Conclusion: The early postpartum period may be an ideal time for nurses to provide targeted education and reinforce the need to continue positive lifestyles changes to improve the health of the mother and ensure a healthy pregnancy in the future. Nurses that provide care for women of reproductive age should provide pre-conception care and health education at every visit. Behavior changes such as smoking cessation, healthy eating and exercise can positively impact future pregnancies and the health of the whole family. Adopting healthy eating patterns and getting regular exercise can improve mood, reduce stress, reduce the incidence of Type 2 Diabetes and improve cardiovascular health. Further longitudinal research to determine if changes in health behaviors made in the pregnancy and postpartum period are sustained and identification of strategies that empower women to improve their health are indicated.

I 12 - Perinatal Health Promotion

Knowledge, Attitudes, and Competency about Providing Perinatal Care to Women With Disabilities

Lorraine Byrnes, PhD, FNP-BC, PMHNP-BC, CNM, FAANP, USA

Abstract

Purpose: Women who are disabled (n=8 million) account for approximately 11% of the childbearing population in the U.S. today. Although there are no available population based studies that report incidence and prevalence of pregnancy and birth in this population, smaller studies find that many women who are disabled desire biological children and plan to become mothers. The majority of women with disabilities report a physical disability (51%) followed by mental disabilities (30%) and sensory disabilities (19%). The purpose of this study is to describe the knowledge, attitudes, and perceived competencies about providing perinatal care to women with disabilities by nurse practitioners and certified nurse midwives.

Methods: A 37 item online, anonymous survey developed for the purpose of this study was distributed via SurveyMonkey to the membership of a leading U.S. based Nurse Practitioner organization after IRB review and approval. Eligibility criteria included licensure as an advanced practice nurse/nurse-midwife and current clinical practice in this role. Of the 185 surveys returned, 150 were eligible for inclusion in the final analysis. This represented almost 7% of eligible participants to whom the recruitment email was sent. Surveys with incomplete data were excluded from the final analysis. SPSS version 22 was used to analyze the data. Descriptive statistics were used to analyze demographics and participants' education and practice histories. Chi-square tests were then conducted to investigate the association between knowledge, attitude, and perceived competency to provide perinatal care to women with disabilities.

Results: Although only 30% of respondents reported receiving didactic information, and 20% of respondents reported receiving clinical experience on providing care to women with disabilities during their academic coursework, a majority of respondents reported positive knowledge, attitude and competency in providing care to this population. There was a significant relationship between professional experience (years of practice and education) and knowledge, attitude, and perceived competency in providing care to women with disabilities. NPs/CNMs who were in practice over 10 years reported greater perceived competency providing care to pregnant women with intellectual ($\chi^2 = 5.18$, $n=150$, $p<.05$) or developmental disabilities ($\chi^2 = 4.14$, $n=150$, $p<.05$). In addition, NPs/CNMs who received either didactic ($\chi^2 = 8.81$, $n=150$, $p<.001$) or clinical ($\chi^2 = 5.81$, $n=150$, $p<.05$) education in this area were more likely to feel that they received sufficient education to attain competency in providing care to disabled women than those who reported receiving none of this content

Conclusion: Advanced practice nurses can help bridge the gaps in care and help ensure positive experiences with the healthcare system. Raising awareness about the unique needs of women with disabilities is one step toward ensuring a more positive experience within the healthcare system. Nurse practitioners reported providing perinatal care to women with physical, sensory, intellectual and developmental disabilities. However knowledge about providing care to women with disabilities came through clinical experience, by working with colleagues who share their own experience and knowledge and experiences learning from disabled patients. We recommend the development of formal didactic and clinical education to prepare NPs to care for this population of women.

I 13 - Service Learning in Undergraduate Nursing

A Diabetes Camp Impacts Nursing Students and Children: Evaluation of an Interprofessional Service Learning Course

Jennifer L. Saylor, PhD, MSN, BSN, RN, APRN-BC, USA
Christina Calmaro, PhD, RN, CRNP-BC, USA

Abstract

Purpose: The purpose of this study was to evaluate an interprofessional service learning, undergraduate nursing course that combines a didactic diabetes focus with a diabetes camp to promote learning beyond the classroom.

Background/Literature Review: Service learning is an established andragogy that aims to translate information presented in didactic courses to real-world situations. This unique teaching approach synergizes the classroom objectives and the application of abstract thinking, which is required in “real-life” situations. The aspect of abstract thinking involved in service learning includes social, ethical, and cultural aspects, which develops and fosters cultural diversity (Adegbola, 2013). Progression from instructive to experiential learning, reflection, and ultimately reciprocal learning, service learning bridges a gap between the classroom and practical application (Schmidt & Brown, 2016). When integrated into the nursing curriculum, service learning not only reinforces academic coursework, but also strengthens critical thinking, responsibility, accountability, and promotes students as change agents in their communities. An undergraduate nursing elective and service learning course (NURS411: “Topics in Healthcare Delivery: Teaching Wellness to Children) combines a didactic and clinical component in the form a diabetes camp.

Diabetes and You: Kamp for Kids (K4K) provides education, camaraderie, and support to children with T1D between 4-17 years old. There are typically 65-85 campers that attend each year, 50-60% of whom have T1D. The scheduled activities and games are based on one of the five topics: diabetes overview, physical activity, nutrition, stress, and “tying it all together”. Each topic is assigned to a different day of camp with different education modalities and learning to cultivate an understanding and knowledge about diabetes and healthy living of all campers.

Course Didactic Component: During the didactic portion of the course, students attend five instructional classes centered on the care and management of children with T1D and also develop the week-long day camp for children with T1D and their siblings and friends. One of the class days is an interprofessional education day sponsored by a local pediatric hospital focused on comprehensive approach to diabetes management. The students interact and learn from a pediatric nurse practitioner, registered dietitian, and a psychologist who all specialize in endocrinology.

Traditionally, nursing students are taught using nursing textbooks and journals. However, this course textbook is the same book that parents receive in the hospital when their child is first diagnosed with T1D and is titled, *Understanding diabetes: A handbook for people who are living with diabetes* (Chase & Maahs, 2016). The students not only learn concepts to assist with camp management, but also the translation of these concepts into clinical practice including glucose management, leadership skills, team building, and conflict resolution. Each class begins with a quiz, followed by small group discussions and interactive activities about teamwork, leadership, conflict resolution. The evaluation methods used in the classroom includes quizzes, direct observation, group discussions, and reflective journals.

Course Clinical Component: The last week of the course incorporates the didactic components into the diabetes camp focused on health and wellness of children with diabetes and their friends/siblings. Each group comprised of four to five randomly assigned students is charged with organizing and managing the diabetes camp for one day. Each morning a pre-conference briefing is held before the campers’ arrival. Safety is reiterated and the logistics of the day are reviewed. Throughout the day, students learn through experiencing family interactions between and among siblings and parents at drop off. Students interact directly with the nursing and psychology staff regarding diabetes management and psychological aspects

associated with children. Besides hands-on diabetes management, this course provides essential “life skills” including teamwork, conflict resolution, management, and interpersonal communication across the lifespan. The camp day concludes each day with a post-conference briefing to celebrate successes of the nursing students and campers. Students identify issues or concerns that occurred that day, which are then presented to the full class for resolution.

Methods: With University Institutional Review Board approval, a mixed method design was used to evaluate the 400 level nursing elective, “Topics in Healthcare Delivery: Teaching Wellness to Children.” As part of the students’ NURS411 course assignments, the students (n = 23) completed a Perceived Confidence Survey in diabetes management during class. The survey was completed 2 days before the week of diabetes camp and again the last day of camp. This adapted survey used a four-point Likert scale for the eight questions, which included the following areas: communication with campers and families, hypo- and hyperglycemic assessment and treatment, insulin pump therapy, and empathy. ((Johnson, 2007)) To avoid bias, faculty did not review the pre- or post-confidence surveys until after student grades were posted. Using the service learning approach, students completed a reflection analysis paper 48-72 hours after camp. As per faculty guidelines, the four to six paper consisted of six open-ended, adapted questions to focus on the course objectives.((Johnson, 2007)) With permission, students were allotted more pages if necessary. The pre- and post-perceived confidence surveys were analyzed using SPSS (version 23). Paired T-test analyzed each question of the pre- and post-perceived confidence survey using an alpha level of < 0.05. Content analysis of the final reflection paper was conducted by the professor and another author who are experienced in qualitative researchers.

Results: The overall mean and standards deviation for the pre and post confidence survey results were 3.2 (.47) and 3.80 (.19), respectively. The largest difference between the mean among the eight questions was related to the students’ confidence in insulin pump therapy with a pre-camp mean of 2.35 (.71) compared to a post-camp mean of 3.48 (.59). Content analysis revealed four major themes with some having subthemes: pre-camp assumptions and fears, growth in confidence, understanding diabetes management in the community, and appreciation for learning beyond the classroom and hospital setting.

Pre-camp assumptions and fears: The students assumed that they would recognize a campers’ high or low blood sugar and that they campers would have a lack of knowledge related to diabetes management because they are nursing students and have more education about diabetes than children. One student said, “ ...these kids know their bodies (which completely blew me away) and they knew when they were feeling low or high and they let their counselors know.” Another assumption was the expectation of chaos and the students’ planned daily schedules included times of all activities would not occur. One student said, “Although there was chaos in some rooms, it was filled with laughter, smiles, and balloons flying through the air.

Growth in Confidence: This course has a positive environment and students’ clinical confidence grows exponentially related to diabetes management, which is natural since the students repeated these skills many times throughout the week. However, managing multiple patients in the inpatient hospital setting and understanding that a nurse’s day is constantly changing requires excellent communication skills, delegation, and teamwork. One student said, “The preparation leading up to and the week of Kamp truly put us [students] in circumstances where leadership and delegation are necessary. Both of which are key components of nursing”. Students’ confidence in themselves evolved throughout the course in many different areas. Another said, “I feel that I personally grew from a nervous and unsure nursing student, to a confident and self-sufficient counselor who is able to help challenge and inspire campers.”

Understanding Diabetes Management in the Community: Using camp to immerse the students into community, fostered the students understanding of how children with and without diabetes interact and manage diabetes on a daily basis. This experience is quite different than a hospital setting. One student said, “Caring for this population wasn’t just about giving shots, and checking glucose levels – it also meant negotiating their social circles, navigating their logical and mental routes and relating to them person-to-person, not just nurse-to-patient.”

Appreciation for Learning beyond the Hospital Setting: Students were able to gain new perspectives on caring for children with T1D. The hospital setting provides nursing experiences in an acute phase. However, there is much more to chronic conditions such as T1D that may only be understood when immersed in a community like setting such as a diabetes camp. One student said, "I never knew how much time and effort they [children with T1D] spent on diet and understanding diabetes [I have] respect for patients, families, and children, who have diabetes." Learning occurs from a different perspective. One student said, "Kamp helped me learn and understand diabetes from the children and family perspective"

Conclusion: Using a service learning approach, the faculty and nursing staff at Diabetes and You: Kamp for Kids are able to foster critical thinking and personal reflection through hands on experience of overseeing a diabetes camp and a reflection assignment. This course also provides a heightened sense of community engagement and responsibility not only to the campers and their families, but also to the camp staff and the students enrolled in the course.

I 15 - Clinical Practice Strategies

Implementing Best Practices Using Appreciative Inquiry

Joyce J. Fitzpatrick, PhD, RN, FAAN, USA
Reynaldo R. Rivera, DNP, RN, NEA-BC, FAAN, USA
Bernadette Khan, MSN, RN, NEA-BC, USA
Wilhelmina M. Manzano, MA, RN, NEA-BC, USA

Abstract

Appreciative Inquiry (AI) is a model of organizational behavior that has recently been applied in a number of health care organizations to improve care. AI is focused on discovering the best that is, and designing a future that could be even better. AI includes 4 cycles: Discovery of the best of what is; Dream what might be; Design what could be; and Destiny: what will be. One important component of the AI experience is that it relies on the collective design of a desired future state that is compelling, thus lifting the conversation to avoid problems and complaints and focus on positive possibilities. We implemented AI by taking the best evidence from the literature related to key areas central to enhancing RN to RN interaction: the bedside shift report and RN floating. We asked clinical nurses providing direct care to describe the evidence and best practices related to each of these areas. The creativity that was generated for each of these challenging situations was impressive, and best practices have been described and implemented on the units. Responses related to “floating” included providing a “buddy system” for nurses who have floated, designing a concise unit orientation system for these nurses, and making sure there is a “check out” to ask the floating nurses “what worked” for you, so as to improve the experience of the next float nurse. Responses related to best practices in bedside shift report including making certain patients are aware of all that is being done to keep them safe, conducting an environmental scan to ensure patient safety, directly communicating to the patient the strengths of the oncoming nurse, thus assuring the patient and the nurse that there is trust in the system. As part of the AI model there is a “check out” after each implementation session. Nurses who have participated in the AI sessions have described the experience as “inspiring”, “empowering” “energizing” and “validating”. Other positive terms for the experience as well as the developmental process will be shared in this presentation. Future plans are to link this work to both nurse and patient satisfaction.

I 15 - Clinical Practice Strategies

Development of a Practice Change Model to Incorporate Tradition-Based Nursing Practices

Annette M. Bourgault, PhD, RN, CNL, USA

Michele J. Upvall, PhD, RN, CNE, USA

Abstract

Purpose: The purpose of this study was to explore factors influencing the use of tradition-based practices and create a model of de-implementation processes to facilitate adoption of evidence-based practice in the critical care setting. This presentation is aligned with the conference objective of discussing research strategies to promote evidence-based teaching and learning influencing interprofessional environments.

Evidence-based practice is an expected standard of clinical practice as the means for optimizing patient outcomes and minimizing cost. Nursing research has focused its attention on the implementation of evidence-based practices without considering de-implementation of existing entrenched, routine practice, also known as tradition-based practice. Tradition-based practices may be devoid of adequate empirical evidence (Prasad & Ioannidis, 2014) and some are described as low-value care (van Bodegom-Vos, Davidoff, & Marang-van de Mheen, 2016). Since tradition-based practices may be potentially harmful or ineffective, de-implementation is necessary to optimize patient outcomes and/or resources (Flynn Makic, Rauen, Watson, & Poteet, 2014). De-implementation or termination of these tradition-based practices is a relatively new approach to changing practice and is necessary to facilitate evidence-based practices in the clinical setting (Montini & Graham, 2015; Prasad & Ioannidis, 2014). Our novel study was the first that we are aware of to study de-implementation of tradition-based practices by critical care nurses.

The research question was: What are the factors and processes necessary for de-implementation of tradition-based practices by critical care nurses to facilitate implementation of evidence-based practices? Specific aims included 1) explore factors that influence the continued use of tradition-based practices by critical care nurses and barriers to stopping these practices, and 2) identify processes that facilitate de-implementation of tradition-based practices.

Methods: Qualitative, descriptive inquiry using semi-structured interviews were used to collect data. Critical care nurses from an acute care hospital in Central Florida were recruited for the study. University and hospital institutional review boards granted ethical approval. A series of demographic and interview questions were asked. Interview questions inquired about practice changes, including roles, facilitators and barriers, processes, and tradition-based practices. Questions evolved based on participant data and interviews ceased when data saturation was reached. Thematic content analysis was used to code and categorize interview data in two phases (Miles, Huberman & Saldaña, 2014). Two researchers reached consensus on coding and derived categories and themes. HyperResearch software was utilized to manage and code data.

Results: The sample consisted of 22 critical care nurses; 4 of the participants were in formal leadership roles and 18 were staff nurses. Nursing experience ranged from 1-39 years (M=10) and 17/22 (77%) of participants held a BSN or higher degree. The major theme that emerged during secondary data analysis was *uncertainty of the scientific underpinnings of clinical nursing practice*. Participants were unsure if their practices were based solely on tradition, evidence, or a combination of sources and most were unable to define and/or identify a tradition-based practice. Uncertainty then became the core concept in our new model for practice change. "Desire to know" was the primary mediator between uncertainty and de-implementation of tradition-based practices and implementation of evidence-based practices. Sources of information to satisfy desire to know and relieve uncertainty included professional organizations, nursing leadership at the unit level including the Unit Practice Council, and previous knowledge acquired from formal nursing education. Additional mediators to de-implementation of tradition-based practices were identified as secondary facilitators and barriers. These facilitators, such as use of a Gemba visual management board and identified barriers to practice change, influenced both de-implementation and implementation processes.

Conclusion: The inclusion of tradition-based practices in this new model for clinical practice changes may facilitate de-implementation of tradition-based practices and enhance the evidence-based practice process. More research is necessary to explore factors associated with uncertainty of the scientific underpinnings of clinical nursing practice. This model will need to be tested in the local critical care setting with consideration to the environment and cultural context. Nurse educators and leaders may play an active role to assist students and nurses to become aware of tradition-based practices and determine methods to de-implement these practices. Additionally, Gemba boards may be a useful tool to identify tradition-based practices and begin discussions about de-implementation. Further research on the effectiveness of Gemba boards in nursing is also warranted.

I 16 - Promoting Research in Nursing

Measuring What Matters: A Multi-Site Study of Self-Reported and Objectively Measured Nursing EBP Knowledge

Darrell Spurlock, PhD, RN, NEA-BC, ANEF, USA
Anglea McNelis, PhD, RN, FAAN, ANEF, CNE, USA
Amy Hagedorn Wonder, PhD, RN, USA
Pam Ironside, PhD, MS, BA, RN, ANEF, FAAN, USA

Abstract

Purpose: Research findings from fields as diverse as psychology and medicine (Blanch-Hartigan, 2011; Zell & Krizan, 2014) suggest that when tasked with evaluating one's own knowledge and abilities, people often over- or under-estimate themselves when their self-ratings are compared to more objective measures. The purpose of this study was to evaluate nurses' self-reported EBP knowledge, attitudes, and skills compared to EBP knowledge measured using a previously developed standards-based, objective test of EBP knowledge. Findings from the current study are compared with past research to provide a wider perspective on the state of nurses' EBP knowledge levels and approaches to measuring EBP knowledge, skills, and abilities.

Methods: Practicing nurses from two Magnet®-designated hospitals in the Midwest United States were recruited to the study. In proctored data collection sessions, subjects completed a 17-item demographic and professional characteristics questionnaire, the self-report Evidence-based Practice Questionnaire (EBPQ; Upton & Upton, 2006), and the Evidence-based Practice Knowledge Assessment in Nursing (EKAN; Spurlock & Wonder, 2015), a 20-item multiple-choice EBP knowledge test developed based on two widely-adopted US EBP competency frameworks. Data from $N=151$ subjects indicated subjects were 95.1% White/Caucasian, 92% female, and had an average age of 40.9 years (Range 23-66 years). Nearly all (99.4%) of subjects reported English as their primary language and 57.7% reported having a bachelor's degree in nursing as their highest degree.

Results: Subjects provided positive ratings overall on the three subscales of the EBPQ. Considering a maximum score of 7, subjects provided the highest average ratings on the EBP attitudes subscale ($M=5.51$, $SD=.98$), followed by EBP knowledge ($M=4.68$, $SD=.81$), and then on practice/use of EBP ($M=4.48$, $SD=1.37$). The mean sum score on the EKAN was 10.58 ($SD=2.87$) out of a possible 20 points. One-way ANOVA (with familywise error correction for alpha) showed no statistically significant difference on any subscale of the EBPQ across nurses' educational levels (e.g., associate's, bachelor's, and master's degree levels). When EKAN scores were compared based on subjects' highest level of education, a statistically significant difference in EKAN scores was observed (9.0 for associate's degrees versus 12.7 for master's degrees; $F_{3,159}=11.84$, $p<0.001$). While scores from each of the subscales of the EBPQ were statistically significantly correlated with each other ($r=.350-.595$, $p<.01$), correlations between EBPQ subscales and the EKAN sum score were small ($r=.017-.123$) and statistically nonsignificant. To further evaluate effect size, a two-step hierarchical regression analysis showed that educational level, but not EBPQ subscale scores, predicted EKAN sum scores ($F_{(1,149)}=30.43$, $p<.001$, $R^2=.170$).

Conclusion: In this study, nurses' EBP attitudes and self-reported knowledge and skills showed a near zero correlation with more objectively measured EBP knowledge. Higher levels of education were associated with higher scores on the EKAN knowledge measure but not with EBP attitudes, practices, or self-reported knowledge. These findings are consistent with those from a broad range of fields showing that accurate self-assessment is often difficult, as illustrated by the low concordance between self-assessed and objectively measured knowledge. Nurses' EBP knowledge levels in the current study are similar to those reported elsewhere (e.g., Spurlock & Wonder, 2015). Implications for leaders and educators in academic and clinical environments include re-evaluating strategies for assessing learning outcomes with a focus on using more direct, objective approaches when possible.

I 16 - Promoting Research in Nursing

Adult Attachment Style and Family Presence Preference During Invasive Nursing Procedures

Nurten Kaya, PhD, RN, Turkey

Abstract

Purpose: This study was carried out in the descriptive and correlational type to examine the effect of adult attachment styles regarding the fact that the patients prefer their family members/relatives/the people they care to stand by them during invasive nursing procedures.

Methods: The study population consisted of patients hospitalized in the observation unit of the internal medicine section in the emergency department of a university hospital. The sample consisted of 76 patients who were selected by random sampling method.

Results: It was found that 56.6% (n=43) of the patients were female, the age average was 47.83 (SD=18.88), 65.8% (n=50) of them were married, 28.9% (n=22) of them had university or higher education, 36.8% (n=28) of them were civil servants, 93.4% (n=71) of them had social security and the remaining 6.6% (n=5) of them had green cards, 65.8% (n=50) of them had children, and 56.6% (n=43) of them were living with their families. 57.9% (n=44) of the patients said that they preferred their relatives to stand by them during invasive nursing procedures. 51.3% (n=39) of the individuals gave yes answer to the question of "Is there someone you would like him/her to stand by you especially during the intervention?". When they were asked to identify the person they want to stand by them, mother/father, child, spouse, sibling, relatives and friends were preferred. 76.3% (n=58) of the patients gave the answer of "me" to the question of who should make the decision of status of the presence of a relative during invasive nursing procedures. When the point averages of adult attachment styles of the patients, who were included within the scope of the research, were examined, it was seen to be (potential point distribution is between 1-5 in all styles) 3.57 in indifferent, 3.02 (SD=0.63), (SD=0.57) in frightening, 2.87 (SD=0.50) in obsessive, 2.79 (SD=0.66) in confident.

Conclusion: In addition, it was determined that the patients' adult attachment styles did not affect the status of demanding someone beside them during invasive nursing procedures ($p>0.05$).

J 13 - End-of-Life Care

The Closing Composition: End-of-Life Communication Strategies

Mary J. Isaacson, PhD, RN, CHPN, USA

Mary E. Minton, PhD, RN, CNS, CHPN, USA

Abstract

Background: Globally, palliative care at end-of-life (EOL) is indicated for over 19 million adults (Connor & Bermedo, 2014). Palliative and EOL care encompasses physical, psychosocial, and spiritual changes which necessitate ongoing intervention and evaluation (Coyle, 2015). Both the World Health Organization (WHO, 2016) and the International Association for Hospice and Palliative Care (IAHPC, 2016) identify the palliative care team's interprofessional composition, of which nurses are an integral component. At the center of the interprofessional, palliative care team is the patient; who desires shared decision-making (Alston et al., 2012). Patients and families are best served when health care communication envelopes the elements of clinician expertise, patient and family goals and concerns, and medical evidence (IOM, 2015). Nurses have a unique and intimate role in the decision-making process by virtue of the amount of time they spend with the patient on a daily basis (Ferrell, Malloy, Mazanec, & Virani, 2016). A systematic review of the literature identified registered nurses in the roles of information broker, supporter, and advocate with patients and families engaged in EOL decision-making (Adams, Bailey, Anderson, & Docherty, 2011). These rich and meaningful roles hold communication as a central component—one which is best characterized by honesty and transparency (IOM, 2015) as well as an engagement that renders explicit the nature of bearing witness to personal suffering (Ferrell & Coyle, 2010). Dahlin and Wittenberg (2015) describe critical communication competencies of the registered nurse which echo the roles of information broker, supporter, and advocate reported by Adams and associates (2011). The imperative for nurse presence, practice expertise, and communication excellence is well established within the palliative and EOL nursing literature (Dahlin & Wittenberg, 2015; Wittenberg-Lyles, Goldsmith, Ferrell, & Ragan, 2013). However, absent in the literature are the strategies used by registered nurses when communicating with patients and families about EOL decision-making (Adams et al., 2011).

Purpose: The purpose of this presentation is to share findings from a qualitative study with hospice/palliative care nurses regarding palliative and EOL communication strategies with patients and families. Our specific aim was to determine the key communication strategies employed by hospice/palliative nurses when engaging patients and families in advanced EOL decision-making.

Methods: Using a phenomenological approach, this study describes hospice/palliative nurses' experiences when engaging patients and families in EOL decision-making. A sample of 10 female hospice/palliative care nurses between the ages of 30-60 years of age participated in face-to-face interviews with both PI's. Interviews lasted approximately 45-60 minutes. Interviews began with three lead-in questions, were audio recorded, and were transcribed verbatim by a qualified transcriptionist. Analysis of the transcripts began with the PI's dwelling with the data followed by a shared process of iterative discovery of the overarching pattern and key themes. To illuminate the pattern and subsequent themes, the researchers employed the use of metaphors. Metaphor in qualitative research assists in the critical reexamination of a common experience through a different lens; expanding understanding and awareness (Carpenter, 2008).

Results: The exemplars shared by these nurses were abundant with context and content. The EOL experience is not rehearsed; throughout the transcripts it was clear how, together, the patient, family, and the nurse must co-create the closing composition—which became the overarching pattern of the communication strategies described by these nurses. Essential to successful implementation of the closing composition is the understanding that these strategies are ever evolving and non-linear. The themes comprising the closing composition are: *establishing context*, *acknowledgement through attentive listening*, *trust*, *wishes/goals of care*, and *honesty*. Hope was interwoven throughout the closing composition and included knowing and accepting the patient and family's journey, building trust through honesty, and identifying how they (patients and families) wish to write the final refrain.

Discussion: New nursing graduates in the United States (US) are expected to provide competent EOL care (American Association of Colleges of Nursing, 2016). They are also entering a healthcare environment caring for more patients with comorbidities, advancing age, and frailty. In the US and internationally (Connor & Bermedo, 2014), the educational environment should be the point of introduction for professional, therapeutic communication. This introduction must incorporate targeted content about palliative and EOL care communication and in on-going learning. Incorporating palliative and EOL case studies or simulation into pre-licensure student learning experiences has demonstrated student reports of enhanced confidence (Gillan, Parmenter, vander Riet, & Jeong, 2013) and the importance of presence when caring for patients and families at EOL (Fabro, Schaffer, & Scharton, 2014). However, the interview participants were quick to note that nothing in their pre-licensure education prepared them for the depth of skill required when communicating with patients and families at EOL. Interview participants acknowledged the positive influence of skilled health care professionals, i.e., physicians, nurses, chaplains, who role modeled several of the communication strategies described. Practicing nurses must be skilled in facilitating advance care planning conversations near EOL that reflect patient and family wishes and goals of care.

Conclusion: Based on descriptions offered by these registered nurses, we conclude that the EOL decision-making communication strategies could be considered universal, crossing cultures and settings. Additionally, conversations in which these communication strategies are used will provide a foundation for advance care planning which has the potential to impact both patient outcomes (Garrido, Balboni, Maciejewski, Bao, & Prigerson, 2015) and fiscal stewardship of healthcare resources (Bischoff, Sudore, Miao, Boscardin, & Smith, 2013).

J 13 - End-of-Life Care

Symptom Burden of Critically Ill Patients at High Risk of Dying: Reliability of Proxy Reports

Peggy Kalowes, PhD, MSN, RN, CNS, FAHA, USA

Abstract

Purpose: Examine the perceived symptom burden (prevalence, frequency, intensity), and overall distress, as reported by (ICU) patients at high-risk of dying and to determine the level of agreement (congruence) of patient-rated symptoms with those rated by designated proxy-responders.

Background: Good symptom control is an essential factor of care at end-of-life (EOL).¹ Patients with life-limiting illness or those actively dying, often experience substantial pain and/or discomfort, whether from their admitting diagnosis, procedures done in the intensive care unit (ICU)², or related with a multiplicity of medical conditions¹. Patient self-report is *gold standard*, however, ICU patients over time, may be unable to self-report, due to declining physical or cognitive function.³ Thus, validating the congruence of proxy perceived assessments related to patient symptom burden is important, as often treatment decisions may be made by family/other proxy decision makers.⁴⁻⁶

Methods: Prospective, correlational design was used to study the reported symptom burden of ICU patients' compared to proxy perception of patient symptoms.

Study was conducted in a 55-bed ICU, 559-bed, academic medical center in western United States. A convenience sample of 80 patients at high-risk of dying and 53 proxy responders were enrolled, based on following criteria: 1) >18 years older; 2) speak, read/understand English/Spanish; 3) able to complete self-report instrument written or alternative method (e.g. if questionnaire read to patient by researcher; 4) normal mental status, assessed by the Richmond Agitation-Sedation Scale (RASS)⁷ and the Confusion Assessment Method for the ICU (CAM-ICU)⁸ and; 5) probability factor of 60-80% risk for hospital death. Exclusion: 1) diagnosis of cancer and receiving treatments; 2) principal diagnosis of dementia with altered cognitive status; or 3) altered level of consciousness.

Proxies were defined as individuals who provided the majority of emotional, financial, and physical support to the patient prior to ICU admission. No legal relation or cohabitation with the patient was required. Eligibility were: 1) non-professional, non-paid caregiver; 2) age \geq 18 years; 3) reliable telephone access; and 4) able to read and speak English/Spanish.

Patient variables were recorded on a demographic Log- age, sex, ethnicity of patient; insurance, diagnosis, admission location, specific treatments (mechanical ventilation; medications, particularly analgesics and sedatives, and comorbidities. The APACHE III Acute Physiologic Score (APS)⁹ and Predicted Mortality (r) for hospital death, was from the APACHE III data system.

Study instruments included: RASS, used to assess the level of agitation-sedation in patients prior to obtaining consent and conducting symptom measurement. Scores on the 10-point observational scale ranged from -5 (unarousable) to +4 (combative). Patients were judged able to provide informed consent and symptom measurement data if RASS score was 0 (alert and calm); *Confusion Assessment Measure for the ICU (CAM-ICU)* used to assess delirium prior to symptom measurement. CAM-ICU assesses four features of cognitive domain including: acute onset or fluctuating mental status, inattention, disorganized thinking, altered level of consciousness. Scores on four domains determined if delirium was present (CAM-ICU positive) or absent (CAM-ICU negative).

To assess patient symptom burden, the *Modified Condensed Memorial Symptom Assessment Scale (CMSAS)*¹⁰ was used, which is a shortened version of Memorial Symptom Assessment Sale (MSAS), a valid cancer tool to assesses multiple dimensions (severity, frequency, and distress) of 32 physical and emotional symptoms. The condensed version of CMSAS rates eleven physical symptoms in terms of distress from 0 (none) to 4 (very much), and three emotional symptoms in terms of frequency from 0 (not

present) to 4 (almost constant). Proxies also completed the CMSAS- Proxy Respondent Symptom Survey, which was modified to state "Which of these symptoms bothered your loved ones in the last seven days" and "Which of these symptoms bothered your loved ones in the past two days". Data points were day-1 and day-3 of the patients ICU stay. Proxies were asked to state their relationship to patient; age; ethnicity; and if they were primary care providers for patient. All study instruments (patient/proxy), were available in Spanish/English.

Procedures: Human subject approval was obtained from institution's Institutional Review Board (IRB). Patients were screened daily using Acute Physiology, Age, Chronic Health Evaluation (APACHE III) score, and mortality risk (r) >.60% in first 24-hours for eligibility. APACHE III Scores and CMSAS data was recorded on Day-1-Day-3 of patient's ICU stay. Patient informed consent was obtained if RASS score was 0 (alert and calm). If patient unable to give informed consent, proxy consent was obtained (n=44, 55%).

Statistical Analysis -Data was analyzed using IBM-SPSS v. 20.0 (SPSS, Inc.; Chicago, IL, USA). Descriptive statistics were used to analyze demographic and study variables. Chi-square test and Mann-Whitney U tests compared prevalence and severity scores of the four most prevalent symptoms in patients. Spearman's rank correlation was used to explore the relationships between four most prevalent physical symptoms in patients and proxy responses. Crosstabs with the Pearson Chi-Square and Cohen's Kappa statistics were computed to assess the concordance between patients and family members on ratings of CMSAS symptom presence. Statistical significance was set at $\alpha = 0.05$, two-tailed.

Results: The Condensed Memorial Symptom Assessment Scale (CMSAS) was used to gain patient/proxy report of symptoms on day-1 and day-3 after admission. N=80 patients who were able to respond to symptom assessments on day-1 while only 66 (80%) completed study survey on day-3. Reasons for attrition: patient expired (10%), patient discharged (5%), or patient lacked capacity (5%), with deterioration of critical illness. Overall, there was no significant difference in age, gender, ethnicity, and ICU admission source among those who did or did not complete day-3 symptom assessments.

Study Characteristics: Patient's mean age was $70.5 \pm$; and primarily male (62.5%). Racial/ethnic composition was diverse with 48.8% White, 22.5% Black, 15% Hispanic, 11.3% Asian and 2.5% other. Participants were predominately English speaking (81.3%), yet 12.5% of the participants completed the symptom survey(s) in Spanish. Among the cohort, the first-ICU-day mean (%) predicted hospital mortality rate was 69%, and mean first-ICU-day APACHE III score was 170 ± 23 . The mean ICU length of stay (LOS) was 10, with a range of 1-49 days and mean hospital LOS was 15, (range = 1.5-73) days. Following discharge from the ICU approximately 16% of the patients had to be readmitted to the ICU from the discharge unit for further treatment. The observed ICU and hospital mortality rates were 19% and 2% respectively. 30% of the patients who died in the ICU, resulted from the decision to withhold or withdraw life-sustaining treatments while in the ICU. Of the 63 patients who survived to hospital discharge, 16 (25%) died within three months following discharge.

Proxy Reporters - Mean age was 59 years (25-92) and (69.8%) were female. Racial/ethnicity was: White (43.4%), Black (17%), Hispanic (20.8%), Asian (15.1%) and other (3.8%). Relationship of proxies to patient included: spouse (43.4%), patient's child (41.5%), patient's sibling (5.7%), patient's parent (3.8%) and significant partner (5.7%). Three quarters (75%) were English speaking, 9.4% Spanish speaking and 13.2% other languages. Approximately 70% identified themselves as the primary caregivers.

Symptom Burden -Majority of patients were symptomatic (98%), reporting an average of 10.23 symptoms. Most common symptoms reported on Day-1, were lack of energy (fatigue) and difficulty concentrating, with a mean symptom distress score of 2.96 (SD = 0.70) and 2.79 (SD = 0.84), scored on a scale of 1 = low symptom distress to 4 = high symptom distress, respectively. The CMSAS Total Distress Score was 2.24 (SD=0.66). The Physiological Symptom Distress Subscale (CMSAS-PHYS) score was 2.19 (SD=0.71). Approximately 97.9% of patients reported psychological symptoms (sadness, worry, nervousness) with a mean symptom distress score of 2.45 (SD=0.66), measured by the Psychological Symptom Distress Subscale (CMSAS-PSYCH). On Day-3, 65 of the patients were still in the ICU. The most prevalent symptom reported was difficulty sleeping (90.8%), with a medium intensity distress score

of 3.79 (SD=1.06). Eighty percent of patients reported additional symptoms: lack of energy, lack of appetite, pain, dry mouth, feeling drowsy, shortness of breath, and difficulty concentrating, with a moderate intensity mean score of 3.42.

Overall distress increased among all symptoms, as measured by the CMSAS-Total Distress Score of 3.17 (SD=0.44), and the two distress subscales: CMSAS-PHYS mean score of 3.07 (SD=0.46) and CMSAS-PSYCH means score of 3.46 (SD=0.52). Hospital mortality was 17 (21%) during initial hospitalization and 16 (25%) at 3-months follow-up. Family members correctly estimated the presence and absence of symptoms 85.5% of the time, yet rated the patients' physiologic symptoms higher than psychological distress.

Conclusions: This study identified that ICU patients *near death*, experience a significant burden of multiple symptoms, yet receive limited treatment for overwhelming symptom distress. A need for widespread symptom management strategies with proven effectiveness is indicated. Data also confirmed that proxy reporter's perception of patient symptom burden can be a reliable alternative, and should be used when patients can no longer self-report. Further research is needed to test new evidence-based interventions to serve as practice standards in the delivery of consistent, high quality care for all dying patients to minimize unnecessary suffering.

Shall We Let Them Die? Factors Influencing the Withdrawal of Life-Sustaining Treatment in ICU

Fiona D. Foxall, MA, BSc, DPSN, PGCE (FAHE), RN, Australia

Abstract

Purpose: Recently across the developed world, there has been an increase in the occurrence of withdrawal of life-sustaining treatment (WLST) in ICUs (Burns, Sellers, Meyer, Lewis-Newby & Truog, 2014). There is a great deal of literature relating to WLST but to date, there is no data relating to the ethical perspectives of nurses and physicians when making decisions about WLST in ICU and the impact these decisions have on them. Where a patient possesses the mental capacity to make a decision, the preferences of the patient should prevail (Beauchamp & Childress, 2012). However, 95% of patients in ICUs are unable to participate in decision-making regarding life-sustaining treatments (Wright, Strong & Welters, 2011). In these circumstances a collaborative decision involving the patient's significant others and the ICU team should prevail (Monteiro, 2014). Nurses have an active role in the implementation of such decisions and therefore it is argued that they should be involved in the decision-making process (McLeod, 2014).

Therefore the purpose of this study was to determine the factors that influence decision-making when considering withdrawal of life-sustaining treatment (WLST) in ICU; and the level of collaboration between nurses and physicians when making such decisions. To explore the process of WLST and how it affects nurses and physicians in view of their personal ethical perspectives.

Methods: Using narrative inquiry, a purposive sample of six senior nurses and five intensivists, who have experience of caring for patients from whom life-sustaining treatment has been withdrawn in ICU, was recruited from a major tertiary hospital in metropolitan Western Australia.

Narrative inquiry is based firmly in the premise that, as human beings, we come to understand and give meaning to our lives through story (Creswell, 2013). Thus, narrative inquiry is the study of the activities involved in generating and analyzing stories of life experiences and reporting the results (De Fina & Georgakopoulou, 2012). Therefore, during narrative interviews, participants were asked to recount personal stories relevant to the issue of interest, while relevant probing questions were used when appropriate. Participants were asked to choose stories that highlighted what they considered to be exemplars of good practice, or situations that left them with a level of discomfort, or culminated in ethical tension.

Following the interviews, transcriptions were 're-storied', which is an important process in narrative inquiry, involving reorganising and rewriting the story to place it within a chronological sequence (Creswell, 2013). Restorying commenced as each interview transcription was completed and the rewritten story was submitted to the participant for member checking to ensure the narrative produced, captured the essence of the discussion. The stories are treated as data and analysis allows themes to emerge that hold within and across stories. Analysis commenced after the first interview and was a continuous process, with content from each interview being used to inform and enhance the following interviews. To triangulate the data, the themes emerging from the narrative interviews were further explored and validated during a focus group discussion.

Results: Eight major themes emerged from the narratives:

1). The Drivers.

This theme refers to the factors that drive the decision to withdraw life-sustaining treatment to be considered and/or made.

2. The Pushmi-pullu Effect.

This theme relates to how nursing and medical staff feel pushed into various actions and as a result may feel emotionally pulled in different directions.

3. The Beast of Burden.

This theme refers to the burden of the decision resting solely on the shoulders of the intensivist.

4. War and Peace.

This theme relates to professional discord and conflict arising as a result of differing perspectives, whilst the team remained cohesive and respectful of each other.

5. The Emotions.

This theme highlights moral distress and differing emotions arising as a result of a delayed decision and the prolongation of the dying process.

6. A Tree with many Branches.

This theme describes the visualisation of a flexible model of decision-making.

7. Letting Die.

This theme refers to the differing processes of withdrawing life-sustaining treatment.

8. Benefit and Harm. This theme relates to the differing ethical perspectives of nurses and physicians related to WLST.

Conclusion: The study has determined that the ethical perspectives of nurses and physicians differ in relation to WLST in one ICU. It has provided a platform for further work to develop a model of decision-making relating to WLST in ICU, which could be transferable to other ICU environments locally, nationally or internationally. A link between a lack of collaboration in the decision-making process relating to WLST, moral distress and professional conflict has been determined. Public education is required to ensure families discuss their values with regard to end-of-life decision-making to reduce suffering in the dying patient, as it is considered that a family's refusal to allow WLST can result in the prolongation of the dying process.

L 02 - Health Behaviors of At-Risk Adolescents and Young Adults Orthorexia Nervosa and Its Relationship to Obsessive Compulsive Behaviors Among University Students in Southern California

Christine B. Costa, DNP, RN, NP, PMHNP-BC, USA
Kholoud Hardan-Khalil, PhD, RN, USA

Abstract

Background: Eating disorders, impact quality of life and can result in distress. Orthorexia Nervosa (ON), is a disordered eating pattern, that focuses on an obsession with healthy eating according to dietary theory. Orthorexia Nervosa is not currently considered a diagnostic category in the 5th edition of the Diagnostic and Statistical Manual of Mental Illness (DSM-5) which outlines diagnostic criteria required for eating disorder diagnosis. However, current research suggests the orthorexia pathology is multifaceted and associated with obsessive compulsive behaviors. These behaviors may interfere with a desire to engage in healthy behaviors for individuals with this disordered eating pattern. The relationship between Orthorexia Nervosa characteristics and obsessive compulsive behaviors are not clearly defined.

Purpose: This study explores the prevalence of orthorexia nervosa and the relationship between obsessive-compulsive behaviors and orthorexia nervosa (ON) behaviors among female and male university students, a nonclinical population.

Methods: A cross-sectional, questionnaire survey study design using a convenience sampling method was used to examine self-report eating behaviors in a sample of 281 students from a large university in the United States, average age from 18 to 43 years. Participants completed a demographic survey, the Orthorexia Nervosa Inventory (ORTO-15), and an Obsessive Compulsive Inventory (OCI-R). The ORTO-15 questionnaire is self-report instrument previously validated in European populations for measuring ON tendencies, comprised of 15-item items with a 4-point Likert scale. The ORTO-15 risk scales scores (EDRS) were used to identify assesses beliefs about attitudes covering food selection, the extent to which food concerns influence daily life, the perceived effects of eating healthy food and habits of food consumption. Lower overall scores on this instrument refer to more ON components (increased ON tendency). Researchers who developed the tool found sensitivity, specificity, and predictive validity values for the ORTO-15 using an original cut-off < 40 in an Italian adult sample. The Obsessive Compulsive Inventory –Revised (OCI-R), composed of 18 items in 6 subscales on a five-point scale was used to measure obsessive compulsive patterns among six domains including checking, hoarding, neutralizing, obsessing, ordering, and washing. **Analysis:** descriptive and correlational analysis using independent t-test and ANOVA. Multiple linear regressions using stepwise entry was used to examine the prevalence of obsessive compulsive behavior patterns among those with orthorexia nervosa characteristics.

Results: The data analysis showed one third of the participants scored below the cut off score of 40 which identifies the presence of orthorexia nervosa behaviors on the ORTO-15. There was a statistically significant difference between male and female on ORTO-15 total score, but not on OCI-R scale. A significant correlation was found between the ORTO-15 total score and OCI-R total score. Orthorexia nervosa predicts only 10% of obsessive-compulsive disorder behaviors in the sample. Significant negative correlations were found between ORTO-15 total score and five out of six OCI-R subscales, the Pearson's correlations for checking, hoarding, neutralizing, obsessive behaviors, and ordering were -.271, -.291, -.276, -.300, and -.287 respectively. There was no significant correlation with the washing OCI-R subscale in this population. Stepwise regression results show that the Orthorexia Nervosa composites significantly predicted five of the obsessive compulsive patterns.

Conclusion: Participants with less orthorexia nervosa related symptoms have fewer tendencies to show obsessive behavior disorder behaviors related to checking, hoarding, neutralizing, obsessive behaviors, and ordering. More women were found to have orthorexia behaviors and there was no gender difference with those who also reported obsessive compulsive behaviors. Further tool psychometric studies on ORTO-15 scale are needed to evaluate its validity, reliability, and scoring criteria in different populations.

Implications: Participants with less orthorexia nervosa related symptoms have fewer tendencies to show obsessive behavior disorder behaviors. The high level of Orthorexia Nervosa score in this study might be attributed to that the original cut off points were developed based on Italian society. Further tool psychometric studies on ORTO-15 scale are needed to evaluate its validity, reliability, and scoring criteria in different populations. There is a need to build appropriate cut off points of orthorexia scale for individuals in the United States to differentiate between healthy eating and pathologically healthy eating. Health care providers should aware the occurrence of orthorexia nervosa among individuals presenting with disordered eating patterns and the influence of obsessive compulsive behaviors on orthorexia disordered eating behaviors.

L 02 - Health Behaviors of At-Risk Adolescents and Young Adults

Role of Race and Ethnicity on Trajectories of Health Risk Behaviors From Adolescence Into Adulthood

Robin Bartlett, PhD, RN, USA

Thomas P. McCoy, PhD, PStat, USA

Eunhee Park, PhD, RN, APHN-BC, USA

Jennifer Toller Erausquin, PhD, MPH, CHES, USA

Abstract

Purpose: Research on the development of risk behaviors including smoking, marijuana use, tobacco use, alcohol use, and sexual intercourse has been limited in several ways. Studies often stratify by race or gender and may adopt a single developmental pathway for each category of interest. There is a lack of understanding about the relationship between race / ethnicity and the chance of following a particular developmental trajectory and this information could aid in the tailoring of interventions to improve health outcomes for specific groups. The purpose of this study was to explore whether there are exclusive subgroups discernable within the trajectories of selected health risk behaviors (sexual behaviors, smoking, alcohol use, and marijuana use) by examining deviations from each trajectory. Then, we examined whether race / ethnicity is a predictor of subgroup membership for each risk behavior.

Methods: We examined selected health risk behaviors in a sample of participants from Waves I-IV of the National Longitudinal Study of Adolescent to Adult Health (Add Health) using an accelerated longitudinal design approach. Including those 12-31 years of age, 9,421 participants interviewed at all four waves of data collection were included in the study. We estimated trajectories over time by performing growth mixture modeling for the outcomes sexual intercourse, smoking, marijuana use, tobacco use, and alcohol use. To assess the association between race / ethnicity and trajectory membership we used multinomial logistic regression. Our research questions included 1. Do trajectories of development of risky health behaviors from age 12 to 21 vary by race or ethnicity? 2. Are there multiple classes of trajectories or is one trajectory sufficient? Life Course Theory guided this study. According to this theory, trajectories of health behavior change across the various life stages, and these trajectories may change depending on cultural context and social factors. The study was institutional review board approved.

Results: We identified two trajectories for heavy episodic drinking and three for sexual intercourse, smokeless tobacco use, and number of days drunk. Four trajectories were identified for cigarette smoking and five resulted for marijuana use. When we controlled for gender and compared with Whites, African American and Hispanic adolescents / young adults were less likely to be late starters for the use of tobacco, and for both heavy episodic and excessive drinking. Again, compared to Whites, Hispanic adolescents / young adults were less likely to be late initiators for marijuana use. Finally, compared to Whites, African Americans were less likely to engage in sexual intercourse as teens or young adults.

Conclusion: There are different developmental pathways for health risk behaviors among adolescents and young adults in the United States. As might be expected, some behaviors begin with experimentation in early adolescence whereas other behaviors have their beginnings in later adolescence or even young adulthood. Race / ethnicity is related to trajectory. In most cases, non-Whites were more likely to be members of trajectories involving later or no instigation of risk behaviors. These trajectories could provide important information about when to best intervene for particular subpopulations. Targeting nursing interventions has the potential to improve outcomes for these groups.

L 02 - Health Behaviors of At-Risk Adolescents and Young Adults

Mindfulness Intervention in At-Risk Adolescents: Participant Voices

Kristen E. Rawlett, PhD, MSN, BS, FNP-BC, USA

Abstract

Purpose: At-risk behaviors are related to poor outcomes among adolescents. Adolescence as a vital time for stress reduction to reduce risk and improve mental health. The purpose of this abstract is to describe qualitative interviews of participants regarding their experiences with mindfulness(MC) as compared to attention only(AC) interventions using the participant's voice. Clinical decision making strategies will be presented.

Methods: Twenty-three students participated. Open-ended questions were asked before and after completion of 6 week interventions. Interview questions included:What two words or phrases best describe you?What distracts you?How do you manage your stress? Responses were independently coded.

Results: MC students were happy, mad and angry. Post-test they were positive being happy, excited, and relaxed. The AC group had mixed emotions, negative emotions such as mad, irked and annoyed remained unchanged. Both indicated auditory interruptions affecting concentration. Distractions were unchanged:people laughing, noises and talking. The MC group used techniques taught in the mindfulness intervention. In post-test, the MC group dealt with stress by listening (to music), body scans, breathing and meditating. The AC group did not demonstrate a change. They managed stress by 'screaming, yelling, hitting and taking it out on 'stuff'. In program evaluation, MC participants referred to specific techniques breathing, paying attention, using silence and listening to music to achieve calm. AC participants focused on the impact. The AC intervention included talking, being able to express true self and getting stress out. A useful aspect of the interventions was learning how to control stress and the support they received from the instructors. Students mentioned wanting to get outside, not having enough space. Students had an acute awareness of others in the group.

Conclusion: Clinically significant is that girls in the MC were able to learn, use and identify specific strategies such as breathing, listening and meditating to reduce stress. Common barriers to stress reduction were auditory distractions and lack of space. Providers can implement knowledge into clinical decision making by providing an opportunity in the inpatient and primary care setting for adolescents to have quiet time and listen to music.

L 03 - Faculty Retention

Leadership Practices, Job Satisfaction, and Faculty Stress Among Dutch Postdoctoral Nurses: A National Survey

Anne Mien Regelink, MSc, RN, Netherlands

Wedela de Lange, MSc, RN, Netherlands

Irina Poslawsky, PhD, RN, Netherlands

Harmieke van Os-Medendorp, PhD, RN, Netherlands

Thóra Hafsteinsdóttir, PhD, MSc, BSc, RN, Netherlands

Abstract

Purpose: Post-doctoral nurses have an important role in evidence based nursing. Leadership is described as “the skill of motivating, guiding, and empowering a team towards a socially responsible vision, whereby leadership is a process, entails influence, occurs within a group setting or context, and involves achieving goals that reflect common vision”(1,2) Leadership practices are defined as both leadership skills and knowledge. Transformational leadership is described by Kouzes and Posner, following five leadership practices: “Modelling the Way, Inspiring a Shared Vision, Challenging the Process, Enabling Others to Act, and Encouraging the Heart”(1). Leadership practices (1) are needed to deal with the complexity of faculty roles, faculty stress, and lack of job satisfaction. Insight into leadership practices of Dutch post-doctoral nurses and the relationship with their job satisfaction and faculty stress is needed to improve the position of nursing research. The psychometric properties of instruments to measure the above mentioned aspects are yet unknown. The main purpose of this study was to identify leadership practices, job satisfaction and faculty stress of Dutch post-doctoral nurses and to investigate the relationship between leadership practices, job satisfaction, and faculty stress. Another, preliminary, purpose was to investigate the psychometric properties of the Dutch Leadership Practices Inventory (LPI) (3-5), Job Satisfaction Scale (MMSS) (6), and Faculty Stress Index (FSI) (7,8), in terms of translational validity.

Methods: A quantitative, cross-sectional survey was conducted to investigate leadership practices of postdoctoral nurses and the association between leadership practices, job satisfaction, and faculty stress, as well as the psychometric properties of the LPI, the MMSS, and FSI in terms of translational validity.

