data. Data was analyzed using percentages, mean, standard deviation, multiple regression and chi square using SPSS version 20

Results: There was 70.6% females and 29.4% males in the study with a mean age of 45±15.6. Majority of the patients (90.5%) had spent between 1-15 days on current admission. More than half, (56.2%) were on special diet while 73.1% relied only on hospital food since admission. Overall, 55.7% had good perception of hospital meal, while 8.5% had poor perception. However, only 4% had high-level acceptance of hospital meal while 59.7% had low level-acceptance. No significant relationship was observed between selected socio-demographic factors (age, gender, educational level and average monthly income) and their perception of hospital meals ($p = 0.301$). However, significant association was found between the types of diet and their level of acceptance of hospital meals ($p = 0.005$).

Conclusion: Patients on hospital admission have high expectations of the meals supplied from the hospital kitchen, hence the need for nurses to act as adequate advocates in this matter thus aiding patient quick recovery.

I 05 - Enhancing the Inpatient Hospital Experience Nurse-Led Mobilization Activities in Intensive Care Unit (ICU) Settings

Deonni P. Stollendorf, PhD, RN, USA

Mary S. Dietrich, PhD, USA

Cathy A. Maxwell, PhD, MSN, RN, USA

Abstract

Purpose: Descriptions of ICU mobility practices are predominantly reported from single or multi-site quality improvement (QI) projects (Campbell, Fisher, Anderson, & Kreppel, 2015; Dammeyer et al., 2013; Timmerman, 2007; Hopkins & Spuhler, 2009; Engel, Needham, Morris, & Gropper, 2013; Hopkins, Spuhler, & Thomsen, 2007; Needham & Korupolu, 2010) or review articles (Hodgson et al., 2013; Hopkins et al., 2009), both considered to be less rigorous than research studies. Bakhru et al., (2015), reported mobilization practices employed by a sample of U.S. hospitals, but lacked in-depth descriptions of the specific nurse-led mobilization. The views of direct care ICU nurses are also underrepresented in studies related to mobilization of ICU patients. For example, Bakhru et al. (2015) surveyed ICU nurse managers or clinical nurse specialists whilst Brotman et al. (2015) sampled nurses in non-ICU settings (Brotman et al., 2015). The **purpose** of this presentation is to describe nurse-led mobilization practices in two community hospital ICUs and to report practice differences between the two settings. This study contributes to the body of knowledge by providing an in-depth description of nurse-specific mobilization practices in the ICU, independent of interdisciplinary collaboration. To describe the frequency and variability in nurse-led mobilization activities in Intensive Care Units (ICUs) after controlling for patient characteristics.

Methods: Design: A cross-sectional exploratory study was conducted. The population studied was critical care nurses and their patients from two medical-surgical ICUs in two Southeastern cities. The sample consisted of a convenience sample of nurses (N=18) employed in a critical care units of two hospitals caring for a total of 124 patients (Hospital A: N=12 nurses making 60 reports; Hospital B: N=6 nurses making 117 reports). Measurement: Nurses self-reported mobilization practices for one month using the Mobilization Initiatives & Levels of Exercise (MOBILE) tracking tool specifically developed and tested (face validity) for the study. The MOBILE tool includes: **patient characteristics** (age, gender, admitting diagnosis, comorbidities, temporal measures (date, ICU admit/discharge dates, intubation date, extubation date), **nurse mobilization practices** (high-flowers, semi-fowlers, beach/cardiac chair, dangle, transfer to chair, stood, ambulate, and range of motion (ROM) active versus passive, and turning), including frequency per shift, and **patient acuity score** derived from the Simplified Therapeutic Intervention Scoring System (TISS-28). The TISS-28 assesses severity of illness (Muehler et al., 2010) based on 28 indicators (interventions) with point values ranging from 1 to 5 (maximum score: 85). Data analysis included descriptive statistics (median, IQR, N, %), Mann-Whitney tests, Chi-square tests of independence and general linear modeling adjusting the standard errors for data arriving from the same nurse and in many cases the same patient (e.g., the same patient reported on by the same nurse multiple times).

Results: Patients (N=124) were a median 66 years of age (IQR: 57-74) with a median Charlson Comorbidity Index (CCI) of 4 (IQR: 3-7) and were approximately equally represented by gender (female: 52%; male: 48%). Considerably higher TISS scores were reported for patients on ICU "A" than for those on ICU "B" [median=26.5 (IQR: 18-33) vs. 17.5 (IQR: 10-17), $p < 0.001$]. The nurses reported that approximately 30% of the patients received more than one intervention during their shift. The most commonly reported types of interventions were mechanical ventilation (41%), tube care (39%), enteral feeding (29%), and fluid replacement (27%). The units varied in the number and types of interventions that the patients required during the nurses' respective shifts. Specific interventions required by a higher proportion of the patients on ICU "A" included: mechanical ventilation (56% vs. 31%, $p=0.006$), tube care (50% vs. 31%, $p=0.034$), enteral feeds (42% vs. 20%, $p=0.009$), and arterial line (14% vs. 4%, $p=0.046$).

Mobilization activities for the patients during each shift in the two ICUs were also analyzed. The most commonly reported mobilization activities conducted per patient per shift were turning of the patient at

least 6 times (82%) and placing the patient in semi-fowlers position (68%). After controlling for patient age, CCI, and TISS, patients in ICU "B" were more likely to be placed in semi-fowlers (88% vs. 30%, $p < .001$) whereas patients in ICU "A" were more likely to be placed in a beach/cardiac chair (33% vs. 3%, $p = 0.015$), be transferred to a chair (35% vs. 16%, $p < .001$), and be ambulated (30% vs. 22%, $p < .001$).

Conclusion: Differences in patient characteristics and nurse-led mobilization activities were observed between ICUs. After controlling for patient characteristics, we found statistically significant differences in nurse-led mobilization activities between the two units. These findings suggest that factors other than patient characteristics may explain differences in nurse-led mobilization activities. Our findings are consistent with other studies indicating that non-patient factors such as safety concerns and workload served as barriers to mobilization in ICU settings. The findings also support prior studies linking nurse-led mobilization to non-patient factors. Further research is needed to investigate specific factors associated with nurse-led mobilization practices, including unit and staff characteristics, nursing workload, and knowledge, skills, and attitude of ICU staff members. The findings of the study hold policy implications for research, practice and policy. Differences in mobilization practices based on patient-related factors reaffirm the need to risk adjust for patient acuity for assessment of mobilization practices. Differences in practices between hospitals (ICUs) highlights the need to explore organizational-level factors (e.g., policies, protocols) that influence early mobilization. National and local policies are also needed to allocate resources to investigate and address non-patient factors. Finally, policies that promote establishment of ICU mobility teams and ensure the purchase of equipment are needed to facilitate patient mobilization.

I 06 - Functional Status of Oncology Patients

The Power Over Pain Coaching Intervention Improves Functional Status in African Americans With Cancer Pain

April Vallerand, PhD, RN, FAAN, USA
Susan M. Hasenau, PhD, RN, NNP, CTN-A, USA
Thomas Templin, PhD, USA

Abstract

Purpose: Functional status, or the ability to carry out meaningful activities, is affected by pain intensity and the patient's belief that they can control the pain to an extent that allows them to participate in those activities¹. African Americans have been found to have higher levels of pain, more pain-related distress, and lower functional status than their Caucasian non-ethnic cohorts^{2,3,4}. Pain-related distress has been shown to mediate the relationship between pain and function^{5,6}. Although pain-related distress is important and should be assessed in all patients with pain, designing interventions to decrease distress is challenging due to the affective nature of the concept. The factors that lead to pain-related distress are more amenable to intervention strategies. Certainly decreasing pain may lead to decreasing distress, however, there may be other factors affecting distress. Perceived control over pain, a factor that had not been previously taken into account, was found to have a direct effect on pain-related distress and mediated the effect of beliefs about pain and pain level on distress in ambulatory patients with cancer-related pain¹. In a previous study, perceived control over pain was found to partially mediate the relationship between pain and functional status in adults with low income attending a primary care clinic⁷. The purpose of this longitudinal randomized control trial was to test the 3-component Power Over Pain – Coaching (POP-C) intervention with 236 African American patients recruited from an urban comprehensive cancer center.