Results: Participants showed considerably strong leadership practices, especially on the domain 'Motivating others to act'. All the subscales of the MMSS showed moderate satisfaction, with a high satisfaction on the number of responsibilities. Participants experienced the highest faculty stress due to self-expectations. Several significant correlations were found between leadership practices, job satisfaction and faculty stress, measured with Kendall's tau analysis. Content validity of the LPI, MMSS, and FSI showed items to be relevant (92%, 74.2%, 85.2%, respectively). Internal consistency was excellent ($\alpha = 0.90$, $\alpha = 0.93$, $\alpha = 0.92$, respectively).

Conclusion: Dutch post-doctoral nurses show considerably strong leadership practices. Additional research is needed to identify the impact of leadership on career development and research productivity, and the societal impact of nursing research.

L 03 - Faculty Retention

Burnout and Intent to Leave Among Mid-Level Academic Nurse Leaders: An Unfolding Crisis

Linda Flynn, PhD, RN, FAAN, USA

Pam Ironside, PhD, MS, BA, RN, ANEF, FAAN, USA

Abstract

Purpose: Much attention has been focused, appropriately, on nursing faculty shortages. Another growing international concern, however, is the critical shortage of mid-level academic nurse leaders such as associate and assistant deans. Since many future deanship vacancies are expected to be filled by current mid-level academic leaders, it is vital to the future of nursing education that we better understand the contributors to mid-level leader shortages (Morton, 2014). Occupational burnout has been found to be associated with job dissatisfaction and attrition in international samples of clinical-focused nurses as well as educators in other disciplines (Aiken, et al., 2012; Brunsting, Sreckovic, & Lane 2014). Therefore, the purpose of this study was to determine the prevalence and predictors of occupational burnout among mid-level academic nurse leaders so that evidence-based retention strategies can be developed.

Methods: To ensure protection of human subjects, the study protocol was approved by the Colorado Multiple Institutional Review Board prior to subject recruitment and data collection. This multi-site, multi-state study recruited 28 schools of nursing from all geographic regions of the U.S. to participate in a comprehensive web-based survey of faculty. A portion of the survey items were dedicated exclusively to mid-level academic nurse leaders who devoted 50% or more of their effort to an administrative position within the school, including assistant and associate deans, program directors, and department chairs. Dillman survey methods were used to obtain a robust response rate resulting in a sample of 140 mid-level academic nurse leaders representing all 28 participating schools. Burnout was measured by the Emotional Exhaustion subscale of Maslach Burnout Inventory; scores greater than 27 are indicative of burnout (Maslach & Leiter, 2016). Satisfaction with various dimensions of work life, intent-to-leave their school, and intent-to-leave academic nursing were measured by survey items tested in previous research (Yedidia, Chou, Brownlee, Flynn, & Tanner). Generalized estimating equations, producing robust logistic regression models that account for clustering of respondents within schools, were used to determine the effects of study variables on the odds on burnout and intentions-to-leave.

Results: There were no associations between any demographic characteristics and burnout or intentions-to-leave. A total of 71.2% of mid-level academic nurse leaders reported that they typically worked more than 56 hours per week, and 12.3% reported working more than 66 hours per week. Importantly, 21.2% reported that they planned to leave their school within one year and 18.8% indicated they planned to leave academic nursing within the year. A total of 37.7% of mid-level academic nurse leaders had a high emotional exhaustion subscale score indicating occupational burnout. The prevalence of burnout within this sample was higher than that found among hospital staff nurses as recently measured across 13 countries, including the U.S. Mid-level academic nurse leaders who were dissatisfied with their workloads were almost eight times more likely to have developed occupational burnout [OR = 7.84 (3.12, 20.0)]; respondents who typically worked more than 56 hours per week were almost three times more likely to be suffering from burnout [OR = 2.80 (1.33, 5.88)]. In models adjusted and unadjusted for age, mid-level academic nurse leaders suffering from burnout were approximately three times more likely to be planning to leave their school within the year [OR = 2.97 (1.26, 6.94)], and more than three and a half times more likely to be planning to leave academic nursing, entirely [OR = 3.64 (1.42, 8.63)].

Conclusion: The future of nursing education can ill afford to lose approximately 20% of the current mid-level academic nurse leaders to attrition that is due mainly to modifiable work environment factors. Fortunately, findings from this study provide valuable insight into strategies that can be implemented to reduce this trend. Heavy workloads and long work weeks contributed to an unacceptably high prevalence of burnout within mid-level academic nurse leaders in this study. Burnout, in turn, was a major predictor of their intentions-to-leave. Schools of nursing must act quickly to re-examine and redesign workloads among this invaluable group of academic experts and future deans. Responsibilities that can be

delegated to support staff should be identified, and schools should ensure that supportive resources are available. Although this study was conducted in the U.S., the growing internationalization of nursing education denotes core challenges that are experienced by us all. Findings from this study not only serve to be the proverbial canary in the coal mine, warning of crises to come, but also provide guidance for preventative strategies that could be implemented in schools of nursing around the world.

L 03 - Faculty Retention

A Comprehensive Needs Assessment to Gauge the Impact and Extent of the Nursing Faculty Shortage

Judith M. Jarosinski, PhD, RN, CNE, USA

Lisa A. Seldomridge, PhD, RN, USA

Tina P. Brown Reid, EdD, RN, USA

Abstract

Purpose: The aim of this presentation was to explore the use of a comprehensive needs assessment to identify common and unique issues related to the statewide shortage of undergraduate and graduate clinical nursing faculty; this project assessed current efforts and resources that are in place for recruitment, training and mentoring of clinical nursing faculty across the State.

Background: Globally, two factors impact the nurse faculty shortage and subsequent student enrollments: Economic migration contributing to a “brain drain” for many countries, and an aging nurse faculty force. (Gutierrez, Candela, & Carver, 2012; ICN, 2015; Newton, Pillay, & Higginbottom, 2012). In the United States the lack of experienced nurses in specific specialty areas and the later age nurses enter graduate schools, also contribute to the nurse faculty shortage (AACN, 2012). The Eastern Shore-Western Shore Faculty Initiative (ES-WSFI) created a needs assessment with the sole purpose of identifying issues related to the clinical nurse faculty shortage in Maryland, U.S.A. The needs assessment provided direction for planning and modifying current strategies addressing the nursing faculty shortage in regionally diverse nursing programs and is supported by a Maryland Higher Education System, Nurse Support Program-2 grant.

Methods: In collaboration with 12 universities, colleges and community colleges, a mixed-methods approach comprised of web-based surveys, faculty focus groups and interviews with deans/directors of nursing education programs was conducted over a two year period. The comprehensive needs assessment included establishment of relationships with prospective partners, collection of demographic information about partner programs (educational offerings, staffing needs by clinical specialty and level), compilation of existing approaches to address staffing needs, identification of untapped resources, and discussions with partners about gaps and possible solutions. A dedicated website was constructed to facilitate communication about the project not only among partner institutions but across the state. A password protected database has been created to house the results of the needs assessment. With statewide data available in a single place, future initiatives can be planned and implemented, maximizing efficiency and effectiveness in utilization of resources while addressing the need for increasing capacity across all levels of nursing education from associate degree through doctoral degrees.

Results:

1. In undergraduate programs the majority of respondents agree or strongly agree there is inadequate clinical faculty for growth; in the graduate programs, only 1/3 of respondents agree there is inadequate clinical faculty for growth.
2. In both undergraduate and graduate programs 75%-80% agree or strongly agree it is difficult to recruit from underrepresented groups. 69% of undergraduate programs find it difficult to *retain* faculty from underrepresented groups, while 50% of graduate programs find it difficult to *retain* faculty from underrepresented groups.
3. Clinical specialties in greatest demand or representing the greatest need included: pediatrics, mental health (both acute and community-based), obstetrics and women’s health.
4. The nurse faculty shortage indirectly impacts faculty member’s ability to mentor, engage in scholarship and meet increasingly stringent promotion requirements. *“Everybody is stretched really, really thin”*
5. Despite concerted efforts to “grow our own” and by encouraging clinical specialists and alumni to teach on a part-time basis, these proactive initiatives to attract potential clinical faculty, as well as nationwide searches for nursing faculty, continue to be a challenge for most programs. *“We have 4-5 open positions at any given time; we are constantly serving on search committees.”*

6. Challenges confronting universities, colleges and community colleges differ regionally and programmatically.
7. In this initiative, primary strategies currently in use to address the faculty shortage are incorporation of weekend clinical experiences or classes, hiring more clinical faculty and limiting the number of students that can be enrolled.

Conclusion: Current practices are insufficient to meet the growing need for nursing faculty. In order to maximize human capital, a renewed focus on twin strategies of attracting faculty and retaining current faculty must include incentives for seasoned faculty such as: increased salaries for experienced faculty, release time or reduced workloads to provide time for scholarship, as well as support strategies for research and mentorship. In order to attract nurses to academia, Nardi and Gyurko (2013) suggest the inception of international cooperatives that would make possible collaborative teaching and enhance the global attractiveness and reach of nursing. They caution that the diminishing pipeline of PhD prepared nurses provide few “role models with whom nursing students can work and emulate in the practice setting” (p. 320).

L 04 - Competencies in Psychiatric Health

Enhancing Mental Health Competencies in Advanced Practice Nursing Graduates

Nancy E. Edwards, PhD, MSN, ANP-BC, USA
Susan J. Kersey, MSN, PMHCNS-BC, USA

Abstract

Purpose: The purpose of this project was to assess the impact of a curricular enhancement of mental health content to Adult Gerontology Primary Care Nurse Practitioner students. The project goal was to demonstrate the influence of this enhanced curricular content on graduating NP students' perceived competence and confidence in providing care for patients with basic mental health concerns in the primary care setting.

Methods: A gap analysis was conducted to determine the mental health content that needed to be integrated into the curriculum. The content was determined by comparing the current curriculum with the 2013 NONPF Population- Focused Nurse Practitioner Competencies- Psychiatric Mental Health. Content was added to the didactic portion (from 6-18 hours), through progressive interactive case studies led by a psychiatric Mental Health CNS, and with clinical integration (30 hours) with psychiatric mental health professionals. A pre-test /post-test evaluation was conducted using a written questionnaire to assess the graduating NPs perceived competence in the knowledge of psychoactive medications and in the treatment of mental health conditions that frequently present to mental health clinics. The questionnaire was given at the completion of their first year, before any clinical or specialty content and again at the completion of their second year, prior to graduation.

Results: The sample included 45 students who completed the Master's of Science Nurse Practitioner at a Midwestern State University between the years of 2013 through 2016. The students (4 male and 41 female) were enrolled in the Adult Gerontology Primary Care Nurse Practitioner program. A significant difference was noted between the pre-test and post test scores in the graduates reported comfort in providing care for individuals with mental health conditions. The students reported a significant increase in their comfort in providing care for individuals who presented to primary care with depression, depression resistant to 1 medication, anxiety, ADD/ADHD and Bipolar disorder. No significant difference was noted in comfort with providing care for individuals with Obsessive compulsive disorder, Victims of domestic violence, addiction, eating disorders and schizophrenia. In relation to psychotropic medications, a significant difference was noted in their comfort in prescribing SSRIs, SNRIs, Norepinephrine-Dopamine Reuptake inhibitors, Antianxiety medications (Benzodiazepines) and ADHD medications. No difference was noted in the reported comfort in atypical antipsychotics and norepinephrine-specific Reuptake inhibitors

Conclusion: Enhancing students exposure and experience in handling mental health concerns through the use of progressive mental health case studies, enhanced didactic content and clinical exposure led to an increase in perceived competence and confidence in the graduates ability to handle many common mental health concerns that often present to the primary healthcare setting. In addition, the graduates were able to identify and appropriately refer individuals with mental health conditions they were not comfortable treating. The graduates also reported increased confidence in ordering medications used to treat common mental health conditions. With the shortage of mental healthcare providers, primary care providers including NPs are called upon to provide increasing mental health

L 04 - Competencies in Psychiatric Health

Mental Health Stigma and Perceived Practice Competence Among Nurse Practitioners: A Cross-Sectional Descriptive Study

Cara C. Young, PhD, RN, FNP-C, USA

Susan Calloway, PhD, RN, FNP-BC, PMHNP-C, FAANP, USA

Courtney Brown, USA

Abstract

Purpose: Approximately 50% of Americans will meet the criteria for a mental health disorder sometime during their life, and the majority of these illnesses begin in childhood and adolescence (Merikangas et al., 2010). Significant health disparities exist among those with a major mental illness who die 10 to 32 years earlier than the general population due to largely preventable causes (NIMH, 2011; Walker, McGee, & Druss, 2015). In order to reduce this health disparity, the Centers for Disease Control and Prevention (2011) developed an action plan outlining specific strategies to integrate mental health promotion and mental illness prevention with chronic physical disease prevention from a public health model. The challenge is for health care professionals to respond to these initiatives.

The Institute of Medicine's report on the future of nursing (2010) identifies the integral role of nurses, particularly advanced practice nurses, in the rapidly evolving healthcare system. Nurse practitioners are ideal providers to reduce health disparities among those with mental illness as they are prepared both philosophically and educationally from a health promotion and disease prevention framework. However, there are multiple barriers to help-seeking that prevent individuals from initiating conversations with their health care provider regarding mental health issues. A primary barrier to help-seeking is perceived stigma regarding those with mental health disorders (Ahmedani, 2011; Calloway, Kelly & Ward-Smith, 2012). Goffman (1963) defines stigma as an "attribute that is deeply discrediting and reduces the bearer from a whole and usual person to a tainted, discounted one (p.3)"

While studies exist describing the attitudes of physicians and other health care providers toward those with mental illness there is a gap in the literature related to stigmatizing attitudes among nurse practitioners. Additionally, it is unknown what facilitators and barriers to effective recognition and management of mental health disorders nurse practitioners experience. Therefore, the purposes of this study are to 1) assess nurse practitioners' attitudes regarding treating individuals with mental health disorders, and 2) examine perceived competence and factors associated with nurse practitioner recognition and management of mental health disorders in non-psychiatric settings.

Methods: A cross-sectional descriptive study was conducted via anonymous surveys at a national nurse practitioner conference. Participants provided demographic and practice data and completed the Medical Condition Regard Scale (MCRS; Christison, Haviland, & Riggs, 2002) for three separate mental health diagnoses (anxiety/depression [A/D], attention deficit hyperactivity disorder [ADHD], and substance use disorders [SUD]). Descriptive statistics were calculated to examine demographic and practice pattern data as well as the distribution of scores on the MCRS for all three conditions. Pearson correlation and Spearman's Rho were used to examine relationships between variables, depending on the level of the data. Student t-tests were utilized to evaluate variation in stigmatizing attitudes based on participants' demographic, educational, and personal factors.

Results: The final sample (N=141) were predominantly female (82%), Caucasian (71%), and reported <10 years of experience in advanced practice (62%). Only 33% of participants reported feeling well-prepared by their nurse practitioner education to manage mental health disorders. Mean values on the MCRS (higher scores indicating more positive attitudes) were highest for A/D (M=39.15, SD=5.93), followed by ADHD (M=35.85, SD=7.19), and SUD (M=35.21, SD=7.77). Examination of individual items revealed 42% of participants reported working with patients with anxiety and/or depression as 'satisfying' while only 26% and 22.7% of participants rated satisfaction with treating ADHD and SUD, respectively. Participants with a personal or family history of a mental health disorder reported more favorable attitudes

towards patients with ADHD ($t = -2.3, p = .024$) than those without a personal or family history, but no differences were detected with A/D or SUD.

Conclusion: Results suggest stigmatizing attitudes towards individuals with mental health disorders may exist among nurse practitioners, and lack of confidence in managing mental health disorders may contribute to this stigma. The majority of participants did not feel well prepared to manage mental health disorders, yet 70% of mental health care is provided in primary care settings (NAMI, 2015). These findings highlight the need for increased mental health content within nurse practitioner curricula as well as the development and implementation of innovative evidence-based educational strategies to decrease stigmatizing attitudes and beliefs towards those with a mental health disorder.

MRI Outcomes of Emotional Regulation: A Feasibility Study

Brenda Marshall, EdD, MSN, APN-BC, NE-BC, ANEF, USA

Abstract

Purpose: The purpose of this study was to evaluate neuronal responses to emotional regulation in healthy adults when exposed to static faces and changing contexts. Emotional regulation is the array of automatic and controlled strategies that either attaches meaning to, or directs attention away from, an event. This project investigated, through the use of a functional Magnetic Resonance Imaging (fMRI), the impact of stories on visual cues, and brain activity in the areas of the brain devoted to memory and thoughtful consideration. The hypothesis was that the changing of the context, despite the attachment of those stories to the same surprised faces, would change the neuronal connections related to memory and trust.

Methods: Ten participants were scanned with functional magnetic resonance imaging (fMRI) as they were exposed to repeating neutral and surprised faces that were coupled with changing contexts of happy stories or scary stories. The volunteers were exposed to 25 neutral faces and 25 surprised faces with no story. Then the same 25 surprised faces were coupled with five sets of different stories (happy or scary). The process duration in the fMRI was about 25 minutes.

Results: Five men and five women were scanned. Images were processed, aggregated, and compared for changes in neuronal firing and regional activity. Results indicated increased regional activation when individuals were exposed to scary and happy stories while looking at static faces compared to no story exposure. Additionally, exposure to scary stories resulted in increased activity compared to happy stories. Regions of activation included the posterior cingulate process, occipital fusiform gyrus, precuneus, cingulate gyrus and intra-calcarine cortex.

Conclusion: The findings support previous studies identifying the posterior cingulate cortex as engaging in a successful mediating role related to memory and emotional regulation. This study reflects the brain's reappraisal mechanisms that exist when patients experience psychotherapeutic reframing and can also be reflective of the process occurring during the establishment of the therapeutic relationship. This study indicates that way a diagnosis is presented to a patient, combined with the facial expression of the healthcare worker can impact the patient's ability to retain information and to understand and process it.

Developing and Validating a Problem-Solving Tool for Caregivers to Manage Antineoplastic Treatment for Family Members

Annamaria Bagnasco, PhD, MSN, RN, Italy

Abstract

Purpose: To develop and validate an educational tool consisting of a deck of cards for caregivers to educate them to autonomously and safely manage biological antineoplastic oral therapy for their family members at home. This will also increase patients' adherence to treatment.

Methods: We started from the definition of 'self-management' coined by Corbin & Strauss (1988): 'Self-management aims at helping patients to maintain a wellness in their foreground perspective' (Lorig & Holman 2003, p. 1). Therefore, self-management is based on the perception patients have about problems linked to their conditions. This led us to choose a method based on the theory of problem-based learning, such as the Barrows Cards (Barrows & Tamblyn, 1977), and applied it to patients with the purpose of improving self-management through therapeutic education.

The Barrows Cards were originally used to test decision-making skills and critical thinking in medical students. This method—also known as the 'Portable Patient Problem Pack' or simply P4 System—uses a situational card that describes a complex problem and learners can choose from a deck of at least 15 cards each of which describes a possible solution to that problem with the support of a picture.

Two focus groups with a group of 12 oncologists and cancer nurses were conducted at our Teaching Hospital in Genoa to define the themes to include in the cards. Also the nursing diaries of the last 6 months of nurses directly caring for cancer patients were included in the study. The 15 cards were then tested on 18 caregivers to verify if the contents (terminology and pictures) on the cards were clear and appropriate.

The instrument development process included the following steps: 1) A review of the literature to retrieve scientific evidence to support the purpose of our study; 2) Obtaining support and advice from 12 cancer experts; 3) Checking the nursing records diaries of the last six months; 4) Obtaining feedback from caregivers on the clarity of the statement provided on each card and on the appropriateness of the picture that illustrates the statement.

Results: At the end of this study, all of the 18 caregivers were satisfied with the deck of 15 cards, plus a situational card initially developed by our cancer experts. On the cards, caregivers preferred to include photographs rather than drawn illustrations. This qualitative process enabled to validate the cards for caregivers.

Conclusion: The lack of adherence to therapy not only reduces the effectiveness of therapeutic treatment but incorrect management of the therapy can also lead to adverse events. Therefore, at home caregivers play an important role in ensuring that the people they care for correctly adhere to the treatment prescribed, and yet the importance of their role is neglected. It is important for nurses to provide caregivers with structured education interventions to help them manage treatment and monitor adverse effects in a more confident manner. This will improve adherence to treatment and outcomes both for patients and their caregivers, who will feel more confident and less burdened by the fear of making mistakes. However, more work will be needed to confirm this.

The Value of Peer Contact in Patients Impacted By "Rare" Diseases

J. Dwayne Hooks, PhD, MN, BSN, APRN, FNP-BC, NEA-BC, AAHIVS, FACHE, USA

Abstract

Purpose: Rare diseases in the United States are defined as illnesses that impact fewer than 200,000 individuals concurrently. Guillain-Barre' syndrome (GBS) is an example of a rare disease that impacts the peripheral nervous system. With the eradication of polio, GBS has become the leading cause of paralysis in the U.S. GBS is an autoimmune illness that generally results in areflexia, paresthesias, and the potential for temporary yet total paralysis.

Because of the significant morbidity that patients face subsequent to the onset of this syndrome, a study was designed to better understand the patient's experience related to this illness. The stated purpose of the study was to gain a richer understanding of the patient's recalled experience of an acute episode of moderate to severe Guillain-Barre' syndrome.

Methods: The study utilized a qualitative descriptive research design with inductive content analysis. Criteria for inclusion in the study were: (a) adult patients 18 years of age and older, (b) individuals with a prior self-identified diagnosis of moderate to severe Guillain-Barre syndrome, (c) individuals who were alert and oriented, (d) individuals able to respond to interview questions, (e) individuals with English as a primary or secondary language, and (f) those who were able to give informed consent.

Results: Fourteen individuals were interviewed about their experience with moderate to severe Guillain-Barre' syndrome. These participants were from 8 states representing primarily states located within the southeastern part of the United States. Seventy one point four percent of the participants were female and 28.6% were male. All of the participants were hospitalized ranging from 5 days to 405 days. Three research questions were addressed through description of five themes and 14 subthemes. This presentation will focus on one of the themes. The theme of focus revealed the value expressed by participants related to contact with a peer who had been impacted with the same illness. There is additional evidence to suggest that patients find value in talking with peers who share a similar illness experience (Doyle, 2015). Having contact with a peer provided hope about what the future may hold including the potential for recovery. Participants described that information shared by someone who had experienced the illness was perceived as being more impactful than information shared by healthcare professionals. Information from individuals impacted with the illness was considered more impactful because it created reassurance that recovery was possible. Information from peers was also seen as being more credible than information from professional caregivers.

Conclusions: Additional research is needed with more individuals impacted with rare illnesses focusing on the value of peer support/peer counseling. It is important for patients diagnosed with Guillain-Barre' syndrome to be linked to the GBS/CIDP Foundation so that peer counselors can be linked if so desired by the individual impacted by this rare neurological illness.

L 07 - Global Management of Chronic Conditions

Self-Management of Medication Regimen in Chronic Disease: Analysis of the Portuguese Nursing Information System (NIS)

Inês Cruz, MNSc, RN, Portugal

Fernanda Bastos, PhD, MsC, RN, Portugal

Fillipe Miguel Soares Pereira, PhD, RN, Portugal

Abstract

Actually, the world is confronted with a high proportion of diseases and premature deaths caused mainly by chronic diseases. Chronic illness represents indeed the principal cause of death and morbidity in Portugal and in the world, with an estimated increase in prevalence in next years. We even see a reality in which people are simultaneously affected by more than one chronic illness which makes the treatment regimen more complex. To control and live with this diseases, patients should integrate several self-care behaviors into their daily lives . These behaviours include taking regular medication, making exercise, reduce fat intake, etc. Since nurses are the professionals who help clients experiencing these illness transitions, the training for self-management is a key area in nursing.

In Portugal, nurses use nursing information systems to document their decision-making process. They document nursing diagnoses and nursing interventions, using the terminology of international council of nurses' classification. Therefore, it is important to analyze how they document the care needs in information systems related to one aspect that is common in the treatment of all chronic disease: taking medication.

Purpose: The aim of this study is to analyse the documentation (nursing diagnoses and nursing interventions) customized in Portuguese nursing information system (SAPE®) about self-management of medication regimen.

Methods: Content analysis of all nursing documentation customized in the Portuguese nursing information system (SAPE® – Nursing Practice Support System) was made, using an a priori model – ISO 18104: 2003 standard. The International Classification for Nursing Practice (ICNP®) language was used as ontology. A total of 31583 nursing diagnoses and 27380 nursing interventions were analyzed.

Results: A total of 598 nursing diagnoses and 509 nursing interventions were identified, related with self-management of the medication regimen. The comparative analysis of different statements revealed multiple redundancies, i.e. different syntaxes for the same semantics. As a result of the content analysis 29 nursing diagnoses and 67 nursing interventions were considered by a panel of experts as being clinically useful, thus they will be included in the clinical data model being developed.

Conclusion: Nurses use different terms and concepts to represent the same care needs and the same nursing intervention. The proliferation of different statements of diagnosis reflecting the same reality makes information management and production of indicators more difficult. The extended variety in the form of documentation does not add clinical utility and hampers the visibility of nursing contributions to people's health.

This is a first contribution to the development of a clinical data model on self-management of the medication regimen, which will facilitate semantic interoperability between different nursing information systems and help nurses' decision making.

Economics and Intimate Partner Violence: Reducing Risk Through Economic Solvency

Heidi Gilroy, PhD, RN, APHN-BC, USA

Abstract

Purpose: Poverty is one of the most consistent risk factors for intimate partner violence. However, little is known about the economic state at which women are no longer at risk for intimate partner violence due to their economic status, which can be referred to as economic solvency. In order to address poverty as a risk factor, we need to understand more about economic solvency. The purpose of this research is to validate a model of economic solvency in women and create a basis for measurement of economic solvency.

Methods: This is a mixed methods study. First, a quantitative study was performed to validate an established theoretical model of economic solvency, which is made up of four factors (human capital, social capital, sustainable employment, and independence). Next, a qualitative study was performed to find out how women described economic solvency and create a separate model to compare with the original model. For the quantitative analysis, data was used from an ongoing 7 year study of women who were applying for a protection order or using a safe shelter for the first time. For the qualitative analysis, women were recruited from area safe shelters. All women in the study had experienced intimate partner violence, spoke English or Spanish, and were at least 18 years old. A confirmatory factor analysis was performed on the quantitative data. The qualitative data was independently reviewed by 2 researchers and themes were noted and compared.

Results:

The model was a good fit for the data according to the confirmatory factor analysis. Qualitative inquiry revealed that women did describe human capital, social capital, sustainable employment, and independence as parts of economic solvency. They also described assets as an important factor that was not included in the original model.

Conclusions:

By comparing results from the quantitative and qualitative research, we created a five-factor model, which includes human capital, social capital, sustainable employment, independence, and assets. The results of this study support programs that address not only poverty in women who have experienced or at risk for intimate partner violence, but also the psychosocial issues that may be preventing them from escaping poverty. These programs should be multi-dimensional, addressing all factors of the model, in order to increase safety and decrease poor outcomes related to intimate partner violence.

L 08 - Conversations on Intimate Partner Violence

Opportunities for International Interdisciplinary Research Collaborations to Improve Health Outcomes for Intimate Partner Strangulation Survivors

Jacquelyn Campbell, PhD, RN, FAAN, USA

Dominic Robert Reed, MLitt, BSc, United Kingdom

Michelle Patch, MSN, APRN-CNS, ACNS-BC, USA

Abstract

Purpose: The purpose of this presentation is to describe the current health care literature on intimate partner strangulation from the US and UK, and to suggest areas for international research collaboration among nurses, physicians and domestic violence advocacy to better understand this unique form of violence and inform practice and policy efforts.

Methods: A literature review was conducted by U.S. and U.K. researchers to illustrate the current state of the science related to intimate partner strangulation (IPS) and its health outcomes in both regions, and to identify gaps in IPS knowledge amenable to international research collaborations.

Results: Internationally, being strangled by a current or former intimate partner is a very real threat to health and life for significant numbers of women (Sorenson, Joshi & Sivitz, 2013). In the most recent U.S. National Intimate Partner and Sexual Violence Survey (NISVS, 2011) (Breiding et al., 2014), approximately 10% of female respondents reported surviving a strangulation attack by a current or former intimate partner at least once in their lifetimes, extrapolating to approximately 11 million U.S. adult women. The estimated prevalence ratio in NISVS shows non-fatal intimate partner strangulation to be 13 times higher in women than men, with men's lifetime prevalence proportion of 0.7% equal to women's 12-month prevalence proportion, suggesting an extreme gender disparity. Additionally, for female victims of intimate partner violence, prior nonfatal strangulation has been associated with a 6-fold odds of future attempted homicide and a 7-fold odds of completed homicide (Glass et al., 2008). In the U.K., evidence exists that strangulation remains largely under-reported and has far outstripped assault with a weapon as a feature of domestic abuse. This was most recently highlighted in a Scottish Crime Survey from 2014/15, in which 22.7% of women with experience of partner abuse since the age of 16 reported their partner had tried to "choke"/strangle them compared to 12.9% reporting a weapon was used against them (Murray, 2016). Nonetheless, the health implications of non-fatal strangulation remain under-assessed. Intimate partner strangulation (IPS) has been increasingly recognized as a significant risk factor for serious negative health outcomes such as carotid artery dissection, stroke, seizures, PTSD, depression and future attempted or completed homicide (Joshi, Thomas & Sorenson, 2012; Kwako et al., 2011; Le Blanc-Louvry, Papin, Vaz & Proust, 2013; Vella, 2013). However, much of the extant literature on IPS outcomes in the U.S. is limited to case reports and descriptive studies with relatively small sample sizes. Similarly, in Scotland and the wider U.K., despite occasional case studies spaced across decades reporting catastrophic injuries in living strangulation victims, there remains a dearth of IPV strangulation research and little assessment of prevalence or long term health outcomes. This is despite the evidence of its potential lethality, illustrated in a homicide report for 2014/15 in England and Wales, showing almost a quarter of female domestic homicide victims are killed in this manner (ONS, 2016).

Conclusion: Taken together, these data indicate an urgent need for more rigorous health care research efforts regarding IPS. Many opportunities for international health care research collaborations exist, such as: greater frameworks for multi-centre, multi-national studies assessing the link between IPS and complex long term injury, using robust longitudinal, prospective and mixed methods designs; psychometric testing of IPS screening tools and protocols in different geographic populations; qualitative studies on women's experiences seeking care after being strangled; and development and testing of staff training on IPS recognition and treatment.

L 08 - Conversations on Intimate Partner Violence

Prevalence and Predictors of Intimate Partner Violence in Mexican and Non-Mexican Hispanic Women from SEPA

Nilda (Nena) Peragallo Montano, DrPH, RN, FAAN, USA
Young Ju Kim, PhD, RN, ACNP, Korea, Republic of (South)
Rosa M. Gonzalez-Guarda, PhD, MPH, RN, CPH, FAAN, USA
Rosina Cianelli, PhD, MPH, RN, FAAN, IBCLC, USA
Natalia Villegas, PhD, MSN, RN, IBCLC, USA

Abstract

Purpose: The purpose of the study was to examine prevalence and difference of intimate partner violence (IPV) between Mexican and non-Mexican Hispanic women residing in the United States. In addition, this study investigated what factors predict IPV in each of two Hispanic subgroups.

Methods: All of measures were drawn from baseline data of two separate SEPA (Salud-Health, Educacion-Education, Prevencion-Prevention and Autocuidado-Self-care) projects. The SEPA projects are culturally specific, theoretically based group HIV-risk reduction interventions for adult Hispanic women. They consist of five small-group sessions covering HIV and STI prevention, violence prevention, condom use, and communication with partner. The SEPA I includes 529 Mexican Hispanic women in Chicago. The SEPA II has 508 non-Mexican Hispanic women in South Florida. The differences and predictabilities of sociodemographic factors (age, education, income, employment, insurance status, number of partner, age difference with partner), acculturation, depressive symptoms, self-esteem, protective sexual communication with partner, alcohol or drug abuse, and physical or sexual abuse during childhood on IPV were assessed by using t-test, chi-square test, and logistic multivariate regression. IPV in the past 3months was measured with 12 questions of the Revised Conflict Tactics Scale. Any positive responses to one or more questions relating to physical or psychological abuse were categorized as being exposed to IPV.

Results: Although the prevalence of IPV was very high in both groups, it was significantly higher in Mexican Hispanic women (79.1%) than non-Mexican Hispanic women (63.5%). Mexican Hispanic women were significantly younger, less educated, less Americanized, poorer, more sexually abused during childhood, and more likely to have partners with a heavy drinking than non-Mexican Hispanic women. Additionally, they had significantly more depressive symptoms and lower self-esteem. Depression and partners' heavy drinking were significant risk factors for IPV in women born in Mexico. Educational years, depression, and partners' alcohol or drug abuse were predictors in women born in other Latin American countries than Mexico.

Conclusion: IPV Interventions should address the culturally specific needs of Hispanic women from different nationalities and geographical locations in the U.S.

A Review and Synthesis of Literature Examining Healthcare Managers' Use of Knowledge in Their Practice

Greta G. Cummings, PhD, RN, FCAHS, FAAN, Canada
Kaitlyn C. Tate, BScN, RN, Canada
Sarah J. Hewko, MHA, RD, Canada
Patrick B. McLane, PhD, MA, Canada
Pamela E. Baxter, PhD, RN, Canada
Susan Armijo-Olivo, PhD, PT, Canada
Carole A. Estabrooks, PhD, CM, RN, FCAHS, FAAN, Canada

Abstract

Background. Despite acceptance of the merits of evidence-based practice, healthcare managers are frequently cited as discounting the value of research evidence to inform management practice. We identified and evaluated the effectiveness of interventions implemented to enhance healthcare managers' use of research in their management practice.

Methods. We searched ten online bibliographic databases. Articles eligible for inclusion reported on interventions targeted to healthcare managers for enhancing research utilization in their practice. Two reviewers independently screened all titles, abstracts and manuscripts using predefined inclusion and exclusion criteria and independently conducted quality reviews on all manuscripts meeting inclusion criteria. Four research team members employed Hoon's (2013) approach to meta-synthesis of qualitative studies to synthesize review results. We validated our findings in two semi-structured focus groups with 16 healthcare managers.

Results. Our database search yielded 15, 715 potentially relevant records. After duplicates were removed, a total of 14, 227 unique references remained. These references were screened and 178 titles moved forward to full text screening. Seven studies of variable quality (reported in 11 articles) met inclusion criteria. Three were case studies with primarily qualitative results. Interventions employed to enhance research use among healthcare managers' included: informal and formal training, a computer-based/desktop application; meeting based, executive-level knowledge translation activities; and a formal residency program. Meta-synthesis yielded four themes including organizational culture/context, prioritization, time as a resource, and capacity building. An additional perspective was identified after reviewing focus group data. Awareness relates to participant's lack of awareness that literature exists to inform management practice in health care or participants' prematurely concluding that there is no relevant research in a particular area.

Conclusions. Methods employed to study interventions to enhance management research use among healthcare managers are primarily qualitative. Qualitative results can inform future studies, with study designs that can demonstrate causation and the relative effectiveness of specific components of an intervention in this area. The small number of studies available in the literature and the diverse strategies employed hindered our ability to identify one intervention or strategy as superior to any other.

L 09 - Nursing Leadership

Leadership Insights of Senior Nurse Executives

Robie Hughes, DSN, RN, CNS, USA

Abstract

Purpose: The purpose of this study was to identify characteristics, behaviors, and context for top performing nurse executive leaders.

Methods: A qualitative study of 8 senior ranking, retired United States military nurse executives was approved by the institutional IRB to conduct semi-structured interviews utilizing the historical narrative method. A modified "Life History Questionnaire: Nurses", developed by Dr. Lucinda McCray was utilized to guide the semi-structures interviews. All interviews were conducted within an eight-month time period. The interviews were audio recorded, and then transcribed verbatim. The transcribed data was examined both in historical context and narrative themes using DiCicco-Bloom and Crabtree's qualitative technique as described in "Making sense of qualitative research" (2006).

Results: Each of the nurses served in a top leadership position during a different time frame. Contextual factors related to health care policies, political environment, and develop of nursing as a profession were discussed. Leadership challenges and accomplishments were identified. Personal characteristics of integrity, service, sacrifice, and humility were consistent, however, leadership strategies varied some based on contextual factors. Stories were extremely touching, emotionally moving, and rewarding.

Conclusion: The combined executive leadership experience of the 8 nurses stretched across 32 years with combined responsibility over 100,000 nurses revealing the stages of nurse advancement from the role of hand-maiden to the role of advanced practice nurse and healthcare executive. The visionary leadership impact of the 8 executive nurses interviewed was nothing less than transformational. The insights from this study have relevance to a broader range of health care leadership roles. Nurses are uniquely prepared through their education and clinical practices to lead teams, but require additional knowledge and skills before successfully moving into executive healthcare leadership. The insight gained from this study demonstrates that retired Senior Nurse Executives can play a vital role in facilitating the success of the next generation of nurse executive leaders.

L 09 - Nursing Leadership

A Global Exploration of Leadership Competencies for Academic Nurse Educators

Anne Marie Krouse, PhD, MBA, RN-BC, USA

Barbara J. Patterson, PhD, RN, ANEF, USA

Abstract

Purpose: Leadership is an essential element of the role of the nurse educator. It is a key factor in creating and sustaining academic institutional quality in that “leadership training and succession planning may contribute to organizational success” (Minnick, Norman, Donaghey, Fisher, & McKirgan, 2010, p. 504). Many nurse faculty leaders are thrust into their positions with insufficient leadership education or experience (Young, Pearsall, Stiles, Nelson, & Horton-Deutsch, 2011). This is of great concern as academic leadership has been shown to affect faculty satisfaction and retention and affect the health of the overall work environment (Brady, 2010). Leadership succession in academic programs is particularly concerning.

Organizational success is dependent upon the competency of its leaders. In nursing education, the NLN has identified eight core nurse educator competencies (Halstead, 2007). One of these competencies specifically focuses on the nurse educator as a leader, that being to “...function as change agents and leaders... to create a preferred future for nursing education, the nursing profession, and health care delivery systems” (Halstead, 2007, p. 116). Nurse faculty are charged to “assume a leadership role in various levels of institutional governance” and “advocate for nursing and nursing education in the political arena” as part of the competency, functioning within the educational environment (Halstead, 2007, p. 156).

This study builds upon three previous studies examining the leadership competencies of nurse educators. Patterson and Krouse (2015) completed a qualitative study of 15 leaders in nursing education from which six leadership competencies emerged. Those competencies were validated through a Delphi study distributed to leaders in nursing education across the country. The results of the Delphi study were used for development of Leadership in Nurse Educators (LNE)[®] instrument. The 3rd study established the psychometrics of the instrument with a sample of 340 academic nurse educators in the United States. This study extends the sample internationally to provide greater depth and understanding to leadership competencies for the academic nurse educator adding the global perspective.

The advancement the science of nursing education and transforming practice requires nurse educators who are prepared to be leaders. While nurse faculty competencies have been clearly articulated by the NLN, there is a gap in the evidence-based literature in regards to the leadership competencies necessary for the academic nurse educators from a global perspective. The development of nurse faculty who have the leadership skills that are essential to take on the challenging roles of higher education is critical. The purpose of this research was to describe leadership competencies of nurse educators from an international sample.

Methods: A descriptive quantitative design was employed to answer the research question. From a list of nursing schools outside of the United States, the investigators accessed the publicly available web pages identifying the nursing school/department faculty and potential participants’ email contact information. Using SurveyMonkey[®], each identified educator was contacted via email informing him or her about the study and requesting study participation. A total of 2138 emails were distributed with a 11% response rate. Demographic data were analyzed using descriptive statistics. Psychometric evaluation of the instrument was completed to determine reliability and validity of the instrument for international academic nurse educators.

Results: Since the state of the science in nursing education research is in its infancy, this study contributes to the evidence for leadership competencies of academic nurse educators globally. The sample consisted of 250 academic nurse educators with a mean age of 52 years and 22 years of teaching experience. Eighty-three percent were women and 67% had a doctoral degree in nursing (92%

PhD, 4% EdD, 2% DNP, 1% DNS/DNSc). The findings of this study were consistent with previous findings from a U.S. sample of academic nurse educators. The LNE[®] was determined to be valid and reliable for use with an international population of academic nurse educators.

Conclusion: Academic nurse educators are challenged to become leaders, using innovation and creativity to create a more efficient and effective learning environment for students. As members of the academic community, they must become leaders in university governance to proactively address increasing regulation in higher education and threats to academic freedom. Developing those leadership competencies necessary to work within the higher education environment is crucial as the challenges faced in healthcare and education become more complex.

In a global nursing community, this study contributes data from an international sample using a reliable and valid instrument for the science of nursing education that can be used to assess leadership competencies in academic nurse educators. The instrument may be used in conjunction with leadership development programs for academic nurse educators to identify areas for development or to assess program outcomes. It may also be used to evaluate relationships between leadership competencies and organizational outcomes in higher education. Faculty development is the critical element (Cleeter, 2011).

L 11 - Interprofessional Collaboration Enhancing Clinical Outcomes Interprofessional Oral-Systemic Health Standardized Patient and Case Study Experience

Judith Haber, PhD, APRN, BC, FAAN, USA
Erin Hartnett, DNP, CPNP, APRN-BC, USA

Abstract

Purpose: The aim of the NYU College of Nursing Teaching Oral-Systemic Health (TOSH) Program Interprofessional Oral-Systemic Health Standardized Patient and Case Study Experience is to promote the acquisition of the Core Competencies for Interprofessional Collaborative Practice and the Interprofessional Oral Health Core Clinical Competencies among future primary care providers by engaging nurse practitioner, nurse-midwifery, dental, and medical students in interprofessional oral-systemic health simulation experiences.

Methods: In 2013, 2014, and 2015, students and faculty from NYU College of Nursing, College of Dentistry, and School of Medicine participated in an interprofessional oral-systemic health simulation experience, featuring a standardized patient and case study teaching-learning strategy, to advance students' competence in both areas. The Interprofessional Collaborative Competencies Attainment Survey (ICCAS) was selected to evaluate the degree to which students, using a pre-test/post-test approach, report a change in perception of their own IP competencies following the learning experience. Data from faculty facilitators was collected to assess their perceptions about the value of exposing students to interprofessional clinical simulation experiences focused on oral-systemic health.

Results: For all student groups, the changes in ICCAS mean scores from pre to post were significant ($p < 0.001$, two-tailed). There was also a statistically significant change in mean scores from pre-test to post-test in each of the six interprofessional competency domains measured by the ICCAS for all participating students ($p < 0.001$, two-tailed). Faculty facilitators reported that the IPE clinical simulation experiences were valuable and positively influenced interprofessional communication, collaboration, patient communication, and student understanding of patient care roles.

Conclusion: These findings suggest that the experience was similarly effective among all student groups in having a positive impact on perceived interprofessional competencies. Topics in which mean post-survey scores were lower are potential opportunities for curriculum refinements to further emphasize those competencies. The Teaching Oral-Systemic Health (TOSH) Program Interprofessional Oral-Systemic Health Clinical Simulation and Case Study Experience is effective as a standardized, replicable curriculum unit, using oral-systemic health as a population health exemplar, to teach and assess interprofessional competencies to nurse practitioner/midwifery, dental, and medical students.

L 11 - Interprofessional Collaboration Enhancing Clinical Outcomes

ABCDE Bundle Adherence: The Influence of Access to ABCDE-Enhancing Supplies and Equipment

Leanne M. Boehm, PhD, RN, ACNS-BC, USA

Abstract

Purpose: The ABCDE interprofessional bundle (**A**wakening and **B**reathing **C**oordination, **D**elirium monitoring and management, and **E**arly mobility) is an evidence-based approach to organizing Intensive Care Unit (ICU) people, processes, and technology to improve collaboration among disciplines and standardize critical care practices. Implementation of the ABCDE bundle is associated with improvements in delirium prevalence (62.3% pre-implementation vs 48.7% post-implementation, $p=0.02$), ventilator-free days (21 pre-implementation vs 24 post-implementation, $p=0.04$), and hospital mortality (20% pre-implementation vs 11% post-implementation, $p=0.04$). Despite this evidence, bundle adoption is limited. The perceived workload burden of ABCDE bundle execution has been inversely associated with likelihood of bundle adherence (OR=0.47, CI=0.28-0.79, $p=0.004$). Furthermore, limited access to supplies and equipment for ABCDE bundle execution is associated with increased difficulty performing the bundle ($r_s=0.37$, $p<0.001$). The objective of this study was to describe accessibility of ABCDE-enhancing supplies and equipment (e.g., overhead lifts and portable monitors) in units attempting to implement the ABCDE bundle.

Methods: This is a secondary analysis of data from a pilot study investigating organizational factors influencing ABCDE bundle implementation. The Conceptual Framework for Interprofessional Bundle Implementation guided the study. Physical environment data were collected from participating medical and surgical ICUs ($n=10$) in six academic medical centers. The principal investigator personally visited each site between April 2014 and August 2015, during which time available ABCDE-enhancing supplies and equipment were logged. Daily execution of the ABCDE bundle was at the discretion of the ICU team and guided by a standardized protocol. Adherence was tracked daily via the ABCDE bundle checklist. ABCDE bundle adherence is defined as all five components being completed on a ventilator day (i.e., **A**wakening trial [SAT], **B**reathing trial [SBT], **C**oordination [SAT precedes SBT], **D**elirium assessment, **E**arly mobility). ABCDE bundle adherence was aggregated at the unit level.

Results: Variation in ABCDE bundle adherence on ventilator days was noted to range between 38% and 85% across units. ABCDE bundle adherence was lesser in surgical ICUs compared to medical ICUs, but this did not reach statistical significance (63% vs. 75%, $z=1.89$, $p=0.059$). Upon evaluation of individual bundle components, **C**oordination (89%) and **E**arly mobility (86%) had the least adherence for mechanically ventilated patients. Unit ABCDE-enhancing supply/equipment comparison demonstrated a range of 3-10 accessible items across units. The highest performing unit (adherence=85%) had access to two ABCDE-enhancing items while the lowest performing unit (adherence=38%) had access to seven ABCDE-enhancing items. The most frequently reported ABCDE-enhancing items ($\geq 80\%$) include walkers ($n=9$) and overhead lifts ($n=7$). The least commonly reported ABCDE-enhancing items ($\leq 20\%$) included nonpharmacologic delirium management tools (e.g., radio, earplugs) ($n=2$), bariatric chairs ($n=2$), portable monitors ($n=2$), turning straps ($n=2$), strength bands ($n=2$), portable ventilator ($n=2$), and sit-to-stand device ($n=2$).

Conclusion: The ABCDE bundle is recommended practice for critical care, but utilization is low and implementation varies. In this study, the number of ABCDE-enhancing supplies/equipment procured by the ICU is not noted to be consistent with greater adherence to the ABCDE bundle. In fact, there were more than twice the number of ABCDE-enhancing items in the lowest ($n=7$) performing unit compared to the highest performing unit ($n=2$). These data suggest that environmental factors contributing to the workload burden of ABCDE bundle execution may not be so much related to the presence or absence of ABCDE-enhancing supplies/equipment, but more so to unit architecture (e.g., configuration, number of corners) or distances to supplies/equipment. However, unit milieu (e.g., teamwork, coordination across disciplines) and policy and protocol factors (e.g., protocol complexity, role clarity) must also be more closely explored.

L 11 - Interprofessional Collaboration Enhancing Clinical Outcomes

Interprofessional Collaboration in Fall Prevention: Home Care Providers' Experience

Kyeongra Yang, PhD, MPH, RN, USA
Keville Frederickson, EdD, RN, FAAN, USA

Abstract

Purpose: Approximately 12 million individuals currently receive home care because of acute illness, chronic diseases, or permanent disability (National Association for Home Care & Hospice, 2010). Diabetes is one of the most frequently encountered conditions in home care (Jones, Harris-Kojetin, & Valverde, 2012). Researchers have found that older adults with diabetes are at high risk for falls (Yau et al., 2013) largely due to poor balance and loss of pressure sensitivity related to diabetic-related neuropathy (Maurer, Burcham, & Cheng, 2005; Morrison, Colberg, Mariano, Parson, & Vinik, 2010; Schwartz et al., 2002). Falls contribute to about 54% of unintentional injuries in older adults and are a leading cause of death in adults 65 years or older and home care providers have become major players in fall prevention among community-dwelling populations (Centers for Disease Control and Prevention, 2014). Research suggests that a multifactorial fall risk assessment can effectively identify the risk of falls among patients receiving home care (James, Kimmons, Schasberger, & Lefkowitz, 2014). An inter-professional team approach also has been identified as the key to improving the quality of fall prevention among older adults at risk of falling in home care settings (Baxter & Markle-Reid, 2009). The purpose of the study was to understand home care providers' inter-professional collaborative experience in providing fall prevention in home settings.

Methods: The study employed a qualitative, descriptive approach through a series of focus groups. Recruitment began after Institutional Review Board (IRB) approval was obtained both from the University and home visiting agency. To be eligible, participants had to be a homecare provider working with patients 65 years or older who are at risk for falls. Study flyers were distributed via agency email listserv at a home care agency in New York to recruit the sample. The focus group (approximately one hour) took place in a quiet and private setting to protect participant confidentiality. Focus group discussions were audio-recorded, transcribed, and coded for content analysis.

Results: Twenty-nine home care providers participated in three focus groups and included nurses (n=12), physical therapists (n=10), occupational therapists (n=5), one social worker and one speech therapist. Twenty-six (89.7%) were female and the mean age was 44.8 years (SD: 10.2). The average number of years of job experience with home care was 11 (SD: 7.8, Range: 2-33) and the years in their profession ranged from 2 to 46 years (Mean \pm SD: 18.8 \pm 11.3). The themes that emerged included, "teaming up" for patient care and communicating through emails, texts, phone calls, and/or in-person meetings with team members; reaching out to team members perceived to have more knowledge or a "better scope" or a "better handle" on both practice issues as well as more experience in specific settings; and working in an agency as a team was a facilitator in providing care yet working with external home caregivers was identified as a challenge.

Conclusions: This study explored the experiences of home care providers toward inter-professional collaboration. Participants reported that effective inter-professional collaboration is essential to ensure the quality of care and improve patient outcomes; therefore, it is imperative to explore best strategies to enhance inter-professional collaboration in a home care setting.

Legal and Ethical Accountability for Nursing Errors: Disclosure and Apology

Susan J. Westrick, JD, CNE, USA

Abstract

Purpose - The purpose of this session is to review the legal and ethical evidence bases for accountable disclosure of errors and apology by nurses, and to provide guidance on best practices for these disclosures.

Error disclosure and apology are evolving concerns for nurses who have increased exposure to liability. The Institute of Medicine (IOM) report *To Err is Human* brought national attention in the United States to the problem of medical errors and preventable injuries that occur every day (Institute of Medicine, 1999). According to this report, it is estimated that 98,000 patient deaths per year can be attributed to preventable medical errors, raising concerns about patient safety. One of the tenets of communication and patient safety is the ethical obligation to promptly disclose medical errors. Transparency is an integral component of providing safe and accountable care and a critical element of transparency is disclosure of harmful errors. This practice has been recommended by United States (U.S.) accrediting organizations and professional bodies. In 2001, the Joint Commission on Accreditation of Healthcare Organization (now called The Joint Commission) issued the first nationwide disclosure standards, requiring patients to be informed of all unanticipated outcomes of care (Weiss & Koch, 2012). In 2006, the National Quality Forum endorsed a new safe practice guideline on the disclosure of serious unanticipated outcomes to patients. Although these guidelines are not legal mandates, the recommendations of these well-known health care organizations comprise professional standards that could be used as evidence in malpractice cases or other legal challenges in the U.S.

In the United Kingdom (U.K.) there is a new law and guidelines for National Health Service (NHS) doctors and nurses that requires them to apologize to patients for mistakes (Merrifield, 2015). These guidelines, issued by the General Medical Council and Midwifery call for a “duty of candor” in disclosing medical errors. The International Council of Nurses (ICN) Code of Ethics for Nurses (2012) and the American Nurses Association (ANA) Code of Ethics for Nurses (2015) provide further support for error disclosure practices.