Methods: Participants were 63% (196) female, mean age was 56.28 years ($SD = 11.49$). Average pain in past 24 hours from the Brief Pain Inventory (BPI) composite was 5.81 ($SD = 2.40$) on a 0-10 scale. The components of Medication Management, Pain Advocacy, and Living with Pain were tailored to African Americans, individualized to the patient, and delivered over 5 weeks. Components were measured by existing and investigator-developed instruments. Perceived control over pain, measured by cognitive, pharmacologic, and emotional control, and feelings of control, was a mediator of the outcomes of pain, pain-related distress, and functional status. The primary outcomes of pain, pain-related distress, and functional status were measured weekly. Intermediate outcomes of perceived control over pain and measure of the intervention components were measured at baseline, week 7 (evaluation of intervention), and week 12 (durability).

Results: There were no baseline differences in gender, marital status, education, metastasis, perceived control over pain, pain, pain-related distress, and functional status. As typical with behavioral intervention trials, a monotone pattern of missing data was observed due to death (5%), illness (10%), and lost to follow-up (9%). The total complete case sample was 236 (24% incomplete cases). Including baseline characteristics in the models did not make any difference in the estimation of treatment effects. Linear mixed model analyses of the primary outcomes of pain, pain-related distress, and functional status, showed significant linear decreases in each of the outcome measures over the 7 weeks over the 7 weeks between baseline and intervention evaluation ($p < .01$). Intervention effects were tested by comparing linear trends across groups. Intent-to-treat (ITT) and complete-case analyses gave similar results for pain-related distress and functional status; in both, differences in linear trend were significant as predicted ($p < .01$). The difference in linear trend for pain was not significant in the ITT ($p = .065$) but significant in complete case analysis ($p = .041$).

Conclusion: This study demonstrated improving perceived control over pain decreases pain-related distress and improves functional status in African Americans with cancer-related pain. Results from a previous study supported the need for nurses to incorporate perceived control over pain as part of the assessment process and to intervene using the potential methods for increasing perception of control over pain as discussed⁸. Potential nursing interventions for increasing control over pain include: educating

patients about pain management modalities; individualizing therapy to meet patient's needs including acceptable modifications of pharmacological regimen; providing options for patients to manage episodes of breakthrough pain; teaching patients how to use nonpharmacological modalities; and educating patients about when to call the clinician if pain is not controlled^{5,9}. The stronger effects observed for pain-related distress and functional status were anticipated because the POP-C intervention was expected to reduce distress and increase functional status irrespective of pain. Perceived control over pain was strongly associated with pain-related distress and is more amenable to the development of nursing interventions that can improve functional status. These results support the POP-C intervention and, validate the effects of the POP-C intervention for African Americans with cancer pain. Transforming these findings into practice, use of the components of the POP-C intervention when caring for African American patients with cancer pain will allow nurses to increase patient's perceived control over pain, leading to improved functional status.

I 06 - Functional Status of Oncology Patients

Effect of Exercise Training on Vascular Function in Cancer Survivors: A Meta-Analysis

Rhys I. Beaudry, MSc, USA

Yuanyuan Liang, PhD, USA

Steven T. Boyton, BS, GSR, USA

Wesley Tucker, PhD, RD, USA

R. Matthew Brothers, PhD, USA

Kathryn M. Daniel, PhD, RN, ANP-BC, GNP-BC, USA

Mark Haykowsky, PhD, USA

Abstract

Purpose: Cancer survivors are at increased risk for cardiovascular disease (CVD)–related morbidity and mortality as a result of underlying CVD risk factors combined with the direct effects of anti-cancer therapy (e.g. cardiomyocyte damage, myocardial and vascular ischemia) and effects of an unhealthy lifestyle (e.g. decreased physical activity) (1). Recent research has demonstrated that cancer survivors have reduced peak VO_2 (1). The mechanism(s) responsible for the reduced peak VO_2 are not well known, however it may be due to impaired peripheral vascular endothelial function, as measured by FMD in response to cuff ischemia, an endothelial dependent stimulus. Moreover, endothelial impairment precedes cardiovascular disease progression, therefore, FMD is a relevant clinical measure for evaluating cardiovascular risk profiles (2,3).

Exercise training is an effective therapy to increase peak VO_2 in cancer patients and survivors (4,5). The underlying physiological mechanisms responsible for increased exercise capacity in patients with cancer are unknown, however it may be due to improved peripheral vascular endothelial function.

Methods: We performed a systematic review and meta-analysis of all randomized trials that examined the effects of exercise training on vascular function and exercise capacity in cancer survivors (including pre, during and post-treatment). Studies were identified via systematic searches of PubMed (1975 to June 2016), EMBASE CINAHL (1937 to June 2016), OVID MEDLINE (1948 to June 2016) and Cochrane Central Registry of Controlled Trials (1991 to June 2016) using the following subject headings: vascular function, endothelial function, reactive hyperemia, flow-mediated dilation, arterial stiffness, cancer and exercise, and related terms.

Results: After screening 189 potentially relevant publications, we identified 4 eligible studies, including 82 survivors allocated to exercise training and 81 to non-exercise training controls (6-9). Three studies measured vascular endothelial function via brachial artery FMD and one measured endothelial function via EndoPat; while 3 studies measured peak VO_2 and one measured treadmill walking time for assessment of exercise capacity. The four studies included in the final analysis included prostate (n=2) and breast cancer survivors (n=2).

Meta-analysis of 4 studies showed that vascular function was significantly improved across exercise training groups relative to the non-exercise training controls (standard mean difference [95% confidence interval (CI)]=0.65 [0.33, 0.96]) and the heterogeneity/inconsistency across studies was minimal ($I^2 = 0\%$). Among the three studies that reported FMD, flow-mediated dilation was increased by approximately 1.28% (weighted mean difference (WMD) [95% CI]=[0.22 2.34]; $I^2 = 23.2\%$) in exercise-trained subjects relative to non-exercise controls. Peak VO_2 was improved in all three included studies relative to non-exercise training controls (WMD [95% CI]=2.22 [0.83, 3.61] ml/kg/min) with minimal heterogeneity ($I^2 = 0\%$).

Conclusion: Exercise training improved vascular function and peak VO_2 in breast and prostate cancer survivors. Improvements in exercise capacity and vascular function have been correlated with decreases in cardiovascular risk and mortality. Specifically, a 3.5 ml/kg/min increase in peak VO_2 is associated with a 12% and 17% decrease in mortality in men and women, respectively (10,11). Moreover, improving FMD by 1% is associated with an 8-13% decrease in cardiovascular risk (3,12). Accordingly, the improved

exercise capacity and vascular function may be associated with reduced CVD-morbidity and mortality in cancer survivors.

Exercise training improves vascular function and peak VO₂ in breast and prostate cancer survivors. Further research is required to elucidate the relationship between improved vascular function and exercise capacity, and if this improvement is associated with decreased CVD-related mortality, across a broader spectrum of cancer survivors.

I 07 - Global Perspectives on HIV Prevention

Predictors of Internet Use for HIV Prevention Among Hispanic Women in South Florida

Natalia Villegas, PhD, MSN, RN, IBCLC, USA
Rosina Cianelli, PhD, MPH, RN, FAAN, IBCLC, USA
Lila de Tantillo, BSN, RN, PhDc, USA
Nilda (Nena) Peragallo Montano, DrPH, RN, FAAN, USA
Brian E. McCabe, PhD, USA
Giovanna De Oliveira, PhD, ARNP, ANP-C, PMHNP-BC, USA
Lilian Ferrer, PhD, MSN, RN, FAAN, Chile

Abstract

Purpose: Hispanics have a high HIV incidence rate in the US, nearly three times that of whites. There is potential to decrease prominent HIV risk factors and increase preventive outcomes through the use of platforms such as the internet or mobile applications through hardware devices (e.g. computers, phones). These technologies can provide access to the appropriate information and/or HIV prevention interventions. Among Hispanic women, some internet interventions have shown that can reduce barriers to accessing preventive interventions and increase STI and HIV preventive behaviors. In the last decades, the use of technologies has increased among Hispanics for example, mobile technologies such as mobile apps or tablets are being used increasingly by many hispanics. However, little is know about the technology access and use, and factors that influence the use of technology among Hispanic women. The purpose of this study if to describe the use of technology and technology preferences to learn about HIV, and assess predictors of the use of internet for HIV prevention among Hispanic women in south Florida.

Methods: This is a secondary analysis study that uses baseline data from SEPA III: The Effectiveness Trial. SEPA stands for Salud/Health, Educacion/Education, Prevencion/Prevention y/and Autocuidado/Self-Care (2P60MD002266-06, NIH/NIMHD). The sample is 320 Hispanic women recruited in Miami, Florida. Recruitment occurred in 2 health care centers and public places that Hispanic women visit frequently. Female bilingual assessors interviewed women in their preferred language (Spanish or English) using a structured interview. We used SPSS version 22.0 to analyze sociodemographic information and descriptive information about women's use of technology. Logistic regression (LR) was used to predict the use of technology to learn about HIV prevention. In terms of regression analysis, the independent variables living with a partner and years living in the U.S. were dichotomized. The other independent variables education, age, and time since the last visit to the health care provider were listed as continuous.

Results: The majority of the women were living with their spouse or partner (219, 68%) and had less than 5 years living in the U.S. (60%). The average length of time in the U.S. was 8.50 ($SD = 8.25$) years. Average age of the women was 34.79 ($SD = 9.23$) years, and average education was 13.73 ($SD = 3.34$) years. The majority ($n = 300$, 94%) of women said the preferred Spanish, with ($n = 14$, 4%) preferring English, and ($n = 6$, 2%) both Spanish and English. The average time (months) since they las saw the doctor or health care provider was 9.4 ± 14.6 months. Participants reported Internet as the highest used technology (93.8%), followed by smartphones (90.6%), and email (88.1%). The majority of the participants (71.3%) reported to use internet to learn about HIV. In the LR analysis, results showed that participants who use the internet to learn about HIV, had a higher probability of reporting lower levels of education ($OR=1.113$, $CI=95\%$), and more time since the last visit to a health care provider ($OR=1.017$, $CI=95\%$) after controlling for age, living with the partner, and years living in the U.S.

Conclusion: The findings from this investigation contribute substantially to our understanding regarding the use of technology among Hispanic women and how it may be implemented as a facet of HIV/STI prevention. The results indicate that members of this population appear to have a high level of access to and comfort with various means of technology and electronic dissemination of health-related information. Another important observation encountered in this investigation is the association between length of time between visit to the doctor and the use of the internet to learn about STI and HIV prevention, as well as

that between education and the use of the internet learn about STI and HIV prevention. These relationships underscore the potential for vulnerable populations experiencing barriers to access to care to turn to Web or other electronic media as a substitute for medical care. While the high levels of electronic literacy among participants in the study can be regarded as positive, Web-based health information may be of varying quality. It is imperative to ensure that women not rely on technology as a substitute for adequate health care. Moreover, health care educators active in HIV/STI prevention efforts should continue work to expand outreach among women possessing fewer years of education and vigilant to combatting misinformation found on the internet.

I 08 - Health Promotion for Patients with Kidney Disease

Novel Barriers to Exercise for Patients With Chronic Kidney Disease

Mary F. Hannan, MSN, APN, AGACNP-BC, USA
Ulf G. Bronas, PhD, ATC, FSVM, FAHA, USA

Abstract

Purpose: Chronic kidney disease (CKD) is a common chronic condition, with an estimated prevalence of 11-13% worldwide (Hill et al., 2016). Despite medical treatment advances, CKD remains a debilitating condition that contributes to a myriad of clinical consequences (Avramovic & Stefanovic, 2012). Exercise is known to promote health and possibly delay certain comorbidities in patients with CKD (Momeni, Nematollahi, & Nasr, 2014; Smart, McFarlane, & Cornelissen, 2013). Despite the potential benefits of regular exercise training, patients throughout the world with CKD are not exercising and 45% have been found to be sedentary and 19% low active (Avesani et al., 2012), as compared to 23% of the world population that is thought to be insufficiently active (World Health Organization, 2015). Nurses have the opportunity to be on the front-line to help initiate healthy lifestyle changes such as regular exercise and daily physical activity. However, for nurses to provide optimal and effective interventions to empower patients to initiate an exercise regimen on their own, a clear understanding of the major reasons patients with CKD do not exercise is needed. Unfortunately, minimal exploration has been completed investigating patient reported barriers to exercise. The aim of this integrative review is to investigate the barriers that adult patients with CKD throughout the world report that prevent them from regularly exercising. Identification of these barriers will enable nurses and nurse researchers to address barriers to promote regular exercise and increases in daily physical activity for patients with CKD.

Methods: Seven electronic databases were searched to locate studies for an integrative review on patient reported barriers to exercise: Medline via PubMed, Medline via Ovid, CINAHL via EBSCO, PsychInfo via EBSCO, Embase, ProQuest Dissertations and Theses, and Scopus. The following key words were utilized, depending on database preference language: barriers; contraindications; hurdles; compliance; patient compliance; adherence; concordance; guideline adherence; self-perception; self-concept; treatment refusal; motivation; health knowledge, attitudes, and practice; exercise; physical activity; motor activity; and versions of phrases for CKD and end stage renal disease (ESRD.) The inclusion criteria were articles that included a) patients 18 years and older b) patients with CKD Stage 3-5 or ESRD requiring hemodialysis or peritoneal dialysis c) patient reported barriers to regular exercise d) and were available in English. Studies were excluded if they a) only discussed associations of exercise limitations and exercise frequency b) listed reasons for not participating in or withdrawing from an exercise intervention study c) or included post-kidney transplant recipients. The final search date was September 30, 2016.

Results: The results of this integrative review had an initial search yield of 384 publications which, after the application of the inclusion and exclusion criteria, were reduced to 14 publications. The included articles were published between 2001-2015. The studies took place in eight different countries. Descriptive quantitative design via survey was utilized in eight of the 14 studies to evaluate patient identified barriers to exercise. Four studies applied a qualitative method, utilizing interviews and focus groups. Two studies utilized mixed methods. Fatigue or lack of energy was the most frequently reported barrier, being found in twelve of the fourteen studies. Self-report of comorbid health problems was the second most commonly reported barrier and was noted in eight of the 14 studies.

Conclusion: The barriers patients with CKD report that prevent them from regularly exercising are complex and diverse. Twenty-four distinct barriers were elucidated through the results of this integrative review of literature from around the world (see Table 1). Fatigue and low energy levels were the most frequently reported barriers noted in the literature. This is not consistent with barriers that have previously been identified in healthy individuals or other chronic diseases. More importantly, this is an area that needs to be addressed in research to improve exercise and physical activity habits for patients with CKD. In previous studies, the barrier to exercise described by healthcare providers of patients with CKD has primarily been reported to be disinterest (Young et al., 2015). In addition, much of the current exercise

intervention research has focused on making exercise convenient (Heiwe & Jacobson, 2011). Fatigue was a common and important barrier to exercise in this integrative review. Fatigue is a devastating syndrome in patients with CKD (Artom, Moss-Morris, Caskey, & Chilcot, 2014). It is clear that more research is needed into methods to treat, prevent, and overcome fatigue in patients with CKD, so they can participate in self-care activities like exercise and increased levels of habitual daily physical activity.

The most important implication for nursing practice from this integrative review is the importance of assessing each patient's barriers to exercise. It appears that the barriers identified by healthcare providers are not the most frequently reported barriers by patients (Young et al., 2015), which emphasizes the need for an individualized approach to address each patient's barriers to exercise and daily physical activity. Nephrology nurses have an important role in the assessment and care planning of patients with CKD who suffer from fatigue. With assessment and collaborative care planning with a multidisciplinary team, nurses can help improve this debilitating barrier that prevents patients from exercising and participating in healthy behaviors. In addition to assessment and care planning, patient education is a critical component of the nurse's role in encouraging exercise interventions and helping patients overcome barriers to exercise (Davies, 2011).