Yet even with these mandates and guidelines, barriers to disclosure exist, and error disclosure has been a subject of debate by healthcare professionals. Errors threaten a practitioner’s competency, adequacy, and self-esteem and may lead to employer or professional discipline (Westrick, 2014). Nurses also may not be aware of U.S. state apology statutes (laws) that protect some statements from use in civil lawsuits for negligence or malpractice. Two law cases involving physicians that apply apology laws are reviewed to illustrate these protections (Airasian, 2008; Davis, 2011). Nurses would be similarly protected as “health care practitioners” under the wording of the statutes applied in both cases.

Successful error disclosure programs in the U.S. and best practices for error disclosure such as the “Michigan Model” (Kalachalia, Kaufman & Boothman (2010) have made a difference in reducing liability claims. The Sorry Works! Coalition was formed in 2005 as an advocacy group that promotes apology for medical errors and fair compensation when appropriate to patients and families (<http://www.sorryworks.net/>). The website provides training materials and toolkits to assist practitioners and organizations in the apology process. Additionally nurse educators are urged to include error disclosure content in nursing curricula as part of safety and quality education, since this is typically not a part of undergraduate or graduate courses for advanced practice nurses (Westrick & Jacob, 2016). Nurses continue to need support and guidance for specific aspects of error disclosure and apology to patients (Meyers, 2011).

L 12 - Nursing Ethics

The Impact of Conscience and Ethical Climate Among Nurses in the Hospital Setting

Theresa Kyzar, PhD, MSN, MBA, RN, USA

Abstract

Purpose: The purpose of this study was to conduct a quantitative descriptive correlational investigation to examine the relationship between ethical climate and the role of conscience in registered nurses who worked in acute care hospital facilities in a southern state in the United States. While the relationships of various types of organizational climates, including ethical climate, have been studied in multiple industries and disciplines, there is a paucity of research that addresses the role of nursing conscience in the acute care environment. The relationship of ethical climate, perceptions of conscience and stress of conscience had not been examined prior to this study. An examination of conscience beliefs and how these beliefs may be influenced by the ethical climate of various hospital nursing units could provide insight into differences and similarities that will add to the collective knowledge in nursing bioethics. A better understanding of the contributing factors to high levels of stress of conscience in nurses should result in improvement in nursing educational ethics programs and in specific support systems designed to aid the nurse during moral dilemmas in the work setting. The data obtained provide additional insight to nurse leaders and assist with needed methods to reduce the likelihood of nurses departing from their chosen specialty, changing employers, or leaving the profession. Additional research findings explaining the interface between the hospital ethical climate and the role of nursing conscience can assist administrators in developing workplace environments suitable for the flourishing of safe places for nurses to voice ethical concerns (Ford et al., 2010).

Methods: A quantitative, non-experimental, descriptive correlational study was utilized to determine the relationship between the variables defined as perceptions of conscience, hospital ethical climate and stress of conscience. A purposive, non-probability-based sampling of 193 registered nurses in the southern United States was surveyed using a web-based survey instrument. Both the ethical climate theory and moral distress theory were utilized to guide the implementation of this study.

Personal characteristics included the respondent's background information (i.e., institutional information, education level, years of experience) and information about the respondent's thoughts on the ethical climate of the patient care unit using the Hospital Ethical Climate Survey [HECS] (Olson, 1995). Conscience was measured by the Perceptions of Conscience questionnaire (PCQ) which assessed different beliefs on where nurses think conscience originates, and what its nature and functions are (Dahlqvist et al., 2007; Gustafson, Eriksson, Strandberg, & Norberg, 2010). Examining background data and information was important to this research to identify factors and characteristics that could be related to the hospital ethical climate where the nurse is employed and attitudes about the importance of conscience. The second part of this study asked respondents to identify concerns that may contribute to a stress of conscience, also referred to as a troubled conscience, by using the Stress of Conscience (SoC) questionnaire (Glasberg et al., 2006). This stress was measured by frequency of selected stressful situations and the amount of troubled conscience the nurse experienced in each of those occurrences. Both multiple and hierarchical regression analyses were conducted to obtain the findings.

Results: The inability to act on one's values leads to internal conflict and situations that prohibit the nurse from expressing ethical or moral concerns and interceding on the patient's behalf lead to moral distress and a stress of conscience. A culture of conformity may suppress the nurse's ability to address feelings associated with a stress of conscience and moral distress. The results of this study verified a significant relationship exists between perceptions of conscience and hospital climate. An additional relationship was established between hospital ethical climate and stress of conscience. There was no relationship found between nursing demographics and job characteristics, however.

Conclusion: Based on the results of this study, the conclusion can be drawn that perceptions of conscience in nursing contribute to the work environment. It does influence how ethically challenging

dilemmas are experienced and are perceived and serves a vital underpinning which allows the nurse to act with moral courage. The important role of team relationships was also duly noted as part of these findings. In ethical climates where nurses perceive that their ability to act on their consciences is suppressed by other nurses or physicians, a troubled conscience ensues. Moreover, the results of this study demonstrate that there is still a significant need to improve the interdisciplinary approach to patient care delivery where all professional contributions, opinions, and ideas foster better collaboration among healthcare team members. These interactions, including ongoing dialogue regarding ethical dilemmas which cause moral uncertainty and distress among the nursing staff are vital for the safety and clinical progress of patients under care. The importance of this and other related research findings from this study cannot afford to go unnoticed by hospital administrators and nurse managers. Their leadership role is critical to finding and implementing solutions that mitigate the negative consequences of poor ethical climates on nursing units and the resulting moral distress, burnout and exodus of nurses from their institutions and the nursing profession. These strategies will assist in combating the growing nursing shortage in the United States and the world.

L 12 - Nursing Ethics

A Collaborative State of the Science Initiative: Transforming Moral Distress to Moral Resiliency in Nursing

Cynda Hylton Rushton, PhD, RN, FAAN, USA

Heidi Kathleen Holtz, PhD, RN, USA

Patricia Rodney, PhD, RN, Canada

Abstract

Background: Moral distress is a pervasive problem impacting health care in numerous settings and at multiple organizational levels (Oh & Gastmans, 2015; Whitehead, Herbertson, Hamric, & Epstein, 2015). First identified in the 1980s (Jameton, 1984), moral distress occurs in situations where “the person is aware of a moral problem, acknowledges moral responsibility, and makes a moral judgment about the correct action; yet, as a result of real or perceived constraints, participates in perceived moral wrongdoing” (Nathaniel, 2002). The American Nurses Association Code of Ethics for Nurses (2015) delineates moral distress as, “The condition of knowing the morally right thing to do, but institutional, procedural, or social constraints make doing the right thing nearly impossible; threatens core values and moral integrity” (p. 44).

Nurses in all roles, and settings, encounter morally distressing situations. A critical care nurse struggles with implementing invasive interventions for a patient with little chance of survival. A nurse on a medical/surgical unit knows they cannot provide good patient care because of insufficient staffing. A nurse administrator fights for required resources only to face significant budget cuts. Widespread moral distress has been linked with *personal* (burnout, empathy fatigue, job dissatisfaction), and *system* (quality of care, staff turnover, poor patient outcomes) consequences (Burston & Tuckett, 2013; Wallis, 2015; Rushton, Caldwell, & Kurtz, 2016). Despite decades of documenting moral distress, few solutions have been proposed for alleviating this problem that is only expected to escalate with increasing health care complexity (Rushton, 2016).

Moral resilience is an evolving concept that offers promise for helping nurses and other providers manage moral distress. Generally, resilience, refers to “the ability to recover or healthfully adapt to challenges, stress, adversity, or trauma: to be buoyant in adverse circumstances” (Rushton, 2016, p. 112). Specifically, moral resilience has been defined as “the capacity of an individual to sustain or restore, or deepen [his or her] integrity in response to moral complexity, confusion, distress, or setbacks” (p. 112). Moral resilience involves cultivating individual capacities and developing systems to support individual integrity in morally distressing situations by creating a culture of ethical practice.

Purpose: A *State of the Science Symposium: Transforming Moral Distress to Moral Resiliency* was held to explore promising evidence-based practices and answer three critical questions:

- What is known about building moral resilience as a strategy to reduce moral distress?
- What is known about individual and organizational strategies for reducing conditions that give rise to moral distress and for supporting moral resilience?
- What are the recommendations for practice, education, research and policy around addressing moral distress and cultivating moral resilience in clinical settings?

The desired outcomes for this project include delineating what is needed to develop individual capacities and systems that will create an environment that will promote ethically grounded, humane, quality care for patients and their families.

Methods: A two day workshop involving forty-six nurse clinicians, researchers, ethicists, organization representatives, and other stakeholders collaborated using several strategies. First, participants were asked to reflect on what each individual's understanding and beliefs were about moral distress and moral resilience. A background synthesis of moral distress research and interventions were presented to participants to build upon a previous symposium held in 2010. Following that conversation a World Café discussion was held in which group facilitators conveyed emerging ideas for addressing moral distress. To move participants' discussion beyond moral distress a manuscript was presented on transcending

moral distress by building moral resilience followed by a panel presentation describing promising interventions that could be developed and implemented to build individual capacities for moral resilience. Succeeding the panel, participants met in small groups to brainstorm and identify essential elements for successful interventions to address moral distress and build individual capacities of moral resilience. These groups focused on what changes and/or additions were needed to move forward in research, education, policy and practice to address moral distress and cultivate individual capacities towards moral resilience.

Day two of the workshop used similar strategies that focused participants towards discussion of promising system and environmental strategies necessary for addressing moral distress and building moral resilience. Small group participation identified key elements needed to build system capacities to support ethical practice; the priorities in research, education, policy, and practice to build systems that support ethical practice; and steps necessary to cultivate systems that support ethical practice.

Results: Participants voted on recommendations for essential elements and next steps necessary for building individual and system capacities to address moral distress, build moral resilience, and support ethical practice. Additionally, participants identified priorities for a research agenda which was formulated into specific research questions to move research forward on addressing moral distress and building moral resilience.

Conclusion: Nurses, other healthcare providers, and administrators can use the results of this workshop to guide discussions, make considerations on how specific ideas can be moved forward, even implemented, through their personal and organizational efforts. With decided action, we can help nurses and other providers mitigate the effects of moral distress, increase the understanding and implications of building moral resilience, improve the ethical environment in which they practice, and improve the quality of health care.

L 13 - Health Promotion in Asthma Patients

Commencement of Global Dissemination and Implementation of a School-Based Academic Asthma Education and Counseling Program

Eileen Kae Kintner, PhD, RN, FAAN, USA

Abstract

Background, Purpose, Aims: One of the most critical issues impeding improvement in public health is the gap between what we know can optimize health and what gets implemented. Dissemination and implementation science seeks to address this gap by understanding how best to transfer efficacious and effective programs into real world settings. The purpose of this presentation is to share the commencement phase of our dissemination and implementation study. We seek to facilitate increased dissemination and implementation of an innovative and effective theory-guided, evidence-based academic asthma health education and counseling self-management program into schools and community settings. We are using the program to challenge an existing paradigm that condition-specific asthma self-management programs are inappropriate for academic settings and to address a critical school barrier to progress in the field of asthma self-management. The novel program, *Staying Healthy-Asthma Responsible & Prepared*[™] (SHARP) has two components: a school component for older school age students with asthma aged 9–14 years enrolled in grades 4–7 delivered by trained certified elementary school teachers in schools during instructional time and a community component for invited members of the students' social networks delivered by public health educators during scheduled evening and weekend events [1–3]. The specific aims of the dissemination and implementation study were formulated to (a) assess the acceptability, integration, and adaptation of SHARP within schools and community settings that serve diverse populations, (b) evaluate the degree of fidelity in whether SHARP's core components are faithfully transported to real world settings, (c) address issues of SHARP's complexity, adoption, sustainability, and cost-effectiveness, and (d) determine the impact of SHARP on community-wide outcomes related to school absenteeism and use of healthcare services.

Framework: The Transdisciplinary Dissemination and Implementation of SHARP Model (TDISM) used to guide the study integrates concepts and processes of three related frameworks: (a) the Consolidated Framework for Implementation Research (CFIR) that provides structure for implementing complex, interacting, and multi-level interventions in real world settings [4], (b) the Logic Model of School-based Asthma Interventions (LM-SAI) that provides structure for implementing asthma health education and counseling programs in school settings [5], and (c) the Acceptance of Asthma Model (AAM) that served as the basis for development and evaluation of the SHARP program.

Participants: We used outreach, engagement, and marketing efforts to launch dissemination and implementation across the United States and around the globe. We contracted with site principal investigators to identify and recruit targeted users as study participants; specifically, program champions who in turn identify and recruit school liaisons, certified elementary school teachers, and public health educators. Champions such as school nurses are responsible for promoting the program within school districts and community settings. School liaisons such as school personnel with access to district-wide databases are responsible for recruiting students with asthma and their caregivers into the program. Certified elementary school teachers identified by the district are responsible for delivery of SHARP's school component. Public health educators are responsible for delivery of SHARP's community component. We orient, train, monitor, and evaluate targeted users in their respective roles and provide them with user-specific packaged program materials.

School-based Intervention: When the National Asthma Education and Prevention guidelines recommended expanding asthma self-management education to schools and community settings to address high morbidity and mortality outcomes in diverse older school age students; schools were reluctant to adopt programs that were not academically-focused. Using a transdisciplinary and community-based participatory approach, we collaborated with health professionals, school personnel, and community partners to develop SHARP as a comprehensive and developmentally-appropriate academic asthma health education and counseling self-management program [1–3]. SHARP has features

that appeal to school administrators because the program complements existing curricula by integrating biology, psychology, and sociology content with related spelling, math, reading, writing, and art assignments as an elective course that meets benchmarks for grades 4–7 and performance-based assessment activity consistent with grade 5. A series of randomized clinical trials confirmed SHARP's feasibility, benefits, efficacy, and effectiveness on improving cognitive, psychosocial, and behavioral factors that impact condition control, quality of life, and use of health care service outcomes in racially-diverse, medically-underserved, inner-city, lower socioeconomic families.

Method: We used the TDISM to guide the commencement phase of dissemination and implementation. During the commencement phase, we partnered with technology and education specialists to transfer our orientation, training, and certification modules as well as monitoring checklists and evaluation surveys to an online format. The online format has the capacity for (a) a public platform to promote and market the program, (b) an individual login platform with a series of eLearning modules for training and certification of targeted users, (c) a user group survey platform for monitoring and evaluating ongoing dissemination and implementation efforts, and (d) a secure platform for ordering program materials, supplies, and products. We created the public platform for advertisement and marketing at the individual, district, community, state, national, and international levels using all forms of communication such as social media, face-to-face, email, pamphlets, presentations, and bulletted-talking-point handouts. In addition, space on the public platform was allocated for sharing students' competitively-selected creative and written expressions of what it is like for them to live with asthma. We created the individual login platform to streamline time and effort invested in training and certification of individually-targeted users. For example, school teacher training was streamlined from 12 face-to-face hours to six online hours while retaining important content and allowing for review using a series of four eLearning modules. We created the user group survey platform to respond to participant feedback in real time and to post responses to frequently asked questions. We contracted to use the university's secure payment platform for ordering, downloading, and/or purchasing SHARP materials and products including: (a) curriculum manuals, student workbooks, community handouts, invitation notecards, and certificates, (b) teaching flip charts for the school component and PowerPoint slides for the community component, and (c) peak flow meters, expandable sponges, stethoscopes, spacers, refrigerator magnets, asthma stat cards, mugs, pins, and stickers.

Evaluation: We chose to use a hybrid, blended, type III implementation design. Study participants include the targeted users; specifically program champions, school liaisons, school teachers, and public health educators. We chose not to include students with asthma and members of their social networks enrolled in the SHARP program as participants in this study because no data will be collected directly from students or members of their social networks. Targeted users will report student participation and progress in aggregate format. We evaluated the commencement phase and will continue to evaluate every phase of dissemination and implementation using online surveys. The user group platform sends emails to targeted individuals and/or groups with links to the online system at preset intervals. We selected reliable and valid measures as well as pragmatic open-ended and guided interview items that map to CFIR domains and constructs to assess and address our dissemination and implementation aims. We modified our existing session-specific checklists to evaluate the degree of fidelity in delivery of SHARP's core components. We integrated reliable and valid scales and sub scales used in our previous studies into program training and ongoing monitoring. We partnered with epidemiologists to obtain public data to determine SHARP's impact on two major health outcomes over time: (a) district-wide school absenteeism rates and (b) community-wide healthcare services utilization rates such as emergency room visits. We determined a multiple-group pre-post interrupted time series analysis, where one group consists of districts that receive the SHARP program and a matched control group of districts not receiving the SHARP program would be appropriate. A matching process based on propensity scores was established and power estimates for sample size were based on minimum detectable effect sizes. We are using the aims to guide analyses of quantitative and qualitative data.

Implications: Findings will be used to advance dissemination and implementation science, guide dissemination and implementation of other efficacious and effective school- and community-based health education and counseling programs, uncover further direction for dissemination and implementation

science, and inform health policy related to delivery of asthma self-management programs in schools and community settings.

L 13 - Health Promotion in Asthma Patients

Can an Asthma Self-Management Intervention Improve Quality of Life in Children Who Have Asthma?

Sharon Dee Horner, PhD, RN, USA

Abstract

Purpose: Asthma is a major public health problem in childhood. Frequent symptomatic days requiring urgent management, disturbed sleep, and limitations in daily activities due to asthma contribute to worsening quality of life (QOL) in children who have asthma (Moreira et al., 2013). Asthma is a heavy burden on children who are members of racial/ethnic minority groups (Akinbami et al., 2012). A randomized controlled trial was conducted to test an asthma self-management intervention in comparison to an attention control intervention of general health promotion on school-aged (7-12 years) children's QOL. The aims of this presentation are twofold: (1) To report results of the intervention on children's asthma-related QOL. Hypothesis: Children in the treatment group will report significantly better asthma-related QOL than children in the attention control group. (2) Noting the heavier burden of asthma on members of ethnic/racial minority groups, we will also explore differences in QOL between Hispanic, Black, and non-Hispanic white children.

Methods: Children were randomly assigned to the treatment or comparison group. The intervention was designed to improve children's asthma self-management and included learning activities related to asthma trigger recognition, asthma symptom prevention and treatment, children's problem-solving in common scenarios, self-monitoring and correct use of a metered dose inhaler (Horner & Brown, 2014; Raymond et al., 2012). All intervention and data collection materials were presented in English and Spanish-language versions. Data on QOL were collected from children at baseline and again at 12 months. The intervention was provided after study enrollment. QOL was measured with Juniper's 23-item scale for children with 3 sub-scales (activity limitations, emotional functioning, and asthma symptoms). Higher scores on the QOL scale indicates worse asthma QOL. Repeated measures ANOVA were run to examine changes from baseline to 12 months (Field, 2013). Follow-up ANOVA were run to examine QOL by racial/ethnic group.

Results: Sample: A total of 257 children and their parental caregiver completed the 12-month study (88% retention) and included 163 boys (63.6%), 94 girls (36.4%); of which 58% were Hispanic, 21% were Black, and 19% were non-Hispanic white (white). The children's mean age was 8.82 years (SD=1.2).

Aim1. Examination of baseline demographics (gender, age, race/ethnicity) and QOL scores revealed no significant differences between the treatment groups. After the intervention, when compared to the attention-control group, QOL was significantly improved in the treatment group: QOL total score, $F=7.53$, $p=.007$; QOL emotional functioning, $F=4.05$, $p=.02$; and QOL asthma symptoms, $F=3.28$, $p=.04$. In terms of activity limitations due to asthma, there were no between treatment group differences – both groups had fewer days with limited activity.

Aim 2. When comparing racial/ethnic groups, additional information is revealed. There were significant differences at baseline in children's QOL: QOL total score, $F=7.05$, $p=.001$; QOL activity limitations, $F=5.89$, $p=.003$; QOL emotional functioning, $F=3.46$, $p=.03$; and QOL asthma symptoms, $F=8.21$, $p<.001$. Black children reported significantly worse QOL than the other two ethnic/racial groups. The children's QOL improved after the intervention, but there continued to be significant differences between racial/ethnic groups 12 months later: QOL total score, $F=3.62$, $p=.03$; QOL activity limitations, $F=3.18$, $p=.04$; QOL asthma symptoms, $F=4.52$, $p=.01$. Whereas, QOL emotional functioning, $F=2.25$, $p=.11$ was not significantly different.

When reviewing the descriptive findings (means & SD) for children's total QOL scores at baseline: 62.30 (SD=19.28) for Blacks, 52.34 (SD=18.96) for Hispanics, and 48.86 for whites we find that Black children had worse total QOL than did Hispanic children, who in their turn had worse QOL than did the non-Hispanic white children. However, the total QOL scores 12-months later were: 48.56 (SD=16.91) for

Blacks, 46.66 (SD=18.83) for Hispanics, and 39.86 (SD=15.18) for whites. The 12-month data shows improvements in their total QOL scores, but the between racial/ethnic group differences remained.

Conclusion: In terms of whether the intervention improved QOL in children with asthma, the hypothesis was supported. The treatment group had significantly better improvements in their QOL than did the comparison group. QOL is a patient-centered indicator of well-being and health. The intervention, which focused on symptom recognition, self-monitoring, problem-solving, and skill development, was an effective way to improve QOL in children with asthma. It is important to note that the treatment and comparison group were composed of equivalent groups in terms of gender and race/ethnicity. The further examination of QOL by racial/ethnic group did reveal significant differences in QOL for children who are members of racial/ethnic minority groups. Nevertheless, their scores also improved after the intervention. While this is a positive finding, the continued differences in QOL reported by children who are ethnic/racial minority group members should be noted. The secondary aim highlights the need for continued work to look carefully at ways to improve asthma self-management and thereby improve the QOL of children who have asthma (Sweet et al., 2014). Interventions may require tailoring to address specific issues of concern to parents and children with asthma who are members of racial/ethnic groups.

Use of Spirometry to Measure Asthma Control in Patients With Sickle Cell Disease

Laurie Duckworth, PhD, ARNP, USA
Gloria Lipori, MBA, USA
Jeanette Green, PhD, PNP-BC, USA
Jeffrey Klann, PhD, USA
Shaun Grannis, MD, USA

Abstract

Purpose: Purpose: The purpose of this study is to determine the use of spirometry testing to monitor and evaluate asthma control in patients with asthma, sickle cell disease and acute chest syndrome, ages 5 to 34 years.

Sickle Cell Disease (SCD) is a common inherited genetic disorder and affects approximately 100,000 people in the United States annually and one in 400 African American births (CDC,2016). Asthma affects 23 million people in the US alone. African American children are disproportionately affected having a greater prevalence rate for asthma compared to Caucasians, in addition to a higher rate of hospitalization and higher mortality rate. SCD, when combined with a diagnosis of asthma, increases the risk of Acute Chest Syndrome (ACS), which can lead to significant morbidity and mortality. Findings from The National Heart Lung and Blood Institute (NHLBI) funded Sickle Asthma Cohort (SAC) study confirm that asthma is a risk factor for ACS in patients with SCD and that one early life ACS episode was a significant predictor for future ACS events (DeBaun et al., 2014). It has been reported that as many as 28% of children with SCD may have asthma (Strunk et al., 2014). While there seems to be increasing recognition of the importance of co-morbid asthma and SCD, asthma continues to be underdiagnosed and undertreated (DeBaun, Strunk, 2016). NHLBI Guidelines for the Diagnosis and Management of Asthma should be followed for patients with SCD and asthma (EPR 3, 2007). This would include routine follow up by a pulmonology provider to ensure proper management of asthma. Part of this routine care would include Spirometry testing to evaluate effectiveness of asthma medications and subtle changes in pulmonary function. Early detection of a decrease in pulmonary function may lead to changes in management, which may decrease the incidence of an asthma exacerbation and possibly prevent an occurrence of ACS. The number of spirometry procedures conducted may be indicative of how many patients with Asthma and SCD are receiving routine pulmonology management. Data gleaned from the EMR database may show that although a significant number of patients with SCD and ACS carry the diagnosis of asthma, very few have spirometry testing to evaluate the effectiveness of asthma treatment or to provide early detection of worsening lung function.

Methods: A descriptive cross-sectional study design was utilized to identify the number of patients with SCD, ACS, Asthma and the number of spirometry procedures performed. The Electronic Medical Record (EMR) using i2b2, (a de-identified data repository) for 4 Academic Medical Centers (AMC) was queried for the count of patients 5-34 years of age seen between 12/01/2010 and 12/01/2015 having co-morbid diagnoses of Asthma, Sickle Cell Disease and Acute Chest Syndrome. Queries to cross-reference those patients with the CPT code for spirometry was then performed. The i2b2 query included; (1) Number of patients with SCD + ACS + Asthma + Spirometry, (2) Number of patients with SCD, (3) Number of patients with SCD + Asthma, (4) Number of patients with SCD + ACS, and (5) Number of patients with SCD + ACS + Asthma. The percentage of SCD + ACS+ Asthma patients having spirometry testing was calculated by dividing SCD + ACS + Asthma +Spirometry by the number of patients with SCD + ACS+ Asthma. The four AMC's were labeled as A, B, C, D.

Results: The combined total number of patients for 4 AMC (A,B,C,D) for categories (1) SCD+ACS+Asthma+Spirometry,(2) SCD,(3) SCD+Asthma, (4) SCD+ACS, (5) SCD+ACS+Asthma are respectively; (1)77, (2)2749, (3) 577, (4) 409, and (5) 249. Number of patients for each AMC for these five categories; (1) Number of patients with SCD + ACS + Asthma + Spirometry, A =<10, B= 18, C= 52, D=<10. (2) Number of patients with SCD, A=428, B=378, C=1202, D=741. (3) Number of patients with

SCD+Asthma, A=79 (18.4%), B=57 (15.0%), C=377 (31.3%), D=64 (8.6%). (4) Number of patients with SCD+ACS, A=72 (16.8%), (B) =78 (20.6%), C=142 (11.8%), D=117 (15.7%). (5) SCD+ACS+Asthma, A=37 (8.6%), B=43 (11.4%), C=146 (12.1%), D=23(3.1%). The percent of patients with SCD+ACS+Asthma who also had spirometry performed for each AMC was calculated (SCD+ACS+Asthma+Spiro/SCD+ACS+Asthma = %); A=<10%, B=41.8%, C=35.6%, D=26%. The total number of patients with SCD+ACS+Asthma for all 4 AMC= 249, those having spirometry = 77, thus (77/249) 30.9% of patients with SCD+ACS+Asthma had spirometry performed.

Conclusion: Asthma is prevalent in children with SCD and may result in episodes of ACS. Across 4 AMC only 30.9% of patients with SCD, ACS, and asthma received spirometry testing. In addition there is considerable variation among the 4 AMC ranging from <10% to 41.8% receiving spirometry. Despite the NHLBI recommendations for children with asthma it appears that only a third of these patients with co-morbid SCD, ACS, and Asthma receive this procedure. Very few are being routinely tested for changes in pulmonary function, or those tests are not being coded and documented appropriately. Better coding and documentation practices for spirometry testing in those with sickle cell disease and asthma will allow better access for providers to utilize those test results for asthma management. If the testing is not being done routinely, further research should be done to determine if there are barriers to obtaining appropriate pulmonology evaluation and management.

"You're Not Alone": The Power of Peer Mentoring for Pregnant Women With Substance Use Disorder

Mary T. Paterno, PhD, CNM, RN, USA

Abstract

Purpose: Substance use disorder (SUD) accounts for an estimated 10.9% of mental health disease burden globally¹. In the United States, SUD is increasing nationwide², particularly in rural areas³, and more than 11% of women of reproductive age and 5% of pregnant women use illicit drugs². For many women, pregnancy is a time of hope and an opportunity to address substance use^{4,5}. Increasing social support is important to the recovery process for pregnant and postpartum women with SUD, particularly through connection with other women in similar situations⁶. Programs that provide social and community support, integrated with clinical care for pregnant women with SUD, are recommended^{4,7}. Peer mentoring models have been demonstrated to be effective in promoting SUD recovery among veterans⁸ but little is known about the effect of peer mentoring for pregnant substance users. This is relevant as substance use during pregnancy has significant maternal and neonatal health consequences⁹ and pregnant women with SUD may fear potential legal consequences, including the loss of parental rights¹⁰. Understanding the value of peer mentoring from the insider perspective of women in recovery who are peer mentors with lived experience of SUD in pregnancy is important in order to develop effective programs to support pregnant women with SUD. Therefore, the purpose of this study was to describe from the perspective of women in recovery with lived experience of substance use in pregnancy, (1) the experience of mentoring currently pregnant women with substance use disorder, and (2) what it means to be in recovery, in order to discover opportunities for nurse-led interventions that could bridge community support and clinical care in a way that will promote recovery from substance use and lead to positive family building.

Methods: Design: Ethnographic, community-based participatory study using narrative inquiry

Participants: Five women with lived experience of SUD in pregnancy who are in recovery and serve as peer mentors for currently pregnant women with active SUD

Setting: A rural community in Massachusetts, United States

Data collection: Peer mentors took part in a 3-day collaborative digital storytelling workshop¹¹, in which each participant wrote and produced a three-minute digital story telling her personal story of peer mentoring, in her own words. Each participant also took part in a follow-up, in-depth, individual interview approximately one month after the workshop. The researchers wrote field notes in and around the digital storytelling workshop and the individual interviews, to document contextual (etic) details. Key workshop activities and the follow-up interviews were audio-recorded to capture emic, or insider, viewpoints.

Analytic approach: At the end of the digital storytelling workshop, the five digital stories were screened and discussed by the group, serving as a first level of analysis. The authors then conducted additional content analysis of the stories and interviews, focusing on findings in the emic data (i.e. transcripts of audio-recordings of digital storytelling activities and follow-up interviews) related to the experience of peer mentoring and what it means to be in recovery from substance use.

Results: Women in the study described the hopelessness and loss they experienced related to addiction, the path to recovery, the meaning of being in recovery, and the ways in which peer mentoring supports each of these phases. Realizing that as women and mothers they were not alone in their struggle with addiction, and seeing other women in recovery, motivated their own recovery and their drive to provide continued peer mentorship to others. The work of achieving recovery was an "inside job", strengthened by social and community support. As women in recovery, they viewed themselves as contributing to the development of hope for women with active addiction. Peer mentoring became an all-

encompassing job, one that not only supported their mentees, but also bolstered the continued recovery of the mentors themselves.

Conclusion: Peer mentoring may be a powerful tool for providing social and community support to pregnant women with SUD in rural settings. Further work is needed to understand the benefit of peer mentoring for women with SUD in other settings in the United States and globally in order to promote health and recovery from SUD. Nurses are in a unique position to link such community level support with existing clinical care programs in order to maximize the health of pregnant women and their neonates who are affected by substance use disorder.

Perinatal Nurse Home Visiting and Rates of Diabetes and Hypertension Among Child-Bearing Mothers

Amy McKeever, PhD, RN, CRNP, WHNP-BC, USA

Joan Rosen Bloch, PhD, MSN, BSN, CRNP, USA

Susan Zupan, MS, RN, USA

Jennifer Barkin, PhD, MS, USA

Abstract

Purpose: Increased rates of maternal mortality in the United States and prevalence rates of diabetes and hypertension especially among women who live in socioeconomically disadvantaged communities, underscore the importance of perinatal nurse home visiting tailored to pregnant women with hypertension and diabetes. Concurrently, an increasing number of maternal and child health (MCH) home visiting services have emerged nationally and internationally as a key strategy to improve population-level health among socioeconomically disadvantaged mothers and their families. Three years of life are crucial in determining an infant's life course, the Affordable Care Act of 2010 allocated increased funding for MCH home visiting services. In addition, the national Maternal, Infant and Early Childhood Home Visiting (MIECHV) program, through the Maternal and Child Health Bureau of the Health Resources and Services Administration (HRSA), provides funding for evidence-based home visiting programs in communities with high rates of infant morbidity and mortality, often in low-income areas with diverse ethnic and racial marginalized minority populations. Specifically, public health MCH models of home visiting that are well studied and that provide programs that focus on reduction of psychosocial risk (e.g., Nurse-Family Partnership, Healthy Beginnings, Healthy Families America; Hayes et al., 2014; Issel, Forrestal, Slaughter, Wiencrot, & Handler, 2011; Olds et al., 2014; Wen et al., 2015) are now eligible for increased funding through the Affordable Care Act. They are listed on MIECHV's Web site (HRSA, 2016). However, the evidence-based transitional care model (TCM) of perinatal home visiting that was developed decades ago by Brooten and colleagues (Brooten, Brooks, Madigan, & Youngblut, 1998; Brooten et al., 2001; Brooten et al., 2007; Brooten et al., 2012) for pregnant women with medical complications is absent from MIECHV's list of eligible programs.

Before the publication of the randomized clinical trial by Brooten et al. (2001), the standard of care for many high-risk pregnant women with diabetes and hypertension was hospitalization. In their seminal work, these researchers implemented in-home nurse interventions for high-risk women with pregnancy-related complications that entailed careful monitoring with tailored nursing interventions that incorporated teaching, guidance, counseling, and activating appropriate referrals for transdisciplinary clinical and community resources (Brooten et al., 2002; Brooten et al., 2007; Brooten et al., 2012). The frequent, long antenatal hospitalizations for pregnant women with hypertension and diabetes no longer exists as a result of these researchers' findings, which changed practice and showed that perinatal nurse home visiting was cost effective (Brooten et al., 2001). However, little is known about the use, processes, and outcomes of perinatal nurse home visiting services that evolved from the original TCM.

Various models of home visiting programs exist to improve maternal child health (MCH) outcomes. In the context of rising maternal mortality rates, an evidence-based translational care model (TCM) of perinatal nurse home visiting tailored for pregnant women with hypertension and diabetes warrants attention. To study access to TCM perinatal nurse home visiting services for medically high-risk pregnant women, we examine referral patterns among this urban population of pregnant women referred for this model of care because of their diagnosis of diabetes and/or hypertension.

Methods: Secondary analyses were conducted to study referral patterns to home visiting and prevalence rates of diabetes and hypertension among childbearing mothers in Philadelphia. During 2012, 595 pregnant women with diabetes and/or hypertension were referred to perinatal nurse home visiting services.

Results: Factors influencing a larger dosage for services included the diagnosis of diabetes, gestational age at the time of referral and having public (Medicaid) insurance ($p < 0.05$). On average, 23,000 women give birth yearly in Philadelphia. The prevalence rate for diabetes was 4.2% with the Asian population having the highest prevalence of 7.8%. The prevalence rate of hypertension was 9.4% with the Black population having the highest prevalence of 12.7%.

Conclusion: The transitional model of perinatal nurse visiting tailored for women with hypertension and diabetes exists. Surprisingly underrepresented in the larger discourse of MCH programs, further research of this model of care is for this medically high-risk childbearing population is needed. Opportunities for innovation in health promotion and prevention interventions among this medically high risk childbearing populations have promise in changing life course trajectories of chronic illness.

Longitudinal Evaluation of a Prenatal Mentoring Program for Decreasing Maternal Anxiety in a Military Sample

Karen L. Weis, PhD, RNC-OB, FAAN, USA

Regina P. Lederman, PhD, MA, RN, FAAN, USA

Katherine C. Walker, MSN, RN, USA

Wenyaw Chan, PhD, MS, USA

Abstract

Purpose: A relationship exists between prenatal maternal anxiety to pregnancy complications, poor birth outcomes and infant/childhood cognitive delays.¹⁻³ Traditionally, high-risk groups of young, unmarried, undereducated primigravidas have been the focus of prenatal assessment and interventions.⁴ Less understood is anxiety in differing samples. The aim of this project was to assess the efficacy of the Mentors Offering Maternal Support (M-O-M-S™) program for decreasing prenatal maternal anxiety in a military sample.

Methods: Two hundred and forty-six military women were consented and randomized to either the M-O-M-S™ intervention or prenatal care without M-O-M-S.™ The PSEQ-SF, EPDS, RSES and BRIEF were administered in each trimester. Women in the intervention attended 8, 1-hr mentored sessions aimed at decreasing prenatal pregnancy-specific anxiety and depression. The efficacy of the intervention across pregnancy was examined for prenatal anxiety, self-esteem, depression and resilience using linear mixed models with autoregressive correlation. Demographic covariates were: age, employment, parity, marital status, education, deployment history, military branch, race, and active duty status.

Results: M-O-M-S™ participants had significantly greater decreases in prenatal anxiety related to *Identification with a Motherhood Role* ($p = .049$) and *Preparation for Labor* ($p = .017$). Nulliparous women had significantly lower anxiety related to *Acceptance of Pregnancy* ($\beta = 1.32$; $se = 0.56$) but five times the anxiety for *Preparation of Labor* ($\beta = -5.01$; $se = 0.51$). Women with deployed husbands had significantly greater anxiety for *Identification of a Motherhood Role* ($\beta = 1.04$; $se = 0.50$). All participants had significantly greater increases in resilience ($\beta = 0.04$; $se = 0.02$). There were no significant findings for depression.

Conclusion: The findings reflected significant decreases in prenatal anxiety for women who received the M-O-M-S™ program. The impact of the father's absence on a women's identification as a mother is extremely important. Military leaders recognize that the well-being of the military family is integral to the morale and readiness of service members.⁵ The findings provide evidence of the effectiveness of a mentored support program for decreasing pregnancy-specific prenatal anxiety predictive of preterm birth and low birthweight in military women. The findings also highlight the need for appropriate assessments and interventions for differing populations.

L 16 - Transitioning From Military to Civilian Nurse

Personal and Professional Transition From Military to Civilian Nursing Practice

Brenda Elliott, PhD, RN, USA

Katie A. Chargualaf, PhD, RN, CMSRN, USA

Barbara J. Patterson, PhD, RN, ANEF, USA

Abstract

Purpose: The purpose of this presentation is to discuss the military nurse officer's transition from nursing practice in a military setting to a civilian setting.

Methods: Naturalistic inquiry paradigm, qualitative description was used to guide this study. The investigators interviewed 10 nurse Veterans from the United States who served a minimum of four years active duty and at least one year in a civilian clinical nursing role, after separation from active duty status. Semi-structured interviews started with an open-ended question asking participants to describe their transition from military nursing to civilian nursing practice. They were also asked to identify any challenges or facilitators to the process. Clarifying and probing questions were used to gain an understanding of the transition. Data analysis occurred simultaneously with data collection and inductive coding to identify patterns was used during data analysis. Data were collected until saturation was reached.

Results: Results suggest that nurses leaving military nursing practice and entering civilian nursing practice progress through four major phase: *Separating from Military Life, Conflict and Chaos, Shifting Sands, and Personal and Professional Reconstruction*. Findings also suggest that these nurses go through two transitions simultaneously. One is in their professional role and one in their personal identity, which can complicate progress through each phase. With the passage of time, nurse Veterans do undergo a transition to a new identity and professional practice, but aspects of the military culture will always remain a part of who they are. Particularly challenging to the transition was the perception that the skills and leadership experiences garnered from their military service did not translate to civilian practice and a temporary state of chaos, resulting from feelings of grief associated with a loss of the military "lifestyle," often occurs. Exit counseling, anticipatory support resources, and confiding in family or other Veterans were identified as facilitators of transition.

Conclusion: Globally, military nurses bring significant value from their military experiences to the civilian sector. However, their transition could potentially take longer due to challenges in the civilian healthcare context and differences between military and civilian cultures. Healthcare organizations need to examine strategies to help assist these nurses throughout the transition process. Having some understanding of the challenges these nurses may face, potential issues that could surface, and ways to utilize their strengths may aid in a smoother transition as well as promote personal and professional growth.

L 16 - Transitioning From Military to Civilian Nurse

Understanding the Experiences of Veterans Enrolled in Prelicensure Nursing Programs in the United States

Teresa Shellenbarger, PhD, RN, CNE, ANEF, USA
Julie L. Decker, DNP, RN, USA

Abstract

Purpose: Following military discharge many veterans return to colleges and universities for further education (Allen, Armstrong, Saladiner, Hamilton, & Conrad, 2014; Ness, Rocke, Harrist, & Vroman, 2014). With financial benefits for veterans and job opportunities available for graduates, the number of veterans enrolling in higher education in the United States continues to remain strong (Cate, 2014). However, little information is available to assist educators to meet the unique needs that veterans returning to school may have (Graf, Ysasi, & Marini, 2015; Jones, 2013; Naphan & Elliott, 2015). Therefore, nursing faculty are challenged to assist these students as they transition to professional nursing roles with little empirical data to guide their work. Given the paucity of research available, a hermeneutic phenomenological study was conducted to fully understand the experiences of veterans enrolled in prelicensure nursing programs in the United States.

Methods: A purposive sample of nine students enrolled in associate and baccalaureate degree nursing programs was recruited through professional colleagues and personal networking/referrals using purposive sampling. After explaining the study, a member of the research team obtained informed consent. Informants then participated in audiotaped interviews which were then transcribed verbatim. A 5-step process guided data analysis. To ensure data quality peer debriefing, data triangulation, and member checking was used to validate the themes.

Results: Findings emerging from the interviews with veteran nursing students revealed four themes. Informants described maneuvering through the mental mind shift, battling conflicting forces, avoiding landmines, and accepting support. Students described feeling lost and adrift as they transitioned from structured military life with their comrade community to the isolated foreign much more fluid landscape of higher education with different rules and norms. Informants described needing to reset their compass as they navigated through this unfamiliar territory. As they return to school the veteran nursing students encountered disparities with classmates and battled generational and professional differences. Additional battles emerge as the student veteran confronted financial, academic, psychological, and personal struggles. These students needed to learn to avoid potential landmines that could adversely affect their educational experience. In spite of encountering multiple obstacles, supportive faculty, diverse teaching and learning methods, and open communication with others provided the needed support that helped the student survive the educational experience.

Conclusion: Based upon these findings, recommendations for faculty and campus communities to support these students are suggested. Nursing faculty need to employ watchfulness, use appropriate communication, make referrals, and customize interventions based on specific needs of the veteran. These findings provide useful guidance in the development of evidence-based approaches that can be implemented to allow veterans to successfully navigate the higher education environment and emerge as professional nurses.

L 16 - Transitioning From Military to Civilian Nurse

The Reintegration Experience of Nurses Who Served in the Iraq and Afghanistan Wars

Mary Ellen Doherty, PhD, RN, CNM, USA
Elizabeth Scannell-Desch, PhD, RN, OCNS, USA

Abstract

Purpose: The purpose of this study was to describe the reintegration experience of U.S. military nurses after wartime deployment to the Iraq and Afghanistan wars.

Methods: A qualitative phenomenological study was conducted to describe the reintegration experience of nurses who served in the Army, Navy, or Air Force during the war years 2003-2013. The sample included Active Duty, National Guard, and Reserve nurses. A purposive sample was drawn from two Veteran organizations and one professional nursing organization. Participation criteria included that the respondents be registered nurses who were able to read, write, speak and understand English and be a current or former U.S. military nurse who served in Iraq or Afghanistan. This method seeks to describe human experience from the perspective of those who have lived the phenomenon of interest and the meaning it holds for them. Once the sampling criteria was met, nurses were mailed informational letters explaining the study. After confirmation of interest, an email was sent to schedule an interview. Data were collected by unstructured interviews, which took place over four months in late 2013. Twenty-three interviews were face-to-face and twelve were conducted via speaker phone because of geographical distance. Informed consent was obtained prior to each interview. Interviews lasted 45 to 90 minutes. Study participants were asked the following research question: "What can you tell me about your reintegration experience?" Additional questions were asked as necessary to clarify or expand what was divulged. Participants were told that they may become uncomfortable with probing questions that could trigger upsetting memories. Although the plan was to provide contact with a mental health practitioner who agreed to provide counseling if needed, no participants needed to be referred. Field notes were taken during the interviews to document emotional reactions, such as crying or laughing, as well as body language such as folding arms or lack of eye contact. The interviews were audio-recorded and transcribed verbatim. Two months later, respondents were sent a copy of their interview transcript to validate content, provide feedback, and check accuracy. Colaizzi's (1978) method for analyzing phenomenological data was employed to guide the discovery of themes embedded in the reintegration experience. Data analysis involved coding, extracting significant statements, and forming theme clusters. Findings were integrated into an exhaustive description of the reintegration experience. The trustworthiness criteria of Lincoln and Guba (1985) was adhered to and rigor was ensured by attending to credibility, confirmability, dependability, and transferability. A limitation of the study may be that the nurses were recruited from veterans and professional nursing organizations and that they may not be representative of all military nurses deployed to Iraq and Afghanistan.

Results: Nine themes emerged from data analysis: 1) homecoming; 2) renegotiating roles; 3) painful memories of trauma; 4) getting help; 5) needing a clinical change of scenery; 6) petty complaints and trivial whining; 7) military unit or civilian job: support versus lack of support; 8) family and social networks: support versus lack of support; and 9) reintegration: a new normal. Participants ranged in age from 25 to 57 years of age with a mean age of 37 years. Most had been home for three years since their last deployment. One half of the participants were married with children while deployed. Thirty-two participants were women and three were men.

Conclusion: The nurses' descriptions of their reintegration experience are similar to those of combat warriors. Their thoughts, feelings, emotions, and stories emanate from their experiences in providing care to military personnel, government contractors, insurgents, local nationals, and children in the war zones of Iraq and Afghanistan. The nurses struggled with reintegration on many levels and with different factions, including family, friends, co-workers, and their communities. Some nurses received support, encouragement, and appreciation from family and social networks, their workplace, and their community. Others experienced a lack of support without thanks or acknowledgement for their service or

recognition that they might be returning mentally and physically exhausted. Their voices were asking for better treatment, patience, understanding, support, and caring. Recommendations for future research include identifying educational and supportive interventions that elevate the current reintegration offerings put forth by the military to a higher level. It appears that the most advantageous and beneficial way to do this is to ask returning nurses for their input. Nursing leaders and therapists need to avail themselves of the latest psychological and therapeutic advances to facilitate healing. The current study fills a gap in the literature by exploring how nurses returning from war transition back into their lives with family, social networks, workplace environment, and community. The nurses shared details of their personal and professional lives and identified conflicts and issues that were sources of frustration, sadness, and stress. They articulated their disappointments and told how individuals and their military leadership could have made a difference. It is important for the American people, as well as those from other countries, to listen to the voices of nurses as they attempt to reintegrate and adapt to a new normal. With nurses being at the forefront of healthcare, it is imperative to hear what they have to say about getting back into their lives and what was helpful and what was not. Their stories provide a lens for others to view the reintegration process. Future research needs to build on this study and further develop interventions to address the reintegration process to ensure optimal functioning for returning nurses both personally and professionally.

M 04 - Cultural Education Initiatives

A Global Approach to Promoting EBP Knowledge: Validating the Translated Version of EKAN Into Spanish

Jan M. Nick, PhD, RN, RNC-OB, CNE, ANEF, USA

Amy Hagedorn Wonder, PhD, RN, USA

Alfa Rigel Suero, MD, BS, Dominican Republic

Darrell Spurlock, PhD, RN, NEA-BC, ANEF, USA

Abstract

Purpose: This study is part of a multi-site research project aimed at documenting the evidence-based practice (EBP) knowledge of nursing students on a global scale. Although the benefits of EBP are widely known, EBP is still not consistently implemented across care settings. A variety of subjective instruments are used in countries to gauge what nursing students know about EBP. The documented lack of correlation between subjective and objective knowledge measures (Zell & Krizan, 2014) coupled with a lack of consistent instrumentation to enable generalizability of findings are two factors that inhibit a global approach toward promoting EBP and collaboratively advancing the science of nursing. The availability of a common, standards-based objective EBP knowledge measure would: a) enable a universal assessment of the state of EBP knowledge in nursing students and nurses, and b) facilitate a collaborative approach toward developing and testing educational strategies across levels of nursing education and practice around the world. The Evidence-based Practice Knowledge Assessment in Nursing (EKAN) instrument was selected for use due to its objective approach to knowledge measurement and solid psychometric properties.

The purposes of this research were to: a) translate the EKAN instrument into Spanish and conduct a validation study in the Dominican Republic, a geographic area that expressed interest in integrating EBP in their nursing curriculum, and b) supply a baseline knowledge assessment for the program to gauge the success of their curriculum enhancement. A secondary purpose included strengthening programs of research at the site institution through a collaborative relationship.

Methods: Using a cross-sectional, descriptive, correlational design, 139 actively enrolled baccalaureate nursing students from a program in Dominican Republic volunteered to participate in the study. Subjects were invited via posters, verbal announcements, and email communication. They were asked to take the EKAN exam, translated into Spanish.

The EKAN is a 20-item multiple-choice objective measure of EBP knowledge with an established item reliability of .98 and strong evidence of validity with infit statistics centering on 1.0, when tested with a similar population in the United States (Spurlock & Wonder, 2015). Using Brislin's (1970) traditional translation method, the EKAN was translated into Spanish by three individuals, then back to English by two additional translators who had not previously seen the original English version. The back-translation was then compared with the original instrument for content, semantic, technical, and conceptual equivalence (Squires et al., 2012) while maintaining focus on cultural and linguistic considerations for the geographic area of study (Palmieri, 2014). A 7-item demographic questionnaire, developed for use with the EKAN, was also incorporated to describe the sample characteristics. Subjects were also asked to self-rate their confidence in delivering evidence-based care using a 5-point Likert-type scale.

The investigators obtained IRB approval from the home institution of the PI and the host institution in Dominican Republic. Subjects completed the Demographic Questionnaire and EKAN-Spanish in paper/pencil format during a proctored data collection session. Most subjects completed the study forms within 35 minutes. Data were later entered into SPSS v.24 for analysis. Additionally, jMetrik (Meyer, 2014) was used to conduct 1-parameter item response theory (IRT) Rasch analysis of the EKAN responses.

Results: After excluding responses from subjects with more than one missing response to EKAN items (because the EKAN is a sum-scored instrument), complete data were available from $N = 123$ subjects.

Subjects were 93.5% female with an average age of 29.6 ($SD = 7.8$) years. The majority (92.7%) of subjects reported the Dominican Republic as their country of origin with 5.7% reporting Haiti and 1.6% reporting another country. Sixty-six percent of subjects were seniors, and reported being in their eighth or ninth term of enrollment in the nursing program (with a range of five to ten terms). A large majority (83.6%) of subjects reporting having already completed a statistics course with 7.4% reporting current enrollment and 9.0% reporting not having yet taken a statistics course. Most (65.5%) subjects reported having completed a special EBP workshop of 1-2 days in length, while 23% reported having completed no special EBP courses.

Using Rasch model analytics, validity indices of the EKAN produced a difficulty index ranging from $\Theta = -1.78$ to 2.22. Mean infit and outfit statistics narrowly centered on 1.0 (WMS $M = .978$; UMS $M = .988$) indicating strong evidence of trait unidimensionality. For reliability indices, separation index values of > 2.0 is a desirable goal. The EKAN-Spanish item separation was robust at 4.27 but person separation was somewhat limited at .38. Item reliability was .94 and person reliability was .13, indicating trait (EBP knowledge) restriction among the study sample. These results compare similarly to the English version of EKAN. Additionally, differential item functioning (DIF) analysis produced no evidence of language-related concern on any of the EKAN's 20 items, supporting translational accuracy.

For baseline knowledge assessment, the mean EKAN EBP knowledge score for the group was 6.52 ($SD = 2.03$) out of 20 possible points, with scores ranging from 2-12 points. No statistically significant differences in mean EKAN scores were found when comparing subjects by level of completion of the nursing program ($F = 1.81$, $df = 5, 117$, $p = .117$) or whether subjects had completed a special EBP course or not ($F = .302$, $df = 4, 117$, $p = .876$). Current enrollment in a statistics course however was associated with higher scores on the EKAN when compared to subjects having not yet taken or having previously taken the course ($F = 4.51$, $df = 2, 119$, $p = .013$).

While subjects' self-rated competence to deliver evidence-based care on a scale from 1 = strongly disagree to 5 = strongly agree was quite high ($M = 4.16$, $SD = .80$), the correlation between self-reported confidence and objectively measured EBP knowledge was small, negative, and statistically nonsignificant ($r = -.041$, $p = .654$).