This is the first integrative review to explore barriers to exercise for patients with chronic kidney disease. The most commonly reported barrier to exercise elucidated in this review was fatigue and low energy. The identification of these barriers helps nurses tailor their assessment and educational practices to address the unique barriers that prevent patients with CKD from exercising. With the appropriate assessment and education on barriers to exercise, patients with CKD may be empowered to begin exercise and receive the health promoting benefits of exercise.

Table 1- Patient Reported Barriers

Reported Barrier	Number of Times Found in the Literature
Fatigue	12
Co-morbid Health Conditions	8
Lack of Time or Access	7
Fear of Falling	6
Pain	5
Depression	3
Lack of Motivation	3
Being Incapable of Exercise	2
Environmental Limitations (weather, air quality, etc.)	2
"Renal disease" (CKD or HD)	2
"Being out of shape"	1
Concern or Complications	1
Dislike of Exercise	1
Employment	1
Exercise Is Tiring	1
Healthcare Provider Guidance	1
Lack of Company	1
Lack of Interest	1
Lack of Money	1
Lack of Understanding	1
Shortness of Breath	1
Stress	1
Vascular Access	1
Weakness	1

I 08 - Health Promotion for Patients with Kidney Disease

Causation and Confounding Factors for 30-Day Readmission of Kidney Transplant Patients: A Descriptive Study

Jean Dowling Dols, PhD, RN, NEA-BC, FACHE, USA
Katie A. Chargualaf, PhD, RN, CMSRN, USA

Abstract

Purpose: According to a recent study analyzing six years of national kidney transplant data, 31% of patients hospitalized for a kidney transplant required hospital readmission within 30 days of discharge (6). This study analyzed data of 32,000 patients for the years 2000-2005 finding 30-day kidney transplant readmission varying by facility from 18% to 51% (6). Some of the risk factors associated with early hospital readmission included age, race, body mass index (BMI), diabetes, heart disease, and length of stay (6). Additional studies identified level of education (8), time on dialysis (2), donor type (3,4), and a lack of understanding of post-transplant medications (2) as significant risk factors contributing to early readmissions. Specific populations found to have a higher rate of readmission include African Americans (11% higher), obese patients (15% higher), and diabetic women (29% higher) (6). Indications for readmission to the hospital are varied. More commonly reported causes include infection (1,2,3,4,5), surgical complications (1,2,3,4,5), and acute rejection (3,4).

The Centers for Medicare and Medicaid Services use readmissions as a proxy measure of hospital quality. While there are an expected number of 30-day readmissions, CMS currently tracks hospital readmissions and reduces Inpatient Prospective Payment System (IPPS) payments for specific conditions, but doesn't currently include transplants in these payment reductions (7). Re-hospitalization increases the cost of care for patients, providers, and payers. It often reflects incidents that may have been preventable and have the potential to increase patient mortality.

The researchers responsible for the national study of kidney transplant data emphasize that better outpatient management systems may reduce the number of rehospitalizations (6). However, the researchers of this study are unsure if that solution is the appropriate one for the kidney transplant population served by our hospital and others in the southern region of the U.S. with a high diversity factor, extensive travel to receive an organ, and the incredibly rapid growth of the kidney transplant population.

Identifying the risk factors and causes for kidney transplant 30-day readmission may enable healthcare facilities to structure care processes to reduce the influence of this population's particular risk factors and the causes of readmission. As readmission may reflect opportunities to improve inpatient care, care transition to another care setting, and outpatient care, a comprehensive analysis of the factors that may place patients at risk and the causes for readmission is essential to assure appropriate selection and effective implementation of interventions to reduce readmissions.

The purpose of this study is to identify the risk factors, causes, and confounding factors for 30-day readmissions in kidney transplant patients in the Southern region of the United States.

Methods: A descriptive, retrospective study was undertaken. The medical records of patients 18 years of age and older hospitalized in a southern region transplant center for kidney transplant surgery December 2015 to June 2016 who were re-admitted to the hospital within 30 days were analyzed. Each patient's hospital and clinic records were reviewed for readmission causes and risk factors identified through the literature and experience of experts in the care of kidney transplant patients and their readmissions using a data collection tool developed by the researchers. Data was analyzed using IBM® SPSS® Version 21.

Results: Findings at the Southern U.S. Region transplant center were uniquely different from the U.S. in the areas of risk factors and causes of readmission. The transplant center has experienced a rapid escalation of kidney transplants increasing over the last 10 years from 152 (62 deceased donor transplants/90 live donor transplants) in 2006 to 313 (140 deceased donor transplants/173 live donor transplants) in 2015. Unlike the predominant U.S. kidney transplant patients who are white, male, and the

recipient of a deceased donor transplant; the patients receiving transplants at this regional transplant center are Hispanic, female, and the recipient of a living donor transplant.

Patients in the study were more likely to be readmitted if they were a recipient of a deceased donor transplant in comparison to the recipient of a live donor transplant, as is the U.S. population of kidney transplant patients. Also similar to the U.S. population, the kidney transplant patients in the study experienced higher 30-day readmissions if they had a deceased donor transplant with a prior history of diabetes mellitus.

Differences in the study population from the U.S. transplant population were that patients 50+ years old were more likely to be readmitted than any other age group whether they were the recipient of a living or deceased donor. Education less than college was associated with increased readmission, as were body mass index 26+, prior history of diabetes mellitus, being a woman, and being Hispanic. 30-day readmissions were more likely to occur within 14 days of discharge. Patients at the transplant center traveled up to 339 miles to receive their transplant and readmission was more likely if the patient traveled more than 20 miles from their home to the hospital.

The cause of readmission reported in the literature varies widely. To improve consistency and allow for comparisons, the causes for the readmissions in this study were grouped into previously reported categories (1,2,3,4,5). Similar to readmission causes for U.S. kidney transplant patients, the most common etiologies included allograft dysfunction (including rejection and Acute Kidney Injury) (46%), infection (18%), and surgical complications (13%). Yet 30-day readmissions for the transplant center were higher than the U.S. kidney transplant population in the areas of symptom management and fluid/electrolyte imbalances related to post-transplant including nausea and vomiting (18%), volume overload/depletion (15%), electrolyte imbalances (13%), and cardiovascular events (hypotension/hypertension) (10%).

Conclusion: Risk factors for 30-day readmission in this sample of patients in the Southern region are significantly different than the U.S. population, as are the characteristics of the Southern population. The causes for 30-day readmission in this Southern U.S. sample also are different in the areas of post-transplant symptom management and fluid/electrolyte imbalance. The results of this study are informing future research studies and intervention plans aimed at reducing the readmissions of kidney transplant patients unique to this region. Recommendations for study include investigation of the clarity of communication and education for Spanish-speaking patients, patients with a lower level of education, and patients by age group. In relation to the causes for readmission, additional understanding and potential interventions are needed regarding the transplant patient's medication knowledge and adherence and their methods of seeking healthcare assistance post-transplant for symptom management and fluid/electrolyte imbalance. Future studies planned include interventional studies that will impact transplant patient readmissions for women, patients who have a Body Mass Index greater than 25, and patients with a prior history of Diabetes Mellitus Type II.

I 09 - Improving Education Through Simulation

Measuring Nurse Tutor Simulation Education Confidence and Competence Following a Collaborative Nursing Education Certificate Program

Mary E. Mckay, DNP, ARNP, CNE, USA

Deborah Salani, DNP, PMHNP-BC, ARNP, NE-BC, USA

Jill Steiner Sanko, PhD, BA, BSN, RN, ARNP-BC, CHSE-A, USA

Abstract

Purpose: The purpose of this presentation is to discuss the impact of a hybrid nursing education certificate program on Guyanese nurse tutor self - reported confidence and competence related to the use of simulation in nursing education. In response to a dire nursing shortage the Guyanese government increased the enrollment capacity for the Guyana Schools of Nursing. Guyanese nursing schools are experiencing decreased student retention and successful completion of the national licensure exam in part due to an inadequate number of experienced tutors(educators). In an effort to address these concerns an agreement with Guyana's Ministry of Health and the Pan American Health Organization (PAHO) Regional Office in Guyana, and the School of Nursing was made to offer a Nursing Education Certificate Program. This initiative supports the objective to educate and develop human resources in nursing. The goal for the nursing education certificate program is to provide nursing tutors with the critical knowledge and skills to provide high quality nursing education. Simulation is an educational strategy utilized extensively in nursing programs in the United States (Aebersold & Tschannen, 2013). A multi-site longitudinal study by the National Council of the State Boards of Nursing (NCSBN) (Alexander et al., 2015) found that up to 50% of clinical time could be substituted with high quality simulation with similar student learning outcomes. There is evidence, promoting the utility of simulation to enhance critical thinking, medication-administration skills, promotion of inter professional communication (Liaw, Si, Zhou, W., Lau, T., Siau, C., & Chan, S., 2013, Pauly-O'Neill & Prion, 2013, Shin, H., Ma, H., Park, I., Ji, E., & Kim., D., 2015). The research aim was to evaluate the effects of the Guyana Nursing Education Certificate Program on the participant's self -reported confidence and competence in simulation knowledge and skills.

Methods: The program consists of 4 courses that combine distance learning via weekly virtual online classes with face-to-face instruction. Faculty made four trips to Guyana to provide onsite education and support. The program was tailored to meet the specific needs of the tutors with the goal of giving participants tools to customize their own curricula. Topics included teaching and learning theory, teaching methodology, and evaluation methods. Specific simulation topics covered throughout the program comprised of the development of simulation objectives, development and implementation of simulation scenarios, incorporation of critical thinking components into simulation activities, use of standardized patients, the role of the facilitator, and the simulation debriefing process. The NCSBN guidelines for Pre licensure Nursing Programs (2015) and the International Nursing Association for Clinical Simulation and Learning Simulation standards (2013) provided the foundation for the content provided. The participants were required to develop simulation objectives, scenarios and debriefing points as part of the course assignments.

A pre/post mixed method design was utilized. Following institutional review board approval twenty-six participants were asked to complete online surveys prior to and following the certificate program. The participants were nursing tutors from four schools of nursing. The survey consists of demographic data, self -reported confidence and competence in the seven-simulation topic areas described above, and qualitative open - ended questions.

Results: Scale analysis for the self - reported confidence and competence survey revealed a Cronbach's alpha value of 0.98 and demonstrated good internal consistency with all item correlations greater than 0.76. Statistically significant pre – post scores were found in the participants self -reported confidence in the areas of the development of simulation objectives ($p = .002$), development of simulation scenario($p = .010$), implementation of scenario ($p = .040$), incorporation of critical thinking ($p = .006$), simulation debriefing($p < .001$), and role of simulation facilitator ($p = .008$). Pre- post scores for self reported confidence in the area of use of a standardized patient in simulation was not statistically significant

($p=.075$). Statistically significant pre – post scores were found in the participants self -reported competence in the areas of the development of simulation objectives ($p = .013$), development of simulation scenario($p=.013$), implementation of scenario ($p = .029$), incorporation of critical thinking ($p=.002$), simulation debriefing($p= .006$), and role of simulation facilitator ($p=.036$). Pre- post scores for self reported competence in the area of use of a standardized patient in simulation was not statistically significant ($p=.10$).

Conclusion: Following the completion of the nursing education certificate program for Guyanese nurse tutors, statistically significant pre-post scores were found in the participants' self- reported confidence and competence scores in the areas of development of simulation objectives, development and implementation of simulation scenarios, incorporation of critical thinking components into the activity, the role of the simulation facilitator and the simulation debriefing process. No significant difference was noted in the post survey in the use of standardized patients in simulation education. These findings offer promise for future plans to repeat the nursing education certificate program for additional Guyanese nurse tutors to improve self reported confidence and competence in the use of simulation as a teaching modality. The increase in confidence and competence may result in an increase in the use of simulation as a teaching modality. Several study limitations exist including a relatively small number of participants and the use of self-reported data. Future offerings of the program will include an increased emphasis on the use of standardized patients for simulation and the use of “virtual” simulation modalities.

I 09 - Improving Education Through Simulation

The Effect of Evaluator Training on Reliability in High-Stakes Assessment Simulations: Pilot Study Results

Jone Tiffany, DNP, RN, CNE, CHSE, ANEF, USA

Linda Blazovich, DNP, RN, CNE, USA

Vicki Schug, PhD, RN, CNE, USA

Abstract

Purpose: Evaluating clinical competency of nursing students is essential as we prepare them for the ever-changing and rapid pace of the healthcare environment. As greater emphasis is placed on high stakes assessment of clinical performance, the training of evaluators to assure good intra and inter-rater reliability of simulation performance is paramount. Supported by recent findings from the National Council for State Boards of Nursing study (NCSBN), simulation is quickly developing into a core teaching strategy for nursing education. Evaluation of learning during simulation, an essential component in the NCSBN study, informed nurse educators about valid and reliable mechanisms to assess achievement and competency in practice. The growing interest in using simulation to evaluate student competency led the National League for Nursing to conduct a four-year study to evaluate the process and feasibility of using mannequin-based high fidelity simulation for high stakes assessment in pre-licensure RN programs. Achieving clarity about the specific behaviors that students need to exhibit in order to demonstrate competency is paramount. Equally important is the training of evaluators to assure satisfactory intra/inter-rater reliability. This presentation describes the results of a pilot study conducted to test the effectiveness of a training intervention in producing intra and inter-rater reliability among nursing faculty evaluating student performance in simulation. The study is an extension of the NLN Project to Explore the Use of Simulation for High Stakes assessment. The pilot study was guided by the questions: What is the effect of (a) a training intervention and (b) faculty personality characteristics on faculty ability to achieve intra/inter-rater reliability when evaluating student performance during high-stakes simulation?

Methods: A pilot study was designed to precede a national experimental study. Basic orientation and advanced evaluator training modules were developed. These modules included orientation documents, *StrengthsFinder Inventory* instructions, a training video for the Creighton Competency Evaluation Instrument (CCEI), a training webinar, and a coaching webinar. Study instruments included the CCEI, student performance videos created for the National League for Nursing (NLN) Project *to Explore the Use of Simulation for High Stakes*, a demographic survey, and the *StrengthsFinder Inventory Survey*. With NLN approval, the student performance videos and the performance assessment tool produced for and used in the NLN feasibility study were used in the pilot study. A training intervention for faculty evaluators was developed. Five simulation experts completed the training intervention and the performance evaluation procedure. Reliability and correlational analysis was performed to evaluate the impact of training and faculty personality characteristics on inter/intra rater reliability. Feedback was collected from the participants to guide modifications to the content and process of the intervention in preparation for a regional, multi-site, experimental study, which began in the fall of 2016.

Results: All pilot participants were female. Three participants were ages 51 to 60; one was age 61-70; and one was age 31-40. Four participants held a master's degree and one held a doctoral degree as the highest academic credential. The participants taught in associate, baccalaureate, and entry-level master's programs. The five participants taught in three different states. Only one participant taught in a program currently conducting high-stakes assessment in simulation. Quantitative analysis was conducted on the CCEI video evaluations. When the analysis of the six videos was compared with the three training videos, a large increase in inter-rater reliability was noted for two subscales: Assessment and Clinical Judgment. Two subscales: Communication and Patient Safety showed little difference. The two overall measures, Yes/No Competency, and Overall score showed little difference. The results were reported in an aggregated format, which obscured the differences between the separate evaluations of the training videos and the experimental videos. Even though the statistics were reported in aggregate, it still appears that the training intervention helped the participants to develop a more shared mental model of

evaluation. These statistics will be analyzed and reported both individually and in aggregate for the full study.