Conclusion: This is a first step in using a unified, standards-based approach to EBP assessment, and the results indicate the ability to use the EKAN instrument in populations outside the U.S. The findings from this study align with those reported previously (Spurlock & Wonder, 2015), with evidence reported here of a slightly lower and narrower EBP knowledge trait range among the study sample. The EKAN-Spanish translation produced good validity and reliability parameters under the Rasch model. This study provides baseline EBP knowledge level information useful for future score norming and educational intervention research among Spanish-speaking populations like those in the Dominican Republic. Also congruent with findings from an increasing number of studies, subjects' self-evaluations of EBP confidence were not related to objectively measured EBP knowledge.

Future translation and validation studies are currently planned for Japan, Korea, Colombia, and Brazil within the next year. Once psychometric properties are demonstrated for each country, nurse scientists can use the EKAN to describe student knowledge across different levels of preparation (AS, BS, MS, Doctoral), or differentiate knowledge within a particular level (i.e., year 1, year 2), thereby providing evidence for curricular decisions or gauge effectiveness of EBP training. In addition, EKAN translations can also be tested in practice settings and provide clinical leaders information on the knowledge base of nurses practicing in their institutions.

Because education is commonly acknowledged as a barrier to the implementation of evidence-based care, it is essential for academic faculty and clinical leaders to accurately evaluate EBP knowledge. Enabling use of the EKAN in non-English language countries will provide nurse leaders the ability to expand EBP knowledge through accurate and systematic measurement in educational and clinical environments.

The collaborative research relationship between countries has provided a validated instrument in Spanish, baseline knowledge of EBP in junior and senior nursing students, a system for annual assessment for nursing knowledge, and a research trajectory for faculty at the host institution. The validation of EKAN into Spanish now has the ability to transform EBP assessment in over 21 Spanish speaking countries.

Influencing Global Health Through Cultural Nursing Education Assignments: Results of a Mixed-Methods Study

Amanda L. Veearsart, PhD, RN, CNE, USA

Abstract

Purpose: To report the results of a research study regarding changes in cultural awareness levels among prelicensure nursing students after completion of a culturally based clinical assignment.

Methods: The Voice Project was a culturally based assignment (CBA) designed to teach nursing students how to provide culturally competent nursing care. The study utilized a mixed methods retrospective, descriptive research design to evaluate the data. For the purpose of the research project, self-reported levels of cultural awareness among senior nursing students before and after the completion of the Voice Project was evaluated. A convenience sample of 252 students was evaluated, divided into two cohorts (A and B). A quantitative data analysis was completed with a Pearson correlation, coefficient of determination, a paired *t*-test and Cohen's *d* for each subscale on the survey. For the qualitative data, narrative inquiry was used to examine students' reflections on the impact of the CBA. The qualitative data were used to report the impact of the completion of the CBA on student's cultural awareness.

Results: The analysis showed a significant impact to the student's cultural awareness levels after completing the culturally based assignment. Student reflections revealed themes such as emotional connections or unexpected biases when caring for diverse patients. Using a mixed methods approach, the data revealed significant differences in 3 of the 4 subscales and a significant difference between Cohort A and B on 1 subscale after completion of the Voice Project. The results were supported by the prior literature review connecting cultural education to changes in cultural awareness levels (Campinha-Bacote, 2011).

Conclusion: Nursing education should take steps to ensure that cultural education is present in the nursing curricula. The profession of nursing as a practice is committed to providing individualized care with attention to the patient's dignity, and uniqueness (Wang, Liu, & Wang, 2015). Nursing professionals are considered the most trusted profession across many nations. Providing educational opportunities, such as the Voice Project, improves cultural competent care and is the first step in continuing this trustworthiness. The lack of cultural education means nursing programs are graduating nurses who are not prepared to care for a culturally diverse population. The results of the study aligned with current literature reviews showing baccalaureate of science in nursing (BSN) students reported feelings of unpreparedness or discomfort when caring for culturally diverse populations (Rew, et. al, 2015; Reyes, Hadley, & Davenport, 2013). Therefore, cultural based assignments, similar to the one used in the current study, should be included throughout nursing education programs.

M 06 - Genetic Health

An Innovative Approach to Teaching Genetics to Graduate Nursing Students Using Interprofessional Teaching Modalities

Dorothy S. Lee, PhD, RN, ANP-BC, FNP-BC, CME, USA
Sharon K. Panepucci, MSN, RNC-OB, CHSE, CLC, USA

Abstract

Purpose: To present an innovative approach to teaching genetics to graduate nursing students using interprofessional teaching modalities.

The Masters' Essentials (2011) mandate the integration of genetic and genomic evidence into the graduate nursing curriculum for use in advanced nursing practice. Faculty strive to answer the question: How can we incorporate current and emerging genetic/genomic evidence into the Masters' Curriculum to promulgate the provision of advanced nursing care to individuals, families and communities utilizing a meaningful, interactive, and motivating approach?

Since the first draft sequences of the human genome (International Human Genome Sequencing Consortium, 2001) the study of human genetics has developed exponentially. Patient's genomic information is currently being used in their clinical care by multiple institutions. Therefore, how can faculty ensure that graduate nursing clinicians have the necessary genetic knowledge to apply genetics/genomics in a clinical setting?

Methods: An active teaching strategy that fosters critical thinking in students is simulation; yet the use of simulation in graduate nursing education is limited. The design and implementation of interprofessional simulations was used to increase confidence, critical thinking and clinical decision making in graduate nursing students. The simulations embodied the presentation, assessment, diagnostics, and intraprofessional outreach needed to arrive at and deliver the diagnosis to the family in an emotionally and educationally supportive manner. The scenario for this strategy focused on the diagnosis of Down's Syndrome.

In addition, concept mapping and reflective thinking were found to be effective strategies to guide students in expressing the meaning of the material and identifying strengths and weaknesses in their thought processes. Both of these strategies were utilized to measure the integration of genetic/genomic knowledge at the clinical and personal level. These complex concept maps encompassed all aspects of the diagnostic and care plan for the family experiencing a genetic disorder such as: the location of the gene on the chromosome, the physical presentation, the diagnostic work up, the treatment, referrals to specialists to assist in treatment of the disorder, and finally the community resources needed for quality of life of the patient and family.

Lastly, the use of a panel discussion was extremely beneficial to impact student learning regarding patients who had experience with cancer that may or may not have had a genetic etiology, and their degree of willingness to pursue genetic testing. This learning modality created a vividly realistic atmosphere as the panelists related their cancer journey. The students researched and composed the panel questions that were preapproved by faculty and were shared with the panelists prior to the panel discussion. By examining the lived experiences of cancer survivors (i.e. what parts of their clinical treatment and care were supportive and which parts caused them despair) the graduate nursing students learned about shared responsibility and empathy of clinicians.

Results: The student evaluations of the teaching techniques were extremely positive: "Having interprofessional interactive sims was helpful in making connections and furthering my understanding", "The concept maps allowed us to feel the investment of the sim character's viewpoint", "The debriefing after the cancer panel was very powerful & emotional. The panelists gave us a valuable glimpse into their journeys; I learned a lot!" and "The simulations complemented the genetics info well".

Conclusion: The use of genetic-based interprofessional sims set the stage for students to engage in a variety of teaching strategies to facilitate learning, critical thinking, and foster clinical decision making in graduate nursing students.

M 06 - Genetic Health

Improving Global Health and Advancing Nursing Science: Parental Knowledge on Genetic Screening and Immunization

Tami L. Thomas, PhD, RN, CPNP, FAANP, FAAN, USA

Jeff Mauer, MS, USA

Kathleen Hickey, EdD, RN, FAAN, FAHA, USA

Abstract

Purpose: The World Health Organization (WHO) has set a priority to reduce disparities in socio economics and health within the next generation. To inform global health initiatives, advance nursing science, and provide data for evidenced based practice, pilot studies were conducted with parents from underserved communities in urban areas and rural areas of the United States. The purpose of these studies was to identify intervention points for nurses in practice and research specifically who are focused on health promotion and disease prevention in the areas of screening for genetic illness (genetic testing) and HPV Immunization. The objective of this investigation was to evaluate the perceived risk and benefits toward genetic testing and among these vulnerable populations. We sought to compare and contrast these findings to elucidate research on health promotion and inform evidenced based practice for nursing and the health sciences.

Methods: After Institutional Review Board approval and meetings with rural community gatekeepers and leaders, a survey was developed to determine parents' levels of knowledge regarding health promotion for their children. Parent Participants completed an 89 item survey that captured 135 participants and their overall health choices and decisions related to health promotion practices in their families and communities.

Results: There were 136 participants (18% males, 82% females) the mean age was 38 years +/- the SD. Descriptive statistics revealed that over 45 percent of parents felt their knowledge about genetic testing and screening was inadequate or non-existent. In addition over 80% of parents knew no one who had ever had any DNA testing and 65% did not understand the connection between Human Papillomavirus (HPV) infection and cancer. In general quantitative results supported three common issues among all groups of parents: (a) fear of poor health outcomes for their children, (b) lack of knowledge regarding HPV vaccination and genetic testing, and (c) concerns regarding cost. Data also revealed concerns genetic testing included cost and application to being able to improve the individuals' health. Limited knowledge of what genetic screening is and the uses of genetic testing were the majority and also identify the need for increased education in this area of health promotion. These findings high light the need for future investigations that include testing ways to increase health promotion education using culturally relevant approaches that are acceptable to parents regardless of geography, economy or cultural background. Additional analysis will also be shared.

Conclusion: Our findings are consistent with those reported in the literature, the National HPV Vaccine Roundtable and highlight the stigma surrounding HPV vaccination and genetic testing. Novel advances in immunization including emerging vaccines for Zika virus as well as the current advances in genetic technology highlight the need for health promotion education in underserved populations to ensure uptake and answer the call from WHO to decrease health care disparities within the next generation. Nurses and nurse researchers who engage in health promotion as part of their research and evidenced based practice in any country can adapt the findings to improve outcomes for patients and families.

M 07 - Global Practices for Pressure Ulcers

Description of Medical-Surgical Nurses' Care of Patients at Risk for Pressure Ulcers (PU)

Barbara J. Mayer, PhD, RN, CNS, USA

Abstract

Purpose: The purpose of this qualitative study was to explore and describe the level of understanding of PU development and prevention and the perceptions of implementing PU prevention measures of nurses caring for patients in MS units.

Methods: The study was conducted in three (3) community hospitals in California within the same healthcare system using an interpretive description approach (Bertero, 2015). Purposive sampling was used to recruit medical surgical nurses. Six (6) focus groups were conducted including a total of thirty (30) participants. Participant comments were coded following each focus group session. Initial impressions and preliminary themes were explored in subsequent focus groups, allowing the investigator to refine and reorient the inquiry. Demographic information was collected to describe study participants.

Results: A total of 30 nurses working in MS units participated in six focus groups. A brief demographic questionnaire revealed the majority of participants were female (90%) and ranged in age between 26-61 years with a mean age of 41 years. Academic educational preparation included a Bachelor's degree in nursing (67%); pressure ulcer prevention continuing education within the last 12 months (83%), with 74% of classes attended by participants including instruction on evidence-based protocols. The majority of participants were employed full time (87%) and years of nursing experience ranged from 1 year to 38 years, with a mean of 12 years. Findings in this study are not dissimilar to those that have been reported elsewhere, but serve to orient us to today's environment in the wake of the 2008 CMS ruling. Four (4) major themes emerged from analysis of the data: 1) nurses' knowledge of PU prevention improved following an educational activity and nurses' experience caring for patients at risk for development of PU was a significant factor in acquiring and maintaining their knowledge level; 2) an accurate risk assessment is essential in determining appropriate PU prevention measures. Risk was determined using a standardized assessment tool, the Braden Scale. However, participants related inconsistent use and interpretation of the scale, rendering patient scores suspect in determining risk. The presence of diagnoses and conditions known by participants, through previous experience, to be associated with patients at risk for PU development was more important in determining the level of patient risk for PU; 3) many factors were identified as influencing nurses' implementation of PU prevention measures. Factors identified as facilitating implementation of PU prevention measures were: nurses' personal motivations, the use of evidence-based treatment protocols to guide decision-making, the use of expert consultants, and leadership support. Factors identified as barriers to implementation of prevention measures were: staffing concerns, lack of equipment and supplies, patient cooperation; family influences, and balancing nurses' ethical need to provide safe, compassionate care with the desire to respect the wishes of the patient; and 4) regulatory mandates, specifically the 2008 CMS ruling on non-payment for hospital acquired PU, were perceived as having improved nurses' care of patients at risk for PU.

Conclusions: This study was undertaken to describe nurses' knowledge of PU development and prevention and to discover factors affecting nurses' ability to implement PU prevention measures. When interventions are omitted assumptions are often made that the nurse lacks the knowledge, skill or desire to provide quality care (Waugh, 2014). This study revealed that, in the case of PU development and prevention, nurses' knowledge was satisfactory, nurses understood the importance of PU prevention, and were motivated to carry out prevention measures. However, barriers and facilitators to implementation of prevention measures were identified. Because every hospital, shift, and patient encounter presents a unique set of circumstances, organizations must assess and identify contributing factors and implement improvements based on their own assessments to ensure quality care. Findings suggest several actions that could be taken to improve nurses' assessment of PU and implementation of prevention measures. Education promoting a common understanding and consistent use of the Braden Scale is essential to its effectiveness in guiding PU prevention measures. Methods within the practice setting to validate

consistency should be implemented. Evidence-based protocols allow the nurse autonomy to implement measures aligned with the patient's individual risk factors. Protocols also remove the necessity of consulting the patient's physician, allowing timely implementation. The prudent organization should consider implementation of the wound care nurse role and/or expanding the involvement of wound care nurses in the direct provision of PU prevention measures, and provide regular formal and informal education regarding PU prevention for the RN as well as assistive staff such as the CNA. Finally, organizational recognition of the importance of PU prevention is required to facilitate consistent implementation of prevention measures. This includes providing adequate staff both in numbers and quality, leaders serving as role models, and public recognition of positive outcomes by leadership.

Marie Hutchinson, PhD, RN, RM, Australia

Steven Neville, PhD, RN, New Zealand

Kim Usher, PhD, MNSt, AM, RN, BADipAppSc (Nsg), FACN, FACMHN, Australia

Abstract

Purpose: Pressure Injuries (PI's) are a major burden to both patients and healthcare providers. NHS England (NHSi, 2014) state 700,000 people are affected by PI's each year costing the NHS £3.8 million per day. Current research and policy position PI's as an acute hospital based problem (Jackson et al., 2016), however the majority of patients are living with chronic PI wounds, receiving treatment within the community (Bennett et al., 2004; Stevenson et al., 2013). Information regarding the extent of PI's in community based adults is lacking and urgently needs addressing as healthcare undergoes a national shift from hospital to home based care provision (NHS 5YFV, 2014). New research is required to not only evaluate the extent of service provision required for community based PI patients but more importantly to understand the care needs and preferences of patients to provide a safe and patient focused service.

Methods: As part of an ethically approved university funded project, all mandatory incident reports of PI's from 2015 were collated from a case study region defined by a single postcode district. Information from reports and district nursing notes were cross-reference to produce detailed demographic and pressure related information. Descriptive statistics (SPSS v22.0 IBM) were used to describe patients within the case study region. To illustrate the burden on service provision, records of PI related equipment given to community dwelling patients were analysed. Semi-structured qualitative patient interviews were conducted with appropriate consent to build a perspective of the burden of living with a PI by individuals within their own homes, and to gain an insight into their understanding and use of pressure relieving equipment.

Results: 50322 adults lived in the case study region, 3086 were aged 75+ (ONS, 2011). In 2015, 103 individuals received community based care for 137 PI's. Multiple combinations of equipment from several manufacturers were supplied, but further analysis showed patients concerns about its use and more patients were likely to not use the equipment as per manufacturer's instructions, than to use it correctly. Narratives of patients revealed the greatest personal burden of living with a PI was living a life of pain, describing days that were clouded in pain; a pain they felt was poorly understood and managed and often out of control. Continuity of care, and the trust built from stable relationships, and knowing their care providers, was fundamental to their personal wellbeing and potential for recovery.

Conclusion: Using a case study approach we have demonstrated that home dwelling patients represent the complete spectrum of PI's including those with full skin thickness damage (Cats 3 & 4). Equipment to relieve or prevent pressure damage is provided extensively into patients homes, even despite a lack of robust evidence that the equipment is beneficial (McInnes et al., 2012). The multiple combinations and choices of specialised equipment supplied perhaps suggest that the system is tailored to meet individual patient needs. However, this study has found that appraisal and re-appraisal of equipment once in a patient's home is lacking and equipment is often redundant or used incorrectly. Furthermore, participant narratives indicated their pain was poorly recognised and under-treated. People living with PI often struggled to maintain continuity of their own care and should have opportunities for dialogue and mutual decision making with health professionals. Further work focusing on the perspectives, understanding and choices of home dwelling patients is imperative because of rapid growth in this sector of the community.

M 08 - Health Promotion of Patients With Catheters

The One Million Global Peripheral Intravenous Catheter Study: Findings From a Large Urban Hospital

Marygrace Leveille, PhD, RN, ACNP-BC, USA

Lori Ewalt-Hughes, BSN, RN, CIC, USA

Abstract

Purpose: Over a billion Peripheral Intravenous Catheters (PIVCs) are inserted each year in hospitalized patients worldwide and data on the care and management of these devices is largely unknown. However, data on the prevalence of PIVCs and their management and infection practices across countries and regions are limited. While PIVCs are deemed critical for medical care, they expose patients to bloodstream infections, endocarditis and thrombophlebitis (Bacerra, Shierley & Safdar, 2016). There are many avenues of research to be explored with intravenous catheters. Should PIVCs routinely be changed out at 72-96 hours? Are there any ramifications to having idle PIVCs? According to Keogh (2013) many PIVCs can be safely changed only when clinically indicated. In an effort to understand how PIVCs are managed, an international study, "One Million Global Catheters: PIVC worldwide Prevalence Study", was initiated by a group of investigators in Sydney, Australia. . The worldwide study included fifty one countries with 418 participating hospitals, fifty three of which were in the United States with a total of 5048 patients (Alexandrou et al, 2015). The total number of PIVCs submitted into the One Million Global (OMG) database was 40,620. The study objectives were to assess the prevalence of PIVCs and their management practices, identify patients and PIVC characteristics, the prevalence of localized symptoms, and PIVC securement and dressing practices.

Methods: A convenience sample of 181 medical/surgical patients were recruited and consented by bedside nurses from a large urban teaching hospital to participate in this prevalence study in March of 2015. The study received approval from the Healthcare system institutional review board. A validated data collection tool was utilized by bedside nurses who were trained in Human Subjects Protection and data collection for this study. All observational data collected was de-identified and maintained in a locked secure area. Data was then electronically sent to the study principal investigators in Sydney via a secure modality. Statistical Software (SAS version 9.1; SAS Institute, Inc., Cary, NC) was utilized for statistical analysis. Each site was then presented with individual findings in addition to individual countries and region findings.

Results: The majority of the patients were 18 years and older (99.5%), and half of them are men. Eighty seven percent of PIVCs were inserted for IV fluid and IV medications orders, and the majority were inserted by IV team and nurses (99%). Ninety four percent of the PIVC sites had a borderless transparent polyurethane dressing which reportedly were clean, dry and intact (87%). The majority of PIVC site assessments were documented in patients' charts in last 24 hours (91%) and with no clinical symptoms (88%). A small proportion of PIVC sites with blood in line (3.9%), pain/tenderness on palpation (2.8%), and bruising/dried blood around PIVC (2.8 %). PIVC site selection was usually the forearm (40%) with a 20 gauge(35%) or 22 gauge (34%), respectively.

Conclusion: Contribution in this international study was a clear positive learning experience for the bedside nurses to have a "lived experience" in conducting research in a large urban teaching hospital. Involvement in this study promoted the transformation of knowledge and practice among 51 countries and 418 hospitals. Study results pertinent to our site specific findings revealed slight gaps in PIVC site maintenance, vigilance of PIVC dressing assessments to maintain dry and intact PIVS dressing, and documentation practices in comparison to other participating facilities. Additionally, nursing practice changes will be supported by additional education and policy making with regards to PIVC site management. As a result, future patient outcomes such as decreased infiltrates, decreased peripheral line infection rates and decreased pain, will be impacted by the increased awareness and education of the bedside nurses assessment skills of PIVC insertion sites and management of the PIVC site.

M 08 - Health Promotion of Patients With Catheters

Association of Catheter-Associated Urinary Tract Infection (CAUTI) With the Practice Environment at the Unit Level

Nancy Ballard, PhD, RN, NEA-BC, USA

Marjorie J. Bott, PhD, RN, USA

Shin Hye Park, PhD, RN, USA

Byron Gajewski, PhD, USA

Peggy A. Miller, PhD, RN, USA

Abstract

Purpose: Identification of elements of the practice environment that influence both nurse satisfaction and patient outcomes is an important area for nursing research. Several valid and reliable tools to measure the components of the practice environment have been developed by nurse researchers. The Practice Environment Scale and Job Enjoyment Scale are included in the National Database of Nursing Quality Indicators® (NDNQI®) RN Satisfaction Survey. In addition the NDNQI provides a database for participating hospitals to collect nurse-sensitive quality outcome data including catheter-associated urinary tract infection rates (CAUTI) for internal use and external benchmarking. All data are collected at the unit level providing opportunity for researchers to explore associations between the nurse work environment and measured quality outcomes.

Leiter and Laschinger (2006) posited the Nursing Worklife Model (NWLM) to explain how the elements identified in the practice environment are interrelated in the complex system of the nurse practice environment with subsequent work that extended the model to include association of nurse perception of patient adverse events. To date, researchers have primarily evaluated the impact of the practice environment on clinical outcomes using administrative data at the hospital or individual nurse level using nurse perceived adverse patient outcomes.

Exploration of the practice environment using the NWLM with catheter-associated urinary tract infections (CAUTI), an identified *never event*, is an important area for research. Care occurs at the work unit level where practice environments may vary. Study of relationships at the unit level with a measured clinical outcome extended previous hospital-level NWLM research. The purpose of this two-phased study was to fit the NWLM to unit level data, validate the fit of a modified NWLM from the first phase and extend the model to evaluate the association with CAUTI rate at the work unit level in acute care settings.

Methods: A secondary data analysis of a national sample ($N= 3,023$) of critical care, step-down, medical, surgical, and combined medical-surgical units from the 2011 NDNQI® was used to fit the NWLM to the unit level data. The modified NWLM was then validated using a national sample, ($N=1,106$), of medical, surgical, and combined medical-surgical unit level data from the 2012 NDNQI® data. Using structural equation modeling (SEM), a modified NWLM of job enjoyment was confirmed and extended to include a unit level outcome measure, the annualized CAUTI rate from the matched units in the 2012 NDNQI® data.

Results: Following indicated modifications to the NWLM pathways in the analysis of the 2011 data, additional significant paths were added to job enjoyment, staffing and resource adequacy, and foundations for quality care resulting in good model fit to the unit level data ($CFI=.999$; $RMSEA=.059$ [$95\% CI=.034-.089$]; $SRMR=.002$). Using the *a priori* model from 2011 data analysis, the modified NWLM at the unit level showed an excellent model fit ($CFI=.995$, $RMSEA=.041$ [$95\% CI=.028-.056$]; $SRMR=.020$) to the 2012 NDNQI® unit level data. The results of the extension of the model to include the clinical outcome revealed a significant ($p= <.01$) negative pathway from job enjoyment to CAUTI rates ($\beta= -.08$). There were significant positive association of CAUTI rate with hospital characteristics that included Academic Medical Centers ($\beta=.13$) and hospitals greater than 500 beds ($\beta=.07$), indicating both had higher CAUTI rates.

Conclusion: The validated model using unit level data supported the importance of the nurse practice environment in reducing negative clinical outcomes (i.e., CAUTI rates). The results demonstrated the importance of the unit practice environment based on the NWLM, for improving quality of care. In addition to emphasis on best clinical practice, strategies to support a culture of professional practice are indicated.

M 09 - Improving Health in the Psychiatric Patient

Improving Dual Diagnosis Care in Acute Psychiatric Inpatient Settings Through Education

Kofi Bonnie, DNP, MSc, BSc(Hons), RPN, USA

Abstract

Background: Patients with co-existing substance use and mental disorder (dual diagnosis) have complex and challenging care needs. They have an increased risk of homicide, suicide, homelessness, incarceration, multiple admissions and infectious diseases such as hepatitis C and HIV. Acute psychiatric care settings play a vital role in providing services for dual diagnosis patients who often do not voluntarily seek treatment. There is evidence that nurses working in these settings often have unmet learning needs regarding dual diagnosis care, posing a challenge to nursing practice with this clientele. This is significant in that recent data reveals that 57% of the psychiatric inpatients at an inner city hospital in Vancouver, Canada are characterized as dual diagnosis.

Purpose: To develop and pilot an educational module which will equip nurses with the skills and knowledge required to deliver evidence-based dual diagnosis care in acute psychiatric settings.

Methods: A survey of 74 nurses working in acute psychiatric settings was completed to identify their learning needs and challenges. This was followed by a comprehensive review of evidence from the literature to identify competencies, knowledge, and skills needed to deliver dual diagnosis care. Content for the educational module was then validated by a panel of leading international experts on dual diagnosis. Two focus groups of acute psychiatric nurses were then conducted to discuss content. After this, an 8 hour educational session was developed and piloted using the content that was reviewed and validated. Evaluation from 55 participants' of the educational session was collected and analyzed.

Results: Thirteen content areas were identified and validated by experts. Evaluations from 55 participants of the educational session suggest improved knowledge, skills and competencies in dual diagnosis care.

Conclusion: This project translates evidence into practice, contributes to the body of knowledge on dual diagnosis care in acute psychiatric settings and improves nurses' confidence and competency in delivering evidence-based care which also will improve patient care outcomes and experiences.

M 09 - Improving Health in the Psychiatric Patient

Working Together to Treat Tobacco Dependence Among Smokers With Serious Mental Illness

Rhonda Schwindt, DNP, RN, PMHNP-BC, USA

Karen Hudmon, DrPH, MS, RPh, USA

Kathy Lay, PhD, MSW, USA

Angela McNelis, PhD, RN, FAAN, ANEF, CNE, USA

Jon Agle, PhD, MPH, USA

Abstract

Purpose: The prevalence of tobacco use among persons with mental illness exceeds the prevalence in the general population by a factor of 2 to 4. Despite strong evidence that tobacco cessation counseling by a health professional can approximately double patients' odds of quitting, clinicians across disciplines are reluctant to offer these individuals effective means by which to quit smoking. The purpose of this pilot study was to estimate the impact of an interprofessional tobacco education program on the perceived self-efficacy and self-rated counseling abilities of graduate health professions students to provide tobacco cessation counseling and their perceptions of interprofessional collaborative practice.

Methods: Investigators used a 1-group, pre/post-test design with quantitative and qualitative analysis. All health professions students ($N=36$ [$n=13$ nursing, $n=9$ pharmacy, and $n=14$ social work]) completed pre-test-post-test surveys, 5 hours of tobacco education training consisting of a 2-hour online module and a 3-hour interprofessional live training session, a simulation experience with a standardized patient, and a post-simulation debriefing session. Data were analyzed using descriptive statistics, correlations, paired t -tests, and qualitative analysis techniques.

Results: Participants' perceived self-efficacy ($t=-9.92$, $df = 35$, $p<0.001$), self-rated counseling abilities ($t=-7.36$, $df = 35$, $p<0.001$), intention to ask about tobacco ($t=-3.16$, $df = 35$, $p=0.003$), and to provide counseling for tobacco cessation ($t=-4.35$, $df = 35$, $p<0.001$) were significantly improved at post-test. In addition, all participants reported high perceived ability to engage in collaborative care and work as part of an interprofessional team. Emergent themes from qualitative analyses of open-field queries were valuing simulations, demystifying disciplines, reflecting on and building skills, critiquing practice, and lessons learned.

Results: Participants' perceived self-efficacy ($t=-9.92$, $df = 35$, $p<0.001$), self-rated counseling abilities ($t=-7.36$, $df = 35$, $p<0.001$), intention to ask about tobacco ($t=-3.16$, $df = 35$, $p=0.003$), and to provide counseling for tobacco cessation ($t=-4.35$, $df = 35$, $p<0.001$) were significantly improved at post-test. In addition, all participants reported high perceived ability to engage in collaborative care and work as part of an interprofessional team. Emergent themes from qualitative analyses of open-field queries were valuing simulations, demystifying disciplines, reflecting on and building skills, critiquing practice, and lessons learned.

Conclusion: Teaching health professions students an interprofessional collaborative approach to treating tobacco dependence for persons with serious mental illness appears to be an effective approach to improve perceived self-efficacy and self-rated counseling abilities and to positively impact their perceptions of interprofessional collaborative practice. These findings have the potential to inform the ways in which students across the spectrum of health professions are educated to provide tobacco cessation counseling. Larger studies are recommended to validate results of this pilot study.

M 10 - Male Sexual Health and Substance Abuse

Substance Use Experiences of HIV-Positive and HIV-Negative Young Black Men Who Have Sex With Men

Austin Nation, PhD, MSN, RN, PHN, USA

Abstract

Purpose: The prevalence of HIV among young Black men who have sex with men (MSM) is three to four times higher than white MSM. Young black MSM are run-aways and homeless, forcing them to survive on the streets by becoming sex workers, engaging in unprotected anal intercourse because either they or their partner is under the influence of drugs or alcohol. Previous studies cite crack cocaine use, sex while high on crack cocaine, marijuana and alcohol, or sharing needles for injection drugs as strongly associated with HIV infection among young black MSM. The purpose of this presentation is to understand the substance use experiences of HIV-positive and HIV-negative young Black MSM.

Methods: This narrative qualitative study, obtained from participant interviews, offers insights about the range of factors and enhance our understanding about the role that substance use plays in the lives of HIV-positive and HIV-negative young Black MSM.

Results: The themes that emerged from the coding of this qualitative narrative study describe an across-case experiential trajectory with a summary of the significant experiences of this population. This information contributes to the limited body of knowledge currently available and will assist with the development of prevention education strategies specifically tailored to this population that address issues surrounding substance abuse in HIV transmission.

The narratives describe experiences with substance use related to the following:

- (1) early substance use exposure and initiation in family - Young Black MSM are exposed to substance use in their family, with family members who are also using drugs.
- (2) for coping with gay sex and being gay – Participants how substance use allowed them the freedom to explore gay sex and their sexuality, including how they bottom (be the receptive anal partner) when under the influence of drugs.
- (3) peer pressure in new community to fit in with others - Participants describes meeting new people through social media and how substance use is a part of that experience
- (4) exposure to lots of methamphetamine in San Francisco – Participants describe the prevalence of methamphetamine in the dominant gay community, in this case White gay men, who are often times use the drug to control young Black MSM.
- (5) to numb feelings- Participants discover the benefits of methamphetamine for numbing, masking feelings and coping,
- (6) sexual enhancement and survival sex – Participants discover the *sexual enhancement* benefit and this leads them to engage in high risk behaviors, often times as a way to obtain food, clothing and shelter.

Here is a summary of the four key findings related to the overall research aims of this study that emerged from the narrative stories of the young Black MSM:

- 1) “There was a lot going on in the homes of these participants.” Almost all of the young Black MSM discussed early substance use exposure in their family, including parents who were also drugs. The young men shared about broken family structures, including abuse and neglect. These social and environment factors contribute directly to their own early substance use initiation (median age 15), as well as early sex initial (median age 15), at times with parents providing the drugs. Mean age for participants is 26.
- 2) Over thirty years into the AIDS epidemic, stigma and homophobia continue to be an issue for these young Black MSM. Most of the participants were either kicked out of their family homes, asked to leave by their family, or wanted to get away from their family so that they could be themselves. This is blatant discrimination. Most came to San Francisco as a safe place, only to face homelessness and having to figure out how to survive on their own. This creates a sense of insecurity.

3) With the prevalence and exposure to methamphetamine in the San Francisco, young Black MSM discover the benefits of this drug for numbing, masking, and coping with everything from being gay, gay sex, dealing with peer pressure, and for sexual enhancement and survival sex. These issues act as drivers for methamphetamine use as an ineffective coping mechanism.

4) Almost all the young Black MSM had some knowledge and awareness about HIV prior to arriving in San Francisco; most were testing regularly every three months. Once under the influence of methamphetamine, the participants don't care about condoms, nor do they have the ability to negotiate condom usage with their partners. There is a sense of anticipation, resignation and acceptance about acquiring HIV; HIV risk reduction apathy.

Conclusion: Clinicians and researchers in all academic and practice settings will encounter HIV-positive and HIV-negative young Black men and need to understand the prevalence of substance use among this population. It is also important to take a thorough family history, social history, as well as sexual health and risk behavior assessment.

M 10 - Male Sexual Health and Substance Abuse

Substance Use Among Middle-Aged Hispanic Men Who Have Sex With Men (HMSM) in South Florida

Beatriz Valdes, PhD, RN, CHSE, RN, USA

Abstract

Purpose: In 2014, Hispanics represented 17% of the population but accounted for 24% (10, 887) of the estimated 44, 784 new diagnoses of Human Immunodeficiency Virus (HIV) infection in the US, and 86% (9, 379) of these cases were in men, of which 84% (7, 893) of the estimated HIV diagnosis among Hispanic men were attributed to Hispanic men who have sex with men (HMSM). If current diagnosis rates continue, estimates indicate that 1 in 4 HMSM will be diagnosed with HIV infection during their lifetime. An abundance of research demonstrates a consistent association between alcohol and substance use and high risk sexual practices among HMSM. High risk sexual behaviors include: unprotected anal intercourse (UAI), multiple partners, and sex under the influence of alcohol or drugs. This study explored the effects that substance use has on high risk sexual behaviors which predispose middle aged HMSM to STIs and HIV infection risk.

Methods: A non-experimental, cross-sectional research method design was used to collect data from a sample of 150 urban HMSM aged 40 to 65 residing in South Florida. Participants completed standardized measures of substance use, sexual behaviors, and demographic characteristics. This study was part of a larger study funded by Sigma Theta Tau International-Beta Tau Chapter.

Results: The sample included 150 HMSM, with a mean age of 45.54 ($SD = 4.71$), ranging from 40 to 60 years. Most of the participants were foreign-born 86% ($n = 129$). Fifty-two (34.7%) participants reported illicit drug use in the past 30 days. Alcohol was the most common substance used by participants in the past 30 days (106; 70.7%), followed by cigarettes (54; 36%), marijuana (28; 18.7%), amil nitrates (14; 9.3%), prescription narcotics (13; 8.7%), club drugs, i.e., Ecstasy (9; 6%), and cocaine (7, 4.7%). Participants reported substance use while having sex (61; 40.7%); history of diagnosed sexually transmitted infections (57; 38%); unprotected sex with serodiscordant partner (21; 14%); participating in receptive anal intercourse, i.e., bottom partner (94; 62.7%); never using a condom as a receptive partner (22; 14.7%); occasionally using a condom as a receptive partner (90; 60%); and sex with women (12; 8%) and transgender persons (10; 6.7%). Number of sexual partners reported in the last three months ranged from 0 to 32, ($M = 5.23$, $SD = 5.51$).

Conclusion: As a population, Hispanic men continue to experience high rates of STIs and HIV infection. This study is the first step in developing interventions targeted to reduce STIs and HIV infection among Hispanic sexual minorities. This study is essential in providing data to direct programs of health education geared to decrease high risk sexual practices among sexual minorities, which will subsequently reduce morbidity and mortality of this high risk group. Future research should build on these findings to develop tailored risk reduction interventions.

M 11 - Pain-Management Strategies

Pain-Management Challenges in Rural Communities Impacted By Multi-Drug Overdoses

Cathy Campbell, PhD, RN, USA

Abstract

Purpose: The purpose of this study is to identify themes that describe pain management challenges experienced by nurses in a rural Appalachian area of the United States (US) that has been negatively impacted by opioid overdoses. Internationally pain management interventions by nurses includes pain assessment, teaching about pharmacological and non-pharmacological modalities, and the evaluation of treatment effectiveness (Doorenbos, Jansen, Oakes & Wilson, 2013). However, pre-licensure nursing and continuing education curricula do not contain content on how to effectively manage pain in people who concurrently are living with substance abuse or addiction to alcohol or drugs (Hamilton & Watson, 2014). Rural communities in the Appalachian area of the United States have been experiencing an epidemic of accidental overdoses of opioids (Campbell, Boyer, Rovnyak & Campbell, 2012, Fetzer, 2015). Health care providers across settings of care such as the emergency department, medical-surgical acute care unit, or in labor and delivery encounter people who not only have a current or past history of substance abuse, but may also be experiencing pain. Yet we have few studies that describe the challenges that nurses practicing in communities impacted by the health care crisis of accidental overdoses are facing in pain management their practice, and therefore the literature lacks the evidence base to guide nursing practice during this epidemic.

Methods: A secondary data analysis of findings from a study of pain management learning needs (Campbell, Boyer, Rovnyak, & Campbell, 2012) was conducted to identify themes that describe pain management challenges experienced by nurses in rural Appalachia. In the original study 2,136 surveys were mailed to registered nurses in seven counties in rural Appalachia and 295 surveys were returned, for a 13.8% return rate. Respondents were 98% Caucasian, 47%.1 had a BSN or higher degree, 52.9% ADN/Diploma. We received sixty-one different narrative responses to two open-ended questions on the survey completed by the participants in the primary study. They were asked to identify additional learning needs and to tell a narrative about challenges related to pain management from their clinical practice.

Thematic analysis was used to analyze the narrative responses in data.

Results: In the original study 2,136 surveys were mailed to registered nurses in seven counties in rural Appalachia and 295 surveys were returned, for a 13.8% return rate. Respondents were 98% Caucasian, 47%.1 had a BSN or higher degree, 52.9% ADN/Diploma. We received sixty-one different narrative responses to two open-ended questions on the survey completed by the participants in the primary study.

Data analysis revealed three themes related to additional learning needs: pain management of people with addictions (including babies born with neonatal alcohol syndrome), pain management in people with chronic pain (back pain, neuropathy, and arthritis), and alternative and complementary therapies for pain management. Four major themes from the narratives about pain management challenges were identified: managing pain in people with current or past history of abuse to opioids and alcohol; managing pain in people with history of anxiety, depression and schizophrenia, poor nurse-physician collaboration, and pain management at end of life.

Conclusion: Implications for nursing education for pre-licensure students and continuing education for licensed nurses will include collaborating with expert nursing colleagues in psychiatric-mental health nursing to develop educational sessions education with topics such as pain management in people who have history of substance abuse and other mental health issues. Palliative care providers can consult with clinical partners on effective treatments to manage chronic pain. Future research should also include studies to explore how interprofessional collaboration in may improve pain management outcomes.

M 11 - Pain-Management Strategies

Supporting Veterans With Chronic Pain: Utilizing an Evidence-Based Self-Care Model

Joseph F. Burkard, DNSc, MSNA, BSN, RN, CRNA, USA

Abstract

Purpose: The purpose of this EB study was to determine the effectiveness of promoting self-care on pain levels and quality of life among veterans with chronic pain. A review of current chronic pain management policies for veterans in southern California was also conducted. Military veterans with chronic pain are frequently more complex in their presentation than the general population due to challenges of returning to civilian life and the influence of past military service on their pain. National veterans chronic pain levels have been noted to be on average 7.13. Quality of Life noted at 3.7. Conventional pain management methods have been largely dependent on the use of prescriptions, over-the-counter medications, and opioids, which are often ineffective for the management of chronic pain. A biopsychosocial model that has been shown to benefit chronic pain patients is the evidence based self-care model. Buckenmaier and Schoomaker (2014) noted that these initiatives recognize the important role the patient plays in maintaining his or her own health and promote practices that have few side effects compared to pain medications and are relatively easy to implement. Active self-management initiatives allow for a more diverse, patient-centered treatment of complex symptoms, promote self-management, and are relatively safe and cost-effective. The 2010 VA/DoD Clinical Practice Guideline for Management of Opioid Therapy for Chronic Pain states that more than 50% of male VA patients in primary care report chronic pain, which may even be higher in female veterans. Standardizing treatment for those with chronic pain using a multitude of complementary and alternative medicine (CAM) modalities has not occurred. Standardized CAM tools need to be established for all providers in the VHA system to use whether in a pain clinic or a primary care clinic. The VHA has a multitude of resources available to their patients but without a guide and protocol these modalities will be underutilized and chronic pain rates will increase.

Methods: Twenty-one veterans with chronic pain were seen in a primary care setting and received a standardized protocol for addressing chronic pain. This IRB approved standardized protocol included the Pain Medication Questionnaire (PMQ), the Numeric Pain Rating Scale, a self-care chart, and a personal action plan contract. Following the assessment, the provider implemented an educational intervention using a self-care model chart addressing alternative treatments to pain beyond controlled medications that promote self-management. At this time, patients were provided with referrals to appropriate resources offered by the VA. Self-care management was assessed at each visit. QOL data, Numeric Pain Rating Scale scores, and the number of pain medications were collected and tracked over time. Patients were seen monthly over a 6-month period. The PMQ score and the Numeric Pain rating scale were used to evaluate project effectiveness in controlling pain. VA Pain and QOL Benchmark was set at 5.0. SPSS version 23 was used to analyze the results. The paired t-test and ANOVA was used to determine if there was a difference in means from baseline out to six months.

Results: Evaluation of pre/post project implementation data: The Self-Care Model for veterans with chronic pain moderately decreased the veterans pain and increased QOL. The veterans pain decreased on average 1.33 (95% confidence interval, .52, 2.71) and was not statistically significant at $p = .057$. The veterans QOL increased on average 1.63 (95% confidence interval, .96, 3.17) and was statistically significant at $p < .039$. Twenty-one veterans started the program and at six months sixteen were still enrolled (76%). Sixty-one percent were diagnosed with PTSD. Seventy-six percent were enrolled in physical therapy and sixty-one percent started CBT. On average, each patient was on 2.5 medications although the program was able to limit narcotic use to seven patients (43%).

Conclusion: Healthcare providers who are effective in providing self-management can help enable patients to take responsibility for their health, decrease their pain, and improve their quality of life over time. Primary care providers are in a significant position to lead self-management programs. Research shows that self-management is highly recommended in the management of patients with chronic pain. Our program has demonstrated that you can decrease narcotic use and still achieve a higher QOL and

decreased pain levels. Future Studies should include phone and text follow-up to improve compliance and encourage follow-up visits.

M 12 - Civility in Education and Practice

Upward Violence in Nursing: A Scoping Review of a Phenomenon of Importance for Nursing

Linda J. Patrick, PhD, MSc, MA, BScN, RN, Canada

Alice Pauline Gaudine, PhD, RN, Canada

Lorraine A. Busby, MLS, BA, Canada

Abstract

Purpose: To describe what is known about upward violence in the workplace through a scoping review of the literature. Upward violence includes violence that is directed from staff to people in positions of authority including staff nurses to nurse managers (Branch, Ramsey & Barker, 2013; Gaudine and Lamb 2015). Upward violence may include physical violence and property damage, but it can also be demonstrated through verbal threats and behaviours such as rudeness, socially ostracizing, bullying, mobbing, or passive aggressive behaviours.

The specific objectives of this presentation are: 1) to define and to describe upward violence; 2) to identify related nursing literature about upward violence and other literature to frame key issues through presenting the findings of a scoping review on upward violence; 3) to identify implications for nursing practice and research.

Background: There is a growing body of literature on violence in the workplace including among nurses (e.g., Budin, Brewer & Kovner, 2013; Chen, Ku & Yang, 2012). Recent research in this area includes the widespread prevalence of this phenomenon (e.g., Dumont, Meisinger, Whitacre & Corbin, 2012). Registered nurses have recognized violence in their profession as a major problem since Meissner (1986) first coined the term “nurses eat their young” in her landmark article. Meissner’s work led to recognition of vertical violence, or the violence of senior nurses to new nurses. Since the 1970s, the terms horizontal violence, lateral violence, bullying, incivility, and mobbing have been used to describe the violence of nurses towards other nurses. Traditionally, vertical violence among nurses was viewed as the behavior of nurse managers towards their employees, or the violence of nurse instructors towards their students. This violence can be described as downward violence.

Methods: We will present the findings of a scoping review of the literature that addressed the question “What is known about upward violence in the workplace?” The search strategy included literature on workplace violence, workplace conflict, and 360-degree performance appraisals from 2006 to the present. We also considered legal cases of employees against managers. From this review of the literature, we outline key concepts related to upward violence. We also identify what is known and what is not known about the phenomenon of upward violence.

Results: Upward violence is the violence that nursing students may direct to a nursing instructor, that nurses direct to a nurse manager, or that nursing faculty members direct towards their nursing director or dean. Upward violence has the potential to be a major threat to nurses entering and remaining in leadership positions. Upward violence is contrary to the assumption that vertical violence is directed downward because nurse managers and nurse instructors are in positions of authority and are the ones with the “tools” to cause harm to their subordinates. In reality, vertical violence that is upward can cause harm to nurse leaders and be a significant issue for practice. In today’s context, nurses are often unionized and students are in programs with regulations that protect them.

Conclusion: The results of this scoping review provide working definitions, and conceptual boundaries of upward violence. The research gaps identified are useful to inform future studies. The implications of upward violence for nursing practice and education will be outlined in the presentation.

M 12 - Civility in Education and Practice

Perceptions of Self-Reported Civility Among Undergraduate Nursing Students

Abby Grammer Horton, MSN, RN, USA
Norma Graciela Cuellar, PhD, DSN, RN, USA

Abstract

Background: Nearly 62% of students and faculty in nursing education have reported incivility in an academic setting. The majority of the evidence in the literature describes Student Incivility as faculty to student or student to faculty. Few studies have identified student to student. It is uncertain how students perceive their level of civility. Incivility between students can impact participation in the class resulting in failure, poor attrition, stress, anxiety, depression, and lack of self-esteem.

Purpose: The purpose of this study was to identify perceptions of self-reported civility in undergraduate nursing students.

Methods: This was a cross-sectional descriptive study of undergraduate nursing students at a large, 4-year public institution in the Southeastern United States. There were no inclusion or exclusion criteria. An email was sent to all freshmen, sophomores, juniors and seniors enrolled at the College of Nursing asking them to participate in the survey. The *Clark Civility Index for Nursing Students* was used to collect data via Qualtrics. IRB approval was obtained.

Results: 1697 emails were sent to students with a response rate of 252 students. Of this number, 202 entries were analyzed. The mean score of self-reported civility was 88.3 (SD = 7.02). There was a significant relationship between incivility with regard to age ($p = 0.02$) and race ($p = 0.08$). Age was significantly negatively correlated with overall civility score, $r = -0.16$, $p = 0.02$, suggesting that civility scores were generally lower among older individuals. However, further inspection of the data revealed an outlier (9 SDs above the mean on age) that likely biased this result. After removing this individual, the correlation between age and overall civility scores was no longer significant, $r = 0.05$, $p = 0.45$. Married and single individuals did not differ significantly in their reported levels of civility, $t(200) = -0.94$, $p = 0.35$.

Note: The outcome of the test described above may have been affected by the low number of married individuals in the sample ($n = 5$). An analysis of variance (ANOVA) revealed a marginally significant effect of program of study, $F(2, 199) = 2.59$, $p = 0.08$. Tukey post hoc tests indicated that students in the RN-BSN nursing program ($M = 78.00$, $SD = 24.04$) scored lower on the CCI than students in the traditional BSN nursing program ($M = 88.91$, $SD = 6.80$), though this effect was only marginally significant ($p = 0.08$). The pre-nursing group ($M = 88.03$, $SD = 6.75$) did not differ significantly from either of the other two groups. An ANOVA indicated a marginally significant effect of race, $F(3, 198) = 2.29$, $p = 0.08$. However, Tukey post hoc testing did not reveal any significant differences between conditions. Because two of the racial categories were represented by only five or fewer students, race as a variable was recoded into a new variable that contained two categories: (1) Majority group member / White ($n = 180$), and (2) Minority group member / non-White ($n = 22$). A t -test using this recoded variable revealed that minority group members ($M = 91.91$, $SD = 5.57$) reported higher CCI scores on average compared to majority group members ($M = 87.86$, $SD = 7.07$), $t(200) = -2.59$, $p = 0.01$. The Cronbach's alpha is 0.853.

Conclusion: Overall findings were that 98% of the undergraduate nursing students were moderately civil to very civil. These findings seem contradictory to the current literature, which reports student incivility at a rate of nearly 62%. There is scant literature on this topic. Our findings could be due to the lack of awareness regarding what incivility is and that the instrument is not valid in a student population. Limitations of the study are self-reporting and findings are from only one university, which cannot be generalizable. Students need to be aware of their behavior and how it impacts their peers. Students must be empowered to understand what student to student incivility is and be able to intervene when it is experienced by students in their classrooms. The issue of incivility exists, yet students' perceptions at this university are not congruent with the evidence in the literature. It is imperative that students understand how incivility impacts the nursing profession globally.

M 13 - Promoting Health Globally

Re-Engendering Sexual and Reproductive Health (S&RH) Services: Evaluation and Strategy Directions for RH Clinics

Erlinda Palaganas, Philippines

Marian Caterial Sanchez, BA (SocSc), BA, Philippines

Cynthia Dacanay Jaramillo, BA (Psych), BA, Philippines

Abstract

Purpose: Sexual and reproductive health (S&RH) care encompasses a range of information, prevention, treatment, and referral services to safeguard complete physical, mental and social well-being in all matters relating to the reproductive system. Women and men alike have entitlements to accurate and comprehensive education, more so to access affordable and relevant options to meet their sexual and reproductive health needs. Since the adoption of the agenda points of the Convention on the Elimination of all Forms of Discrimination Against Women (CEDAW 1979) and later the Program of Action of the International Conference on Population and Development (ICPD 1994) governments and civil society advocates have claim milestones in (1) shifting the paradigm from macro-demographic to human population and rights centered perspectives, (2) recognizing the need for advancing women's empowerment, and (3) setting out a comprehensive range of issues related to sexual and reproductive health (Haslegrave, 2014.)

However, amidst the recognition of S&RH as nexus for social justice and development, the issue of unmet needs among women in developing nations and the delivery of needs-responsive and gender-equitable services remain formidable challenges. Women living in conditions of poverty experience series of wanted, mistimed, and unwanted pregnancies, miscarriages, stillbirths, unsafe menstruation inducements and neonatal and infant deaths (Ravindran and Mishra, 2001.) Likewise, high fertility, reproductive and sexual morbidity and mortality, and unmet reproductive intentions prevail not only among non-users of contraceptions but also ever-users and current users of sexual and reproductive health services. The lack of access to S&RH technologies, the persistence of cultures preventing informed fertility options and decisions, and the inability of providers to contextualize services for clients, women specifically, in the wider context of their socio-cultural, political, and economic predicaments are but a few causes of these continuing concerns (Berer, 2014.) Understanding the extent to which individuals are able to achieve their sexual and reproductive intentions in good health and the identification of factors affecting responsive delivery of sexual and reproductive health care services thereby warrant attention.

Government and non-government organizations have actively spent decades laying down the foundations and actively promoting gender equitable S&RH care in the country. These organizations recognize men and women's equal autonomy on their S&RH lives as well as the gender-differentiated barriers men and women face in accessing development opportunities and entitlements.

This study was designed to systematically capture and utilize client, stakeholders, and literature insights for enhancing institutional relevance and performance. Exploring what entails engendering S&RH care, it is based on the recognition of gender-differentiated needs and the commitment to counteract the constraints and barriers to people, especially women's S&RH entitlements. Specifically, the study aimed to: 1) facilitate institutional resource and performance analysis; 2) examine through literature review the potential methods, models, and materials for enhancing responsiveness and relevance in S&RH program and project implementation; 3) apply the principles of feminist research and elicit RH Clinics stakeholders' perspectives on what constitutes client-centered and gender equitable service delivery; and 4) draft strategy directions for increasing RH Clinics institutional success in S&RH championing in the country

Methods: This descriptive evaluation research made use of multiple data collection methods espousing a feminist perspective. The first component involves the Institutional Capacity Assessment and Scoping study. This involved a systematic review of relevant related literature to guide practice. This component also used the results of the client exit interview findings (2013 and 2014) to evaluate nine (9) RH Clinics

delivery performance; identify RH Clinics result achievement drivers and barriers, situate the RH Clinics standing against competitors, review communication and marketing channels, and outline potential strategies for enhancing service delivery.