Conclusion: It was evident that conducting a pilot study was invaluable. When data collection instruments, study procedures, and data analysis are complex, one can expect difficulties that require problem solving. This study has raised some critical questions relative to high stakes assessment, including: 1) what is the “right” amount and format of training? and 2) how do you help teams of faculty develop a shared mental model? This pilot study provided the opportunity to implement study procedures and make changes where issues and problems were discovered.

I 10 - Interventions in Birth Outcomes

The Critical Role of Fathers to Reduce Stillbirth in India

Lisa R. Roberts, DrPH, MSN, RN, FNP-BC, CHES, USA
Susanne Montgomery, PhD, MPH, USA

Abstract

Purpose: The purpose of this study was to explore how men and women experience stillbirth in India, and their respective needs, to inform locally sustainable interventions.

Millennium Development Goal 4, to reduce child mortality, cannot be achieved without reducing the world's 3.3 million stillbirths (Yoshida et al., 2016). India has the highest number of stillbirths in the world (Blencowe et al., 2016). A confluence of medical and sociocultural factors contribute to the high stillbirth rate among poor, rural women in central India, and the effects are devastating. For women, fertility is correspondent to worth, yet social norms increasing the risks of stillbirth include: lifelong malnutrition due to girls/women receiving less food, of less quality, after males have been fed; young (due to early marriage) or advanced maternal age (as women continue trying to get pregnant with a boy child), lack of reproductive health choice/resources, and the quest for sons; maternal socioeconomic disadvantage as girls receive less education, are less likely to work in the formal workforce, and are unable to inherit property; short birth intervals and lack of antenatal care; and lack of skilled birth attendants due to lack of infrastructure in addition to women's low general autonomy and specifically lack of health care decision making power (McClure et al., 2015). When stillbirth occurs, women in India and other low-middle income countries suffer perinatal grief that may persist for years, but is unrecognized, repressed, and untreated, resulting in mental health sequelae such as depression, anxiety, somatic symptoms, decreased functioning, and increased risk for domestic violence, stigma, and abandonment, or isolation (Burden et al., 2016; Lawn et al., 2016).

All too often multiple stillbirths occur in one family, as stillbirth begets stillbirth. In India's patriarchal society with its strong son preference and deficient women's autonomy, sex-selective abortion occurs, putting women at risk for future preterm birth—increasing the risk of poor infant outcomes, including stillbirth (Ahankari, Myles, Tata, & Fogarty, 2015; Bharadwaj & Lakdawala, 2013; Straus & Mickey, 2012). While few studies have explored how fathers experience grief after stillbirth, previous studies in the West indicate that fathers—unlike mothers, have increased psychological symptoms the more time elapses before another pregnancy (Cacciatore, Erlandsson, & Rådestad, 2013). In India, this tendency combined with social pressure to try to conceive a son soon after stillbirth, may actually cause men to unwittingly reduce their chances of fulfilling desired fertility expectations (Kozuki & Walker, 2013). Therefore, men's perceptions and knowledge regarding maternal-child health and reproduction are important to achieving a reduction in stillbirth rates in India.

Methods: We used mixed-methods in two parallel studies; (a) evaluation of a short mindfulness-based pilot intervention which was culturally adapted and implemented in collaboration with local nurses, for women ($n = 22$) who had experienced stillbirth, and (b) formative work exploring men's experiences with stillbirth using key informant interviews ($n = 5$) and structured interviews using a survey based on identified themes ($n = 23$).

Results: Women who had experienced one to three stillbirths participated in the Mindfulness-based intervention (MBI), 6-week, and 12-month follow-up assessments. Anxiety and depression symptoms were significantly reduced, as measured by HSC index ($M = 2.17$ (SD 0.60), $M = 1.81$ (SD 0.48), and $M = 1.59$ (0.47) respectively). Likewise, significant reductions in the perinatal grief index as well as the active grief, difficulty coping, and despair subscales were noted at each assessment over time. Mindfulness was positively correlated to resilience, and at 1 year, 95.4% of the participants were still practicing mindfulness skills. Women reported that mindfulness was useful in helping them feel calm, increased their sense of peace in mind and body despite stressors, and gave them positive energy making it easier to function in their roles despite never forgetting their stillborn babies.

Men (three who were fathers of stillborn babies) acknowledged their medical and reproductive decision making power matter-of-factly as well as the lack thereof for their wives, and while they saw it as a natural a right, they also experienced it as a burden. They often felt they lacked knowledge and readiness for decision-making. Wives were not allowed/encouraged to discuss their stillbirth and men accede societal expectations for fertility, pushing their wives to conceive again soon. If unsuccessful, or a son was not produced, a second wife was seen as a possible solution.

Of the 23 men who completed surveys, 18 had experienced stillbirth. These men, compared to those without a history of stillbirth, were significantly more likely to have anxiety or depressive symptoms and perceived lower social provision of support. They also had significantly more egalitarian attitudes towards women, though they were also more abusive of their wives. They reported a greater number of days as normal for women to grieve after stillbirth and employed greater use of positive religious coping, but still reported frustration with their wives crying or otherwise showing grief and wished their wives would just get on with life. Once aware of the MBI for women, men were supportive of the program.

Overall, men reported granting far greater autonomy to women than women themselves perceived. Additionally, men were more likely to report abusing their wives than women were to report being abused. There was, however, concordance of reports by both men and women that approximately half of the stillbirth deliveries had been conducted by unskilled birth attendants at home.

Conclusion: Our short, culturally adapted MBI was found to be effective in reducing perinatal grief and increasing resilience for poor village women in rural central India, with not only sustained but increased improvements at one year. However, men in the same villages were often unaware of the need or that the intervention had been offered. Fathers of stillborn babies had unmet needs for support, yet dealing with perinatal grief possibly provided an opportunity for them to gain new insight, experience personal growth and develop empathy resulting in the more egalitarian view towards women noted in our results. Providing support to fathers might reduce their increased propensity for abuse and symptoms of anxiety and depression, while increasing capacity for the positive changes in attitudes found towards their wives.

Miss-matched perceptions between men and women regarding women's autonomy and abuse are opportunities for community engagement and discussion. The link between stillbirth and the low use of skilled birth attendants/facilities represents an opportunity for education and community-based intervention. Nurses, who interact with both genders and are knowledgeable of the cultural context are already positioned in the community. Local nurses are ideal collaborative partners for community engagement and with appropriate training and support can implement community-based interventions.

As Kofi Annan has said, "When women thrive, all of society benefits and succeeding generations are given a better start in life." Clearly, if progress toward reducing stillbirths is to be made both men and women have to be involved in intervention efforts. In a patriarchal society like India, stillbirth studies should explore fathers' perceptions, attitudes, and behaviors regarding stillbirth so that appropriate interventions can be developed for men, ultimately supporting women. While societal norms would require separate interventions, an effective intervention such as the pilot MBI for women is promising and may be adaptable for fathers too.

I 10 - Interventions in Birth Outcomes

Should Our Approach for Reducing Poor Birth Outcomes Differ in Urban and Rural Populations?

Judy Griffin McCook, PhD, RN-BC, USA
Beth A. Bailey, PhD, MA, BS, USA

Abstract

Purpose: Location of residence has long been recognized to impact maternal-child health disparities. For decades, women residing in urban areas have experienced high rates of poor pregnancy outcomes. More recently, rural disparities in birth outcomes have been recognized, and have been found to occur at rates similar to those reported for urban populations. In order to appropriately address poor birth outcomes in such highly disparate environments, a better understanding of the modifiable factors that may differentially drive these outcomes is needed. The current study had two objectives. First, we examined potential differences between rural and urban women on modifiable factors known to impact birth outcomes. Second, we examined whether these factors differentially predicted two specific adverse birth outcomes, preterm delivery (PTB, 9.6% nationally) and intrauterine growth restriction (IUGR, 9.9% nationally), for urban and rural newborns.