The second component is ground data generation through qualitative research methods. It involved generation of data using qualitative research methods such as focus group discussions at three levels (institution, clients and other stakeholders), case studies and key informant interviews. This research is backed by the perspective that the documentation of clients and stakeholders' experiences, knowledge, and perceptions is the primary guidepost for enhancing S&RH services, hence the adoption of the most suitable strategies for data gathering: Focus Group Discussion (FGD) and Key Informant Interview (KII) or Small Group Interview (SGI).

Responses were gathered from the 9 RH Clinics from various parts of the country: 9 FGDs among RH Clinic Staff (total of 40 participants); 9 FGDS among outreach providers (124 participants); 9 FGDS among Female Clinest (94 participants); 9 FGDs among male clients (55 participants) 9 FGDs among RH Clinics partners (59 participants); KIIs among 10 competitors

Results: This study has revealed immeasurable baseline data for evaluating the relevance and effectivity of RH Clinic programs and services. Cross referencing the various perspectives from stakeholders and using the principles of *Client centered S&RH Service Delivery vis-à-vis* the four Elements of the Right to Sexual and Reproductive Health as proposed by the UN-CESCR (2016), namely: Availability, Accessibility, Affordability and Quality of Care. The study highlighted the success and enhancement windows (gaps and challenges) of the RH Clinics programs and services using indicators for the four elements.

Following the recommendations of Malarcher and Shan (2011) on basic care threads or service delivery factors to be considered on enhancing S&RH service provision, a model was developed as an illustrative guide and outline of PSPI's strategy directions. The model *The Social Determinants and Care Threads of Engendered S&RH Service Provision Model* is premised on the following: 1) Any S&RH care initiative must be consciously situated to the socio-cultural, economic, and political milieu of its intended beneficiaries or clients users; 2) There are various organizational factors that affect the design, implementation/delivery, monitoring, and evaluation of S&RH services; 3) Clients or care seekers and their access to S&RH is determined by a combination and/or dynamics of different factors; 4) Between S&RH providers and care seekers, there are service and initiative intermediaries; these links may likewise play the roles of communication and monitoring; and 5) More than plain service provision, the value of care thread is to contribute to interlinked outcomes/impacts. The attainment of these outcomes/impacts determines the success of any S&RH initiative or service programs.

Conclusion: RH Clinics in the Philippines are well-established having sustained their operations for many decades nation-wide complete with essential facilities; having capable and competent human resources and maintaining a steady funding source in carrying out its defined S&RH services and programs. The RH Clinics however must deal with and address particular issues as identified in the study affecting the delivery of S&RH services that would make the institution more responsive and relevant to the needs of its intended clientele such as: 1) look into ways of empowering personnel and democratizing organizational processes that would make feedback mechanisms more institutionalized; 2) Literature scoping provided valuable theories and insights on re-engendering S&RH services; 3) Utilizing the principles of feminist research by drawing insights from client's perspectives, revealed the realities of gender-related concerns confronted RH Clinics. The lack of appreciation of gender-related issues which lead either to possible mishandling women clients on one hand or putting too much bias for women which consequently leads to unnecessary assertion and conflict with their partners is another concern needing appropriate attention. This also oftentimes relegates men to the background who do not get to become actively involved in S&RH concerns reinforcing the common misconception that S&RH issues are merely women's concerns. The delivery of S&RH services requires a gender lens from the service providers; 4) It is recommended that RH Clinics utilize the *The Social Determinants and Care Threads of Engendered S&RH Service Provision Model*.

Listen to Me: Noncaregiving Adult Children's Needs From Healthcare Providers

Munira Wells, PhD, RN, USA

Connie Rutan Kartoz, PhD, RN, FNP-BC, USA

Abstract

Purpose: Based on findings from a phenomenological study, the purpose of this abstract is to present the ways in which nurses can assist non caregiving adults to navigate a life-stage that involves independent but aging parents. Extended lifespans, globalization and transnational migration will significantly reshape twenty-first century societies (Horn & Schweppe, 2015; The United Nations, 2015). In the United States, more than half the population may live up to 80 years of age, with much of that time in a relative state of good health (Arias, 2015). Adult children can expect to spend time as equal adults in this non-caregiving relationship with their aging parents. For adults with healthy and moderate to highly functioning, independent parents, this time is not defined by the stress associated with caregiver burden, but it does have its own characteristics that impact upon the emotional and physical health of these aging families. It is important for healthcare systems and specifically nurses to recognize this new aspect of the family life course. As healthy aging is a relatively new phenomenon, little is known about the lived experience of adult children with aging parents. There is however, data to suggest that the quality of the pre-caregiving intergenerational relationship and planning for caregiving can improve clinical outcomes for the aging family during caregiving (Quinn, Clare & Woods, 2012; Fowler & Afifi, 2011).

Methods: A descriptive phenomenological approach was used to analyze interview data obtained from study participants (N=16). After IRB approval, purposive and snow ball sampling yielded sixteen participants who met inclusion criteria (English speaking, non-caregiving adult children with at least one living parent over the age of 65). Upon data saturation, the sample consisted mainly of females (75%), aged 30 to 60s, and living in the east coast of the US. Three of the participants had parents that lived transnationally in Asia (1) and Europe (2). Two in-depth, semi-structured interviews, ranging from 45 to 90 minutes were conducted and transcripts were analyzed independently by the two investigators. Joint review confirmed emerging themes.

Results: Data analysis revealed that despite self-identifying as individuals who were not caregivers, adults did, in fact, provide care to aging parents. While asserting that parents were independent, participants described activities that ranged from minor chores (taking parent shopping) to larger, more time consuming activities (accompanying parent to medical appointments and managing finances). Participants also engaged in a constant, often unconscious, evaluation of changes in parents' functionality and health, resulting in feelings of worry and concern related to potential loss of parental good health and independence. In addition, participants identified shortcomings in a healthcare system that often provides care in silos and communication between parents, healthcare providers and adult children is fragmented or absent. Lack of communication was a particular issue for participants whose parents lived internationally. Adult children want healthcare providers to avoid making assumptions about their aging parents, and to actively acknowledge individual and cultural differences. The creation of a new role of care navigator was raised by several participants. Lastly, the need for health care providers to identify and assist in self-care activities of adults with aging parents emerged.

Conclusion: These findings confirm previous studies that show adult children spend time assessing their parents for possible needs (Fingerman, Sechrist & Birditt, 2013) and also support the idea that definitions of caregiving are variable (Van Durme, Macq, Janmart & Gobert, 2012). The desire for more effective communication suggests that adult children welcome input as they anticipate a potentially stressful demand for care and support of parents. This also raises significant questions of how nurses will communicate with adult children living internationally. As globalization and expanded lifespans are likely to continue, nurses who understand the needs of aging families from a global perspective will be most likely to provide effective anticipatory guidance for this life stage. Confirmation of findings with more globally diverse researchers and participants may provide insights into interventions to reduce strain and improve clinical outcomes in aging families across the globe.

M 14 - Promoting Outcomes in Oncology Patients Cancer Nursing Research in Africa: Scoping the Landscape

Lize Maree, DCur, RN, ANSA, South Africa
Vivien Herbert, MSc (Nsg), RN, South Africa
Agnes A. Huiskamp, MA (Nsg), RN, RM, RPN, South Africa

Abstract

Purpose: The purpose of the study was to perform a scoping review of existing literature on studies conducted in Africa by a nurses and midwives affiliated to an African institution over the past decade, to identify and describe the work completed, identify gaps and define priorities for future research.

Methods: We used a scoping review for our study and used the terms *Africa + cancer nursing* and *Africa + oncology nursing* to search PubMed, CINAHL, Web of Science, Scopus and SA e-publications for literature published between 1 January 2006 to 31 December 2015. Articles were included if it was conducted in an African country with a nurse/midwife affiliated to an African institution as one of the authors. The work also had to be written in English, peer reviewed, have an abstract with a full text available through the university's electronic data bases or interlibrary system. A data extraction sheet was developed to record the name of the journal, the year of the study, the country where the study was conducted, the names of the Africa nurse/midwife author, the study design, the cancers and topics investigated. The titles and abstracts were individually reviewed for inclusion by the authors. All the authors analyzed work which was confirmed through a consensus meeting.

Results: Our search produced 529 articles of which we excluded 427 for either being duplicates or not meeting the inclusion criteria; 57 papers were included in the review. The work was conducted in 8 of the 54 countries in Africa with more than 60% (n=36) in South Africa. The studies were published in 28 journals of which 9 are based in Africa. More than 50% of the articles (n=30) was published in international journals. The number of authors ranged from 1 to 11 (median 4.5) and 17.5% (n=10) of the work had a single author. Eighty four nurses/midwives from Africa authored/co-authored the articles with most (82.1%; n=69) contributing to only 1 article. Only 2 (2.4%) authors contributed to more than 3 papers. The studies were primarily quantitative (36.8%; n=21) while 17 (29.8%) were qualitative and 11 (19.3%) have non-specific designs. Only a small percentage (8.8%; n=5) were intervention and outcomes studies. Cervical cancer was the focus of the majority of studies (57.9%; n=33) followed by breast cancer (17.5%; n=10) with prostate cancer the focus on only one study. Six topics were investigated; primary and secondary prevention of cancer, cancer care, experiences of patients living with cancer, access to cancer care, nurses and nursing practice issues. More than 50% (n=33) of the studies investigated an aspect of primary and secondary prevention with 27 (47.4%) exploring knowledge/awareness/practices. The 12 studies (21.1%) addressing nursing practice mainly investigated cervical cancer screening programs.

Conclusion: In a 10 year review of the cancer nursing research conducted in Africa by Africa nurses/midwives, 57 articles were found. Considering the fact that Africa consists of 54 countries, 57 articles in 10 years seem to be a very low research output. However, the number of studies compare favorable to the 73 found in a review on clinical nursing and midwifery research in African countries conducted over a 10 year period ending in 2014. It was positive to find that most of the work was published in international journals. What is of concern is the large percentage of authors involved in only one study supporting evidence that Africa lacks dedicated cancer nurse scientists and that Africa's nurses contributes poorly to global scientific publications. The cancers investigated do not match the cancer disease profile of Africa. Breast and prostate cancer, the most common cancers in women and men in Africa received little attention whilst cervical cancer, the second most common cancer in women, were the most investigated, possibly because it can be prevented. Other common cancers in both men and women such as liver and colorectal cancer and cancer of the esophagus were not investigated. Studies focusing on symptom management and the family and care giver of the patient also lack. Although studies on knowledge, attitudes and practices can provide baseline data, this field of study is over exhausted and we need to move forward and prioritize developing and testing innovative ways to prevent and detect cancer

early. It was positive to find some work focused on nursing practice which would enable us to start developing evidence for Africa specific cancer nursing practice.

M 14 - Promoting Outcomes in Oncology Patients Collaboration and Communication in Pediatric Oncology: A Case for the Clinical Nurse Leader (CNL)

M. Danielle Gunter, PhD, RN, CPN, USA

Abstract

Purpose: The purpose of the study was to determine the types of supportive measures found to be most helpful and realistic for families of children with cancer during the first three months after diagnosis and to identify facilitators and barriers toward the implementation of these measures. Early support interventions improve coping behaviors and facilitate adaptation and have been recommended in adult populations (Chien, Wang, Chien, & Hwang, 2011; Sekse et al., 2014). This pediatric cancer program has tried to sustain supportive programs such as classes and support groups in the past, but has not been able to sustain participation in them. It is unclear why. The hope was by investigating this question, the researcher would be able to identify possible interventions and develop an implementation plan to facilitate familial adaptation during the cancer treatment process.

It has long been felt that the lack of a nurse coordinator or clinical nurse leader was hindering the coordination of care within the program. Other pediatric cancer programs provide for this as an integral part of their healthcare team (Howitt, 2011). Reviewing the patient/family and team member concerns would help validate the need for the provision of this valuable resource. The inclusion of a clinical nurse leader (CNL) in chronic care programs has proven to be an effective way to improve patient care and patient safety outcomes (Bender, Mann, & Olsen, 2011; Coleman, 2013; O'Grady & VanGraafeiland, 2012). The American Association of Colleges of Nursing (2013, p.4) describes the CNL as a person who "...assumes accountability for patient-care outcomes through the assimilation and application of evidence-based information to design, implement, and evaluate patient-care processes and models of care delivery. The CNL is a provider and manager of care at the point of care to individuals and cohorts of patients anywhere healthcare is delivered." This role would be ideal in addressing many of the concerns within this pediatric cancer program due to the level of care coordination required, the number of specialty health care professionals on the team, and the higher need for evidence-based practice integration at the bedside.

Methods: Descriptive single embedded case study of a south Texas children's cancer program using purposive sampling of parents of children with cancer and various members of the health care team. Total sample included 21 participants (15 HCT members and 6 parents). A case study provides a comprehensive view from all perspectives and data sources and does not require control over or manipulation of events. This case study was descriptive in nature because the researcher examined thoughts and feelings rather than looking for a specific cause of those feelings. Multiple sources of data included: demographic questionnaire, recorded interviews, observations of family activities on the unit/clinic, and research field notes. Interviews and observations continued until data saturation, when no new themes or concepts began to emerge. The demographic questionnaire provided descriptive statistics for participants. Interviews were transcribed and N-VIVO-9 software was used to analyze and code concepts and recognize themes by cross-matching across all interviews and field notes.

Results: It was thought the findings would focus on parental needs and perceived barriers, but in fact, the study also revealed underlying concerns within the health care team collaboration and overall resources for the program. Identified themes included: facilitators and barriers of family adaptation and power differentials between team members hindering effective collaboration.

Facilitators included an intact nuclear family, extended family and community support, higher education levels or professional employment that allowed more flexibility with work schedules and larger financial resources. Also, parents that sought out information tended to have more positive perceptions of their treatment experience and thus adapted more easily. Opportunities for sharing between families was reported as helpful after the initial shock from the diagnosis wore off, but no program activities to facilitate this type of interaction existed. Patient education delivered was inconsistent and dependent on large

volumes of reading material and rushed prior to discharge. Education during treatment transitions was nonexistent. Lack of education or communication regarding upcoming changes in the treatment plan led some parents to feel abandoned and increased their distress.

Barriers to adaptation included families with a lower socioeconomic status, single parent families, financial stress, previous psychological concerns such as depression and anxiety, and poor communication regarding medical care expectations completed by parents. There was a perceived difference in levels of psychosocial support offered to different families. These included counseling, case management follow up, and financial support. This led some families to report feeling more isolated when the same services were not offered to them. This was unintentional on the part of the healthcare team and could have occurred during a change in support service personnel (social worker and case manager). However, it did identify a gap in the services provided when these professionals are absent from the team.

Perceived power differentials reported from various members of the team led to delays in available interventions due to fear of repercussions from the providers even when medical orders were not necessary to implement an intervention. Some members of the healthcare team felt they were not allowed to provide the services they could offer until formally consulted by the patient's oncologist even when their services may have been most helpful prior to a formal cancer diagnosis and could be offered without a medical order. All participant members of the healthcare team reported they did not wish this to be the case and wanted to reduce the perceived power differentials to improve the patient/family care experience.

Conclusion: In order to address these concerns a system for early identification of family stress and individualized education needs should be implemented and repeated at key time frames during the treatment for childhood cancer. These time frames include the first two weeks after diagnosis, the two-three months following diagnosis, and at each treatment phase transition period. Repeating education information during the first two weeks is crucial to ensure that key treatment information is retained while parents are still in shock and adjusting rapidly to their child's needs. Parents are most receptive to information after this shock has worn off around two to three months after the diagnosis. This is when parents reported they are ready to learn, both from the staff and from other families going through similar situations. Facilitating family-based activities that allow for sharing coping mechanisms may help encourage adaptation during this period.

In the past, difficulties with team collaboration and communication has caused a breakdown in services offered. A clinical nurse scientist was formerly an integral piece in this process, but the position was decreased to a part time staff educator several years prior to this project. The current resources do not allow for proper mentoring of staff in patient education techniques or for updating the information based on the most recent evidence-based practice. Lack of consistency related to the provision of accurate patient education materials and role modeling the education delivery has led to increased incidence of patient safety concerns. It is recommended that a return of this full time position be provided to serve as a role model to staff and a coordinator of patient education throughout the treatment process.

Decreasing the power differentials and improving communication between team members and helping to identify clear expectations for each member's role within the team will improve the collaboration and coordination of patient care. It will reduce delays and improve safety by adhering to family-centered care guidelines. Making sure information is shared with parents with the appropriate support system available at delivery will help improve trust and communication effectiveness and inclusion within the plan of care. The provision for a full time clinical nurse leader is strongly recommended to serve as a lateral integrator; someone who will support the frontline staff by providing patient education resources, role modeling the education delivery, reviewing quality improvement and safety processes, bringing evidence-based practice to the bedside, and facilitating a focus on team communication and collaboration. Doing so will improve the overall patient care outcomes, satisfaction scores, and increased financial resources to the program. This in turn, can only help improve the strength and quality of the program and enhance the patient/family experience.

M 15 - Cognitive Impairment Effects on Clinical Outcomes Perceived Cognitive Deficits in Persons With Multiple Sclerosis (MS)

Alexa Stuijbergen, PhD, RN, FAAN, USA
Ashley M. Henneghan, MSN, RN, USA

Abstract

Purpose: Multiple sclerosis (MS), a chronic autoimmune-mediated demyelinating disease of the central nervous system, is estimated to affect the lives of 2.3 million persons around the world. (National MS Society, 2016). As many as 75% of those with MS may experience some cognitive dysfunction, potentially the most disabling symptom for those with MS and their families (Amato et al., 2013). Difficulties with learning and recalling new information, attention, processing speed, and verbal fluency are the most common cognitive deficits reported by those with MS.

Historically, researchers studying those with MS have found either no relationships or weak relationships between cognitive performance measures (neuropsychological tests) and self-report measures of cognitive function (Strober, Binder, Nikelshpur, Chiaravalloti & DeLuca, 2016). In addition, health care providers may question self-reports of cognitive dysfunction because the accuracy of patients' accounts might be confounded by symptoms such as fatigue and depression. Although some have suggested that the weak correlations between self-report and cognitive performance measures indicate that self-reports are not "accurate" depictions of a person's cognitive status, an alternative explanation is that performance and perception might reflect different aspects of cognition. Recent studies with fMRI imaging have shown that self-reported deficits in memory are correlated with structural alterations in the hippocampus of persons with MS (Pardini et al., 2014). This suggests that self-reports of cognitive function do indeed reflect structural and functional changes in the brain.

A better understanding of self-reported cognitive function in persons with MS is necessary as these measures are more useful in clinical settings than neuropsychological assessments which require specifically trained personnel and substantial time to administer. Self-report measures can be given in a short period of time and represent the individual's perception of everyday cognitive function. The Perceived Deficits Questionnaire (PDQ) is one self-report instrument that is used to evaluate cognitive function in persons with MS (Strober et al., 2016). The purpose of this study was to assess the cognitive deficits reported by a community-based sample of persons with MS (N=183) and to explore relationships between the PDQ and other measures of cognitive function in persons with MS.

Methods: Following approval by the Institutional Review Board, data were collected as part of the screening process and baseline data collection for a multi-site randomized clinical trial of a cognitive rehabilitation intervention for persons with MS. Recruitment for the study occurred in three major metropolitan areas in the southwestern United States through contacts with neurologists, self-help groups, and the National MS Society. All potential participants responded to the 20-item PDQ as part of the phone screening for study eligibility and completed the additional measures described below at baseline. Analyses of data included descriptive statistics, internal consistency reliability analysis of the PDQ, and correlational analyses between the PDQ scores and other self-report measures (The PROMIS Short Form v2.0—Cognitive Function Abilities, the Center for Epidemiologic Studies-Depression Scale, the Memory Strategies scale, the Compensatory Cognitive Strategies scale) and a neuropsychological testing battery that included five performance tests of verbal fluency and word finding, verbal learning and memory; nonverbal learning and memory, auditory information processing speed and flexibility and a measure of complex scanning and visual tracking.

The PDQ, is part of the MS Quality of Life Inventory (MSQLI), a health-related quality of life instrument designed specifically for people who have MS. The PDQ's 20 items assess the frequency of different types of cognitive problems that have occurred over the past 4 weeks. Respondents rate each item on a scale of 0 (*never*) to 4 (*almost always*). Total scores can range from 0 to 80, with higher scores indicating greater frequency of cognitive problems.

Results: The average age of the 183 participants was 49.35 years (SD 7.96) and they had been diagnosed with MS for an average of 12.64 years (SD 7.97). The majority (87%) were women and most participants reported they were white (75%), married or living with a significant other (63%), and unemployed (66%). Most were well educated and over half had earned a bachelor's or graduate degree (58%).

The means and standard deviations for each of the 20 PDQ items were ranked in order of the frequency that they were experienced. The most frequently reported cognitive complaints were (1) "I find my mind drifting"; (2) Trouble holding phone numbers in my head even for a few seconds"; and (3) "I forget what I came into the room for". Cronbach's alpha, a measure of internal consistency reliability, was .91 for the PDQ scale. There were significant ($p < .05$) small to moderate correlations between PDQ scores and the measures of self-rated cognitive abilities, depressive symptoms and use of memory and other cognitive strategies, but not to the neuropsychological performance tests.

Conclusion: The assessment of cognitive dysfunction is essential in MS treatment and management, especially because perceived cognitive function is a significant predictor of quality of life (Samartzis, Gavala, Zoukous, Aspiotis & Thomaidis, 2014). The PDQ is a reliable, valid measure of perceived cognitive difficulties in the domains of attention, prospective memory, retrospective memory, and planning/organization, and it can be easily administered. Furthermore, the PDQ is feasible to use in clinical settings because it can be administered in approximately 5 minutes and easily scored. The significant relationships between the PDQ and depressive symptoms and the utilization of compensatory strategies are clinically relevant.

M 15 - Cognitive Impairment Effects on Clinical Outcomes

Psychometric Properties of the Problem-Solving Inventory in Caregivers of Persons With Memory Loss

Meihua Ji, MSN, RN, USA
Susan M. Sereika, PhD, MPH, USA
Jeffrey M. Rohay, PhD, MSIS, USA
Judith A. Erlen, PhD, RN, FAAN, USA

Abstract

Background: Having adequate problem solving skills is important for caregivers of persons with memory loss to adjust to the changing needs and behaviors of the care recipient as their cognitive function declines (Berry et al., 2012; Chiu et al., 2015; Sousa et al., 2016). There is limited evidence evaluating problem solving abilities among caregivers of persons with memory loss using validated instruments.

Purpose: The purpose of this study was to evaluate the psychometric properties (reliability, factor structure and validity) of the Problem Solving Inventory (PSI) among informal caregivers of community-dwelling persons with memory loss.

Methods: For this secondary analysis, data from the baseline and 2-month post-baseline assessments of a randomized controlled trial designed to improve informal caregivers' problem solving skills related to medication management of community-dwelling persons with memory loss was used. The 32-item PSI which was originally tested among undergraduate college students with three subscales (problem solving confidence, approach-avoidance style, and personal control) was used to measure caregivers' level of problem solving, with lower PSI total scores indicative of better problem solving. Reliability of the PSI was examined considering internal consistency using Cronbach's alpha as well as test-retest reliability over a 2-month period for control group participants. Construct validity of the PSI was explored using principal component analysis for extraction with varimax rotation to explore the factor structure of the PSI. Pearson correlations between the PSI total score and scores on the Beck Depression Inventory II (BDI), Newest Vital Sign (NVS) for health literacy, as well as Self-Efficacy for Managing Chronic Disease (SEM) was tested at baseline for convergent validity. It was hypothesized that there would be at least a moderate positive association between PSI total score and BDI score; a moderate negative association between PSI total score and total scores of NVS as well as SEM.

Results: Participants (n=78 with complete data) were mainly white (87.2%), female (71.8%), and on average \pm SD 66.5 \pm 12.3 years of age with 14.7 \pm 2.8 years of education. Estimates of internal consistency for the PSI using Cronbach's alpha were 0.92 for the overall total score, and 0.90, 0.82, and 0.84 for the problem solving confidence, approach-avoidance style, and personal control subscales, respectively. Estimates of test-retest reliability over 2 months were 0.562 ($p < 0.001$) for the total score and 0.435 ($p = 0.006$), 0.587 ($p < 0.001$), and 0.559 ($p < 0.001$) for the problem solving confidence, approach-avoidance style, and personal control subscales, respectively, for caregivers in the control group (n=39). Exploratory factor analysis using principal component analysis extraction revealed seven factors for the PSI. Two factors were dropped due to less than three items having loaded on those factors, and a total of 4 items were excluded following exclusion of the two factors as well as considering a factor loading threshold of ≥ 0.40 . As a result, five factors were retained with a total of 28 items, where factors one and two were "personal control" (8 items) and "problem solving confidence" (9 items) as originally identified for the PSI. Most of the items for factor three "proactive approach" (3 items), factor four "avoidance style" (4 items) and factor five "decision processing" (4 items) were included in the approach-avoidance style in the original PSI. Pearson correlations showed a moderate positive relationship between PSI total and BDI total scores ($r = 0.372$, $p = 0.001$), and a moderate negative relationship between PSI total and SEM total scores ($r = -0.408$, $p < 0.001$); however, the association between PSI total and NVS total scores ($r = -0.096$, $p = 0.411$) was not significant.

Conclusion: The 32-item PSI was internally consistent and showed temporal stability over 2 months for measuring problem solving abilities in informal caregivers of persons with memory loss. The extracted

factors for PSI (five factors with 28 items) within this context revealed a somewhat different factor structure compared to the original scale which was tested among undergraduate college students, with more specific factors of “proactive approach”, “avoidance style” and “decision processing” that could be helpful in explaining problem solving behaviors among caregivers of persons with memory loss. The correlation between PSI total score and total scores of BDI as well as SEM showed convergent validity, but not with the NVS total score.

Implication: The PSI has the potential to help healthcare providers more adequately evaluate problem solving behaviors among informal caregivers of persons with memory loss and ultimately aid in identifying interventions to improve clinical outcomes. Given the limitations of having a small and homogeneous sample in the current study, future research should include a confirmatory factor analysis of the identified structure in current study in a larger sample of informal caregivers, the psychometric assessment of the instrument in caregivers for different patient populations, and the examination of concurrent validity using another problem solving instrument.

M 16 - Enhancing Quality of Patient Care Through Communication

A Systematic Review of the Impact of Intentional Rounding on Patient Safety in Acute Care

Angela Christiansen, PhD, MSc, BSc (Hons), RN, PGDipEd, Australia

Elisabeth Jacob, PhD, RN, FACNM, Australia

Diane Esma Twigg, PhD, MBA, BHLthSc (Nsg) (Hons), RN, RM, FACN, FACHSM, Australia

Lisa Whitehead, PhD, MA, BSc (Hons), RN, Australia

Linda L. Coventry, PhD, MS, BSc, DipAppSc, RN, Australia

Abstract

Purpose: The purpose of this paper is to report on a systematic review of the evidence of the impact of intentional rounding (IR) on patient safety in adult acute healthcare settings.

Methods: A systematic mixed method review was undertaken using the Joanna Briggs Institute (JBI) Reviewers Manual. An electronic search of CINAHL, MEDLINE, EMBASE, COCHRANE, and SCOPUS using key terms 'nursing' AND 'intentional rounding' OR 'hourly rounding' identified 89 English language citations. The titles and abstracts of the papers were reviewed independently by two researchers and 33 were deemed to meet the remit of the review. Following appraisal for methodological quality using the JBI-MASrAR and JBI-QARI nine studies failed to meet the minimum quality threshold and were excluded leaving 12 quantitative studies, 4 qualitative studies and 4 mixed method studies. The papers were published between 2006 and 2016 and reported on studies undertaken in the USA (n=13), Australia (n=5), Iran (n=1) and Saudi Arabia (n=1). Insufficient homogeneity of outcome measures precluded a meta-analysis of data so a narrative synthesis approach was used construct the data into themes.

Results: Overall the methodological quality of the studies was weak. Quantitative designs included quasi-experimental pre-test post-test designs using one, two or three non-equivalent, separate samples design. Information relating to selection bias, study withdrawals and confounding variables were limited. A lack of standardised definitions and the use of a variety of data collection tools further compromised the comparison of study outcomes. Qualitative studies included ethnographic, descriptive and action research designs.

Study findings were contradictory. For example ten studies reported the impact of IR on the incidence of falls involving adults during an acute inpatient episode. Five studies reported a statistically significant reduction in the number of reported falls (Brosey & March, 2015; Dearmon *et al.* 2013; Goldsack *et al.*, 2015; Meade *et al.*, 2006; Saleh *et al.*, 2011) and five studies reported a reduction in reported falls that was not statistically significant. Similarly ten studies reported the impact of IR on patient satisfaction with a focus on nurse responsiveness but only four of these reported a statistically significant improvement in patient satisfaction (Krepper *et al.* 2012; Meade *et al.* 2006; Negarandeh *et al.*, 2014; Tea *et al.*, 2008). Five studies reported on nurse call bell use as an indicator of how well patients' needs were being proactively anticipated and as an indicator of patient satisfaction. However while a significant reduction in call bell use following IR implementation was reported in some studies (Meade *et al.*, 2006; Cann & Gardner, 2012) another found that the total number of call bell use increased significantly in both the study and control groups (Krepper *et al.*, 2012).

The effectiveness of IR was reportedly impeded by low compliance with IR protocols caused in part by competing initiatives, priorities and workloads (Deitrick *et al.*, 2012; Harrington *et al.*, 2013). Staff skill mix, staff patient ratios and staff turnover, unclear accountability lack of leadership support and the difficulty of integrating IR into nurses existing workflow was also identified as compromising the effectiveness of IR (Flowers *et al.*, 2016; Harrington *et al.*, 2013).

Conclusion: This paper highlights a lack of consistent evidence to support or preclude the use of IR to enhance the safety and quality of patient care. The widespread adoption of IR clearly impacts on the processes of care and the capacity of nurses to keep patients safe. However an overly prescribed IR protocol may hinder the critical thinking and surveillance role of nurses by requiring an allocation of time

to be spent all patients regardless of assessment and clinical need. A more rigorous evaluation of IR is therefore needed and this paper makes a number of recommendations in regard to future studies.

M 16 - Enhancing Quality of Patient Care Through Communication Quality Improvement Initiative Evaluation to Determine Effectiveness of Provider- Patient Communication in a Wound Clinic

Stacy Eva Usher, DNP, CRNP, USA

Abstract

Purpose: The purpose of this clinical project is to improve provider communication skills and, thereby, improve patient health outcomes. This researcher participated in Patient Centered Caring Communication (PCCCI) training. The PCCI tool, however, required evaluation to determine its effectiveness at improving communication between the patient and provider in order to improve health outcomes.

Methods: The project was a face to face provider to patient clinic visit held between the researcher and the patient across a total of three visits over approximately two weeks per patient. The researcher communicated with the patient verbally, teaching through demonstration, at regular clinic visits in a wound care office with the patients and caregiver about wound care. Intervention included researcher use of the PCCCI tool which advocates use of (a) patient-centered communication (b) reflective listening, (c) active listening, (d) relationship building, and (e) PEARLS (partnership, empathy, apology, respect, legitimization, and support) to improve patient-provider communication. Implementation of these communication techniques were objectively measured through researcher use of a Provider Communication Checklist across all three visits. Evaluation of patient-provider communication was evaluated through researcher use of a researcher evaluation form. The wound length, width, depth, and amount of exudate was monitored to assess wound improvement and response to treatment. Data collected was analyzed at the completion of the three office visits. The demographics form and researcher evaluation form were analyzed using SPSS. The demographics and modifying factors were analyzed using SPSS descriptive statistics, frequency distributions to describe and summarize the data. The data was used to assess patient recall of wound care instructions with assessment of how demographics affect patient understanding of the instructions. Outcome measures were patient understanding of wound care and compliance with wound care instructions and home dressing changes. Independent-samples t test and chi-square test of independence were used to analyze relationships between demographics and wound healing. Chi-square test of independence tested whether the variables were independent of each other. Independent-samples t test were used to compare the means of two different groups.

Results: Thirty-five wound patients were assessed in this project. The age range was from 20 to 94 years old with a mean age of 57 years. Fifty-one percent of the patients were male and over 80 percent were college graduates. Eighty-three percent were non-smokers and seventy-one percent of patients were on oral antibiotics. Eighty-six percent had assistance with wound care. Only one out of the thirty-five patients did not have English as a primary language.

Fifty-one percent had no significant past medical history to effect wound healing such as diabetes, PVD, cancer, or other conditions. The other conditions listed that may affect wound healing were obesity, lymphedema, and autoimmune disorders such as Crohns and Ankylosing spondylitis. Eighty percent of the patients had acute wounds from surgery or injury, and twenty percent were from chronic conditions such as diabetes, PVD, or radiation therapy. One hundred percent of the patients or caregivers were able to verbalize the wound care plan correctly on the first visit. On the second visit, 96 percent were able to and four percent were unable to correctly explain the plan of care. Fourteen percent did not answer the question due to no second visit due to healed status, no show, or the follow visit is pending. One hundred percent of the patients or caregivers correctly explained the plan of care for the third office visit. Wound improvement was evaluated as met/not met (with one point assigned for the presence of improvement on each of the following 6 criteria: decreased wound size, improved granulation and wound edges, and no infection, tunneling or undermining. The mean wound improvement for visit number two was 4.92 out of 6 and for visit three 5.45 out of 6. In summary, the patients in this project were primarily status post-acute surgery without significant past medical history to affect wound healing, well educated, English speaking non-smokers.

Independent-samples t test comparing mean scores of the group with wound care assistance and the group without assistance found a significant difference between the means of the two groups ($t(24) = t = 3.944, p < .001$). The mean of the group without assistance was significantly lower ($m = 2.33, sd = .577$) than the mean of the group with assistance ($m = 5.26, sd = 1.251$). Independent samples t-test determined gender in this cohort did not affect wound healing. No significant difference was found ($t(24) = .273, p > .05$). The mean score for men ($m = 5, sd = 1.468$) was not significantly different from the mean of women ($m = 4.83, sd = 1.642$). No significant difference was found in wound healing scores when considering use of tobacco products ($t(22) = -1.583, p > .05$). The mean of the non-tobacco users ($m = 5.1, sd = 1.500$) was not significantly different from the mean of tobacco users ($m = 3.6, sd = .289$).

A comparison of wound healing scores between chronic and acute type of wounds required use of Chi-square test of independence. A significant interaction was found ($\chi^2(4) = 10.87, p < .05$). Sixty percent of the patients having chronic wounds had a wound improvement score of 5-6/6 and 76 percent of those having acute wounds had the same wound improvement score of 5-6/6. No significance was determined for the relationship between past medical history, education level, wound medications, and English as a primary language with wound healing.

Diabetes patients scored 5.25, PVD 3, cancer 2, no PMH 5.29, and other 5.5 out of a possible 6 points. The post-graduate patients scored the highest mean at 5.5 on wound healing, followed by college graduates at 5 point and high school graduates at 4.6. Despite the results not being statistically significant, the higher educated and healthy patients scored higher on wound improvement. A large majority of the patients were English speakers and on antibiotics.

Conclusion: The patients were able to verbalize their wound regimen correctly and list signs and symptoms of wound infection. The two who were not able to at visit number two were on the ends of the age spectrum. One was in the age range of twenties with a new acute wound and the other elderly with a newly diagnosed chronic disease. Every patient across all three visits was able to state the signs of infection except for two on visit number two. There was data for all three patient visits except for five on visit two and seven on visit three because the wound healed, the patient no-showed, or the patient was referred to a higher level of care. The lowest scores for wound improvement were a two out of six points from four patients found on opposite ends of the age spectrum and primarily associated with chronicity of the wound. The low scores all improved on the third visit except for the wound with wound dehiscence. There was no correlation between tobacco past and current use with poor wound healing scores except for a young active duty patient. Diabetes had a delayed affect on wound healing, but the patients all eventually healed. The patients with cancer and PVD had lowest scores for wound improvement. However, the patients with obesity and autoimmune disease scored high on wound improvement. Patients who had assistance with dressing changes scored higher on wound healing scores than the group without assistance. The healing scores for chronic wounds were lower than acute wounds since chronic wounds have an underlying condition that needs to be addressed. The use of PCCCI gave the researcher the confidence and skills to communicate effectively with the patient as evidenced by the patient verbalizing the plan of care correctly and improved wound healing. Evidence supports that effective communication leads to good health outcomes, and this project shows promise being able to support that finding. However, the healthy and well educated military cohort cannot be dismissed as contributors to the high wound healing scores.

The PCCCI assisted the researcher with staying on track with the patient-centered interview. Instead of asking the exhausting list of provider questions, she asked the patients what brought them to the FBCH. She provided open ended questions and let them answer without interrupting. This helped her elicit all the information related to the visit and prevent steering the conversation. In the end, the tools allowed for her to get even more details in a shorter amount of time.

N 04 - Communication Care Practices

Communication, Power Distance, and Medication Errors: An Ethnographic Exploration of Cultural Care Practices

Luanne Ruth Linnard-Palmer, EdD, MSN, BSN, USA

Abstract

Purpose: The purpose of this ethnographic research was to capture the experiences of practicing acute care nurses who work in the San Francisco Bay Area where health care environments are richly diverse. The aim of the study was to discover how practicing nurses communicate and negotiate with culturally diverse patients and families. Specifically, the purpose was to discover how nurses navigate through difficult clinical scenarios where families may experience power distance (the feelings of inequality or the extent in which people accept that inequality exists in society) that lead to misunderstandings, lack of full disclosure and ultimately the refusal, delay or limitation of medical treatment, or the development of medical or medication errors.

Methods: Ethnographic methodology was used via in-depth interviews of unlimited length. Interviews were audio-taped and transcribed for content analysis and thematic identification.

Results: Demographics demonstrated the mean age of participants was 53 years, and mean years in nursing practice was 25.8 years. Participants were culturally diverse with Asian, Hispanic, African American and Caucasian descent. Emic extractions, induction processes and empirical formulations (Leininger, 1985) were used to help make connections and identify perceptions, knowledge and language in terms of how people perceived and interpreted their experiences. Based on 33 interviews, the researchers found that power distance contributes to the development of errors. Analysis of the participants' narratives and responses included three major themes: 1) power distance creates barriers to effective communication; 2) understanding the impact of strained communication contributes to errors; and 3) nursing education woefully prepares nurses to assist ethnically and culturally diverse families during difficult clinical scenarios when trust and feelings of inequality interfere with effective and safe care.

Conclusion: Nurses who work with culturally diverse interdisciplinary teams and culturally diverse patients and families must understand that power distance creates barriers to safe care. Cultural perspectives and care practices may not be disclosed to health care providers if patients or their families feel threatened, misunderstood or disrespected. Medical and medication errors can occur if power distance is not identified and families feel supported and listened to. The study has several implications related to practice and education. After analysis, the research team came to consensus that teaching the impact of the role of power distance new nurses is a directive, teaching how individualism/collectivism influences care and communication, and identifying early for the avoidance of potential errors related to strained cultural communication is important in all settings.

N 04 - Communication Care Practices

Trust Development Between Patient and Nurse: A Grounded Theory Study

Sharon M. Jones, PhD, RN, CNE, USA

Abstract

Trust is an important factor in the nurse-patient relationship and is part of collaboration in patient-centered care. Interpersonal trust between two people incorporates five key factors: risk, vulnerability, power imbalance, familiarity, and good will (Baier, 1986; De Raeve, 2002; Sellman, 2007). There has been limited research related to the development of trust in the nurse-patient relationship. In a research study related to trust development for the patient in the hospital setting, the researchers examined the patient-provider relationship including physicians and hospital staff but not exclusively the nurse-patient relationship (Hupcey, Penrod, & Morse, 2000). More recently, in a grounded theory study of the development of trust between the nurse and the hospitalized English-speaking Mexican-American patient in the USA, findings indicated that if the patient did not develop trust with the nurse, the patient may be less likely to ask questions or share personal information (Jones, 2015b). This reluctance to confide or share information was seen in previous studies related to culturally congruent care and Mexican American patients (Warda, 2000; Zoucha, 1998). In a follow-up study with Spanish-speaking Mexican American patients in the USA, the researcher again found trust was needed for the patient to be willing to share and, more importantly, the establishment of trust was evident even when a language barrier between the nurse and the patient was present (Jones, 2015a). In both these studies (Jones, 2015a, 2015b), trust with the Mexican American patient was examined because trust is an important Hispanic cultural value (National Alliance for Hispanic Health, 2001) and Hispanics in the USA report lower levels of trust compared to non-Hispanic white patients (Kaiser et al., 2011). However, trust may develop differently for non-Hispanic patients which led to the current study of how trust develops for the non-Hispanic patient in the USA.

Purpose: The purpose of this study was to explain how does trust develops between the non-Hispanic English-speaking patient and the nurse in the hospital setting from the patient's perspective.

Methods: Classic grounded theory (Glaser & Strauss, 1967) was used in this study since the goal is to explain a basic social process, trust. Inclusion criteria for the study were a) non-Hispanic, English-speaking adults, b) hospitalized at least 36 hours on medical-surgical or obstetrics unit, and c) anticipated discharge within the next few days. Patients were excluded if they were a) cognitively impaired (dementia, confusion) or b) admitted to a unit for treatment of a mental health condition. Participants were interviewed face to face in a private setting while hospitalized in the Midwestern United States. The researcher used a semi-structured interview guide and interviews were digitally recorded and transcribed verbatim. Data analysis was done concurrently with data collection using constant comparison, comparing incident to incident (Glaser, 2001). In data analysis, codes were generated from transcript review and then collapsed into categories forming a model of how trust develops and a core category emerged.

Results: Findings from this study led to a model of the development of trust including outcomes presented as categories and the core category. Findings indicated that trust developed through the nurse's initial approach toward the patient including the nurse's attitude. Factors leading to trust included being genuine, being present, and talking personally. Interesting findings in this study were the development of a friendship-like bond between the nurse and the hospitalized patient. Another interesting finding was the vulnerability the patients felt when specific incidents led to trust development and participants referred to the nurse "saving the day". This reflected the nurse acting on patient concerns rather than dismissing concerns. Outcomes of the development of trust included the patient confiding in the nurse, being willing to ask, and making the hospital stay easier.

Conclusion: The development of trust is important for patients in the hospital setting and the nurse can do simple things which leads to trust such as talking personally and acknowledging patient concerns. Although this study was done in the USA with patients having unique cultural values, the model of how

trust develops may be transferable to the nurse-patient relationship in other hospital settings throughout the world and have global implications. The findings are useful to promote the knowledge of how to develop trust with patients which may lead to improved individual patient outcomes and ultimately advance health. Findings from this study and previous studies will be used to build a middle range theory on the development of trust in the nurse-patient relationship with hospitalized patients.

N 06 - Gerontological Nursing Care

Developing Clinical Guidelines to Improve the Care of Older People With Diabetes

Trisha Lynette Dunning, PhD, MEd, AM, RN, CDE, ACN-DLF, Australia

Abstract

Background: Diabetes is associated with functional, cognitive, and social changes. Polypharmacy and under-or malnutrition, pain, depression, falls, confusion, delirium and significant medicine-related adverse events including hypoglycaemia are common (Munshi et al. 2016). There are a number of existing guidelines for the care of older people with diabetes but conversations with staff caring for older people with diabetes indicated that such guidelines do not address core components of the care such as sexual health and end of life. There is limited clinical trial evidence to support recommendations and low regard for expert/consensus opinion. Older people with diabetes are often excluded from studies: when they are included they were basically healthy and prescribed none or only one medicine (Bayer & Tadd 2000).

Aim:

- a) Develop a guideline development framework that followed National Health and Medical Research (NHMRC) clinical guideline development recommendations (NHMRC 1998).
- b) Engage key stakeholders (older people with diabetes and health professionals) in the development process.
- c) Determine the value of consensus/expert opinion when developing guidelines CPGs.

Method: We followed the National Health and Medical research council (NHMRC) clinical practice guideline development recommendations. We conducted a structured literature review, appointed an expert advisory group and subjected the draft guidelines to peer-review. In addition to the NHMRC recommendations, we formally evaluated the Guidelines in four small rural and one large metropolitan aged care facilities before they were released into the public domain. Data were collected using anonymous self-completed questionnaires and interviews with staff and older people with diabetes before and nine months after the guidelines were distributed to the care homes and staff used them to plan care. A medical record audit was undertaken to ascertain whether the guidelines were used to plan care. In addition, the guidelines were subjected to external peer review by international experts in the care of older people with diabetes.

Results: Very few randomised controlled trial were identified, therefore most of literature was graded at level 3 or 4. Eighty nine residents: 58% female, 82% had type 2 diabetes, all had at least one diabetes complication. Thirty one staff members, mostly nurses, participated. There was some evidence from the medical record audit that some guidelines influenced care, especially the risk hypoglycaemia and medicine adverse event assessment tools that form part of the guidelines. The advice from the Expert Advisory Group (consensus opinion) and evaluating the guidelines in the clinical settings they were designed for enhanced their value and played a valuable role in the content validity and clinical relevance of the final Guideline, the McKellar Guideline. A key outcome of the staff evaluation was a suggestion to include information about how staff could use the document to plan care. Consequently, an accompanying document, The McKellar Way, which suggests strategies for implementing the Guideline recommendations to personalise care, was developed (Dunning et al. 2013).

Impact and outcomes:

- A suite of information that consists of a philosophical framework to guide care (Dunning et al. 2013),
- Clinically relevant, usable clinical guidelines for managing older people with diabetes: The McKellar Guidelines (Dunning et al. 2013; The McKellar Way (Dunning et al. 2013).
- Awarded the Barwon Healthcare Innovation Award for Excellence in Healthcare.
- Became policy in our health service in a large regional/rural area in 2014.
- The Guidelines are cited in and were the basis for the older person section in the Australian Government National Diabetes Strategy 2016–2020 released on World Diabetes Day, 2015.

- Medical record audits undertaken before the Guidelines were implemented in 2014 and approximately nine months after implementation show changes consistent with Guideline recommendations in residents' care plans, including evidence that care is based on Guideline recommendations and is being personalised.
- Staff is required to attend annual professional development sessions that are based on the Guidelines,
- The Guidelines are being implemented in various other Australian and some international practice settings
- The risk assessment tools in the Guidelines were translated into Norwegian.
- Discussions about translating the Guidelines into Chinese were held with a Chinese geriatrician.
- The Chief investigators mentored beginning researchers to build research capacity.
- Clinical indicators were developed and will be evaluated in a follow up study.

Conclusions: The guideline development process combined several strategies with the NHMRC recommendations, namely key stakeholder engagement throughout the development process, which enabled methodological issues to be addressed. It resulted in clinically relevant guidelines for caring for older people with diabetes that meet stakeholders' needs and have been translated into and changed practice. Combining consensus/expert opinion with clinical evidence engages key stakeholders and contributes valuable practical information not reported in clinical trial.

N 06 - Gerontological Nursing Care

Changing Attitudes With a Gerontological Nursing Course

Monica L. Tenhunen, DNP, GNP-BC, ANP-C, USA

Abstract

Purpose: The purpose of the study was to determine baccalaureate nursing student attitudes toward older adults and if a gerontological nursing course changes their attitudes. In 2013, older adults comprised 14.1% of the population and by 2040 are expected to be 21.7% of the population (Agency on Aging, n.d.). The American Association of Colleges of Nursing (AACN) requires nursing programs to provide relevant knowledge about aging and states education needs to address incorporation of attitudes in providing care (AACN, 2010).

Multiple studies indicate nursing students do not desire to work with older adults and that their attitudes about this population influence this desire (Henderson, Kelton, Paterson, Siegloff, & Xiao, 2008; Matarese, Dhurata, & Federic, 2010; Matarese, Lommi, Pedone, Alvaro & De Marinis, 2013; Shen & Xiao, 2012). A systematic review completed in 2013 by Liu, et al., indicated inconsistent attitudes among nursing students regarding older adults and that there were not any consistent predictors of attitude.

Education can increase knowledge on a topic. Mattos, et al. (2015), completed a study that showed the knowledge level of students increased with a course on gerontological nursing but there was no change in attitudes. Another study showed an increase in knowledge along with more positive beliefs about older adults (Baumbusch, Dahlke, & Phinney, 2012). There is limited research in the United States on nursing student attitudes regarding older adults.

As the older adult population increases, nursing education needs to focus on preparing graduates to not only understand the special needs of the population, but also to value positions in care of older adults. This study increases evidence regarding how education can influence attitudes in undergraduate nursing students and could promote the advancement of health for older adults.

Methods: The study includes approximately 55 nursing students in two different cohorts enrolled in an undergraduate baccalaureate-nursing program who consented to participate in the study. The nursing program added a one-semester unit gerontological nursing course to the curriculum, which was not included in the first cohort of students' curriculum. University Institutional Review Board approval was obtained. Instruments included are a demographic survey, Palmore's Facts on Aging Quiz (FAQ) and Kogan's Old People Scale (OPS). Permission was obtained to use both of these scales. The FAQ and OPS were shown to be reliable and valid in previous studies (Mangen & Peterson, 1982; Matarese, et al., 2013; Palmore, 1980; Yen, et al., 2008).

The instruments are completed at four different times during the program for students that have the gerontological nursing course as part of their program. The instruments were completed at the end of the program only for the cohort that did not have the course. Data entry was completed by a trained research assistant and verified by a statistician.

Results: Data analysis using SPSS to determine ANOVA with repeated measures and t-tests to analyze changes in attitudes will be completed for the cohort graduating in December 2016. The 2016 cohort will be compared to the 2015 cohort at the end of their program for further analysis regarding the benefit of the course on influencing attitudes. Results will be compared with other studies to determine consistency of findings.

Conclusion: Limitations of the study include a small sample size, the study was completed in only one university nursing program, and other factors may have influenced the attitudes of the nursing students. Plans are to continue the study with additional cohorts of students and involve another university nursing program for comparison. The results of this study add to the evidence regarding how education influences

attitudes. Educators can use the results to plan and implement teaching to advance future nursing practice.

N 07 - Global Retention

Perceived Strategies to Decrease Attrition Rates Among Nurses Practicing at Healthcare Institutions in India

Llewellyn Prater, PhD, RN, USA

Shelby L. Garner, PhD, RN, CNE, USA

Leena Raj, MSN, MPhil, India

Abstract

Background: A profound nursing shortage exists in India, where nurses are increasingly out-migrating to practice nursing abroad. A robust nursing workforce is needed to improve health outcomes in India. Until recently, nursing was not considered a profession in India and research suggests nurses historically experienced marginalization and oppression (Johnson, Green, & Maben, 2014). A recent positive shift in the perception of nurses as professionals in India creates a timely milieu in which to give nurses a voice so that they may express their ideas and perceptions (Walton-Roberts, 2015). Strategies to decrease attrition rates among nurses in India could also shape health policy in other countries that may be facing similar shortages.

Purpose: To explore a subset of nurses' perceived strategies to decrease attrition rates among nurses practicing at healthcare institutions in India.

Methods: A qualitative descriptive approach was used. Purposive sampling resulted in 10 participants. First, participants were asked to complete a short written questionnaire to provide information on socio demographics and nursing experience. Participants were then interviewed using face-to-face semi structured, in depth, individual interviews. The interviews started with open-ended questions related to each participant's lived experience as a nurse in India and moved into open-ended questions to solicit their ideas on strategies to decrease attrition rates among nurses in India. Data were collected from November 2014 to March 2015. Interviews were audio recorded and transcribed. A directed content analysis approach was used to derive codes, themes, and subthemes.

Results: Coding and thematic interpretation resulted in three themes and multiple subthemes. Perceived strategies to decrease attrition rates included the need to: 1) implement reasonable remuneration through establishing equitable and aligned salary scales, 2) provide safe and effective environments by standardizing nursing workforce policies, ensuring equipment availability, and offering transportation services for nurses, and 3) recognize nursing as a profession by offering increased opportunities for nurses to become leaders and providing opportunities to recognize the value of nurses in the healthcare workforce.

Conclusion: Participants in this study advocated for change in nursing and workforce policy to start from within the nursing profession towards positive practice environments to increase nursing capacity in India and globally.

N 08 - Improving Health Using Dogs

Man's Best Friend: The Role of Companion Animals in the Lives of the Homeless

Susan K. Lee, PhD, RN, CNE, USA

Pamela Willson, PhD, RN, FNP-BC, CNE, FAANP, VHF, USA

Abstract

Purpose: It is estimated that 28,000 persons are homeless in Texas on any given night (Texas Homeless Network, 2016). Many homeless people have companion animals to fulfill social needs: friendship, while demonstrating unconditional, nonjudgmental love; and satisfying basic needs of love and self-worth (Smolkovic, Fajfar, & Mlinaric, 2012). Over the past 25 years, multiple studies demonstrated human health benefits of relationships with companion animals. Companion animals were thought to play a significant role in effecting change or providing stability to the homeless as there are psychological, physiological, and social benefits associated with having companion animals (Labrecque, & Walsh, 2011; Slatter, Lloyd, & King, 2012). Recent work with homeless veterans and their companion animals successfully demonstrated a high degree of pet attachment displayed by homeless veterans, along with difficulty in finding housing, and the veteran's willingness to refuse opportunities for placement if companion animals were not allowed (Lee & Willson, 2016). According to Pets of the Homeless Organization (2016), two cities in Texas have shelters that accept homeless persons and their companion animals. The purpose of this project, therefore, was to expand previous work with homeless veterans in selected counties to include a sampling of the general homeless population across Texas and to describe homeless shelter administrative policy/practices for companion animals.

Methods: Specific aims were: to determine the experiences of homeless individuals across Texas with companion animals in securing services, and to explore facilitating space for companion animals with homeless shelter administrators in selected locations across Texas. It was believed that homeless participants across Texas would demonstrate high levels of Comfort from Companion Animal Scale scores, would have difficulty finding housing, and would refuse opportunities for placement if companion animals were not allowed. Additionally, it was thought that, as homeless shelter administrators, key informants would be able to describe the strengths, weaknesses, opportunities, and threats of their facility's policy/practices for homeless individuals with companion animals.

For Aim 1, a descriptive mixed method design was used to investigate homeless Texans' experiences with companion animals in securing homeless services. Subjects were recruited over one year through direct recruitment at homeless shelters, facilities offering free food and veterinary care for companion animals of homeless people, at soup kitchens, near churches, and in parks where the homeless congregate. A sample of 60 participants comprised of the accessible population who are male and female, English-speaking, homeless people who had no shelter other than homeless shelters, and who have companion animals, was sought and interviewed until saturation was thought to be reached. Inclusion criteria consisted of participants ages 18 years and above, with the exception of emancipated minors who were younger than 18 years of age. Exclusion criteria included people with homes, or who did not speak English.

When a potential participant indicated an interest in participating in this research project and the inclusion criteria was met, the investigator explained the purpose of the study and the interview process, including the estimated amount of time that would be spent in the interview, the steps to maintain confidentiality and to offer privacy, and how the information collected would be handled. The participant was given an opportunity to ask questions during this time. When the participant indicated he/she had no further questions, that the purpose of the study and role in the interview process was understood, oral and written informed consent form was obtained.

Data collection methods included direct observation; individual, unstructured, face-to-face interviews; and tape recordings, along with completion of a demographic questionnaire and the Comfort from Companion Animals Scale (Zasloff, 1996). The demographic questionnaire included age, sex, marital status, employment/military history, living accommodations, length of time homeless, and history of companion

animal relationship. Interviews were conducted in a public area, yet out of hearing range of other people to protect confidentiality. Interviews were semi-structured with a prepared, modifiable list of broad prompts and questions that were altered as the situation warranted, gaining a better understanding of the origins and nature of issues experienced. The investigator took field notes while conducting taped sessions. The interviews were completed in one conversation, some of which lasted up to one hour.

For Aim 2, a qualitative structured interview process was applied to explore facilitating space for companion animals with homeless shelter administrators in selected locations across Texas. The Facilitator Structured Interview Guide was framed by a Strengths, Weaknesses, Opportunities, and Threats (SWOT) analysis. Homeless shelter administrators and recruitment sites were identified by internet searches of the Texas Homeless Coalition, Texas Homeless Network, and snowballing technique. Locations were sought state-wide to encompass both large and smaller cities (i.e., Amarillo, Austin, Corpus Christi, El Paso, Fort Worth, Houston, Plano, San Antonio, Temple, and Tyler). Homeless participants were offered a \$20 recruitment incentive and administrators were offered an agency donation incentive of \$150. Phenomenological analysis approach was used to code the narratives looking for themes that expressed the meaning that the experience had for the participants.

Results: Data analysis was conducted and each interview was analyzed and compared to previous interviews to reveal repeated themes and categories. Once all interviews were transcribed, compared, and analyzed, no new concepts were observed, and data saturation was felt to be achieved, a central concept was identified.

Conclusion: Homeless persons have a strong, unyielding bond with their animal companions that overrides personal needs. Interviews revealed that the homeless claim companion animals save their lives, help to overcome adversity, factor into the decision-making process to facing a better future, and become the impetus for wanting to move out of homelessness, thus encouraging responsibility. Further, animal companions provide unconditional love and decrease lapses into unsafe behavior, such as that associated with drugs and alcohol.

This project built on past work and was designed to address the access of Texas homeless persons with companion animals to a basic necessity of life—shelter. The benefits of companion animals to the health and welfare of individuals is established and the science will continue to grow with the use of “service animals” and “therapy animals” to improve psychological and physiological health conditions (Henry & Crowley, 2015). Through gained knowledge and understanding from this research, it is hoped policy/practices of services offered homeless persons without terminating the companion animal relationship will be formed- a future that could likely involve a service or therapy animal. As a community and primary care professional, working with culturally diverse, marginalized populations to improve living conditions and health outcomes is an on-going professional obligation and personal desire. There is a shared responsibility of Texans to ensure that men and women who are homeless have access to the quality, timely resources and are allowed to keep their companion animals.

Service Dogs' Influence on Military Veterans' Health: A Qualitative Study

Cheryl A. Krause-Parello, PhD, MSN, BSN, RN, FAAN, USA
Kristie Morales, BA, USA

Abstract

Purpose: Military service members from across the world returning from active duty may be vulnerable to challenges associated with service-connected medical conditions. There is little debate that conditions such as loss of limb(s), traumatic brain injury (TBI) and posttraumatic stress disorder (PTSD), significantly impair a large segment of military veterans (Creamer, Wade, Fletcher, & Forbes, 2011). Invisible wounds such as PTSD and TBI are correlated with an increased risk in developing anxiety, depression, substance use (e.g., alcohol use), and engaging in suicidal ideation (Wisco et al., 2014). This presents unique challenges to veterans, making them a particularly vulnerable population that may contribute to poorer clinical health outcomes. Moreover, many veterans continue to experience PTSD related symptomology and sequela despite receiving standard care. In many of these cases, veterans are turning to alternate assistive interventions, such as the utility of a service dog for visible and invisible wounds (Krause-Parello Sarni, & Padden, 2016).

Methods: The aim of this qualitative study was to elucidate the impact of service dogs on health outcomes for a US veteran population. Service dogs are trained to do work or perform tasks for the benefit of an individual with a disability and can help to assist with tasks needed for daily functioning. This presentation reports the breadth and depth of service dogs for service connected conditions (e.g. PTSD and TBI). In-depth interviews were conducted with veterans ($N = 21$) and analyzed using interpretive phenomenological analysis. The interviews were recorded and transcribed verbatim. Atlas.ti software was used to explore, interconnect, and organize the data in-depth for the presence of reemerging content and meaning. Five superordinate themes emerged from the thematic analysis: Procurement of service dog, psychosocial functioning before service dog, impact of service dog, importance of service dog to veterans' health and reintegration, and issues.

Results: Factors that were related to obtaining a service dog after military service were connected to the symptomology and sequela associated with invisible wounds such as PTSD, anxiety, depression, and TBI. The impact of utilizing a service dog was found to reduce the symptomology associated with invisible wounds, provided psychosocial support, served as a protective mechanism against suicidal ideation and substance use. The service dog also allowed some veterans to reduce or cease psychotropic medications used for depression and anxiety, improving health outcomes and perceived quality of life.

Conclusion: The results substantiated the positive impact on health promotion and clinical outcomes that service dogs provide for veterans; a call to action for change in public policy is needed regarding service dogs as a reimbursable medical expense for invisible wounds.

N 09 - Improving Outcomes in Patients With Neurological Injury Comparison of a Nurse-Driven Mobility Protocol to Multidisciplinary Mobility Protocol for Subarachnoid Hemorrhage Patients

Megan T. Moyer, MSN, ACNP-BC, CNRN, USA

Bethany C. Young, MSN, RN, AGCNS-BC, CCRN, USA

Abstract

Purpose: The presence of invasive neuromonitor devices, such as an external ventricular device (EVD), may be a deterrent to aggressive, early mobilization due to fear of catheter dislodgment, hemorrhage, or inappropriate cerebrospinal fluid drainage (Kocan & Lietz, 2013). These drains and monitor devices have historically required strict bedrest. Extended periods of immobility in intensive care units are linked to acquired medical complications. These complications are detrimental to the patient and can lead to higher economic costs for patients, caregivers, institutions, and third-party payers resulting from prolonged hospital lengths of stay, extended rehabilitation stays, and higher levels of disability. In contrast, early mobilization in the intensive care unit may be associated with improved peripheral and respiratory muscle strength, increased quality of life, more ventilator-free days, decreased delirium, and greater functional independence (Kayambu, Boots, & Paratz, 2013; Brahmhatt, Murugan, & Milbrandt, 2010; Miller, Govindan, Watson, Hyzy, & Iwashyna, 2015). No definition exists in literature for the ideal time of early mobilization in general intensive care units or neurological intensive care units (McWilliams, Atkins, Hodson, & Snelson, 2016). Early mobilization in the neurological intensive care unit has been demonstrated as both safe and feasible. Varying clinical practice guidelines and standards exist for patients with external ventricular devices in the neurological intensive care unit due to the intricacies of each disease process, complexities of developing mobility algorithms, and specialized monitoring required by the staff during the mobility process. This subset of patients in neurological intensive care units with external ventriculostomy drains create an opportunity to develop and implement practice guidelines to implement nurse-driven early mobility.

In January 2016, our Neurointensive Care Unit progressed from mobilizing patients with external ventricular devices (EVDs) only with physical and occupational therapy (Phase I), to utilizing a nurse-driven mobility protocol (Phase II).

Methods: The Phase II EVD Mobility Protocol allowed nurses to independently mobilize subarachnoid hemorrhage patients with EVDs. Patients could remain out of bed with the EVD clamped for a maximum of 3 hours per session. Physical and occupational therapists (PT/OT) continued normal consultation and recommended the safest mobility method for each patient. Standard protocol for the management of Subarachnoid hemorrhage patients was maintained for the duration of the study. Patients with subarachnoid hemorrhage who also had an external ventriculostomy drain and demonstrated tolerance to a 30-minute drain clamping trial were included in this initiative. Patients who were unable to tolerate 30 minutes of drain clamping, exhibited sustained intracranial hypertension (defined by intracranial pressure (ICP) of greater than 20), or whose code status progressed to comfort care or hospice care were excluded. Delayed cerebral ischemia was not an absolute contraindication for mobilization, however if patients were experiencing fluctuating neurologic exams due to fever, infection, medication administration, or delayed cerebral ischemia, mobilization was held for that particular day. Pulmonary and/or cardiovascular instability or patient refusal could also preclude mobility. The nursing and medical teams re-evaluated every patient on a daily basis to determine mobility readiness for that day.

Results: 6/13 patients (46%) were men. Mean age did not differ significantly between Phase I and Phase II [57.1 (27-84) versus 54.8 (19-83); $p=0.67$]. A total of 213 activity sessions took place over 6 months during Phase II, compared with 71 sessions during one year of Phase I. Of 213 sessions, nurses independently completed 135 sessions (63.4%); PT/OT participated in 78 sessions (36.6%). On average, mobility occurred 1.2 days earlier in Phase II [day 5.96 (1-13) versus day 4.75 (2-12); $p=0.32$]. Phase II patients were mobilized an average of 6.7 times (+/-4.7) with their EVD compared with 2.96 times (+/-1.33) in Phase I ($p=0.02$). Mean hospital LOS trended lower in the Phase II group [20.5 days (+/-7.39) versus 24.6 days (+/-8.29); $p=0.14$]. Ventilator days also trended lower in Phase II [6.3 days (+/-3.81)

versus 12.3 days (+/-10.47); p=0.14]. No Phase II patients received a tracheostomy, compared to 16.7% in Phase I (p=0.12). All patients in Phase II were discharged home or to acute rehab (p=0.18).

Conclusion: Nurse-initiated mobilization of patients with EVDs is safe, feasible, and may lead to earlier and more frequent ambulation compared to a therapy-driven protocol. Nurse-driven mobility may be associated with fewer ventilator days, shorter hospitalization, and improved discharge disposition. No major complications were attributable to early mobilization.

The primary goals of this quality improvement initiative were to promote and establish a culture of early, progressive mobility in the Neuro ICU and to demonstrate improved patient outcome. Standardizing the processes by which we mobilize our patients with external ventriculostomy drains allowed for multidisciplinary engagement in the process and embedded a new culture of mobility in our unit. Nurse-driven mobility has allowed physical and occupational therapy to engage in more complex therapy techniques with patients, such as more mobilization with ventilators, and to explore the use of other novel therapy devices.

N 09 - Improving Outcomes in Patients With Neurological Injury Patient and Facility Characteristics Related to Hypertension Control After a Transient Ischemic Attack (TIA)

Greg Arling, PhD, USA

Fitsum Baye, MS, USA

Jason Sico, MD, FAHA, FACP, USA

Priscilla Arling, PhD, USA

Laura Myers, PhD, USA

Dawn Bravata, MD, FAHA, FACP, USA

Abstract

Purpose: The purpose of this study was to identify patient and facility characteristics associated with hypertension control for TIA patients in the 90 days following discharge from an ED or inpatient setting.

Hypertension is one of the risk factors targeted for better management by the United States Veterans Health Administration (VHA), the largest health system in the nation with 168 VHA Medical Centers and 1,053 outpatient sites of care of varying complexity (VHA outpatient clinics), serving more than 8.9 million Veterans each year. Hypertension control is particularly important after a TIA, as it can be a major factor in preventing a recurrent stroke ([Kernan et al., 2014](#)) or other vascular event.

Hypertension control after a stroke or TIA is often below accepted targets ([Ovbiagele et al., 2011](#)). Prior work in the VHA system found that only 56% of stroke patients had blood pressure (BP) control (<140/90 mmHg) at 6 months post-discharge from their index hospitalization ([Ross et al., 2011](#); [Roumie et al., 2011](#); [Roumie et al., 2015](#)). Those studies found that the quality of care during an inpatient stay was generally unrelated to hypertension control or other risk management quality measures post-discharge for stroke patients. That research included patients with stroke but excluded TIA patients.

Relatively little is known about hypertension management for VHA patients after a TIA. While guidelines for treatment and interventions exist, providers may not systematically counsel patients regarding stroke and TIA prevention ([Schmid, Andersen, Kent, Williams, & Damush, 2010](#)). Interviews conducted in other studies by the authors suggest that TIA-patients care needs may be viewed as less urgent than patients with other disease processes. Specifically, TIA patients may not garner the same amount of attention by care providers as patients diagnosed with a stroke. Both patient and facility factors could contribute to or impede risk factor management for patients with a TIA. Gaining a better understanding of patient characteristics affecting hypertension management could help target patients for interventions. Identifying facility factors could guide system-level changes to improve care.

Methods: We used electronic health record data to select a sample of 3676 patients with a TIA who were cared for in the emergency department (ED) or inpatient setting in 132 VHA facilities from October 2010 to September 2011. Patients with an ICD-9 code of 435.x excluding were classified as having a TIA. For patients who were cared for in the ED only, the ICD-9 code for their ED visit was used; for patients who were admitted, the primary discharge diagnosis code was used. Patients were excluded from the analysis if they did not have valid BP measurements within 90 days of discharge, died during the index ED visit/hospitalization or within 90 days of discharge, were discharged to hospice, or were transferred to a non-VA acute care facility. A sample of 3508 TIA patients from 105 VHA facilities were included in the analyses.

VHA inpatient and outpatient data files were used to identify past medical history, healthcare utilization (e.g., hospitalizations, office visits) and receipt of procedures. Pharmacy Benefits Management (PBM) data were used to identify medications; Corporate Data Warehouse (CDW) data were used for vital signs, laboratory data allergies, orders, and consults. Finally, linked VHA-Centers for Medicare and Medicaid Services (CMS) data were used to identify comorbidity, and hospitalizations in non-VHA facilities.

The outcome variable was BP control at 90 days post-discharge from the index ED or inpatient admission. Control was defined as systolic BP <140 mmHg and diastolic blood pressure <90 mmHg. Other patient characteristics included BP control at discharge from the ED or inpatient setting; demographics of gender, age, marital status, and race (African American); and past medical history of hypertension, hyperlipidemia, sleep apnea, dialysis, and depression. Facility characteristics included VHA stroke center designation of primary stroke center or limited hours stroke facility, urban location, 25 or more stroke admissions per year, and FTE internal medicine staff.

For the outcome of BP control at 90 days we fit a hierarchical general linear model (HGLM) with a logit link function and a facility random effect. Independent variables were BP control at discharge, other patient characteristics, and facility characteristics.

Results: At discharge, 58% of patient has their BP controlled, while at 90 days post-discharge, 78% of patients had their BP controlled. Ninety-five percent of the Veterans were male age. They had a mean age of 69 (SD=12). Fifty-one percent were married and 19% African American. Their past medical history included hypertension (82%), hyperlipidemia (76%), sleep apnea (19%), dialysis (3%), and depression (40%). Thirty-two percent of patients used the ED only and 68% had an inpatient admission, while 63% had a neurologist consult in the ED or inpatient setting. Fifty-nine percent of facilities had a VHA stroke center designation, 91% were in an urban location, 62% had 25 or more stroke admissions per year, and their internal medicine staffs averaged 1.1 FTE/100,000 patient visits.

As expected, patients with uncontrolled BP at discharge were significantly less likely to have BP control at 90 days (Adjusted Odds Ratio [AOR] .36, 95%CI [.30-.44]). Neither black race nor other demographic variables were significantly related to BP control at 90 days. A history of hypertension (AOR .45, 95%CI [.30-.44]) and dialysis (AOR .57, 95%CI [.34-.96]) were associated with absence of BP control; whereas, patients with a history of hyperlipidemia (AOR 1.37, 95%CI [1.09-1.72]), sleep apnea (AOR 1.29, 95%CI [1.00-1.64]), and depression (AOR 1.27, 95%CI [1.04-1.54]) were significantly more likely to have BP control. Neither an inpatient admission (as opposed to ED only) nor having a neurology consult was related to subsequent BP control. Facility characteristics significantly related to BP control at 90 days were a stroke center designation (AOR 1.45, 95%CI [1.08-1.94]), being in the top quintile of FTE internal medicine staff (AOR 1.45, 95%CI [1.08-1.95]), and percentage of all patients with BP control (AOR 1.14, 95%CI [1.03-1.25]).

Conclusion: We expected that patients with a history of hypertension and those with uncontrolled BP at discharge would be more likely to have uncontrolled BP at 90 days post-discharge.

Interestingly, patients admitted to the inpatient setting and those with a neurologist consult were no more likely to have their post-discharge BP controlled than patients seen only in the ED or without a neurologist consult. Risk factor management in the days and weeks after the TIA event may be the deciding factor in hypertension control rather than the setting for care immediately after the event. The role of comorbidities is complex. Patients with multiple conditions, such as a history of hyperlipidemia, sleep apnea, or depression, may have their risk factors managed more intensively after discharge. On the other hand, dialysis patients may be more difficult to manage due to fluctuations in BP due to fluid status. Our findings suggest that post-discharge hypertension management may be best achieved in facilities with a designated stroke center, greater primary care resources (FTE internal medicine) and a track record of better overall hypertension management.

In another arm of the study, we conducted interviews with health care providers at 14 high-volume VHA Medical Centers to inquire about successes and barriers to good TIA care. A major factor that stood out was the presence of an RN stroke coordinator, who was able to bridge the care transition post-discharge. The stroke care coordinator was pivotal in arranging for follow-up care in the stroke clinic, if available, and with the primary care provider.

Our study prompted a multisite intervention in VHA Medical Centers to improve quality of care through coaching and sharing of quality metrics. The intervention is taking advantage of existing VHA infrastructure and applying it to the care of patients with TIA. For example, we have created protocols and

templates for pharmacists who were not previously involved in the care of either stroke or TIA patients and now they are serving as a bridge between the inpatient and outpatient settings. Similar protocols/templates have been developed to guide the post-discharge primary care RN calls to patients. We found that many patients had a history of poor BP control prior to their TIA. These patients may benefit from intensification of medications at discharge followed by appropriate monitoring through primary care ([Roumie et al., 2015](#)).

N 10 - Maternal Education in Preterm Infants

Behavioral Intervention With Maternal Participatory Guidance Improves Preterm Infant Outcomes

Rosemary C. White-Traut, PhD, RN, FAAN, USA

Abstract

Purpose: This completed randomized controlled trial of 198 premature infants born at 29-34 weeks gestation and their mothers examined the impact of the H-HOPE (Hospital to Home: Optimizing the Preterm Infant's Environment) intervention on infant behavior, infant feeding and growth during hospitalization, mother-infant interaction, and illness visits when the infants reached 6-weeks corrected age (CA). The research was guided by two models: Developmental Science and Adult Learning Theory.

Methods: Mother-infant dyads were randomly assigned to the H-HOPE intervention group or an Attention Control group. H-HOPE is an integrated intervention that included (1) twice-daily infant multisensory stimulation using the ATVV Intervention (auditory, tactile, visual, and vestibular-rocking stimulation) offered prior to feeding and (2) four maternal participatory guidance sessions by a nurse-community advocate team. Infant behavior was measured weekly during hospitalization via the proportion of alert states and the frequency of orally directed behaviors when infants were able to feed orally. Infant feeding was measured weekly during hospitalization by Medoff-Cooper's nutritive sucking apparatus and growth was determined by daily weight gain and weekly length. Mother-infant interaction was assessed after hospital discharge at 6-weeks CA using Barnard's Nursing Child Assessment Satellite Training-Feeding Scale (NCAST, 76 items) and Censullo's Dyadic Mutuality Code (DMC, 6-item contingency scale during a 5-minute play session). Illness visits from hospital discharge through 6 weeks CA were reported by the mothers.

Results: There were no differences between the groups at baseline for any of the dependent variables. The infant behavior data showed that by day 7, the intervention group exhibited a significantly higher mean frequency of orally directed behaviors when compared with the Attention Control group (12.6 vs. 7.1 pre-intervention, $p < 0.10$; 51.8 vs. 33.2 during intervention, $p < 0.10$; and 8.9 vs. 5.3 immediately prior to feeding, $p < 0.05$). Also on day 7, the H-HOPE intervention group exhibited a significantly higher proportion of time spent in an alert state during intervention (0.26 vs. 0.11, $p < 0.05$) and immediately after intervention (0.28 vs. 0.06, $p < 0.01$).

Infant feeding during hospitalization differed between the two groups. A quadratic trend was observed for infant feeding as measured by the number of sucks, the number of sucks per sucking burst, and a sucking maturity index. The intervention group experienced an increasing significantly improved oral feeding by day 7 (Model estimates for group by day: number of sucks - $\beta = 13.69$, $p < 0.01$; number of sucks per sucking burst - $\beta = 1.16$, $p < 0.01$; and the sucking maturity index $\beta = 0.12$, $p < 0.05$). Sucking pressure increased linearly over time, with significant between-group differences reached at day 14 ($\beta = 45.66$, $p < 0.01$). During hospital stay, the H-HOPE group infants gained weight more rapidly over time when compared with infants in the control group ($p = 0.04$) and grew in length ($p = 0.015$) more rapidly than control infants, especially during the latter part of the hospital stay.

After hospital discharge and when the infants reached 6-weeks CA, NCAST and DMC scores for the Control and H-HOPE groups were compared using *t*-tests, chi-square tests and multivariable analysis. Compared with the Control group ($n = 76$), the H-HOPE group ($n = 66$) trended toward higher NCAST scores overall and higher maternal Social-Emotional Growth Fostering Subscale scores and had significantly higher scores for the overall infant subscale and the Infant Clarity of Cues Subscale ($p < 0.05$). H-HOPE group dyads were also more likely to have high responsiveness during play as measured by the DMC (67.6% versus 58.1% of controls). After adjustment for significant maternal and infant characteristics, H-HOPE group dyads had marginally higher scores during feeding on overall mother-infant interaction ($\beta = 2.03$, $p = .06$) and significantly higher scores on the infant subscale ($\beta = 0.75$, $p = .05$) when compared to controls. Infants assigned to the H-HOPE group were also half as likely to have

illness episodes (illness visit to the clinic, emergency department (ED) or hospital readmission) as control infants (OR = 0.46, 95% CI = 0.22, 0.95).

Conclusion: Intervening with both mother and preterm infant during initial hospitalization and the first month following hospital discharge is a promising strategy to support infant behavior, oral feeding, and infant growth, improve mother-infant interaction, and reduce infant illnesses following hospital discharge.

N 10 - Maternal Education in Preterm Infants

Development and Evaluation of a Tailored Mother-Infant Interaction Program for Premature Infants

Da Hae Rim, MSN, RN, Korea, Republic of (South)

Hyunsook Shin, PhD, RN, CPNP-PC, Korea, Republic of (South)

Abstract

Purpose: Recently, with the increasing rate of premature babies, the number of programs for promoting mother and infant interaction has been increasing. Positive mother-infant interactions help cognitive and emotional development of premature. Mothers' sensitivity is a very important factor in forming mother-infant interactions well. But, if the mother's sensitivity does not recognize the meaning of the signal sent by the premature infant, it is often emotional difficulties such as burden of care or depression. The health status of premature infants varies from baby to baby. However, previous studies on the mother-infant interaction programs were limited providing individual mother and infant with more effective nursing strategies. Therefore, the purpose of this research is to develop a tailored mother-baby interaction program for premature and to evaluate its effect on the maternal sensitivity.

Methods: This study was completed using two stages of development and evaluation. In the development stage, a tailored mother-infant interaction program was developed based on the Barnard Mother-infant interaction model. The developed program included assessment tools of mother-infant needs and capacity, interpretation procedure, and tailored nursing strategies. In the evaluation stage, we checked the maternal sensitivity before and after the program. A total of 12 premature babies and their mothers participated in this study in 2015. To evaluate the program effect, one-group pretest-posttest design was used.

Results: At the program development stage, methodological research method was used. The mother's competence level and the characteristics of the child (underlying disease, sleep cycle, corrected age, etc.) were identified and the program composition was organized according to the characteristics of the premature and mother. The characteristics of the child were based on the findings checked by the nurses' evaluation. The characteristics of the mother were identified by self-questionnaire based on mother characteristics in Barnard Mother-Infant Interaction Model. The findings from the paired t-test present that the scores of maternal sensitivity among participants significantly increased ($t=-7.62, p<.001$) after completing the developed mother-infant interaction program.

Conclusion: Tailored program depending on the mother-infant need and capacity may facilitate maternal sensitivity leading to promotion of the mother-infant interaction. The program developed through this study is expected to reduce the burden of mothers who are raising premature infants. We recommend future studies address guideline development and training opportunities for nurses and mothers on the tailored process of the mother-infant interaction program.

N 11 - Palliative Care in Education

Using Multicultural Role-Play to Improve End-of-Life Care Education

LaToya Janelle Lewis-Pierre, EdD-CI, MSN, RN, USA

Mary E. Mckay, DNP, ARNP, CNE, USA

Jill Steiner Sanko, PhD, BA, BSN, RN, ARNP-BC, CHSE-A, USA

Maha McCain, MFA, USA

Abstract

Purpose: The purpose of the study was to evaluate the effectiveness of an undergraduate End-of-Life education with simulation. In 2012, the World Health Organization (WHO) reported 56 million deaths worldwide. Furthermore, the 2014 Institute of Medicine report *Dying in America* called for improvements in end-of-life care. Providing dying patients with high-quality family and patient-centered end-of-life care that aligns with the patients' values and informed preferences poses challenges. One aspect of the problem is nursing curricula and clinical rotations often lack educational opportunities that address such challenges related to end-of-life (EOL) care conversations. As a result, many nurses are uncomfortable or ill prepared to carry out appropriate end-of-life conversations.

Simulation-based education presents a realistic way to practice these skills and provide a safe environment to where mistakes can be made in the absence of patient harm (Founds, Zewe, & Scheuer, 2011). Simulation creates a valuable opportunity for students to have authentic experiential experiences that support the development of technical, cognitive, therapeutic, and psychological skills (Roberts & Greene, 2011). End-of-life care simulation experiences, that include a unique blend of promoting competence with therapeutic communication, cultural competence, medication management, nursing interventions, and empathy, can help to better equip nurses to deal with end-of-life care. Standardized patients (SPs) are instrumental in providing realism in scenarios, but SPs can be costly, and difficult to find. To address this problem, we present an innovative approach that utilizes multicultural arts and sciences students enrolled in a theater course that trains them to be SPs. The SPs were culturally representative thus allowing the nursing students to experience a variety of diverse patient care demands that are common in today's healthcare.

This approach also utilizes a unique two-phased debriefing process that allows nursing students to experience immediate in-character feedback at the bedside followed by traditional debriefing in a separate area. The traditional debriefing is replete with a debrief and a reflection of the in-character feedback as well as the scenario action. This approach allows students to reflect on the experience as a whole as well as benefit from the "patient" view of their care.

Methods: Students participating in a theater course were trained to play SPs followed with the more specific training to be able to realistically play the family member of a dying patient. This tactic also allowed for the inclusion of cultural considerations to be woven into the end-of-life scenarios. The scenario presented a woman with Non-Hodgkin's Lymphoma who was brought by the Emergency Medical Services (EMS) to the Emergency Room. The students enter the "scene" to find the SP, playing either the patient's daughter or son, at the bedside. The major objective of the scenario was for the nursing students to provide therapeutic communication as they managed the care of patient and the family as they navigate the end-of-life process.

During the initially run sessions, SP feedback was given as part of the usual debriefing process, with the SP staying in character. However, upon receiving feedback from the nursing students that this approach was not well received, modifications were made to instead include in-character feedback immediately following the end of scenario action at the bedside. Subsequently this was followed with traditional debriefing in a classroom.

Results: Fifty-six participants completed a mixed method study. The Katherine Frommelt (1991) Attitudes toward Care of the Dying (FATCOD-B) survey was administered at two time points (pre/post). Qualitative research questions with content analysis tapped into the participants' attitudes related to the end of life

educational experience. Responses from the nursing students revealed that receiving feedback from a SP was a new experience and something to which they were not initially receptive. Following the change to the two-phased approach, the nursing students' opinions of the overall experience was more positive. They felt more aware of the family members' needs and shifted from a patient-focused care approach toward a family-centered care approach. When asked about their simulation experience, what their thoughts were related to end-of-life, and their feelings related to end of life care, respondents described the scenario as being realistic and a valuable learning opportunity. Participants were also asked "which learning situation had the biggest impact on your thoughts and feelings related to end-of-life care?" Many stated the simulation influenced their thoughts and feelings on end-of-life care; one participant mentioned that when an SP daughter asked "if her mother died" it created a lasting impression.

Conclusion: Preparing to interact with patients and families at the end-of-life requires individuals to be psychologically and physically present in the patient's care. Using SP students was a novel way to provide a rich learning experience and added realism to an end-of-life simulation experience. Realism was further deepened through the integration of SPs from different cultures and genders, another important element that reflected the influence of culture on end-of-life nursing care. While the approach was generally successful, there are important considerations to heed. Both groups of students must understand each other's roles, pre-briefing is vital to inform nursing students that the SPs will provide in-character feedback, and immediate bedside in-character SP feedback is received may be better received than having SPs participate in debriefing. Finally, the debriefing should include a discussion of the bedside feedback to give the opportunity for learners to reflect on receiving feedback from the "patient's" perspective. Creating experiential learning with a multicultural element in simulation is integral toward preparing future nurse for culturally diverse healthcare.

N 11 - Palliative Care in Education

Transforming Nursing Students' Attitudes Toward End-of-Life Care

Pamela L. Mahan, PhD, MA, BS, RN, USA
Helen M. Taggart, PhD, RN, ACNS-BC, USA
Sherry L. Warnock, MSN, RN, USA

Abstract

Purpose: The purpose of this research was to examine the effect of an actual compared to a simulated hospice clinical experience on nursing students' attitudes toward end-of-life care; and.

Methods: A pretest and posttest nonequivalent two-group design consisted of a sample of 65 undergraduate nursing students enrolled in a community health course. All students enrolled in the community health course have one day for hospice experience, and a two-hour orientation from the nurse educator at a local hospice agency. Students enrolled in the first seven weeks were paired with a hospice nurse and conducted home visits. Students enrolled in the second seven-week session participated in two simulated hospice experiences on campus. Thirty-two students were in the experimental group (simulated hospice) and 33 were in the control group (actual hospice). Attitudes toward end-of-life care was measured pre and post intervention with the The Frommelt Attitude Toward Care of the Dying (FATCOD) scale, Form B (Frommelt, 2003).

Results: The findings indicated positive attitude changes toward end-of-life care, and clinically relevant information for the development of a hospice clinical experience. After the clinical hospice experience, both groups appeared to show increases in their mean FATCOD scores possibly indicating a greater comfort with caring for dying patients. Paired t-tests for each group were conducted. The increase in the mean FATCOD score for the control group, 8.6 (SD = 9.4), was statistically significant ($p < 0.001$) indicating the students in the control group did experience a significant rise in their positive attitudes toward end of life care, on average. The increase in the mean FATCOD score for the experimental group was significantly smaller, 1.7 (SD = 11.4), and was not statistically significant ($p = 0.42$). Thus the students in the experimental group had little to no change in their mean FATCOD score indicating their positive attitudes toward end of life care was virtually unchanged

Conclusions: The findings have important implications for incorporating didactic and clinical components of end-of-life care throughout the undergraduate nursing curriculum. The clinical hospice experience can increase student comfort with caring for dying patients and families. The greatest increase in comfort with when caring for dying or end-of-life patients was from actual hospice clinical experiences. Since this is not always available, simulated experiences provide an acceptable substitute. The end-of life clinical can be a transformative experience allowing nursing students to develop greater compassion and increased decision-making skills when caring for the dying patient. Further research is needed to evaluate the efficacy of a hospice clinical compared to a simulated hospice experience.

N 12 - Preventing Childhood Obesity

The Impact of Feeding and Parenting Guidance on the Prevention of Child Obesity

David McCormick, MD, ., USA

Elizabeth Reifsnider, PhD, FAAN, FAANP, WHNP-BC, PHNCS-BC, USA

Michael Todd, PhD, ., USA

Lucy Reyna, BA, CCHW, USA

Irma Pecina, AA, CCHW, USA

Abstract

Purpose: The purpose of this study was to test an intervention, guided by public health nursing practice and delivered by community health workers, to prevent the development of obesity in infants and young children who are at risk of obesity because of maternal body size, income status, and ethnicity. We followed the Institute of Medicine's (IOM) 2011 report on early childhood obesity prevention policies, which recommended five approaches to preventing obesity: assess, monitor, and track growth from birth to age 5; increase physical activity and decrease sedentary behavior in young children; support breastfeeding and be responsive to children's feeding cues; limit screen time; and promote age-appropriate sleep for young children.

Methods: We recruited 150 high-risk pregnant Mexican-American women from the Houston Texas Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) and followed them and their infants from birth to age 3. The research design used was randomized clinical trial with two groups; the intervention group received 9 home visits by a community health worker across 2 years while the control group received nutrition education from the WIC clinic staff. The content delivered during the home visits was manualized but adapted to address specific issues such as overfeeding or physical play space. Children and mothers in both groups received measurement home visits from a data collector blinded to group assignment. Measures collected focused on anthropometrics for child and mother, diet recalls, home environment, sleep quality and quantity, maternal stress, and food insecurity.

Results: Compared with non-intervention controls, infants in the intervention group grew on a healthier weight-for-length trajectory from birth to age 24 months. Statistically significant improvements in preventing excessive weight gain were attributed independently to breastfeeding and to the educational intervention provided by the community health workers. Mothers in our study who breastfed for at least 2 months were thinner at 6 months postpartum than mothers who did not breastfeed, even non-exclusively, for 2 months.

Conclusion: Major changes in the diet occur from birth to 18 months and dietary patterns are set by age two years. Additionally, the first 2 years of life are a critical time period where parents can help their child to establish healthy patterns that may well last a lifetime and could help curb the obesity trend. Community Health Workers are effective in public health research, especially with low-income or racially and ethnically diverse populations. Conducting home visits is an effective method of data collection that minimizes the burden on subjects. Many low-income parents have difficulties maintaining regular well-child visits due to transportation barriers, lack of work flexibility, language differences, and lack of childcare for their other children. A community-based participatory research (CBPR) approach enhances researchers' ability to recruit and retain subjects. Our CBPR approach is effective for recruiting and retaining participants and leads to improved health outcomes in studies with Hispanics. To our knowledge, our application is unique in its use of CBPR to study child obesity in partnership with WIC, which serves a low-income, racially/ethnically diverse population. Our innovative use of an ecological model allows us to study multilevel, intersecting influences on childhood obesity. Use of the ecological approach will enable researchers to view the complex environment surrounding children holistically to identify those factors of greatest significance to child obesity.

N 12 - Preventing Childhood Obesity

Smart Nutrition and Conditioning for Kids (SNACK): An Interprofessional Approach to Nutrition and Physical Education

Tracy J. Perron, PhD, RN, CNE, CSN, USA
Tami L. Jakubowski, DNP, CPNP-PC, CSN, USA
Anne Farrell, PhD, USA

Abstract

Purpose: The purpose of SNACK was to increase the fitness and health of elementary school age children and to empower parents and caregivers to encourage healthy food choices. SNACK was developed in response to the 2010 Childhood Obesity Study recognizing a 49% childhood obesity rate in Trenton, New Jersey. Lifestyle influences contributing to childhood obesity and Type 2 diabetes mellitus include poor food choices, inadequate access to healthy foods, decreased physical activity and insufficient access to safe play environments. SNACK provided nutrition lessons to second grade students in an urban and urban rim elementary school during regularly scheduled physical education class. SNACK included physical activity and health education in the areas of fitness, healthy eating, and healthy lifestyles. The implementation of SNACK was aimed at reducing the risks for obesity and Type 2 diabetes in school age children. The overarching premise was that if children and parents/guardians are reached at an early age before lifestyle choices are ingrained: healthy behaviors can be formed to potentially reduce the incidence of chances they will face obesity and type 2 diabetes. It is important to engage parents/caregivers to encourage healthy food choices and increased physical activity at home as well as in the school to maximize health benefits to children.

Methods: An interprofessional collaborative model (IPC) in conjunction with the Coordinated School Health Program provided guidelines for the establishment of a diverse multidisciplinary group to improve the health of urban/urban rim children. The intervention was performed twice a week in physical education class for 8 weeks. Pre and post Fitnessgram fitness tests (FIT) were completed by each child. Pre and post study nutritional knowledge assessments were completed by each child. Nutrition lesson plans were developed to educate the children on healthy eating in a fun, interactive manner during physical education class. Video links were provided on the participating schools' websites to inform parents of the nutrition content being addressed during the SNACK program.

Results: The SNACK program afforded participants with opportunities to share ideas from their discipline with members of the interprofessional team to positively impact all participating members. The College of New Jersey School of Nursing, Health, and Exercise Science developed new and stronger partnerships with urban and urban rim schools. Undergraduate majors observed faculty and other professionals' model continued learning, interest in their discipline and in those of others while collaborating with peers. Fitnessgram fitness test (FIT) scores improved for all fitness tests for both the experimental and control groups in both schools ($p < .05$). Significant differences between groups was found in 4 areas of FIT testing: PACER, push-up, curl-ups, and long jump ($p < .05$). CATCH (Coordinated Approach to Child Health) nutritional knowledge improved overall with the experimental group in both schools ($p < .05$). The CATCH Healthy Choices survey improved with the experimental groups in both schools ($p > .05$). Videos may have encouraged parents to include healthier food choices into their family meals or spurred conversation with their children about healthy food habits. SNACK elementary school students and their parents found the program to be informative and fun.

Conclusion: A coordinated school health program (CSHP) can be implemented to meet the needs of the whole child and maximize the positive effects on student, schools, and communities while integrating cooperation of multiple disciplines. The FIT program is one example of an approach to improving fitness levels with minimal time and resources. SNACK an interdisciplinary approach to early intervention that teaches children how improve their fitness, nutrition and overall health.

N 13 - Enhancing Patient Care With the Use of Technology

Mobile App to Prevent Depression in the Dominican Republic: Sociocultural Adaptations and International Collaborations

Tariana V. Little, MS, USA
Susan Caplan, PhD, FNP-BC, USA
Adrian Aguilera, PhD, USA
Ester R. Shapiro, PhD, USA
Angelina Sosa Lovera, MPH, Dominican Republic
Patricia Reyna, PsyD, Dominican Republic
Jenny Arianny Sánchez Castillo, BA, Dominican Republic
Pak Chau, USA

Abstract

Purpose: Globally, depression is among the most significant contributors to burden of disease (Whiteford et al., 2013). The rapid increase of mobile phone use in low-and-middle income countries provides an opportunity to leverage technology-based interventions to improve global health (mHealth) (World Health Organization (WHO), 2011). This study builds on previous research and ongoing collaboration with the Dominican Ministry of Public Health on mental health stigma and mental health service needs in the Dominican Republic (DR), which found unmet mental health care service needs, particularly in terms of access to care, affordability of treatment, and stigma (Caplan, Little, Reyna, Sosa Lovera, Garces-King, Queen, & Nahar, 2016). Nearly 85 percent of the population in the DR has cell phones (WHO, 2011), thus mHealth is a feasible alternative to address some limitations of face-to-face mental health service delivery. However, research is needed about methods to socioculturally adapt mHealth interventions for mental health in low-resource settings (Farrington, Aristidou, & Ruggeri, 2014), specifically in terms of incorporating voice in mHealth and the many ramifications of the use of voice. We report on findings related to the sociocultural adaptation of an evidence-based face-to-face cognitive behavioral therapy (CBT) delivered through a mobile application (app) to treat depression among Dominican patients.

Methods: With ongoing collaboration with mental health professionals in the DR and the United States, the face-to-face CBT program was modified for use in the app. Modifications were designed to compensate for the absence of therapist/patient live interaction by incorporating daily salutations and dichos (short parables or instructive comments. These modifications were piloted among a convenience sample of 24 interview participants (14 patients and 10 clinic staff in different capacities). The validated Spanish language Patient Health Questionnaire (PHQ-9), a depression measure was administered to patients and clinic staff in a primary care clinic in Santo Domingo, DR to identify a purposive sample of subgroup of respondents who had symptoms of depression. All three interviewers were Spanish-speakers with substantial experience working with Dominican populations; one was trained in psychology and from the DR. Semi-structured individual interviews were used to assess demographics, mental and physical health, use of mental health care, and use of mobile phones and applications for health behaviors. Participants offered structured feedback on the content of the sample messages, their voice gender preferences (woman vs. man), and emotional resonance with their mental health needs. Additionally, participants provided feedback on the length, wording, clarity, and comprehension of the audio messages. Qualitative interview questions were iteratively changed as participant perspectives contributed new areas of inquiry, such as questions about safety concerns in publicly using a cellphone in the DR. Survey data were reviewed and systematically analyzed by the investigators using descriptive techniques. Our study was approved by the Rutgers Institutional Review Board.

Results: Most participants had a mean age of 37 years and were women (n=17). One-fourth of all participants scored at least “moderate” depression symptoms. Some patient participants and a few clinic staff disclosed mental health challenges, and a limited subset reported previous use of mental health resources, including face-to-face therapy. Overwhelmingly, participants preferred in-person therapy over medications. Early all participants had cell phones, predominantly smart phones, and almost all reported interest in mobile application therapy due to its convenience, privacy, and affordability. Regarding mobile

application features, most participants reported a preference for the female voice because they perceived a woman's voice to be more calming and reassuring than a man's voice, who was perceived as more emotionally detached. Almost all participants responded that the sample of audio messages could be helpful to manage life stress. Both patient and clinic staff participants found the recording on meditation to be relaxing but expressed concern about the culturally-implied religiosity of the word "meditation," and proposed a substitute word, "relaxation." Most participants preferred informal salutations in the messages, and said that they would like to receive cell phone messages multiple times daily or weekly. There were differences between patient and medical doctors (a subset of the clinic staff) as to the appropriateness of some of the recommended treatment strategies. Specifically, doctors felt that the use of humor in one of the audio messages would be ineffective, which was a reflection of provider conceptions of patients with depression as being incapable of responding to humor. Patient participants were in general interested in and responsive to the humor message. Lastly, a number of modifications that were suggested by participants were incorporated into the final contents of the app.

Conclusion: Our findings from participants in a low-resource clinic in urban DR reveal strong enthusiasm for using a mobile application to provide preventative cognitive behavioral strategies for symptoms of depression. Participant feedback informed the further sociocultural and linguistic adaptation of the mobile app. The subsequent proof-of-concept study will be conducted in spring 2017 to assess acceptance, feasibility, perceived helpfulness, and preliminary depression outcomes among Dominican primary care patients. Study findings address gaps in the literature pertaining to specific qualitative aspects of voice-based mHealth interventions and the methodology of sociocultural adaptation of mHealth mental health interventions (Farrington, Aristidou, & Ruggeri, 2014) across diverse settings and target groups (WHO, 2011), particularly in Latin America (Janevic et al., 2016).

N 13 - Enhancing Patient Care With the Use of Technology

Patient Care Technology: Where the Patient Meets the Nurse

Belinda M. Toole, PhD, RN, CCRN, CCNS, USA

Abstract

Purpose: Technology and technological device use has proliferated. Globally we are connected, often more to devices than each other (Rosen, 2012; Turkle, 2011). This reliance on technology in daily life has also led to an imperative to incorporate technology and device use in healthcare (Weitz, 2013).

Historically, a key component of nursing practice is the holistic, humanistic relationship between the nurse and the patient. More recently, there has been a movement to embrace patient and family centered care in healthcare delivery (Kitson, Marshall, Bassett, & Zeitz, 2013). Yet technology has an allure and presence, which may influence the interactions between patients and care providers (Barnard & Sandelowski, 2001). Qualitative studies provide perspectives from patients and nurses and describe technology and device use paradoxically – providing a sense of security and reassurance but also an awareness of dependency and distraction (Kongsuwan & Locsin, 2011; Locsin & Kongsuwan, 2013; Price, 2013; Stayt, Seers, & Tutton, 2015; Tunlind, Granström, & Engström, 2015).

The purpose of the research study was to examine how patient care technology mediates the interpersonal relationship between the patient and the nurse during care delivery in the acute care setting. The conceptual framework for the study was derived from three mid-range theories: Locsin's Technological Competency as Caring in Nursing (2005); Swanson's The Structure of Caring (1993); and Kostovich's Model of Nursing Presence (2012). Study aims were to quantitatively describe the levels of nurse technological competency as caring, patient perceptions of caring and nurse presence, and to examine the relationships among demographic variables and the study variables. Secondly, the study qualitatively explored nurses' and patients' perceptions of technological device use in care delivery.

Methods: Following Institutional Review Board approval, a non-experimental, concurrent, mixed-methods design was used to address the research aims. The setting was a community adult acute care hospital in the southwestern United States. Participant recruitment occurred in early 2014. Quantitative convenience sampling resulted in 112 nurse and 115 patient participants, and qualitative purposive sampling recruited a subset of 23 nurses and 15 patients. Quantitative data was obtained from three instruments. Nurse technological competency as caring was measured using the Technological Competency as Caring in Nursing Instrument (TCCNI; Locsin, 1999; Parcels & Locsin, 2011). The TCCNI is comprised of 25 items on a 0-100 mm dichotomous visual analogue scale (strongly disagree = 0; strongly agree = 100). The TCCNI has a Cronbach's alpha of 0.81 (Locsin, 1999) and a S-CVI/Ave of 0.96 (Parcels & Locsin, 2011). Patient perceptions of caring were measured using the Caring Behaviors Inventory (CBI), a 24-item, 6-point Likert scale (1 = never to 6 = always). The CBI produces an overall score and four subscale scores (assurance of human presence, professional knowledge and skill, respectful deference to others, and positive connectedness). The CBI has a reported Cronbach's alpha of 0.96 (Wu, Larrabee, & Putman, 2006). Patient perceptions of nurse presence were measured with the Presence of Nursing Scale, a 25-item, 5-point Likert scale (1 = never, 5 = always) instrument with a Cronbach's alpha of 0.95 (Kostovich, 2012). Qualitative data was derived from semi-structured interviews using a consistent set of six exploratory patient questions and four exploratory nurse questions. Data was analyzed using SPSS, Version 22 and by first and second cycle thematic coding.

Results: Nurse participants were predominantly female (83.9%), white (56.3%) with a mean age of 34.88 years, and with a Bachelor's Degree in Nursing (80.2%) and 9.42 mean years of nursing experience. Overall nurses rated their technological competency as caring high ($M=87.72$, $SD = 7.56$). There were no significant differences related to demographic variables and TCCNI scores except for the variable of race. Asian nurses (29.5% of participants) scored themselves higher than whites ($p = .002$).

Although 115 patients were initially recruited, a notable amount of missing data resulted in analysis of only patients who had complete data on both instruments ($n=87$). Final sample patient participants had a

mean age of 58.9 years, were male (54.0%), white (66.7%), and had a college (47.1%) or post-graduate education level (18.4%). Patient subjects were admitted for medical (55.2%) rather than surgical reasons, and had a 9.92 day mean length of stay when the data was collected. Patients' rated perceptions of caring behaviors ($M = 5.44$, $SD = .58$) on a 6-point scale. Examining relationships based on demographic variables, patient perceptions of caring differed significantly by gender and pain. Male patients rated overall caring behaviors significantly higher ($M = 5.56$, $SD = .47$, $p = .040$) than females ($M = 5.29$, $SD = .66$). Patients in pain rated positive connectedness ($M = 4.94$, $SD = .92$, $p = .047$) lower than those without pain ($M = 5.30$, $SD = .74$). Patients' perceptions of nurse presence were high ($M = 115.82$, $SD = 10.55$), and there was a positive relationship between age and presence scores ($r[85] = .295$, $p = .006$).

Qualitatively three themes were associated with device use for both patients and nurses: safety, learning, and balance. Both groups felt technological devices provided a safety net. Learning associated with the device varied by group. Patients learned about devices by observation or provider explanations, whereas nurses described learning in operational terms -- to achieve competency in device use and skill in troubleshooting. Balance in technological use was described as achieving an equilibrium between patient and device focus and was dependent on the care context and viewpoint of the operator or receiver. For patients (receivers), technological device use provided a sense of safety and expedited the process of care delivery. However, patients viewed devices negatively when the devices were used brusquely or without explanation. Nurses also appreciated the inherent safety measures provided by devices but were frustrated by the time required for both initial learning and subsequent troubleshooting when devices malfunctioned. Both nurses and patients felt operationalization of devices signified a measure of skill, not only in machine use, but also in how devices were integrated into the care delivery process.

Conclusion: Globally, technology and technological device use is pervasive in general society and healthcare. The goal of nursing is to provide humanistic and holistic care, but interpersonal interactions can be influenced by device use. In this study, technological device use in care delivery created a presence, which was perceived as positive or negative depending on the care context and how the device was operationalized. Nurses, and all healthcare providers, should be aware of how patients perceive device use and then integrate these new methodologies and devices as adjuncts to patient centered care.