Methods: Data were extracted from birth certificates for all live births in the state of Tennessee for a 3-year period from 2012-2014. Rural Urban Commuting Area (RUCA) Codes were assigned based on maternal residence zip code, and participants were classified as either urban (Metropolitan, codes 1.0 – 2.1) or rural (Rural, codes 10.0-10.3). Those with micropolitan and small town RUCA codes were eliminated from further analysis. Birth outcomes of interest were PTB (birth prior to 37 weeks gestation) and IUGR (birth weight for gestational age < 10th percentile). Modifiable dichotomous predictors included maternal weight based on BMI (underweight prior to pregnancy, overweight prior to pregnancy, gained too little weight during pregnancy, gained too much weight during pregnancy), smoking (smoked cigarettes at any point during pregnancy), time between pregnancies (previous pregnancy ended < 6 months prior to current pregnancy), prenatal care (inadequate based on timing of entry and number of visits, no prenatal care), and existing or emerging chronic health conditions (prepregnancy and gestational hypertension, prepregnancy and gestational diabetes). Chi-square analyses were used to compare the urban-rural groups on the predictors, while logistic regression was used to look at the odds of poor birth outcomes relative to each predictor separately for urban and rural participants, while controlling for possible confounders (maternal age, race, infant gender, and eligibility for income-based government benefits).

Results: The final sample contained 183,703 maternal-infant dyads (9,385 classified as rural). The urban and rural populations did not differ significantly ($p > 0.05$) in rates of PTB (10.9% vs 11.4%) or IUGR (11.8% vs 11.3%). The two groups differed significantly ($p < 0.05$ – $p < 0.001$) on all predictors of interest. Compared to urban women, rural women had significantly higher rates of being underweight prior to pregnancy, being overweight prior to pregnancy, gaining too little weight, and gaining too much weight. Compared to urban women, rural women were more than twice as likely to have smoked during pregnancy (27.3% vs 12.2%), had a short inter-pregnancy interval, and had substantially higher rates of prepregnancy and gestational hypertension and diabetes. The only predictors for which urban women were worse off than rural women were related to prenatal care – urban women were 10% more likely to have inadequate prenatal care, and almost twice as likely (2.1% vs 1.1%) to have had no prenatal care. Logistic regression analyses revealed similar predictor patterns for urban and rural women for PTB, with gestational hypertension the strongest predictor (aOR=3.39 for urban women, aOR=2.82 for rural women). Prepregnancy hypertension and diabetes were significant predictors for both groups of women, more than doubling the chances of a PTB. While gaining too little weight predicted PTB for both groups, being overweight prepregnancy and inadequate prenatal care were strong predictors for rural women, while no prenatal care and pregnancy smoking were strong predictors for urban women. Prediction models were very different for urban and rural women regarding IUGR, with pregnancy smoking the strongest predictor for urban women, and prepregnancy hypertension the strongest predictor for rural

women. Being underweight prepregnancy significantly predicted IUGR for both groups, as did gaining too little weight, with prenatal care factors only marginally important and only for urban women.

Conclusion: PTB and IUGR are important indicators of not only newborn wellbeing, but of long term growth and development. In our sample, rates of PTB and IUGR in our urban and rural groups were higher than national averages, but not different between the two regions. This is despite the fact that rural women had significantly higher rates of most modifiable predictors of these adverse birth outcomes. Differences in what predicts PTB and IUGR in the two groups emerged, and may suggest avenues for differentially tailored interventions in urban and rural settings, especially with regard to how to better prioritize improved management of chronic health conditions, addressing weight preconception and weight gain during pregnancy, intervening with smokers, and increasing engagement in prenatal care. However, results also show that just because a potential determinant occurs at a higher rate in a specific region does not mean addressing it to the exclusion of other factors will lead to the greatest improvement in birth outcomes, and interventions should consider the predictors of poor birth outcomes in specific populations. Future research should examine potential buffers or resilience factors in rural samples who, based on rates of predictors of adverse birth outcomes, might be expected to have higher rates of PTB and IUGR than even urban women.

I 11 - Nursing Students and the Care of Vulnerable Populations Using Trigger Films as a Bariatric Sensitivity Intervention to Improve Nursing Students' Attitudes and Beliefs

Margory A. Molloy, DNP, RN, CNE, CHSE, USA

Abstract

Purpose: This project was a program evaluation. Its aim was to develop, implement, and evaluate the effects of a bariatric sensitivity intervention (BSI) on nursing students' attitudes toward obesity and their beliefs about caring for obese patients.

Methods: One-group repeated measures design used surveys immediately before the intervention, immediately after the intervention, and 30 days after the intervention to evaluate the effects of the BSI on nursing students' attitudes toward obesity and beliefs about obese persons. The BSI was delivered to a convenience sample of 70 first-semester nursing students enrolled in the introductory clinical nursing course of an accelerated BSN program. The entire class viewed the trigger films, participated in a debrief session facilitated by the project investigator, and completed surveys during regularly scheduled class time. Survey completion was optional, but all 70 students elected to participate in the surveys. Student survey packets were coded to ensure anonymity but allow matching of the surveys completed by each student at the 3 time points for analysis. For protection of human rights, this project was reviewed and approved by the institutional review board of the author's university.

The BSI developed for this project included the creation of 6 short video vignettes, or trigger films, along with a facilitated debrief. Trigger films are short social guidance educational films intended for student audiences and focus on themes that engage the affective domain. The trigger films highlighted simulated scenarios involving interactions among members of the health care team and, in some cases, interactions with patients. Key learning points built into the BSI included: recognizing the multifactorial etiologies of obesity, avoidance of 'blaming the victim', and understanding the consequences of attributing the lack of personal willpower as the cause of all obese conditions.

The Nurses' Attitudes Toward Obesity and Obese Patients Scale (NATOOPS) developed by Watson, Oberle, and Deutscher (2008) is a 36-item questionnaire framed on 100 mm visual analog scale that was used to measure students' attitudes toward obesity and obese adult patients at 3 time points. The Beliefs About Obese Persons Scale (BAOPS) developed by Reto (2003) is a questionnaire with 8 items, each scored on 6-point Likert scale (total score 0 to 48). Each item assesses extent of agreement or disagreement with statement about controllability of obesity. Both instruments were administered before, immediately after, and 30 days after delivery of the BSI

Results: NATOOPS subscale scores showed significant improvement in attitudes toward obesity for 3 of 5 subscales from pre-intervention to immediately post-intervention and 2 of 5 subscales from pre-intervention to 30-day post-intervention. BAOP total scores showed significantly more positive beliefs about controllability of obesity from pre-intervention to immediately post-intervention, from pre-intervention to 30-day post-intervention.

The BSI produced immediate changes in nursing students' attitudes (NATOOPS) and underlying (explicit) beliefs about individuals who are obese (BAOP). However, sustainability of this intervention needs to be explored further.

Conclusion: A well-designed Bariatric Sensitivity Intervention (BSI) exploring obesity issues can positively impact nursing students' attitudes toward and beliefs about caring for obese patients. Attitudes about obese persons are positively changed when obesity is attributed to genetics and/or environmental factors. However, beneficial effects of this intervention may not be sustained unless mechanisms are in place to reinforce its content throughout the educational curriculum. Faculty should consider exposing students to simulations using bariatric-sized mannequins/models and bariatric equipment prior to clinical entry, sharing current research on causes, health risks, and effective nursing interventions associated

with obesity with nursing students in order to reduce stigmatization of obese patients. Modeling use of supportive communication / language when talking to overweight or obese patients should be demonstrated by faculty in the classroom, clinical and laboratory settings. This project could be replicated to determine whether delivery of BSI would be more effective if delivered at time points later in the nursing curriculum. Further research is needed to develop effective interventions for improving student attitudes and reducing bias, stigma, and discrimination toward obese patients.

I 11 - Nursing Students and the Care of Vulnerable Populations

What Do Nursing Students Know About the Homeless and Their Care Experiences? A Qualitative Study

Kim Schafer Astroth, PhD, RN, USA
Cindy H. Kerber, PhD, PMHCNS, BC, USA
Sheryl Henry Jenkins, PhD, APN, ACNP-BC, RN, USA
Wendy M. Woith, PhD, RN, FAAN, USA

Abstract

Purpose: The **purposes** of this qualitative study were to: a) explore the attitudes and knowledge of nursing students regarding the homeless, b) describe their experiences with the homeless, c) examine their perceptions of nursing care of the homeless, and d) identify possible strategies for teaching nursing students about care of the homeless. Vulnerable populations, especially homeless people, may be particularly at risk for experiencing uncivil behavior from nurses. Studies have demonstrated that homeless people believe they are not treated as well as others when seeking healthcare; they have reported experiencing incivility and lack of compassion by nurses. These nursing behaviors constitute a barrier to care of the homeless. There is little literature regarding nursing students' attitudes toward the homeless and how these attitudes may impact the care of this vulnerable population.

Methods: We interviewed 19 undergraduate nursing students, aged 20 to 21, from a baccalaureate nursing program in the Midwestern United States. We obtained informed consent and demographic data immediately before initiating the audiotaped interviews. Audiotaped interviews took an average of thirty minutes to complete and were later transcribed verbatim. Field notes were maintained with each interview to allow for an audit trail. Qualitative data were analyzed through content analysis identification of themes. Coding categories were generated from the data, with final themes identified through an iterative process, until data saturation was reached. Themes were examined for fit with Leininger's model and were also compared to themes found in the literature and examined for congruency. Descriptive statistics were used to explore participants' characteristics. Trustworthiness was enhanced through use of an audit trail and member checking.

Results: Four major themes emerged from data analysis: a) student perceptions of the homeless, b) student experiences with the homeless, c) healthcare of the homeless, and d) how best to teach students about the homeless.

Student perceptions of the homeless. Students defined homelessness as lacking both a physical home and basic necessities, not having a job, and, interestingly, an absence of an emotional sense of belonging. Most students believed homelessness was primarily due to circumstances beyond the individual's control. Some mentioned that homelessness may also be caused by poor personal choices, such as drug use, but they believed that this described only a minority of homeless people. In describing the appearance and behavior of homeless people, students asserted that the homeless wear old clothes in poor repair, have poor hygiene and grooming, and carry all their belongings with them in bags or boxes. Students envisioned a typical day for the homeless as one spent in looking for resources, food, shelter, money, and work. They described a typical night for the homeless as cold and frightening. Many thought it would be very difficult to find a safe place to sleep. Students also expressed a strong sense of empathy for the homeless. They felt sadness, shock, and humility as they described their experiences. A few reported feeling guilty if they ignored the homeless because they didn't have anything to give them.

Student experiences with the homeless. Students reported both self-directed and community-directed experiences with the homeless. Self-directed experiences included chance encounters on the street in which they gave money, water, or left-over food to the people they met. Community-directed experiences included working at soup kitchens, food pantries, and homeless shelters with school or church groups. Some of the community-directed experiences were superficial in that students merely dished up food or bagged items without interacting with recipients. Others were deeper in that they actually spent time in

conversation with the homeless. These students described trying to get to know them and understand their circumstances.

Healthcare of the homeless. Half of the students thought that homeless people usually did not seek professional healthcare, but instead tried to care for themselves. The other half said homeless people seek care at free clinics or hospitals. In addition, students believed that homeless people receive help from friends, family members, or strangers on the street. Lack of money or health insurance, inadequate transportation, fear of inequitable care, and stigma were described as major barriers to care. Students suggested nursing care of the homeless should be empathetic, attentive, compassionate, and equitable.

How best to teach students about the homeless. Students identified four specific teaching strategies. They suggested discussing homelessness as a topic inserted into an existing course. They also asserted that simulations in which students experience what it is like to be homeless could be informative and also give students an entirely new perspective. Several recommended developing clinical experiences in which students work in low income clinics or shelters to provide direct care for the homeless. Finally, a few students believed that cultural immersion, in which students interact with the homeless in natural environments, would be most helpful.

Conclusion: Nurses have a responsibility to advocate for the needs of vulnerable populations including the homeless. In order to be effective advocates, nurses and nursing students must thoroughly understand the issues related to homelessness. Students in this study had varying types of involvement with and knowledge of the homeless and their care experiences. Many of their perceptions were based on stereotypes, and some were patently erroneous, such as assertions that most homeless people have jobs, or that substance abuse has negligible impact on homelessness. This suggests that student nurses need more comprehensive education concerning the needs of this vulnerable population.

Preconception Health Planning: Improving Outcomes

Julie A. Fitzgerald, PhD, RN, CNE, USA

Abstract

Purpose: Current data suggests that lack of engagement in preconception health planning is a global problem and new approaches are needed to prevent preterm births and improve pregnancy outcomes. Many pregnant women make lifestyle changes during pregnancy to promote their health and the health of the fetus. Studies note that pre-conceptual health of both the mother and father influence pregnancy outcomes (Ding, Li, Xie & Yang, 2015; Moss & Harris, 2015). The CDC and Workgroup of the National Preconception Health and Health Care Initiative (Frayne, Verbiest., Chelmow., Clarke, Dunlop, Hosmer, & ... Stuebe 2015) identified the need for preconception health screening, assessment and education to improve birth outcomes. They estimate as many as one in ten women had a poor birth outcome and needed interventions to improve health, with minority and poor women at higher risk (CDC, 2006, 2015). The CDC recommends that risk assessment and health education be part of all primary care visits (CDC, 2015; Hurst & Linton, 2015). In spite of these recommendations PRAMS data from 2004-2010 from twelve states in the United States reported that only one third of women who delivered reported receiving preconception health planning (Ozra-Frank, Gilson, Keim, Lynch & Kiebanoff, 2014). The government of China, offered free preconception health planning to Chinese men and women to improve birth outcomes. A survey of over 12,000 pregnant women and men living in China, revealed that although the majority knew of the service, only 40% accessed the service (Ding, Li, Xie & Yang, 2015). Likewise, a survey of pregnant women living in London, noted that although 73 % of women planned their pregnancy less than 50% received pre conceptual care (Stephenson, Patel,Barrett, Howden, Copas, Ojwuku et. al. , 2014). Further assessment of this population revealed although many reduced alcohol and quit smoking prior to conception, only 51% reported taking folic acid. Few studies have focused on the postpartum as a time to incorporate pre-conception health planning.

Methods: Based on the need to improve birth outcomes and reduce the number of preterm births, the March of Dimes funded a Nurse Educator/Health Coach to work with mothers of infants admitted to the NICU. The Nurse Educator/Health Coach recruited (N=70) mothers of preterm infants admitted to the NICU, to learn about stress reduction and healthy lifestyles. Since mothers who give birth to preterm infants, often have health risks and may have a subsequent preterm birth the education focused on preconception care. The Nurse Educator assigned to the project, administered a pregnancy quiz (to assess knowledge of healthy pregnancy) a Risk Assessment Survey, and provided patient education with a Preconception Health Education Module developed by the March of Dimes. All participants received individualized risk assessment and education regarding importance of folic acid intake prior to conception, pregnancy spacing, postpartum depression, healthy eating, importance of management of chronic diseases, stress reduction techniques and the value of exercise. Additional education was targeted related to specific clinical conditions or knowledge deficits, including hypertension,obesity, diabetes, substance abuse, weight loss and diabetes, based on an evaluation of the individual mother's risk assessment and pregnancy quiz. Mothers were encouraged to identify one health goal and define strategies to achieve that goal. The nurse educator used motivational interviewing to discuss the benefits of the goal selected. As part of the evaluation for the educational project, mothers who participated were contacted two to six months after the intervention to assess if they had made changes in their health behaviors.

Results: Seventy mothers from diverse backgrounds, received education in the NICU during the project year. Twenty-five successful follow up phone calls were conducted. Nineteen women (76%) of those in the follow up group reported positive lifestyle changes. These changes included: fourteen women reported eating healthier, with six reporting weight loss, three reported increasing exercise, and two reported a decrease in smoking behavior. One reported quitting completely and one reported decreasing the number of cigarettes smoked daily. Six participants reported no change in health behavior. Overall, it appears that women are receptive to health education during the postpartum period. Some participants reported although they wanted to make lifestyle changes such as exercising, they were overwhelmed

caring for their infant and planned to try in the future. Many follow ups could not be completed due to the fact participants changed phone numbers or used cell phones that did not accept calls.