N 14 - Promoting Well-Being in the Workforce

Promoting Health and Well-Being: A Review of the Effectiveness of Interventions to Prevent Workplace Bullying

Patricia Gillen, PhD, RN, RM, United Kingdom
Marlene Sinclair, PhD, RN, RM, RNT, United Kingdom
George Kernohan, PhD, United Kingdom
Cecily Begley, PhD, RGN, RM, RNT, FFNRCSI, Ireland
Ans Luyben, PhD, RM, United Kingdom

Abstract

Globally, research about bullying in workplaces including healthcare institutions has been shown to reduce the physical and mental health of employees. Generally, employees who have been bullied have lower levels of job satisfaction, higher levels of stress and are more likely to leave their job with the effects of bullying considered to be more devastating than all other types of workplace stress put together 1. A recent survey by the Trade Union Congress in the UK 2 identified that 46% of those who responded had reported that bullying had negatively affected their performance at work and their mental health. In the US, a 70% rate of exposure to bullying behaviour was recorded among 212 registered nurses 3 with bullied novice nurses' reporting a negative impact on their ability to manage their workload4.

To date, most research has focused on how to manage bullying once it has happened, rather than preventing it. Indeed those who have been bullied choose to leave their job rather than face up to the bully 5. At a time when recruitment and retention of staff is particularly challenging, it is important to know what can be done to prevent bullying.

Purpose: To review of the effectiveness of workplace interventions in preventing bullying in the workplace using a Cochrane Systematic Review approach.

Methods: We searched a wide range of databases and found 19,544 references of which 125 were considered to be of some relevance. More detailed reading, and data extraction, excluded all but five studies that reported on the effectiveness of interventions to reduce the incidence of workplace bullying. The outcomes of bullying such as workplace absenteeism were also explored.

Results: Two studies reported on organisational interventions that consisted of policy measures and stress management and measured bullying as incivility 6-7. One of the studies also showed a reduction in incivility and absenteeism. An expressive writing task 8, showed a reduction in the amount of bullying. Cognitive behavioural therapy was used with employees who had a learning disability, and showed a reduction in bullying 9. The overall effects of these interventions were small. One study evaluated education and policy interventions in combination, across five organisations, resulting in a small non-significant increase in bullying 10.

Conclusion: This review showed that organisational and individual interventions can prevent bullying in the workplace but, like many interventions to address complex phenomena, the evidence is of very low quality. We suggest that the small effects of interventions in large populations might represent stronger outcome in small subsets of those who suffer in silence from bullying in the workplace. More focussed studies are needed with better outcome measurement to evaluate the effect of all preventive interventions.

N 14 - Promoting Well-Being in the Workforce

Nursing Workforce Well-Being and Quality of Life: Predictions and Recommendations

Lin Perry, PhD, RN, Australia

Robyn Gallagher, PhD, RN, Australia

Christine Duffield, PhD, MHP, BScN, RN, FACN, FAAN, Australia

David W. Sibbritt, PhD, Australia

Xiaoyue Xu, PhD, RN, Australia

Abstract

Purpose: A person's quality of life (QoL) is defined by their goals, standards and concerns, especially in their cultural context. It is a subjective summary measure of wellbeing, reflecting 'complete physical, mental, and social well-being' (WHO 2006). All aspects of an individual's life contribute and, for those who are members of a workforce, work life makes a sizable contribution, especially for full time workers. Links have been demonstrated between QoL and job satisfaction, and increased QoL and job satisfaction in nurses improves job performance and reduces turnover, directly influencing the quality of healthcare they deliver (Milosevic et al. 2011), and in turn reducing costs to healthcare providers (Duffield et al. 2014).

How a person feels about their job relates to individual goals and expectations and hence to QoL. Some influences on work life quality of life and/ or job satisfaction are well-recognised, such as workplace violence, bullying and harassment, workplace stress and burnout (Bartram et al. 2012; Budin et al. 2013), psychosocial work factors such as job strain, psychological job demand, decision latitude/ authority and job control. The occupational pressures associated with the nursing profession are increasingly recognised and affect all ages; the problems of stress and distress, compassion fatigue, burnout, absenteeism and staff turn-over are globally significant. Irrespective of the job satisfaction reported, for nursing this has been linked to working conditions, environment and culture; to job stress, role clarity and content, organizational and professional commitment. However, these factors differ with differing work settings.

Individual health can also be influential, including on intention to leave (Perry et al. 2015); chronic, non-cancer and musculoskeletal pain have all been associated with reduced QoL, as have chronic diseases such as diabetes. Increased weight leads to poorer health but does not necessarily affect QoL. Given the diversity of potential individual and workplace influences, we sought to identify:

- To what extent health and workforce characteristics influence nurses' and midwives' quality of life, and how this compares to that of the Australian general population;
- What recommendations can be drawn for future interventions to promote QoL and job satisfaction for nurses and midwives?

Methods: This was an online cross-sectional survey including the Short Form-12 version 2 (Sanderson & Andrews, 2002) as a measure of QoL, calculated using the QualMetrics algorithm. This paper describes these nurses' and midwives' quality of life and compares this to that of the Australian general population (Avery et al. 2004).

Participants were nurses and midwives employed in New South Wales were recruited through the email mailing list of the NSW Nurses and Midwives Association (the NSW nursing and midwifery professional body) and by snowball distribution through professional groups and networks between May 2014 and February 2015.

The survey instrument comprised a mixture of validated instruments and items examining demographic information, workforce, health, job satisfaction and quality of life, using the Medical Outcomes Survey Short Form-12 (which produces separate physical and mental component scores: PCS and MCS). Taking a 'mental health day' (MHD) as sickness absence, anecdotally a common phenomenon in Australia, was

determined by asking how many sick days were taken in the previous 12 months and then, “How many of these sick days would you classify as ‘mental health days?’” [6]

Sample characteristics were reported using descriptive statistics. Demographic, workplace, work and health-related potential predictive variables were analysed in relation to quality of life and job satisfaction using univariate and multivariate regression models.

Approval was granted by South Eastern Sydney Local Health District and University of Technology Sydney Human Research Ethics Committees. Study details were available on the survey webpage and informed consent was presumed with submission of a completed online questionnaire.

Results: Nursing and midwifery participants

Of 5,446 completed questionnaires, 405 (7.4%) were excluded due to missing data or non-NSW practice. SF-12 physical and mental component scores could be calculated for 4,592 (91.1%) of survey respondents. These participants had mean age 48 (SD 11.5, range 18-78) years; 65.8% were 45 years of age and older. Most (87.7%) were female, worked full-time (53%) and shift work (53.1%) including night shifts; almost three quarters (70.6%) were employed in foundational roles (Registered Nurse/ Clinical Nurse Specialist grades); the majority were metropolitan (65.7%) and hospital-based (59.6%). These nurses were well-educated; most (64%) had at least a Bachelor degree and 39% had postgraduate qualifications. Overall their average working week was 34 hours, but 39% reported working more than 40 hours in an average week.

Health and Quality of life: General health was overall rated at median score 2 (‘very good’) but 14.6% self-rated their health as only fair – very poor. Chronic disease diagnoses and symptom frequency have been reported elsewhere (Perry et al 2016) but with an overall median of one diagnosis each, 17.7% of participants reported 3 or more diagnoses.

Overall, these nurses reported an average SF-12 physical component score of mean (SD) 51.7 (8.1) and mental component score of 48.6 (9.6). Age and sex-matched scores were not dissimilar to Australian normative values (Avery et al. 2004) but for all ages and both sexes nurses’ and midwives’ physical component scores tracked somewhat higher and mental component scores lower than population values.

Predictive factors: We used multiple linear regression with forced entry of demographic, health and work-related variables for the SF-12 physical and mental component dependent variable scores, separately. Thirteen variables explained 41.5% of variability in physical component scores. Working in a foundational versus other role, any workplace injury or admission to hospital in the previous year, any diagnosed mood disorder, increasing numbers of chronic disease diagnoses and prescribed medications, greater frequency and severity of recent pain and sleep disorder, being post-menopausal, having a higher Body Mass Index and being a current smoker all predicted lower physical component scores. Those who took more sick days identified as ‘mental health’ days had higher physical component scores ($F=47.481$, $df28$, $p<.001$).

Twelve variables explained 41.6% of variability in mental component scores. Higher mental component scores were predicted by increasing age and job satisfaction, working office hours rather than shift work and part-time rather than full-time, taking fewer ‘mental health’ sick days, having a higher Body Mass Index and working in a non-hospital setting. Any workplace abuse or mental health diagnosis, greater numbers of ill-health symptoms, increasing frequency of pain in the last four weeks and sleep problems were all associated with lower mental component scores ($F=49.865$, $df28$, $p<.001$). Two scores were borderline significant: being post-menopausal and experiencing any workplace injury.

Conclusion: Health is an important influence on nurses’ and midwives’ quality of life. Given the impact of QoL both for workforce wellbeing and in support of care quality, interventions to support workforce wellbeing are needed. These findings indicate new recommendations for policy and practice. Including a focus on foundational staff, interventions might entail occupational health services to complement primary healthcare for earliest detection and initiation of treatment for chronic disease including pain management and mental health disorders; addressing workplace injury rates; health education and promotion initiatives

encompassing sleep hygiene, healthy eating, menopause management and smoking cessation; site-based initiatives to provide and promote healthy food choices in cafeterias and facilities to store, heat and eat home-cooked food on the premises; roster flexibility.

These recommendations for policy and practice capitalise on study findings to promote quality of life and hence quality of care and longevity in the health workplace.

N 15 - Simulation Education for Entry-Level Nurses

Impact of High-Fidelity Simulation on Teaching Medical Nursing

Yaohua Gu, MSN, RN, China

Zhijie Zou, MSN, RN, China

Yanqun Liu, PhD, RN, China

Abstract

Purpose: The purpose of this study was to examine the High-Fidelity Simulation to improve disease-related knowledge level of junior students in a Bachelor of Science in Nursing program and to explore the students evaluation on High-Fidelity Simulation.

Methods: The study used a within-group, pre-post test design with twenty-three students of a nursing school in central city in the People's Republic of China. Students were divided into four groups of five to six students. Facilitated by the same teacher, the four groups performed simulations in four different days. For each group, three simulation scenarios with high-fidelity simulator were implemented. In each group, students alternated to practice as the nurses in three scenarios. At the end of the simulations, every student performed as the nurse and the observer. The three scenarios were designed based on the case of a patient with Chronic Obstructive Pulmonary Disease (COPD). The objectives of the simulations were to take care of the COPD patient with acute exacerbation and perform individualized health education. COPD-related knowledge questionnaires were used to measure the knowledge level before and after the simulations. The Student Satisfaction and Self-confidence in Learning Scale (13 items), the Simulation Design Scale (20 items) and the Educational Practices in Simulation Scale (16 items) were completed at the end of the simulations to measure students' perception of High-Fidelity Simulation.

Results: The student knowledge increased significantly from pretest to posttest. All the simulation scales are five-Likert-type scale ranging from 1 (*strongly disagree*) to 5 (*strongly agree*). The means and standard deviation of the three scales were 4.28 ± 0.45 , 4.32 ± 0.44 and 4.39 ± 0.50 respectively.

Conclusion: In this study, High-Fidelity Simulation can significantly improve the disease-related knowledge of junior BSN students. High-Fidelity Simulation received relatively high scores for students' satisfaction and self-confidence. Student perceived high-fidelity simulation as an effective teaching strategy. However, further study is needed to explore the specific way it integrates with baccalaureate curriculum.

N 15 - Simulation Education for Entry-Level Nurses

Integrating Simulation-Based Education Into the Healthcare Setting: Newly Licensed Nurses Learn to Transition

Kelly L. Rossler, PhD, RN, CHSE, USA

Katherine Hardin, MSN, RN-BC, USA

Marygrace Leveille, PhD, RN, ACNP-BC, USA

Abstract

Purpose: Transitioning from pre-licensure student into the role of the practicing nurse can be an overwhelming experience to a newly licensed registered nurse. It is anticipated the novice nurse will be prepared to enter the clinical practice setting ready to work within the scope of practice of a licensed registered nurse (American Nurses Association, 2015). In the healthcare industry, nurse internship programs are recognized as a standard process to acclimate the novice nurse to the practice setting. Yet, teaching-learning methodologies are constantly evolving to inform entry into practice success (Pfaff et al., 2014; Rush et al., 2013). It is crucial to identify teaching-learning methodologies which can positively and directly impact the transition of a newly licensed registered nurse into clinical practice. Human patient simulator mannequins have evolved to address both the educational needs and practice initiatives of pre-licensure nursing students (Kardong-Edgren et al., 2012; Katz et al., 2010). As an experiential teaching-learning strategy, human patient simulation has the capacity to promote this necessary transition. Yet, outcome measures connecting transition to practice in a formal nurse internship program with human patient simulation are still lacking in the literature (Ying et al., 2014; Zigmont et al., 2015). The purpose of this project was to explore graduate nurse interns' perceptions of the addition of simulation-based education into a nurse internship program to promote transition into the clinical practice setting.

Methods: Simulation-based education was incorporated into an existing graduate nurse internship program at a university medical center in Northern, Texas. A Hermeneutic phenomenology research design was used to address the research questions. A non-probability, purposive convenience sample of graduate nurse interns' hired into either the medical-surgical, telemetry, or critical care essentials internship during the summer of 2016 participated in the research study. Study procedures commenced after Institutional Review Board approval. Participants attended five simulation-based education sessions coinciding with the didactic theory portion of the internship for each practice unit. The simulation-based education sessions were facilitated by a Certified Healthcare Simulation Educator and were designed to follow the recognized International Nursing Association for Clinical Simulation and Learning *Standards of Best Practice: Simulation* guidelines (INACSL, 2013; 2015). The setting was a simulation education room located on the study site. A total of 25 participants completed all study processes.

Results: Qualitative data was collected during individual participant face-to-face interviews. Qualitative data was explored using the procedural steps outlined by Streubert and Carpenter (2011) as naïve reading, structural analysis, and interpretation of the whole aligning with hermeneutic phenomenology. Rigor was maintained by following the guidelines of credibility, dependability, confirmability, and transferability. Data saturation was achieved with the participant sample size. The two overarching themes of *Gaining Comfort with Relationships* and *Talking it Out* emerged from the qualitative analysis.

Conclusion: The incorporation of a simulation-based education program into the existing graduate nurse internship has the potential to enhance the successful transition of the graduate nurse intern into the practice setting. Outcomes such as improvement of self-confidence in practice, successful role socialization, and effective communication are essential and universal acquisitions for newly licensed nurses to achieve. Research findings support the advancement of simulation science within the healthcare industry. In addition, findings demonstrate the need to conduct research not only focused on transition into practice, but also to determine the optimal capacity to integrate simulation-based education into the curricula of existing nurse training and internship programs.

N 16 - Surgical Pain Management

Effect of Paravertebral Block on the Outcomes of Patients Undergoing Video-Assisted Thoracic Surgery

Myra I. Torres, MSN, RN-BC, PCCN, USA

Linda A. Minnich, BSN, RN, CPAN, USA

Abstract

Purpose: The purpose of this study was to determine if there was a relationship between the introduction of paravertebral block pre-operatively and patient's post-operative pain scores, length of urinary catheter use and length of hospital stay.

Methods: The study design is retrospective data collection of 40 patients undergoing Video-Assisted Thoracic Surgery (VATS) with wedge resection at a small community hospital in Northern California between March 2013 and March 2015. The decision on whether to apply paravertebral block was based on surgeon preference. All patients included in the study received the usual surgical pain regimen of systemic opioids. At the Post-anesthesia care unit, all patients receive systemic opioids using patient controlled analgesia (PCA) until post-op day 2.

Half of the patients (control group) did not receive the paravertebral block, while the other half received paravertebral block pre-operatively. Those who received paravertebral block had a continuous infusion from the pre-operative period up to 48 hours after surgery.

Convenience sampling was used. No patient was identified by name or MRN number. Permission to study was granted by the hospital nursing research committee Wilcoxon signed-rank test was used.

Results: VATS patients who received paravertebral blocks reported lower pain scores from the afternoon of post-op day 2 until post op day 4 ($p=0.04$ on post-op day 2, $p=0.006$ & $p=0.08$ on day 3, $p=0.03$ & 0.06 on day 4), had earlier urinary catheter removal ($p<0.001$) and had shorter length of stay ($p=0.0017$) compared to patients who did not receive paravertebral blockade. Patients had no demographic differences other than average body mass index (BMI), which was higher in the treatment group ($p=0.006$) and may have contributed to a surgeon's decision on whether or not to use paravertebral blockade.

Conclusion: The study shows that paravertebral blockade in patients who are undergoing thoracic surgery with wedge resection can have beneficial patient outcomes such as decreased pain levels, shorter urinary catheter use and decreased hospital length of stay. All of these, in turn, may be factors in increasing patient satisfaction, preventing device-related infection, increasing hospital reimbursement and decreasing hospital costs.

N 16 - Surgical Pain Management

Transforming Practice With Scripted Messages: Improving Pain Management in Outpatient Surgical Patients

Lanell M. Bellury, PhD, RN, AOCNS, OCN, USA

Abstract

Purpose: Outpatient surgeries are increasingly common because of patient convenience, lower cost, and reduced stress but most patients experience pain postoperatively requiring nursing attention to pain management (Mitchell, 2015; Subramanian et al., 2014). Scripting, recommended for consistent, targeted communication with patients, has limited evidence to support its use (Alaouf et al., 2015; Monterroso et al., 2013). The purpose of this study was to explore the effect of providing scripted messages related to pain management in the outpatient surgical setting on self-reported pain control and patient satisfaction in outpatient surgical patients. Additionally, the feasibility of practice change research in clinical settings was examined. The findings may assist others interested in the conduct of clinical research and adds to the body of knowledge around the effectiveness of scripted messages delivered by nurses.

Methods: A retrospective record review pre and post a practice change intervention evaluated implementation of a pain management scripted message delivered at two time points (preoperatively and postoperatively). Intention to treat analysis was used to compare patient reports of pain control and patient satisfaction with care 48 hours post-discharge from outpatient surgical procedures. Feasibility of data collection and measurement issues were also explored.

Results: 231 records (98 pre-intervention; 133 post-intervention) were analyzed. The sample included 144 (62%) male and 156 (68%) married with mean age 57.6 (SD=16.1) years. The large majority (90%) received general anesthesia and the most common surgical procedures were urologic (24%), colorectal (17%), and laparoscopy (13%). A Mann-Whitney U test indicated patient reported pain control was statistically significantly greater for the post intervention group (Mean rank=62.66) than for the pre-intervention group (Mean Rank = 51.95), $U=1258$, $p=0.015$. A large number of missing data related to the standard of care post-op phone calls (54% missing) and receipt of the intervention (47% receiving the script at time two).

Conclusion: While it is encouraging that even the small dose of scripting had a significant effect on postoperative pain control, the feasibility issues related to data collection and intervention fidelity will require considerable resources to surmount. Practice change is a complex process requiring sensitivity to work and patient flow especially in specialty care units. Overcoming resistance to change when evidence is not robust is challenging and may be especially difficult related to scripting, which is often perceived as a mandated intrusion into the nurse-patient relationship.

N 17 - Telehealth

What Do Nurses Ask About? A Review of Nursing Questions in a Brazilian Telemedicine System

Jacqueline E. Brixey, MSc, MA, BJ, BA, USA

Juliana J. Brixey, PhD, MPH, MSN, RN, USA

Abstract

Purpose: Across the globe, nurses are often on the front lines for health care delivery in places where physicians are scarce or nonexistent, such as in rural areas or urban slums [2]. For example, the constitution of Brazil guarantees free public healthcare to every citizen, however, many doctors and specialists are concentrated in the large coastal cities of the country, with populations in the rural interiors drastically underserved by health care professionals [3]. The Health Ministry of Brazil implemented the Programa Telessaúde Brasil Redes to combat this issue by providing health support, advice from specialists, and permanent health education via telemedicine. Telemedicine can connect any member of the health care team across the continuum of care to enhance outcomes. This connection can entail submission of asynchronous questions via online systems for expert consultation.

Rede NUTES is an extension of the Programa Telessaúde Brasil Redes based in the northeastern state of Pernambuco in Brazil. Rede NUTES offers telehealth services to its 80 municipalities by offering web seminars, telecare service, and second opinions on submitted questions via their online submission system for other health care professionals [7]. Data from the Rede NUTES submitted questions were analyzed and explored using big data methods to gain insights into how and for what Brazilian nurses utilized the system, as well as gain new understanding from the questions that nurses answered.

Methods: Step 1 was to explore and analyze the data, questions submitted by nurses, nurse technicians, and the two categories combined were identified and isolated from the complete data set to understand ratios of how often nurses and nurse technicians were using the Rede NUTES system in comparison to their peers. Questions that were answered by nurses at Rede NUTES were also queried from the general data to review the frequency of responses given by this group of users.

In step 2, the questions were reviewed by calendar months. This visualized usage trends over the course of a year for questions both submitted and responded to. A histogram was created to visualize this trend.

Step 3 entailed determination of question themes per calendar each month. For example, a spike in gynecology questions dealing with pregnancy was typically followed by a corresponding increase in obstetrics questions nine months later. By visualizing question topics and clustering those topics in a timeline, it was possible to understand trends in the data for nurses. These question topic clusters were compared to the questions submitted and answered by the other medical professionals utilizing the online question system.

In the final step, the data were reviewed for lexical relationships using Linguistic Inquiry and Word Count (LIWC) program in Portuguese [6]. LIWC returns values on dimensions such as number of self-references, level of positivity, and number of cognitive words.

Results: As stated in [2], the nurses and nurse technicians in Pernambuco are indeed on the frontlines of serving their communities. Nurses and nurse technicians submitted the most questions to Rede NUTES out of any of the health practitioner categories for two out of the three years reviewed (38% in 2010 and 32% in 2011), and in all three years combined (36%). Furthermore, in the majority of the months in the years reviewed, nurses and nurse technicians submitted the largest percent of the questions from any health care practitioner category, submitting 92% of all questions in December of 2012. The top question topics across submitted concerned cardiology, gynecology, obstetrics, pediatrics, and dentistry for all three years. In 2012 and 2013, the top question theme dealt with electrocardiograms, while

Another notable result was that nurses also answered the most questions during the three years reviewed. Questions that were responded to followed a similar thread as to those that were submitted, with specialized nurses responding to the majority of questions dealing with obstetrics, gynecology, and pediatrics, with the top question theme dealing with hypertension.

Conclusion: Exploratory data analysis is the first step in using big data for future experiments [8]. It allows researchers to detect mistakes in the data that could skew machine learning results, while also checking intuitions about relationships in the data. Future work on this data set will explore relationships in the data for other medical fields.

While asynchronous online telemedicine applications to obtain expert counsel such as Rede NUTES offers positive features, likewise negative features must be acknowledged. There are legitimate causes for concern over privacy and protection of data. Likewise, as many people fear receiving a break-up text, so should bad news of a diagnosis be conveyed in person. Future research should work to mitigate these concerns while enhancing positive outcomes.

Factors Associated With the Successful Implementation of Telehealth in a Retail Health Clinic

Elizabeth Ornelas, DNP, RN, FNP-BC, USA

Marlaine Skaggs, MSN, RN, FNP-C, USA

Abstract

Purpose: The purpose of this presentation is to identify the factors that influence adoption of telehealth in a retail health clinic setting.

Methods: A cross-sectional design was employed to address project aims. Nurse practitioners and licensed vocational nurses from four southern California counties completed an online Likert scale survey in fall 2014, which included demographic items as well as a telehealth adoption tool adapted from the Instrument to Measure Perceptions of Adopting an Information Technology Innovation (Benbasat & Moore, 2014). This instrument measures five diffusion of innovations theory (DIT) constructs (relative advantage, compatibility, trialability, observability, complexity) as well as result demonstrability, voluntariness, and image (Benbasat & Moore, 2014). Three open-ended questions were also included. The DIT and Promoting Action on Research Implementation in Health Services model (PARiSH) provided theoretical and conceptual foundations for this project (Rycroft-Malone, 2013).

Results: A convenience sample of sixty-three nurses from the retail health organization completed the survey (response rate 68%). Of these, 43% worked in high-adoption counties (regions achieving 77% of all telehealth visits). High adopters and low adopters (those underutilizing the innovation of telehealth) did not differ in terms of years of experience, levels of education, and months on telehealth at baseline.

Two questions related to the construct of voluntariness were significantly associated with telehealth adoption. For the question, "Although it might be helpful, using telehealth is compulsory in my job," there was a ten-fold difference between high adopters and low adopters ($\chi^2 = 18.911$, $p < .0001$). For the question, "My boss requires me to use telehealth," the high adopters were five times as likely to agree with this statement as the low adopters. Clearly, there was a difference between high and low adopters in the views related to voluntariness.

The construct of voluntariness assumes that adoption could be viewed either as voluntary or compulsory, and that there may be a higher adoption rate if a person is free to choose whether to use it or not (Rogers, 2002). In this sample, all the nurses were informed that telehealth was a mandatory requirement for employment. However, 91.9% of the low adopters believed it to be "voluntary" rather than mandatory. Freedom of choice provides the adopter with control and the desire, therefore, to achieve success.

Furthermore, the company may "expect" an employee to use an innovation, but the employee's perception may be that it is "voluntary," as the example above shows. The fact that the company believes it to be compulsory does not ensure that the employee will view it in the same way. In addition, the literature suggests that voluntariness may be perceived differently by individuals of certain social statuses, which may depend on one's professional role within an organization (Benbasat & Moore, 2014; Rogers, 2003).

Two items reflecting compatibility were statistically associated with telehealth adoption. Both questions reflect an individual's perception that telehealth is consistent with their needs, current existing beliefs or values, and past experiences (Rogers, 2002). Although these quantitative results yielded a negative compatibility, the qualitative responses (discussed below) showed the opposite. Low adopters were three times as likely to disagree with the statement ($\chi^2 = 5.360$, $p = 0.024$), "I think that using telehealth fits well with the way I like to work," and four times as likely to disagree with the statement, "Using telehealth fits into my work style," as high adopters.

Within the qualitative data, the free-text questions provided insight into other aspects of compatibility. The perceived loss of patient contact that occurs with telehealth was viewed as a barrier to adoption. Several nurses stated that they felt patient interaction was compromised during a visit. However, in a telehealth visit, the patient becomes an active participant in their care, thus improving interactions and communication. When the patient can visualize his/her own disease process via pictures, numbers, or trends on a screen, s/he may become more visually aware of his/her own health, and this may improve adherence to their treatment regimen (Rogers et al., 2011). This can increase both clinicians' and patients' satisfaction, improve daily work flow, as well as reduce the health-care dollars spent.

Conclusion: To improve the adoption of telehealth in the future, it is important to identify strategies to improve perceived voluntariness. One suggestion is to have managers regularly visiting low-adoption clinics to ensure that telehealth is being offered to all the appropriate patients, as per company protocols. Due to the logistical constraints that managers face, however, they might consider appointing telehealth champions—both LVNs and NPs—who excel in the operation of telehealth (based on excellent customer service scores and on practice in a high-adoption region). According to Bradshaw and Lowenstein (2014), students respond best to clinicians who exhibit passion for their work, including commitment, trust, collaboration, caring, and achievement.

The Diffusion of Innovations theory suggests that early adopters have more positive perceptions of innovations than the non-adopters (Rogers, 2002). Since diffusion is a process by which an innovation is communicated through certain channels over time among members of a social system, the messages being communicated require attention (Rogers, 2002). This diffusion or spread of messages also introduces an element of uncertainty both to the individuals and the organization as they must digest new ideas that represent proposed innovations. Innovations spread at different rates and it is the characteristics of an innovation, as perceived by the individuals in the social system, that truly influence the rate of adoption.

In this project, the idea that it is an individual's choice to utilize telehealth, despite the company's expectation, was a strong predictor of adoption. It is important to recognize the construct of compatibility to continue to nurture team support (between the LVNs and NPs) and to monitor the compatibility of work flow. Based on the evidence gathered, successful implementation strategies can be developed and generalized to other similar settings.

O 10 - Global Concerns for Cancer Clinical Trials

Informed Consent Practice in Cancer Clinical Trials in Taiwan

Chi-Yin Kao, PhD, RN, Taiwan
Mei-Chih Huang, PhD, RN, Taiwan

Abstract

Purpose: To understand the current informed consent process in cancer clinical trials in Taiwan.

Methods: Using semi-structured interview guides to interview clinical research nurses and cancer patients. Content analysis was used to analysis the data.

Results: 10 clinical research nurses and 10 cancer patients were interviewed from three medical centers in Taiwan. From clinical research nurses' practice, informed consent of cancer clinical trials normally happen on a very stressful situation for patients after they were informed bad news regarding their cancer progression by physicians. If the patient is not ready for the informed consent, clinical research nurses normally explain the trial information to family members first and let family members discussed with patients. Therefore, family member is an important role in patient decision making under Taiwanese culture context. In order to achieve patient understanding, informed consent is a continuous communication process for clinical research nurses. Both clinical research nurses and patients reported that trust physician, a hope for personal benefits, no standard treatment options, financial considerations, and special care services are the main reasons for patients to enroll in a cancer clinical trial. Fear of possible risks and adverse effects of study drugs, time investment and travel, and frequent tests were repeatedly addressed as the main barriers to trial participation. More than 70% of patients reported that they made the decision to attend a trial treatment and signed the consent form directly after informed consent. Over 50% of participants mentioned that the language of the consent form was too hard to understand and after they finished reading, they still did not understand the information. Clinical research nurses indicated that patient misunderstanding/poor understanding of clinical trial, trust of recommendation from their physician and different opinions with physicians are the dilemmas of informed consent.

Conclusion: Information, comprehension and voluntariness are three essential elements of the consent process. However, our interview study indicated that patients receive a trial treatment is because they are under the pressure of disease progression and choose to trust their physician's recommendation, not based on understanding of trial information. Further research could be conducted to improve patient autonomy and understanding of cancer clinical trials.

O 10 - Global Concerns for Cancer Clinical Trials

Impact of Health Literacy on Clinical Trial Enrollment for Breast Cancer Patients

Jessica Keim-Malpass, PhD, RN, USA
Christine Kennedy, PhD, RN, PPCNP-BC, FAAN, USA
Shayna Showalter, MD, USA
Aubrey Doede, MSN, RN, USA

Abstract

Purpose: Health literacy, or the ability to obtain, appraise and integrate health-related knowledge, is recognized by the Institute of Medicine as an integral component of high-quality health care. In adults, limited health literacy can be a critical indicator of adverse health outcomes such as: diminished health-related knowledge, increased measures of morbidity, poor adherence to medication regimens, and high utilization of health care resources. It is estimated that 20 - 36% of all adults in the United States have limited health literacy, and that the prevalence rises to closer to 50% among those who are also from a low income background. DeWalt and colleagues have demonstrated that adult patients with limited health literacy are less likely to participate in shared medical decision-making and adults with limited health literacy are more likely to experience shame, low self-esteem, and limited social support. With a renewed focus on patient-centered approaches, limited health literacy can diminish patient engagement in care and autonomy in self-care management.

Health literacy has been understudied in cancer, where patients must navigate difficult health care decisions and self-care management. Therapeutic clinical trials remain a predominant aspect of cancer care delivery and is the gold standard for developing new medical treatments and translating biomedical discoveries. A key barrier to participation in clinical trials is the process of randomization, and how the treatment and side effects of the treatment are explained during the clinical trial consent process and very little previous research has focused on health literacy as a critical component of this process. Therefore, the purpose of this prospective correlational study was to determine if patient's level of health literacy predicts the decision to enroll in a clinical trial among breast cancer patients.

Methods: From June 2015 through September 2016 a health literacy questionnaire was administered to all new breast cancer patients and all breast cancer patients seen in follow-up. The health literacy questionnaire is a valid and reliable 3-item self-report screening tool with ranges in score from 3-15 (higher scores represents lower health literacy). Pertinent clinical outcomes related to the diagnosis and treatment was obtained for all patients with a health known health literacy score. Enrollment of a clinical trial was designated as a yes/no dichotomous outcome variable and included chemotherapy, radiation, and surgical clinical trials pertinent to the breast cancer diagnosis. Descriptive statistics were calculated to describe health literacy and patient characteristics, and a multivariate logistic regression was calculated to determine the relationship of health literacy on decision to enroll in a clinical trial.

Results: 512 breast cancer patients were included in this analysis. Among these women, 12.1% of the patients were identified as having the lowest level of health literacy (limited health literacy) and 13.5% were identified as having marginal health literacy. 12.9% of the study population were enrolled in a clinical trial (n=66). In logistic regression, there was no statistical significance in the relationship between health literacy and enrollment in a clinical trial ($p = 0.09$).

Conclusion: Health literacy is not well defined in the breast cancer patient population and the health literacy-specific aspects of the clinical trial informed consent process have been understudied. Our findings did not demonstrate a relationship between health literacy and enrollment in a clinical trial. One limitation to our findings was that chemotherapy, radiation and surgical clinical trials were included in the same outcome variable. Each of those clinical trials has various risk/benefit profiles and future study is warranted investigating the relationship of health literacy to individual trial types. Nurses play a key role in understanding a patient's health literacy and offering tailored educational and shared decision-making support.

O 11 - Palliative Care Simulation

Assessing Interprofessional Palliative Care Movie Simulation and Debriefing: A Multisite, Multinursing Track Perspective

Mary Val Palumbo, DNP, MSN, BS, APRN, GNP-BC, USA

Kathleen Marie-Anne Huun, PhD, MSN, MS, BS, BSN, RN, USA

Abstract

Simulation has become commonplace in undergraduate nursing programs and “opens doors for students to experience today’s complex and challenging patients and it enhances their critical thinking skills” (Davis, Kimble, & Gunby, 2014, p. 149). In addition, a focus on inter-professional (IP) education/collaboration has also become a constant thread due to the imperatives issued by health service policy makers and educational accrediting bodies. According to Saylor, Vernoooy, Selekman, and Cowperthwait (2016), “simulation focusing on palliative care is an effective modality to promote IPE beyond acute care and crisis scenarios” (p. 129).

Providing the opportunity for traditional undergraduate nursing students to participate in simulation and collaboration on interprofessional patient care is nothing short of a scheduling and time management nightmare. The problem is compounded when distance (fully online) undergraduate, baccalaureate nursing completion (BNC) students (LPN to BSN and RN to BSN) are factored into the mix. Thus, a means to offer an opportunity for various tracks of undergraduate nursing students (multi-site) to receive simulation and an interprofessional collaboration experience was requisite. As such, a novel means to equitably facilitate learning gave rise to the use of an *Interprofessional Palliative Care Movie Simulation*.

“Video-recorded simulation is a teaching technology that allows one to present reality under controlled conditions, both of the environment and the individuals involved, which in turn favors learning” (Cardoso et al., 2011, p. 709). Likewise, video/movie simulation can be accessible via online access as is needed for online students in the BNC program, or as an in class presentation for face-to-face traditional undergraduate nursing students. As palliative care practice readily depicts rich examples of interprofessional team work, a carefully developed movie portraying end of life team care of a patient with amyotrophic lateral sclerosis (ALS) was chosen. This movie had been scripted from audio recordings of students responses during an actual simulation of end-of-life care for a patient with ALS and his husband. The movie was filmed using standardized patient actors playing the patient, husband, sister and the student healthcare providers. The use of standardized patients in simulation “provide rich clinical experiences for undergraduate nursing students” (Sideras, McKenzie, Noone, Markle, Frazier, & Sullivan, 2013, p. 425). The movie is segmented into five scenes; the first four include assessment of patient and family needs by nursing, physical therapy, primary care provider, social work and speech language pathology; the final act is a death scene.

Purpose: Although evidence supports simulation and the use of video technology, an interconnection of the two and the delivery of complex inter-professional collaborative care content calls for an investigation into the success of these measures to facilitate learning. As such, the purpose of the investigation is to 1) assess student satisfaction and self-confidence in learning using the *Interprofessional Palliative Care Movie Simulation* and 2) compare online discussion board debriefing with an in person post movie simulation debriefing.

Methods: The National League for Nursing (NLN) Student Satisfaction and Self-Confidence in Learning survey was utilized for assessment. This 13 item tool utilizes a five point scale. Reliability has been “tested using Cronbach’s alpha: satisfaction = 0.94; self-confidence = 0.87” (“Description of Available Instruments,” 2016). Questions from a previously developed tool (University of Vermont) based on the Interprofessional Competency Domains of 1) Values/Ethics, 2) Roles/Responsibilities, 3) Interprofessional Communication, and 4) Teams/Teamwork were also utilized. The tool had been reviewed by faculty in each discipline providing content validity. Reliability of the survey instrument was not tested or established.

The distance students accessed the movie simulation assignment via their online learning platform. The students asynchronously viewed the movie simulation and answered debriefing questions via discussion board format. At the close of the discussion board, the students were given access to Qualtrics links for the NLN survey and the IP competency survey. The traditional undergraduate students, participating in person, completed the NLN survey and the IP competency survey after the conclusion of a synchronous movie viewing and debriefing completed in one continuous group session.

Results: The traditional undergraduate nursing students (n=82) who participated “in person” were 89% female and 11% male, 3% Hispanic, 91% White/Caucasian, 6% Asian and 1% Black/African American. The average age was 23 years. The BNC students (n = 25) who participated online were 96% female, 4% male, 76% White/Caucasian, 4% Asian, and 16% Black/African American. The age of these non-traditional students ranged from 24 to 54 years. All students were in their senior year.

Regarding the teaching methods used in this simulation, 94.39% of respondents agreed or strongly agreed that the methods were helpful and effective. When grouped as questions regarding satisfaction in learning, the results of respondents answering agree or strongly agree were 94.54% (RNs), 91.90% (LPNs), and 86.56% for traditional nursing students. Likewise, for questions regarding self confidence in learning, the results of respondents answering agree or strongly agree were 92.05% (RN), 84.17% (LPN), and 79.12% for traditional nursing students.

One question in particular that revealed the most undecidedness or disagreement was: “It is the instructor’s responsibility to tell me what I need to learn of the simulation activity content during class time.” The results of respondents answering agree or strongly agree were 54.54% RN, 40% LPN, and 40.74% for traditional nursing students. These results are considerably different from the overall favorable impression of all other survey questions. And, in contrast to this question, students responded positively to a similar question, “It is my responsibility as the student to learn what I need to know from this simulation activity.” The results of respondents answering agree or strongly agree were 100% RN, 100% LPN, and 89.75% for traditional nursing students.

In regards to self confidence in learning, statements that revealed the most undecided or disagreement were: “I am confident that I am mastering the content of the simulation activity that my instructors presented to me” (UNDECIDED, 20.99% and DISAGREE 3.66% of traditional nursing students only); and “I am confident that this simulation covered critical content necessary for the mastery of medical surgical curriculum” (UNDECIDED, 18.18% RN, 13.33% LPN, 17.28% traditional and DISAGREE, 6.67% LPN, 6.54% traditional).

In regards to the debriefing methods used (face-to-face interaction or online discussion board), the response was extremely favorable and students felt they were able to express their thoughts in a manner conducive to learning. Specifically, in response to the question, “I expressed my knowledge and opinion during the case discussion” results of respondents answering agree or strongly agree were 100% RN, 100% LPN, and 97.53% for traditional nursing students.

Five questions regarding interprofessional collaboration were utilized. Overall 85% of undergraduate nursing students felt they learned about interprofessional team work following the simulation. Students overwhelmingly indicated that they would forge relationships with other healthcare professionals to improve care for elders with 100% RN, 100% LPN, and 97.56% traditional nursing students responding agree or strongly agree. Likewise students recognized the necessity of utilizing a healthcare team to provide care for patients at the end of life with 100% RN, 93.33% LPN, and 97.53% traditional students responding agree or strongly agree.

Conclusion: All tracks of undergraduate students reported acceptance of the responsibility for their learning and are comfortable with the use of simulation even when it involves watching a previously recorded simulation. Student responses show that this format is a useful means to allow for online simulation (via a movie) and shows evidence of satisfaction (mode of simulation) and self-confidence in learning and perceived competency in the interprofessional palliative care of a patient. Thus, at least for this pilot survey various tracks of nursing students (multi-site) learning via differing formats (online versus

face-to-face) may have direct benefit from this educational modality. This finding is helpful as the logistics for and cost of simulation for large groups of interprofessional students is considerable.

A significant amount of literature supports the use of simulation for enhancing critical thinking. Thus, the development of specific (level appropriate) video case study simulations may broaden the teaching strategies available to bring simulation to students of nursing and other interprofessional disciplines. Thus, the use of a movie simulation (based on health concepts/case scenarios) appropriate to the level of learning can reach a wide audience outside of a simulation lab whether a distance or local student.

Recommendations for Future Research: As more nursing education is delivered using an online format, innovative online simulation activities which expose students to interprofessional practice must also be continually developed, implemented, and evaluated. The use of faculty developed medical movie simulation scenarios in conjunction with other technological advances such as virtual clinics, video conferencing, and mobile robotic telepresence have and may continue to open up new avenues for interprofessional simulation education albeit, this type of innovative pedagogy must be further evaluated and disseminated. In addition, these modalities can be utilized synchronously or asynchronously whether online distance student or face-to-face campus student. Consistent evaluation of interprofessional practice competency domains must also be included in all educational activities. Likewise continued evaluation of movie simulation as a modality of simulation is recommended in nursing as well as in other disciplines. As an additional measure, multi-site, multi-educational mode (face-to-face and online) comparisons are encouraged.

O 11 - Palliative Care Simulation

A Patient's Last Breath: An Analysis of Hospice Clinical vs. Hospice Simulation Experiences

Stephanie M. Jeffers, PhD, MSN, BSN, RN, USA

Abstract

Purpose: The literature has shown that registered nurses continue to feel inadequately prepared to address end-of-life issues, due to a lack of education on the process of dying and how to manage patient symptoms, cultural considerations and an awareness of their own attitudes and values about death (Al Qadire, 2014; Cui, Shen, Ma, & Zhao, 2011). In addition, pre-licensure nursing programs have been slow to integrate end-of-life care into their curricula. In those pre-licensure nursing programs that do offer courses on end-of-life care, student outcomes include positive attitudes toward dying patients and a positive influence on the students regarding the philosophy of palliative care, as the teaching strategies of the courses were geared toward the affective domain. Students who completed courses on end-of-life care reported feeling increased sympathy and empathy towards their patients, and they found an end-of-life care course to be an essential part of the nursing curriculum (Hold, Blake, & Ward, 2015). In several studies, students noted that the curriculum contributed to their personal and professional development (Ballesteros, Centeno, & Arantzamendi, 2014; Conner, Loerzel, & Uddin, 2014).

There is a dearth of research examining nursing students' experiences in a hospice or palliative care unit. This may be due to several factors including barriers to acquiring hospice as a clinical site or assigning a dying patient to a student. These barriers may include staff, patient, family or faculty comfort level and/or lack of knowledge to teach end-of-life concepts (Doucette, et al., 2014; Jeffers, 2014).

This study had two purposes. The first was to compare two teaching strategies, hospice simulation and hospice clinical, to outcomes resulting from teaching undergraduate nursing students about end-of-life nursing care. The second purpose of this study was to strengthen understanding of the attitudes and perceptions of nursing students caring for dying patients and their families in both simulated and hospice clinical settings.

Methods: This investigator used both descriptive comparative and qualitative descriptive designs. Fourth year nursing students enrolled in a Medical-Surgical Nursing III course participated in the study (n=151). Prior to the study, Institutional Review Board approval was obtained from the university and participants were provided with an informed consent form detailing the purpose of the study.

Data collection involved three instruments. First, the investigator used a demographic questionnaire developed by the principal investigator for this study to collect information such as the participant's age, gender, experience with caring for dying patients in a clinical setting, experience with the loss of a family member or friend, ethnicity and religion. Second, to assess student attitudes about providing care, the investigator administered the Frommelt Attitude Toward Care of the Dying Scale (FATCOD) as a pretest prior to the simulation or clinical and a posttest after simulation or clinical. Finally, the investigator used a third instrument, a reflection journal administered before and after the hospice simulation or clinical experience. This reflection journal provided qualitative data pertaining to students' feelings and experiences related to the assigned teaching strategy.

Students were randomly divided into two groups: hospice simulation and hospice clinical. The students assigned to simulation participated in a scenario about an actively dying man in hospice. After the simulation, students were debriefed, explored their perceptions of end-of-life care and discussed their feelings regarding the simulation.

Participants in the hospice clinical experience attended a hospice clinical site, with an adjunct clinical instructor. The students participated in family planning meetings with the interdisciplinary team, communicated with patient, family and interdisciplinary team, and provided care for the dying patient as needed. The students debriefed about the experience in clinical post-conference.

Quantitative data analysis was conducted using descriptive statistics, including independent and paired t-tests. Thematic analysis of the reflection journals was conducted. Key phrases and themes were identified and the major themes were described.

Results: Findings include changes in student attitudes towards the dying patient and end-of-life care, in both groups. Prior to the hospice simulation or clinical experience, students reported feeling anxious caring for a dying patient or a patient who has just died. After the hospice simulation or clinical, students reported feeling more comfortable discussing end-of-life preferences with the patient and interdisciplinary team. Thematic analysis of the qualitative data offers student insights about the care of a dying patient in both a clinical setting and a simulation setting.

Conclusion: The results of this study demonstrate the benefit of a hospice clinical experience for pre-licensure nursing students which is supported by the literature (Chmura, 2016; Spicer, Heller, & Troth, 2015). The data support an improvement in overall attitudes towards the dying patient in both clinical and simulation settings. Students in both groups reported a preference for learning about end-of-life care in a clinical setting, rather than in a simulation. This study contributes to the advancement of nursing science and improvement of end-of-life care by highlighting an additional teaching strategy for end-of-life education. Further research is needed on the inclusion of hospice clinical settings for pre-licensure nursing students.

Abstract

Introduction: Nurses acquire knowledge from biological, psychological and social sciences, with a special emphasis in the human sciences resulting in the ontological conception of caring. At the same time, nurses have their own personal beliefs, attitudes, and experiences which can impact their perceptions about patients as well as the way they care for them. Importantly, some perceptions about patients result in negative caring behaviors that produce stigmatization, solace, and hopelessness among others. If these perceptions are identified early, preventive and transformative interventions can be implemented to improve patient care and quality of life. The literature provides evidence that fears and misunderstanding persist among nurses and nursing students towards caring for People Living with HIV (PLHIV); however, research about faculty attitudes towards caring for PLHIV is almost nonexistent (Leyva-Moral et al., 2016).

Background: As there are more than 33 million PLHIV (UNAIDS, 2015), understanding nurse perceptions about caring for PLHIV is an important area for research to inform evidence-based practice. In global studies about perceptions and caring, nurses still report negative perceptions about caring for PLHIV. For example, Turkish nursing students have negative attitudes about caring for PLHIV; preferring not work with these patients because they fear being infected (Bektaş & Kulakaç, 2007; Nazik, Arslan, Özdemir, & Apay, 2012). Thai nursing students recognize their insecurity about caring for PLHIV. Perceiving high risk of HIV infection, the students are preoccupied with exceeding the level of universal precautions when interacting with PLHIV (Earl, 2010). Also, fear for caring for PLHIV is identified amongst nursing students in the United States, South Africa, Singapore, Sweden and the United Kingdom. They express negative homophobic behaviors, avoidance conduct, non-compassionate care, and rejection (Atav, Sendir, Darling, & Acaroglu, 2014; Pickles, King, & Belan, 2009, 2012). Yet, there are locations, such as Berlin, where nursing students report positive attitudes about caring for PLHIV (Lohrmann et al., 2000). The collective personal experience of this research team believes nursing faculty have attitudinal aspects similar to those indicated by the student literature but objective data to affirm this hypothesis is absent. Thus, the objective of this study is to identify the attitudes of caring for PLHIV among nursing faculty.

Methods: This was a multi-center cross-sectional study. Data was collected using an anonymous web-based version of the validated Healthcare Provider HIV/AIDS Stigma Scale (HPASS) (Wagner, Hart, Mcshane, Margolese, & Girard, 2014). This is Likert scale instrument with 30 items, explores 16 prejudices, 11 stereotypes, and 6 discriminations. A Spanish version of the HPASS, produced with a forward and reverse translation, and expert content, culture, and language validation, was used in Spanish-speaking countries. Sociodemographic data were also collected. This study was approved by the Texas Woman's University Institutional Review Board (Protocol# 19213 / Approval# FWA00000178). Four colleges of nursing participated in the study: Two from Peru, one from Spain, and one from the United States. The scale score ranged from 35 points to 175, with a lower score indicating better attitudes. Generalized linear modeling (McCullagh & Nelder, 1989) was used for data analysis. This technique is a more flexible generalization of ordinary linear regression, permitting the evaluation of

associations between response variables of several kinds (scores in our case) and potential explanatory variables (importance of religion, gender, age, university and highest level of studies).

Results: A total of 119 valid questionnaires were collected for a general response rate of 89.1%. The mean participant age was 49.8 years (SD=12.3) with an average of 14.8 years of teaching experience (SD=12.1). The majority of the American and Spanish faculty (55.00%) hold doctoral degrees while the majority of Peruvian hold Master degree (55.55%). Only 11.11% of the Peruvian faculty hold a doctoral degree. The effect of the potential to explicate variables “importance of religion”, “gender”, “age”, “university” and “highest level of studies” over total score and stereotyping, prejudices and discrimination subscales was analyzed by means of generalized linear models. In relation to the total score for the Stigma scale, very low importance of religion was significantly associated with lower scores ($p = 0.009$), or positive attitudes about caring for PLHIV. Also related to the total score, Peruvian faculty had higher total scores ($p = 0.008$ and $p = 0.012$ respectively) which equates to negative attitudes about caring for PLHIV. No other explicative variables showed a significant association to the total score. A positive attitude for not discriminating was associated with very low importance of religion on the discrimination subscale ($p = 0.010$, $p = 0.001$ and $p = 0.002$ respectively). With respect to the stereotype subscale, the faculty indicating very low importance to religion had lower scores ($p = 0.049$); with an observed higher tendency to stereotype for the older faculty ($p = 0.003$). Regarding the prejudice scale, only the faculty indicating very little importance to religion reported significantly lower scores ($p = 0.014$).

Conclusions: The Spanish and American faculties were more highly educated than the Peruvian faculty. Attitudes about caring for PLHIV were mainly positive among nursing faculty although religiosity seemed to significantly influence discriminatory and prejudice attitudes. The Peruvian faculty were more influenced by religion than were the American and Spanish faculties. Also, the Peruvian faculty scored higher on the discrimination and stereotype scales than the other faculties. The implication of this study is that religion negatively influences the attitude about caring for PLHIV. The limitations of this study were a limited sample size, and the diversity of participant faculties.

Recommendations: Future research should explore the relationship of religiosity to caring for PLHIV. An educational intervention may be appropriate to improve the care of PLHIV by those faculties highly influenced by religion. Cultural diverse and population health practices in HIV/AIDS need to be studied to determine the impact on both the caregiver and the person receiving care.

Determining Knowledge, Attitudes, and Beliefs About Pre-Exposure Prophylaxis (PrEP) Among Transgender Men

Stefan Rowniak, PhD, RN, FNP, USA

Chenit Ong-Flaherty, DNP, MSN, AB, RN, APHN-BC, CNL, USA

Nancy Selix, DNP, FNP-C, CNM, CNL, USA

Niko Kowell, BA, USA

Abstract

Purpose: The United States has witnessed a real shift in HIV prevention practices over the past several years. The prevention techniques that had been employed since the beginning of the epidemic have focused on behavior change. This meant the promotion of condoms for safer sex and engaging high-risk individuals in intensive behavior change counseling, among other interventions. The current shift has been away from individual behavioral approaches to more community-based biological approaches that include testing and immediate treatment and the lowering of the community viral load to ensure that transmission is significantly decreased (Centers for Disease Control and Prevention, 2012, 2014b; San Francisco Department of Public Health, 2014).

The biological intervention that has engendered some of the most interest is pre-exposure prophylaxis (PrEP). The iPrEx study demonstrated that with the daily use of emtricitabine and tenofovir disoproxil fumarate (FTC-TDF), also known as Truvada, participants had a 44% lower rate of infection with HIV compared to those who received placebo. In the same study, those participants who had detectable blood levels of the drug had a 92% lower rate of infection with HIV as compared to those without detectable levels. This suggests an even greater protection for those who are able to take the drug on a daily basis (Centers for Disease Control and Prevention, 2012, 2014b, 2014c; Cohen, Liu, Bernstein, & Philip, 2013).

Since the results of the study were reported, the US Food and Drug Administration approved the emtricitabine and tenofovir combination for PrEP in 2012. Though uptake of PrEP among providers has been slow throughout the country, in locations such as San Francisco, the Health Department and other health providers have been engaged in active promotion of PrEP in a campaign to “get to zero” with regard to new HIV infections (San Francisco Department of Public Health, 2014).

One of the most important questions with regard to PrEP is at whom should the promotion and use of PrEP should be aimed. The iPrEx study recruited primarily men who have sex with men (MSM). This makes perfect sense since MSM have been documented as the population most profoundly impacted by HIV since the epidemic began. Also young MSM of color represent the only group demonstrating increasing incidence of HIV in the US (Centers for Disease Control and Prevention, 2014a).

HIV disproportionately affects transgender women on a worldwide basis (World Health Organization, 2015). Currently there are attempts to actively recruit more transgender women into PrEP programs in San Francisco and throughout California. However, there has been little attention paid to transgender men as being at risk for HIV and also as candidates for PrEP. Several studies have demonstrated that there are transgender men who are the sexual partners of gay men, identify as gay men, and are embedded within the gay male community thus having the same risks for HIV as non-transgender gay men (Rowniak & Chesla, 2012; Rowniak, Chesla, Rose, & Holzemer, 2011; Sevelius, 2009). The lack of inclusion of transgender men in the discussions and promotion of PrEP has meant that not only are many medical providers overlooking transgender men as PrEP candidates, many in the community of transgender men have not understood how PrEP may be relevant to their lives and health. The purpose of this study was to examine the knowledge, attitudes and beliefs of transgender men (trans men) regarding pre-exposure prophylaxis (PrEP) for HIV

Methods: Three focus groups of trans men were conducted with a trans male facilitator for a total of 21 participants. Each of the primary researchers attended one of the focus groups. They took field notes during the session and wrote up their impressions of the focus groups within 24 hours. All focus groups

were recorded and then transcribed. Transcripts were placed in the Atlas.ti computer program and a thematic analysis was conducted comparing each focus group to the others.

Results: Six themes were identified; a lack of adequate information about PrEP and possible side effects, the economic realities for trans men, finding a trans competent provider, trans male sexuality, the importance of contraception, and condom use.

Conclusion: Despite identified risk, many trans men still lack adequate information regarding PrEP. There exist significant barriers to PrEP access for trans men including economic hardship that is impacted by a person's transgender status and a lack of cultural competent providers for transgender people. Also, participants commented how many providers avoid important discussions regarding sexuality. As a result, most stated that their medical providers assumed that the participants had female sex partners and did not know that they had gay male sex partners and were therefore at risk for HIV infection and appropriate for PrEP. Interestingly, most participants reported a high level of condom use and stated they would continue to use condoms even if they were taking PrEP. This could, in part, be explained by the concern voiced over the risks of pregnancy and the need for contraception. There is a need for PrEP education and outreach to the trans male community. The education of healthcare professionals must include competency in working with transgender populations, which includes an understanding and appreciation of the variabilities in transgender sexuality. More research is needed with regard to interactions between PrEP, testosterone, and hormonal contraception.

O 13 - Community-Based Health Promotion

Strengthening the Evidence for Community-Based Wellness: An Academic-Practice Approach to Support Evaluation and Dissemination

Vicki L. Simpson, PhD, MSN, RN, CHES, USA

Abstract

Purpose: Chronic diseases remain a public health challenge, with 49.8% of the US population diagnosed with at least one chronic condition in 2012 and 11.7% diagnosed with three or more chronic conditions (Ward, Schiller, & Goodman, 2014). Additionally, in 2010 treatment of chronic diseases accounted for 86% of US health care costs (Centers for Disease Control and Prevention [CDC], 2016). Chronic diseases are generally very complex and require the generation of evidence to support the design of effective strategies for use by public health practitioners. The purpose of this study was to evaluate the effectiveness of a community-based wellness program offered by a local grassroots coalition in a rural, Midwest, largely Hispanic county to address chronic disease prevention and management. This county ranks 66/92 counties in Indiana in relation to health outcomes. The coalition began providing services to this vulnerable population in 2014 at a variety of sites including manufacturing, low-income housing, service, and faith-based institutions. Monthly health screenings and education as well as referrals to local resources are provided to address the multiple determinants which underlie chronic disease development. An academic-community partnership between a nurse researcher and the community-based coalition was created with the support of a collaboratively developed clinical and translational sciences grant. The grant provided support to enhance data collection, evaluate program outcomes, and disseminate evidence of best practices. Across the US, many community-based programs such as this one are supporting population health improvements and addressing health disparities, however these programs are often not evaluated with the rigor necessary to establish evidence of effectiveness nor are results disseminated for use by other communities. Academic-practice partnerships offer the ability for collaboration between nurse researchers and communities to support design and testing of such programs to develop practice-based evidence for dissemination (Ammerman, Smith, & Calancie, 2014).

Methods: A community-based participatory research approach (CBPR) was used to guide this repeated measures descriptive study to evaluate an existing community based wellness program provided by a community coalition. The CBPR approach was used to support equal engagement of community partners in the research. This approach is useful in rural settings to identify best practices to meet the needs and characteristics of rural populations (Young-Lorian et al., 2013). After receipt of the grant, multiple meetings were held between the nurse researcher and coalition members and providers. These meetings resulted in development of: 1) a research protocol, 2) an enhanced data collection system, 3) questions to more formally capture data concerning lifestyle behaviors, and 4) increased use of technology to easily capture data for analysis. Data from the screenings and lifestyle behavior questionnaires was collected over an 11-month period, de-identified and sent to the researcher for analysis. During the grant period, the academic researcher and coalition providers communicated frequently with several meetings to discuss any issues or concerns.

Results: In the 11-month time frame, 1,169 health screenings were completed for 457 unique individuals and three new sites were added. 23.02% of the individuals participated in at least two screenings and 12.03% participated in five or more screenings. The population was 67.18% female with a mean age of 50.33 years (SD 17.18) ranging from 38.38 (SD 11.08) to 68.56 (SD 14.26) across the sites served. Mean BMI was 30.26 (SD 6.43) with 33.62% of the population classified as overweight, 32.54% obese, and 6.29% extremely obese. A diagnosis of diabetes was reported by 11.06% of the population; 42.08% had a diabetes risk score indicating high risk for diabetes. Hypertension was also prevalent in the population attending the screenings with 42.08% classified as pre-hypertensive and 34.49% classified as hypertensive. Data related to lifestyle behaviors and intent to adopt healthy lifestyle behaviors captured changes related to smoking, diet and exercise. Of the 79 smokers who completed tobacco use surveys, 4 individuals reported efforts to quit smoking. 6.78% of the population reported making dietary and activity changes during the program including portion control and a decrease in "sugary" substances as well as increasing activity or joining Weight Watchers. 10.38% of the visits resulted in referrals to a variety of

programs and providers including Diabetes Prevention Programs, Tobacco Cessation, clinics/physicians, prenatal programs and healthcare navigators. Additionally, information gathered during the screenings resulted in the provision of personalized education to 7.44% of the population. During meetings, program providers also shared evidence of policy, systems and environmental (PSE) changes occurring at several of the screening sites secondary to this wellness program including: 1) creation of lower cost healthier food items in the site cafeteria, 2) provision of information concerning health insurance in Spanish as well as English, 3) provision of awards to employees who adopted healthier behaviors, and 4) creation of smoke-free policies. To document the PSE changes occurring, the nurse researcher and coalition staff collaborated to successfully obtain a second grant to continue collection of data at the individual level and to design a protocol to capture PSE changes as they occur. There were many benefits and challenges during this project. The most significant challenge was related to data collection. Participants, particularly at the worksite settings did not have time to complete the lifestyle behavior surveys, while others had difficulty using the iPads to complete the surveys. Program staff had difficulty adapting to the excel worksheet to enter data, preferring paper and pencil entry of the data. Multiple errors were present in the data sent to the researcher, requiring extensive work to create a database valid for analysis. Benefits included the ability for providers to quickly identify those at risk via the enhanced excel-based data collection tool, allowing for on-the-spot education and referrals. This tool also provided support for analysis of changes over time and linkage to data from the behavioral surveys for analysis. Finally, the ability to aggregate the data collected to provide an overall view of the population being served has been useful to support the need for such a program in this community.

Conclusion: This study generated data which supported program impact and effectiveness. While there is not yet enough data to demonstrate gains at the individual level due to the long-term nature of the behavior change process, multiple PSE changes have been noted. This program is reaching vulnerable populations in the county including Hispanics, low-income elderly and the uninsured, allowing the ability to provide education, support and access to resources to successfully prevent or manage chronic disease. The academic-practice partnership has successfully created a strong relationship to support program evaluation at multiple levels as the second grant period begins. As well, the use of a CBPR approach in this project has helped to identify a community-based wellness program that is helping to reduce health disparities for the population. Currently, the nurse researcher and coalition providers are developing a toolkit for dissemination to support program replication in other communities.

Participatory Rural Appraisal for Community Assessment of Health Needs in Rural Haiti: A Pilot Study

Amy L. Knowles, PhD, MPH, RN, USA
Penelope Lynn Neal, PhD, MSN, CPNP, USA

Abstract

Purpose: The country of Haiti has a population of 10 million people and is the poorest country in the Western Hemisphere. The nation ranks 168 out of 187 on the Human Development Index (WHO.int; MidwivesforHaiti.org). While there has been limited research in Haiti, the majority of previous work focuses on specific disease topics, such as Human Immunodeficiency Virus (HIV) transmission and prevention (Conserve et al., 2014). What is missing from the literature is a comprehensive review of the significant health issues affecting Haitians, especially in the rural areas, and an opportunity of empowering the locals to participate in identifying their greatest health challenges and prioritizing their health needs. The purpose of this study was to gain a better understanding of the comprehensive health needs of a rural village in Haiti. Knowledge gained from this study will be utilized for the development of a community health nursing program, which will embed healthcare workers into remote Haitian communities.

Methods: The Conceptual Model for Partnership and Sustainability in Global Health served as the framework for this study (Leffers & Mitchell, 2010). The Participatory Rural Appraisal (PRA) methodology, as endorsed by the World Health Organization as a best practice (Loewenson et al., 2014), was utilized to identify particular health needs of the community and develop strategies and priorities for health needs and interventions. This type of participatory action research generates knowledge of a social system with the aim of bringing about change (Sethi & Belliard, 2009).

Results: Results from the PRA mapping, scoring, transect walk and focus group discussions were analyzed for trends and themes. Findings from this study prioritize the overall health and community needs as determined by the community members. A desire for mutual goal setting and community ownership of strategies to improve health was discovered. Additionally, sustainable partnerships with mutual health and education goals are needed to optimize the health of the community.

Conclusion: This research provided partnerships with community leaders to empower them to identify and develop strategies to address their own health needs. This completed pilot study will be replicated into other rural communities and knowledge gained from this community assessment will be used to assist in training of community health nurses. A follow-up PRA of the selected community will be conducted after a community health nurse initiative has been embedded in the region to determine effectiveness of the program.

O 14 - Psychological Health in Minority Women

Caught in the Middle: Intersectionality and Mental Health Among Asian Indian Women

Semran K. Mann, MPH, CHES, USA

Lisa R. Roberts, DrPH, MSN, RN, FNP-BC, CHES, USA

Susanne Montgomery, PhD, MPH, USA

Abstract

Purpose: Our aim was to explore intersectional tensions affecting Asian-Indian immigrant women's mental health.

Mental health is a serious and globally prevalent health care issue, though certain groups—such as immigrants—are specifically vulnerable to experiencing negative mental health consequences. Immigration alone is known to cause stress that can affect mental health, yet literature is lacking on AI immigrant mental health needs and preferences for care in the US. However, recent studies have identified AI women, both English and those with Punjabi language preference, to be at high risk of experiencing mental health issues (Roberts, Mann, Montgomery 2016; Roberts, Mann, Montgomery, 2015). The confluence of immigration stress and gender discrimination from within the community and the dominant society predisposes AI immigrants, especially women, to mental health issues. Within the US, AI immigrants are one of the fastest growing minority groups, with many residing in California, including Punjabi AI immigrants (Chandra, Arora, Mehta, Asnaani, & Radhakrishnan 2015).

AI women are particularly vulnerable to experiencing mental health challenges. In addition to typical immigration related stressors such as language barriers, adjusting to minority status and facing discrimination, learning to navigate different education and health care systems, and finding employment, women must also contend with gendered roles, family structure, and intergenerational tensions to a greater extent than their male AI immigrant counterparts. Gender role related factors, such as fertility expectations, shaped by prevailing cultural norms have also been associated with mental health issues (Singh & Bhayana 2015). Thus, AI immigrant women face conflicting social values (Indian vs US), and the combined intersectional effects of gender, race, and class and as a result experience multiple tensions putting them at risk for mental health issues.

In our current era of global migration, using the socio-historical understanding that an intersectional framework provides, of the issues faced by a vulnerable subgroup of AI immigrant women is particularly relevant to addressing the pressing mental health needs.

Methods: A community-engaged research approach was used to guide the research design and data collection. As part of a larger study, “Understanding HER PAIN” and in collaboration with Sikh community members, we used convenience sampling, to recruit male and female participants to complete an anonymous survey during events at Gurdwaras (Sikh churches) in Central California. Quantitative data analyses for this paper were conducted with female respondents only ($N= 217$) and used SPSS 24. For model building purposes, we conducted correlations between independent variables which included standard demographics, a set of intersectionality variables, and depression and anxiety, with our dependent variable, attitudes towards women. Using only significant variables, in addition to mental health variables, we then ran hierarchical linear regression models exploring the additive contribution of these independent variables. Qualitative data collected to contextualize our population's experiences (which were audio recorded, transcribed verbatim, and coded using grounded theory methods), were then aligned with quantitative results.

Results: Survey language preference, years spent in the United States, education, living jointly with family, integration, number of live births, ability to choose family planning methods, and negative religious coping were significantly correlated with attitudes towards women. Block 1 included education, years in the US, survey language, and living in a joint family, and explained 14% of the model variance; only language was significant. When negative religious coping and integration were added in block 2, 22% of

the variance was explained and language, integration, and negative religious coping were significant. In block 3 we added reproductive variables (live births and choosing family planning methods), which accounted for 29% of the variance. Language, integration, live births and choosing family planning methods remained significant. In the final block, depression and anxiety were added; 33% of the variance was explained, and language, integration, live births, choosing family planning methods, depression, and anxiety were significant. Emerging themes highlighted the intergenerational expectation differences for gendered roles, and conflicts experienced between sociocultural expectations and dominant society.

Conclusion: The aim of intersectional analysis is to reveal meaningful distinctions and similarities in order to overcome discriminations and put the conditions in place for all people to fully enjoy their human rights. Nurses involved in direct patient care who understand these tensions affecting the women they serve can be more effective in clinical care provided. It is critical to note that cultural values supersede language proficiency and generational status. Our findings clearly show that there is more to the story than may be readily apparent. Taking time to allow patients to express preferences and concerns will enhance communication and quality of care for culturally diverse women.

O 14 - Psychological Health in Minority Women

Psychological Stress and Acculturation Impact on Health Promotion Lifestyle Behaviors' Adoption Among Arab American Women

Kholoud Hardan-Khalil, PhD, RN, USA
Ahlam Jadalla, PhD, RN, USA

Abstract

Purpose: to explore the association of perceived stress, acculturation, and health promoting behaviors among a group of Arab American Women (AAW) in Southern California.

Methods: A survey study using self-report explored AAW health promoting lifestyle behaviors. The survey was available in Arabic and English languages, participants responded to the questionnaire based on their language preference. Participants responded to the Psychological Stress Measure (PSM-9) (Lemyre & Tessier, 2003), Acculturation Rating Scale of Arab- American II (ARSAA II) (Jadalla & Lee, 2013), and the Health Promotion Lifestyle Profile II (HPLP II) (Walker & Hill-Polerecky, 1995). The PSM-9 consists of 9 items measured on likert scale from 1= not at all to 8= extremely. ARSAAII consists of 30 items, the study sample factor analysis gave two main factors; Arabic acculturation factor (ARF) and American acculturation factor (AMF), the responses are measured on likert scale 1 = "not at all" to 5= "Extremely often, or almost always". The HPLP II consists of 52 items, it is designed to measure the patterns and frequency of self-reported health-promoting behaviors in six areas: health responsibility (HR), physical activity (PA), nutrition (NU), interpersonal relations (IPR), spiritual growth (SG), and stress management (SM). The scale responses are rated on a 4-point Likert-type scale "1 = never, 2 = sometimes, 3 = often, 4 = routinely". Descriptive, comparison, and correlational analyses were employed through the Independent samples t-test and Pearson's Product-Moment Correlations.

Results: A total of 265 women participated, of those 65% responded to the Arabic version of the survey, the participants had age range between 18 and 80 years ($M = 38$, $SD = 13$). The length of residency in the U.S. ranged between 1- 47 years ($M = 15$, $SD = 10.15$). The majority of the participants were Muslim (95.5%), while Arabic was considered the mother tongue by 93% of participants, only 70 % reported that Arabic was their primary spoken language at home. women completed the Arabic version of the survey reported lower levels of psychological stress compared to women who responded in English language ($M = 36.31$, $SE = .740$) $t(265) = -3.485$, $p < .01$. Significant correlation found between Acculturation American Factor (AMF) and health promotion lifestyle behaviors II (HPLP II) $r = .279$, $p < 0.01$, spiritual growth (SG) $r = 0.262$, $p < 0.01$, physical activity (PA) $r = 0.326$, $p < 0.01$, interpersonal relations (IPRs) $r = 0.302$, $p < 0.01$, nutrition (NU) $r = 0.122$, $p < 0.05$, and stress management $r = 0.168$, $p < 0.01$. Additionally, significant correlations were found between Acculturation Arabic Factor (ARF) and health promotion lifestyle behaviors II (HPLP II) $r = .185$, $p < 0.01$, spiritual growth (SG) $r = 0.191$, $p < 0.01$, health responsibility (HR) $r = 0.241$, $p < 0.01$, interpersonal relations (IPRs) $r = 0.226$, $p < 0.01$, nutrition (NU) $r = 0.122$, $p < 0.05$, and stress management $r = 0.167$, $p < 0.05$. ARF was negatively correlated with psychological stress measure $r = 0.167$, $p < 0.01$. A significant correlations were found between the participants' length of residency in the U.S. and their responses on HPLP II, PA, SG, and IPRs, $r = 0.190$, 0.181 , 0.177 , 0.238 (265) $p < 0.01$ respectively. However, Physical activity found to be negatively correlated with women completed the Arabic version survey.

Conclusion: Among Arab American women, psychological stress, acculturation and length of residency influence their engagement in healthy lifestyle behaviors. More studies are needed to assess sources and types of stress among AAW. The findings of this study highlight the need for nurses and other health providers to consider the cultural and psychological factors when designing or implementing health promotion and disease prevention programs.

O 15 - Infant Safety Interventions

Parental Readiness for Infant Safe-Sleep Interventions

Kimberly T. Hodges, DNP, RN, NE-BC, USA

Abstract

Purpose: Infant safe sleep practices and the reduction of Sudden Unexplained Infant Deaths (SUID) is a public health priority in the United States and throughout the world. According to the American Academy of Pediatrics (AAP) (2016), Sudden Infant Death Syndrome (SIDS) is the leading cause of death in children between one month and one year of age, occurs without warning, and is associated with an episode of sleep. The Centers for Disease Control and Prevention (CDC) states approximately 3,500 SUID events occur each year in the United States (2016). The gap in the literature lies in researching parental readiness in executing safe sleep behaviors after discharge from the hospital.

Parents of well newborn and neonatal intensive care (NICU) infants have been studied to identify parental readiness to follow safe sleep guidelines after hospital discharge. Gelfer, Cameron, Masters and Kennedy (2013) studied infants discharged from the NICU to determine if modeling safe sleep practices during the hospital stay would provide a positive influence on parental behaviors regarding safe sleep post discharge. After providing a safe sleep crib card, educational programming for nurses and parents and auditing safe sleep compliance in the NICU setting, parental compliance for safe sleep behaviors post discharge increased by nearly 60% (Gelfer et al.). This study implied parental readiness is influenced by safe sleep observations witnessed in the hospital.

In a longitudinal study conducted by Knight, Webster, Kemp and Comino (2013) 159 mothers were surveyed for readiness to provide safe sleep environments. A higher level of maternal education was associated with identification of two or more SIDS risk reduction strategies in the study (Knight et al., 2013). A review of the literature reveals that parents, specifically ones of certain ethnicities, races, and educational levels, do not provide safe sleep environments during the first year of the infant's life (Knight et al., 2013). A gap in the literature lies in identification of which factors impact parental readiness to execute infant safe sleep behaviors after discharge from the hospital.

This prospective descriptive study identified behavioral perceptions and readiness factors of parents to abide by infant safe sleep practices upon discharge from the hospital in conjunction with implementation of a standardized infant safe sleep education toolkit. The purpose of the study was to identify factors impacting parental readiness to execute infant safe sleep practices related to infant sleep environments in an urban Maternity Center.

Methods: Icek Ajzen's Theory of Planned Behavior (2006) served as the conceptual framework guiding this study. The survey used the Theory of Planned Behavior concepts to survey parental perceptions of executing infant safe sleep guidelines in the first year of the infant's life. Approval for this exempt research study was obtained from the a Midwestern university Institutional Review Board.

The sample included mothers delivering well newborns at an urban Midwestern hospital. Well newborns were defined as stable term (> 37 gestational weeks) or late preterm (34 to 36 gestational weeks) infant admitted to the well newborn unit after delivery and remaining under the care of a well newborn physician until discharge to home from the well newborn unit. Inclusion criteria for the study included the following: mothers must be 18 years of age or older; not incarcerated; gave birth to a well newborn admitted to the Well Newborn Nursery (not admitted to and/or discharged from the Neonatal Intensive Care Unit). Mothers giving birth to an infant receiving care in the Neonatal Intensive Care Unit were also omitted from the study.

After completion of the initial pilot study, the main prospective descriptive study was conducted from January 1st until April 30th, 2016. The study was developed and conducted at a large 700-licensed bed Midwestern hospital on the Mother-Baby unit. The hospital is a Level One Trauma Center and is Magnet designated. The Mother-Baby unit is a 28-bed unit caring for approximately 3,700 infants born annually.

An informational flyer was given to each eligible mother in the Mother-Baby unit describing the study, the topic and investigator's contact information (N= 792). Participants were given the option to opt out of the survey. Surveys were collected by the nursing team upon completion and placed in the locked box on the nursing unit.

The Theory of Planned Behavior (TPB) survey template is a free tool developed by Izek Ajzen and was utilized in the main study to create an infant safe sleep survey. The initial pilot study (n=35) was conducted in August 2015 to determine the constructs for infant safe sleep as related to the theoretical components. Using the results of the pilot study, the initial survey was constructed and tested for reliability. Cronbach's Alpha for the following sections is reported as Section One (Behavioral Beliefs) = 0.708; Section Two (Normative Beliefs) = 0.719; Section Three (Control Beliefs) = 0.751.

The initial draft for the 23-item survey was tested for content and face validity. A panel of five maternal-child medical and nursing experts reviewed the survey for content validity with an 80% return rate that generated feedback regarding the survey content. Additionally, a group of ten patients on the Mother-Baby unit reviewed the survey for face validity. Survey feedback for face validity produced a 100% return rate. The consensus of the patient group was that they understood the theme of the survey to be safe infant sleep and the survey questions described preparing to have safe infant sleep.

The instrument consisted of 23 items designed to analyze Theory of Planned Behavior framework. The main topics addressed in the survey include opinions of infant safe sleep behavioral beliefs, infant safe sleep normative beliefs, and infant safe sleep control beliefs. All items listed in the main survey were generated from the initial pilot study. The participant answered each question using a Likert scale of one to seven.

Demographics of the study sample and correlation of TPB components were calculated from the survey results. Spearman Rho correlation factor was utilized to calculate correlation and level of significance for the data results was reported as $p < 0.01$. The Statistical Package for Social Sciences, version 23, was used to examine statistical findings.

Results: One hundred fifty mothers completed the survey with a completion rate of 18.9%. A relationship between the behavioral beliefs of infant safety and maternal attitude towards infant safety ($r = .406$, $n = 150$, $p < 0.01$) was noted in the survey results. A second association between behavioral beliefs of improved health for infant and maternal attitude towards improved health for the infant ($r = .448$, $n = 150$, $p < 0.01$) was also established in the results. Additional relationships between normative beliefs of the significant other ($r = .461$, $n = 145$, $p < 0.01$) and control beliefs for limiting caregivers ($r = .472$, $n = 146$, $p < 0.01$) were calculated from the data.

The findings from this study revealed significant relationships between behavioral beliefs of the safety of the infant, improved health for the infant and attitudes towards those beliefs. Participants reported positive attitudes towards desiring safety and improved health for the infant. When identifying safe sleep practices as components, Fowler, Evans, Etchegaray, Ottenbacher and Arnold (2013) found parental preference as a barrier to safe sleep with parents reporting they felt safer with the infant in bed with them. The study signifies a need for health professionals to speak to current AAP 2016 recommendations for room sharing instead of bed sharing for the safety of the infant.

Normative beliefs revealed a relationship between safe sleep behaviors and the influence of maternal significant others. The thoughts and influence of a significant other had the most impact of predicting readiness for providing safe sleep behaviors after discharge from the hospital. Control beliefs disclosed three relationships, however the strongest of the three control behavior constructs was limiting caregivers for the infant. The results found a moderate relationship between limiting caregivers for the infant and being successful in following infant safe sleep behaviors.

When discussing infant safe sleep content with parents, several themes should be included in the delivery for optimal readiness to execute the behaviors. The importance of complying with infant safe sleep

behaviors for a positive impact on the infant's health and safety is a motivational factor to enhance readiness for the behaviors. Including the mother's significant other in delivery of the educational component allows for influential people in the mother's life to understand the significance of safe sleep behaviors. Supporting methods to reduce multiple caregivers for the infant in the first year of life or providing means to educate various caregivers regarding infant safe sleep guidelines may support readiness to perform the behaviors.

Conclusion: Factors that affect ability to execute safe sleep behaviors include beliefs of infant safety and improved health. Including key individuals in educational delivery, such as the mother's significant other, can also influence readiness to execute safe sleep behaviors. Healthcare professionals should provide methods to communicate infant safe sleep guidelines to multiple caregivers or ways to reduce the number of caregivers in the first year of life to support readiness for infant safe sleep behaviors.

O 15 - Infant Safety Interventions

Change in Caregiving Activities in Preterm Infants Over the First 14 Days of Life

Debra Brandon, PhD, RN, CNS, FAAN, USA

Ashlee Vance, MA, BSN, RN, USA

Abstract

Purpose: High-risk term and preterm infants are some of the most vulnerable to an altered microbiome due to the atypical Neonatal Intensive Care Unit (NICU) environment of care following birth. Infants typically develop their microbiome in close contact with the mother and the home environment. Research on the impact of microbial colonization on the health of preterm infants has grown significantly recently (DiBartolomeo & Claud, 2016). Yet, most of the research to date has focused on how the mode of delivery, use of antibiotics, and environmental surfaces of the NICU could impact the microbiome. How specific health caregiving activities in the NICU impacts the development of the preterm infant's microbiome is largely unknown (Hartz, Bradshaw, & Brandon, 2015). Understanding the nature of caregiving that could influence the microbiome is a critical first step. Therefore, the purpose of this study was to describe the frequency and change in caregiving activities of extremely low birthweight infants over the first 14 days of life that have the potential to alter the development of the skin, gut and pulmonary microbiome.

Methods: A longitudinal multiple case study design was used to examine caregiving interventions. Infants were videotaped over the first 14 days of life while receiving care in their incubator in a Level IV NICU. Observational coding of the frequency and length of caregiving activities was conducted using Observer XT ver. 11.5. Development of the coding schema over five iterations resulted in 26 caregiving codes. Four coders were trained to 80% Kappa reliability. The case history of each of the five extremely preterm infants were established to examine major events across the first 14 days of life including respiratory support, feeding status, medications, severity of illness and major diagnoses.

Results: The five infants contributed 817 hours of data over 54 days. Descriptive statistics were used to calculate frequency and percent of each of the 26 categories per day. All 26 categories were discussed and categorized based upon the category's relationship to infant skin, gut, or pulmonary systems. Consensus for placement of each caregiving activity categorization was obtained between the authors. Some of the caregiving activities were not present. Skin caregiving activities coded included *infant touch*, *diaper changing*, *cleansing*, and *infant removal from the incubator*. Gut caregiving activities included oral care, oral or nasal pharynx suctioning, nasal gastric or oral gastric tube, and pacifier placement. Pulmonary caregiving activities included endotracheal placement (ETT) and ETT suctioning.

Across the five infants, the average number of times an infant was touched each day ranged from 58.9 to 122.8 times. The co-occurrence of case history events and changes in the frequency of caregiving activities were also explored. The number of times touched per day was highly variable across the first 14 days of life and associated with the infant's severity of illness. While hands in the incubator mirrored the *infant touch* frequency they were typically more *hands in the incubator* than touch time across the 14 days of life. Across the first 14 days of life routine caregiving activities were more consistent across time. For example, the mean number of *diaper changes* were 2-4 per day and the mean number of *oral care* events were 1-3. These caregiving activities were consistent over time. The frequency of other caregiving activities was associated with rarer procedural events. For example, *cleansing* activities were associated with placement of percutaneous inserted central catheters. Therefore, these caregiving activities did not have a pattern of change over time, rather they co-occurred with procedural events.

Conclusion: Caregiving activities for extremely low birthweight infants were easily grouped into skin, gut, and pulmonary categories with the potential to influence the developing microbiome. Over the first 14 days of life caregiving activities that were more routine such as diaper changes were consistent over time while other activities such as infant touch was associated with infant severity of illness or procedural events. These findings provide beginning description of events that should be mapped with microbiome development. Routine caregiving activities such as oral care may influence gut microbiome while the

frequency of infant touch can influence the skin. Future research should map microbiome development of the skin, gut, and pulmonary systems in relationship to specific caregiving. Modifiable caregiving strategies should be considered based upon the microbiome.

O 16 - Symptoms and Treatment of Cancer

Global mHealth Interventions for Self-Management of Symptoms Following Breast Cancer Treatment

Mei R. Fu, PhD, RN, FAAN, USA

Abstract

Purpose: Breast cancer-related lymphedema (hereafter, lymphedema), an abnormal accumulation of lymph fluid in the ipsilateral body area or upper limb, remains an ongoing major health problem affecting more than 40% of 3.1 million breast cancer survivors in the United States. Lymphedema is a cardinal sign of an impaired lymphatic system. Impairment in lymphatic system leads to a chronic disease state with multiple associated symptoms that require ongoing symptom management. Similar to risk reduction and management of other chronic diseases (e.g. diabetes and prediabetes), proactive and preventive education on signs and symptoms of lymphedema and risk reduction activities is essential for early identification and treatment of lymphedema. Yet, this proactive approach to risk reduction is not a standard of care for those at risk for developing lymphedema associated with breast cancer treatment. Sadly, this leads to patients at risk for lymphedema self-diagnosing lymphedema and seeking professional help only after visible swelling is present. This reduces the opportunity for early identification and treatment which is associated with better patient outcomes. More importantly, the experience of lymphedema symptoms is a cardinal sign of an early stage of lymphedema in which changes cannot be detected by current objective measures of limb volume or lymph fluid level. Without timely assessment and intervention in this early disease stage, lymphedema can progress into a chronic condition that no surgical or medical interventions at present can cure. mHealth can be broadly defined as the use of information and communication technology that is accessible to patients or healthcare professionals via mobile technology to support the delivery of patient or population care or to support patient self-management. Patient-centered care related to lymphedema symptom management is often inadequately addressed in clinical research and practice. mHealth plays a significant role in improving self-management, patient-clinician communication, and access to health information. *The-Optimal-Lymph-Flow* mHealth system is a multi-language, patient-centered, web-and-mobile-based educational and behavioral mHealth interventions focusing on safe, innovative, and pragmatic electronic assessment and self-management strategies for lymphedema symptoms.

The purpose of this presentation is to describe the development and test of TOLF system to evaluate reliability, validity, and efficacy of mHealth assessment as well as usability, feasibility, acceptability and efficacy of mHealth interventions for self-management of lymphedema symptoms among the end-user of breast cancer survivors.

Methods: The development of *TOLF* was guided by the Model of Self-Management for Symptoms and designed based on principles fostering accessibility, convenience, and efficiency of mHealth system to enhance training and motivating assessment of and self-management for lymphedema symptoms. Test of TOLF was accomplished by conducting a psychometric study to evaluate reliability, validity, and efficiency of the electronic version of Breast Cancer and Lymphedema Symptom Experience Index, a usability testing and a pilot feasibility testing of mHealth self-management interventions.

Results: Findings from the psychometric study with 355 breast cancer survivors demonstrated high internal consistency of the electronic version of the instrument: a Cronbach's alpha coefficient of 0.959 for the total scale, 0.919 for symptom occurrence, and 0.946 for symptom distress. Discriminant validity of the instrument was supported by a significant difference in symptom occurrence ($z=-6.938$, $p<0.000$), symptom distress ($z=-5.894$, $p<0.000$), and total scale ($z=-6.547$, $p<0.000$) between breast cancer survivors with lymphedema and those without it. Findings of usability testing showed that breast cancer survivors were very satisfied with the mHealth **self-management** interventions: 90% rated the system having no usability problems; 10% noted minor cosmetic problems: spelling errors or text font size. The majority of participants 96.6% strongly agreed that the system was easy to use and effective in helping to learn about lymphedema, symptoms and self-care strategies. Feasibility testing demonstrated that a 12-week one group intervention using TOLF had significantly positive effects on less pain ($p=0.031$), less

soreness ($p=0.021$), less aching ($p=0.024$), less tenderness ($p=0.039$), fewer numbers of lymphedema symptoms ($p=0.003$), and improved symptom distress ($p=0.000$) at 12 weeks after intervention. Themes from the qualitative data included empowerment, high quality information, loving avatar simulation videos, easy accessibility, and user-friendliness.

Conclusion: mHealth is important for delivery of quality nursing care globally. TOLF system using the electronic version of the instrument is able to assess patients' lymphedema symptoms with high reliability and validity. Thus, patients can report their lymphedema symptoms anywhere and anytime globally. Findings of psychometric testing on the ability of TOLF system to collect health, clinical, research data support the reliability and validity of electronic instruments administered by TOLF system. Findings of testing on TOLF system have provided evidence for breast cancer survivor's acceptance, usability and feasibility of TOLF system to enhance self-care strategies for lymphedema symptom management. TOLF provides a much-needed mHealth system for advancing the science of self-management for lymphedema symptoms and a foundation for transformation of healthcare from reactive and hospital-centered to preventive, proactive, evidence-based, patient-centered and focused on well-being rather than disease, the very important core of nursing care.

O 16 - Symptoms and Treatment of Cancer

Hope and Symptom Interference Predicting Quality of Life in Colorectal Cancer Survivors: A Pilot Study

Yi-Chen Huang, MSN, RN, Taiwan
Ya-Jung Wang, PhD, RN, Taiwan

Abstract

Background: Colorectal cancer is the third cause of cancer incidence and fourth cancer mortality in Taiwan. Early detection and chemotherapy improve patients' survival. However, patients still suffer from side effects from cancer and its treatment. Evidence indicated that hope helps cancer patients in a better adaptation.

Purpose: The aims of this pilot study was to preliminarily explore relationship among hope, symptom interference, and quality of life in Taiwanese colorectal cancer population; as well as to shape the study in a better design for a further study.

Methods: This is a descriptive, correlational study with a preliminary result. We recruited patients with colorectal cancer, aged 20 years and more, and received at least one cycle of chemotherapy. Study instruments included Total Neuropathy Score- clinical version, Patient Neurotoxicity Questionnaire, Herth Hope Index (HHI), MDASI-Taiwan Form for Cancer Treatment - Colorectal cancer and Taxane. Data analysis applied mean, standard deviation, frequency, percentage, Pearson's correlation and linear regression.

Results: A total of 40 patients with a mean age of 60.1 years were included in this pilot analysis. Twenty-two of participants were male and 75% of them were with PN. Results indicated patients' hope significantly and positively predicted their QOL in this sample ($\beta=.383$; $R^2=.147$; $p<.05$). In addition, symptom severity ($\beta=-.667$; $R^2=.445$; $p<.001$) and symptom distress ($\beta=-.76$; $R^2=.578$; $p<.001$) significantly and negatively predicted QOL in Taiwanese patients with colorectal cancer.

Conclusion: Results of this pilot study suggested that the prevalence of PN was relatively high and those with PN had a declined QOL. We also found symptom severity and symptom distress interfered patient's QOL in the present study. However, hope is an inner power to support patients with cancer, to overcome their symptom interference, and to advance their QOL. The preliminary findings help researchers to modify the further study design and to confirm the instruments matched the study population.

O 17 - Educational Learning Environment

Diverse Educational Strategies Enhance Multigenerational Learning in the Classroom and Workplace

Joyce I. Karl, DNP, MS, BSN, RN, ANP-BC, COHN-S, USA
Oralea Pittman, DNP, APRN, FNP-BC, FAANP, USA

Abstract

Purpose: This presentation will examine similarities and differences among generations and how diverse educational strategies can be developed for the multigenerational classroom or workplace. It will also discuss how traditional, interactive, and problem-based intergenerational activities may benefit all participants.

Review of Literature: In the classroom, three generations are often present among the faculty and students; baby boomers, Generation X, and millennials (Generation Y). Although it is important to avoid assumptions about individuals, each group has values and skills which are different. Baby Boomers prefer structured learning. Hard work is the way to earn respect and advancement in the workplace (Gallo, 2011; Gillispie, 2016).

As learners, Generation X want to know the relevance of information and the most efficient way of learning it. They are independent and skeptical. Their respect must be earned (Gallo, 2011; Gillispie, 2016).

Millennials prefer learning with technology to reading from textbooks. They understand the half-life of knowledge is short, and want quick feedback. They learn best in active environments where they can practice what they are learning (Gallo, 2011; Gillispie, 2016).

Educational strategies for multigenerational, multicultural cohorts promote reciprocal exchange of knowledge among participants so they can learn together and from each other. Instructors should explore their own generational identity/awareness and facilitate the same in students to enhance intergenerational communication, respect, learning, decision-making and conflict management (Sánchez & Kaplan, 2014). Content should start simple and build in complexity. Learning activities must be designed for growth in the cognitive, affective and psychomotor domains. Problem-based learning strategies help students translate knowledge into practice and achieve professional clinical competencies (Distler, 2015). Student-centered approaches such as the flipped classroom have shown mostly positive or neutral outcomes compared with traditional approaches (Betihavas, Bridgman, Kornhaber, & Cross, 2016; Gillispie, 2016; Robinson, Scollan-Koliopoulos, Kamienski, & Burke, 2012)

Summary: Multiple teaching techniques are essential for successful intergenerational learning: traditional, active, cooperative and collaborative. Lectures and readings may still be appropriate for some content; but podcasts/webcasts, audio books, and e-books are also good options. Low stakes, self-reflection assignments and case-based or literature-based sessions as written assignments or blogs are appropriate for all learners. Attention grabbers such as guest speakers from the field, audience response systems, YouTube videos, Wikis, games, or video vignettes can enhance multigenerational engagement. Harnessing virtual and simulated activities using standardized patients and/or interprofessional teams with peer and faculty feedback together with actual clinical experiences shows promise for successful, competent nursing and advanced practice nursing graduates. We will share our experience utilizing several of the suggested strategies with nurse practitioner and interprofessional health students.

Implications for Practice: Intergenerational differences in learning styles and work styles are present in nearly every professional classroom, preceptorship, and practice. Understanding and appreciating the different attitudes and skills that different generations and professions bring to the relationships can increase student, faculty, and employee confidence and self-efficacy as they learn new skills from each other.

O 17 - Educational Learning Environment

A Systematic Literature Review of the Effect of Culture on Learning

Christine L. Sommers, MN, RN, CNE, Indonesia

Abstract

Purpose: Teaching in a culturally congruent manner is important to the nursing discipline. Cultural norms and ways of learning influence learning expectations, which may influence the development of critical thinking skills, clinical reasoning, and clinical judgment in nursing students. The purpose of this presentation is to describe a systematic literature review on the impact of culture on learning, including teaching and curricular implications. This review examined literature in healthcare, education, and social sciences. The examination concluded that culture does affect learning. To best prepare nursing graduates to provide safe and effective patient care that meets complex healthcare needs globally, it is imperative that nurse educators teach in a culturally congruent manner.

Background: Different cultural groups demonstrate and define critical thinking in different ways (Tian & Low, 2011). Some even struggle with related concepts, such as questioning those considered experts or authority figures, questioning published literature, and asking questions in class. In a literature review related to problem-based learning methods to promote critical thinking among nursing students from differing cultures, the researcher found scant data in nursing scholarship that examined the relationship between culture and learning (Sommers, 2014). The researcher concluded that in order for nurse educators to prepare nursing graduates to meet patient care needs globally, they need to teach in a culturally congruent manner, and therefore, need to know more about how culture affects learning (Sommers, 2014).

Learning style preferences vary with individuals' cultural values (Holtbrügge & Mohr, 2010). Approaches to learning are embedded in the learner as socio-cultural issues and the learners' background shapes and influences approaches to learning (Brown, Ward-Panckhurst, & Cooper, 2013). Therefore, it is vital that nurse educators understand the needs of ethnically diverse students to develop culturally sensitive and supportive educational environments in nursing education (Veal, Bull, & Miller, 2012).

Methods: The PubMed, CINAHL, ERIC, PsychINFO, and ProQuest databases were searched for papers published between 2010 and 2015. The search was limited to articles and dissertations that accessible in the English language. Inclusion criteria included a description of how learning was affected or related to culture and a description of a particular viewpoint or particular audience. Varied combinations of the search terms culture, learning theory, learning approach, learning behavior and student were used. The initial search identified 206 papers. Once duplicates were removed and full text reviewed, 31 papers met the criteria. An additional two papers were added during a secondary search for a total of 33 papers reviewed.

Results: Thematic analysis identified four major themes that describe the effect of culture on learning: a) occurrence of surface learning among non-Western students, b) the effect of previous educational experiences on learning, c) the effect of cultural values on learning, and d) teaching strategies to promote learning. The five teaching strategies identified to promote learning were a) maintain awareness, b) respect culture, c) provide support programs, d) utilize technology, and 5) develop reflective practices.

Conclusion: As there is an effect of culture on learning, nursing educators need to consider culture when teaching, not to change core outcomes of a program, but to culturally contextualize teaching styles, assessments, and activities so that students successfully achieve the core outcomes. Students from different cultures have different perspectives; how they learn and process information is also different; therefore, culturally appropriate evaluation systems should be used to evaluate the learning (Henze & Zhu, 2012). Since learning is closely linked with culture, different cultures have different norms related to critical thinking, roles of students and instructors, and learning styles.

Furthermore, how students previously learned greatly influences current learning preferences and expectations. It is important to recognize and respect students' different cultural backgrounds and expectations regarding learning to assist the students in meeting the objectives and expectations of a unique curriculum that may involve new ways of learning. This will include adapting teaching methods but not essential learning outcomes of the curriculum. Adapting the teaching methods will include additional coaching and instruction to students, culturally contextualizing the teaching method, being aware of one's own cultural learning norms, and using a variety of teaching methods and styles to meet different learning style preferences.

More research is needed regarding how culture affects learning in nursing education and what teaching practices work best in nursing education with students with diverse cultural backgrounds. To meet the challenging, complex, and unpredictable demands of today's healthcare needs globally, nurse educators must be prepared to recognize that culture does affect learning and be willing to adapt and develop teaching strategies for use with diverse cultures that promotes critical thinking, clinical reasoning, and clinical judgment. The themes from the literature on culture and learning, as well as the themes relevant to teaching strategies that promote cultural congruence, provide faculty direction for self-assessment and a review of the curriculum to promote cultural congruence.

P 09 - Enhancing Education Through Storytelling Using Digital Stories to Increase Nurse Educator Cultural Competence in Ontario, Canada

Patricia Bradley, PhD, MEd, RN, Canada

Abstract

Purpose: To share the preliminary results of the Internationally Educated Nurses (IEN) project (funded by Ontario Ministry of Citizenship and Immigration (2014-2017) on Digital Storytelling (DST) as a tool to increase nurse educator cultural competence.

Digital Storytelling has been identified as a deep learning tool in education in general and in nursing education in particular (Benmayor 2008, Barrett 2006, Dip 2014, Haigh et al 2011, Miller et al 2015). Through stories, learners embrace the nature of issues, community and cultural contexts, or raise awareness about differences (Billings 2016, Clausen et al 2014, Oermann 2015).

Addressing the health care needs of the culturally diverse country such as Canada requires new models to educate healthcare providers and educators. Using Digital Stories is one approach to increase cultural competence in educators and students. This study used Digital Storytelling for nursing faculty professional development. A model of Digital Storytelling was developed and used in the project and will be shared with participants.

Methods: This paper uses a qualitative method to explore the learning experience and awareness of faculty participants about cultural diversity after viewing digital stories. These 24 internationally educated nurse developed stories (with images, voice and music) describe the experience of learning to transition into the Canadian healthcare setting.

Results: The faculty participants realized that they were not fully aware of the complexity the internationally educated nursing students were facing. In addition the faculty realized that they lacked awareness of their own cultural competency and communication skills. The analysis of the stories led to themes that are guiding further faculty development. In addition the process of DST making is an emotional one for student participants when they revisited their most memorable moments in the journey to become a registered nurse in Canada. In the creation of the stories students expressed that they felt more powerful and motivated to fight for a better future. Students expressed that they "found their voice."

Conclusion: The results showed that DST indeed is powerful tool to improve cultural competency of the participants. This study is a unique approach to cultural competence as a majority of studies focus on the measuring or assessment tools of cultural competence (Kardong-Edgren et al 2010, Wilkinson 2012). Some studies have focused on how to teach cultural competence using simulation (Jeffreys 2015, Long 2012, Truong et al 2014). This study approached the need for educators to be culturally competent in addressing when teaching diverse students. In the presentation we will discuss analysis methods of DST as well as DST as a tool to enhance cultural competency. We will share lessons learned about using the DST process to enhance cultural competence and future research plans.

P 09 - Enhancing Education Through Storytelling

Using Storytelling to Teach SBAR as a Crucial Conversation Skill to Improve Patient Safety

Gwen Sherwood, PhD, RN, FAAN, ANEF, USA
Jen-Huei (Vicky) Yeh, BSN, RN, USA

Abstract

Purpose: The Quality and Safety Education for Nurses (QSEN) project (Cronenwett et al., 2007) has defined six competencies 1) patient-centered care, 2) teamwork and collaboration, 3) evidence-based practice, 4) quality improvement, 5) safety, and 6) informatics to have collaborative ready practitioners. Effective team communication is an essential attribute of the teamwork and collaboration competency to coordinate care amidst the complexity of care environments, yet most health care curricula fail to provide effective teaching strategies. In part this is because we have insufficient evidence as to what and how to teach these competencies to promote safe quality care (Cronenwett et al., 2007).

Story, as narrative pedagogy, is reported as a powerful change agent in developing a new mindset for healthcare quality and safety. Narrative pedagogy applies experiential learning theory in helping learners work within concrete situations (story) to apply what they know from previous situations and providing a context for applying new knowledge. Knowing how to speak up is a critical communication skill. The study evaluated use of a story based education intervention to help learners know how to observe, identify and analyze practice situations for gaps in care, and then compose a standardized communication to another health professional using I-SBAR (Foronda et al., 2015). The aims of the study were to better understand the use of story in teaching effective crucial communication about a critical event using I-SBAR from the learner's perspective, assess effective team communication about a critical event using I-SBAR, and examine the link between team communications using I-SBAR and previous work experience. Participants were recruited from students enrolled in a Health Services Improvement course in a school of nursing.

Methods: The study was determined exempt following IRB review. Participants in a senior level Health Services Improvement Practicum watched a 15 minute video theory burst on crucial team communication, had a brief review of I-SBAR (Identity-Situation, Background, Assessment, Recommendation) (Foronda et al, 2015), listened to a 4 minute recorded story from the StoryCare® online collection of a critical clinical incident requiring physician communication, and completed a three part online exercise: 1) composed an I-SBAR communication to another team member, 2) completed an online self-assessment 15-item checklist to rate how well their I-SBAR met stated criteria, 3) completed four reflective questions using a Likert scale about story as an instructional strategy and four demographic questions. Data analysis was done by descriptive statistics.

Results: Participants (N=43) self-assessed their own I-SBAR with the 15 items. Four items were correctly completed by all participants: caller identity, reason for the call, patient interventions, and potential reason for patient current condition. The four lowest scored items (less than 30% of participants correctly included) were admission date, vital signs, level of consciousness, and repeat back physician orders/responses. On the Likert survey, 85% of participants rated the use of story as satisfactory/very satisfactory, reported they would be able to apply the concepts of crucial conversation to respond to other professionals, they could transfer the I-SBAR skill to other situations, and rated use of story as an effective teaching strategy compared to other methods. Participants' health related work experience ranged from 0 – 12 years but did not have a statistically significant link to their I-SBAR scores.

Conclusion: Much attention has been given over the past decade to the demand to improve quality and safety outcomes in health care. Communication is a leading cause of health care errors that contribute to adverse events. Education is a key strategy increase awareness, knowledge, and skills of health care providers to improve patient outcomes. By examining the results of this study, we can begin to develop more strategic learning activities to prepare learners for the dynamics of real world practice in a low

stakes learning environment. This study also offers an efficient and effective online approach for teaching skills.

P 10 - NCLEX Success

The Relationships Among Standardized Exam Results, Remediation Time, and Licensure Success

Susan C. Mills, PhD, RN, USA

Pamela Williams, PhD, RNC, USA

Darrell Spurlock, PhD, RN, NEA-BC, ANEF, USA

Abstract

Purpose: The purpose of this study was to explore the relationships among standardized exam scores, time spent on exam specific remediation, and licensure exam results using data from three years of senior classes.

Background: Preparing pre-licensure nursing students for a rapidly changing health care environment requires that students are able to think critically and synthesize data from multiple sources. A curricular revision in one program prompted the foundation of a constructivist approach to helping students synthesize knowledge from previous and concurrent courses. The four knowledge synthesis courses incorporate an inquiry based approach that includes students working in small groups to actively participate in problem solving. Case studies and assignments in these courses reflect theoretical and clinical concepts that correlate with what is being taught during the semester and utilize previous learning. Faculty members teaching in this program have structured medical surgical, pathophysiological, and specialty concepts to tie together in the knowledge synthesis courses. A secondary objective of the knowledge synthesis courses is to help students begin to utilize standardized tests to identify areas of weakness and gaps in knowledge. With the help of faculty members students formulate a plan for remediation as a means of preparing for licensure examination.

In the first semester of their junior year, students review the licensure exam categories alongside concepts of care and case studies that reflect what they are studying in their other nursing courses. Test taking skills and methods to reduce test anxiety are discussed and practiced. The second semester of the junior year continues the focus on testing that incorporates weekly medication calculation questions designed to strengthen the student's calculation knowledge. The students also self-identify their learning needs with exercises that have them reflecting on their emotional intelligence, testing decision making and integration of material learned in concurrent courses. Their second standardized test in the curriculum has a focus on the care of the older adult and draws on information that was presented during both semesters of their junior year.

In the senior year the objective of the utilization of standardized examinations is to support students in identifying areas of weakness. Students are encouraged to use test specific remediation to improve grades. This is done by using two versions of a custom built comprehensive exam that is given at the beginning and end of the first semester. Based on the score of the first exam students are motivated to complete test specific remediation on areas of weakness as part of their course grade. In the second semester of the senior year students begin and end the semester with a standardized comprehensive exit examination. The students are encouraged to remediate but test specific remediation is not part of their course grade. The emphasis in the second semester continues to be the identification of areas of weakness and filling in concept and content gaps through the use of active learning strategies including several simulation scenarios, small group case studies, and presentations.

Methods: This retrospective, descriptive, correlational research study utilized descriptive and correlational statistics to identify relationships among three years (2014-2016) of senior nursing students' data ($N = 364$) including: two custom comprehensive exam scores, two exit exam scores, time spent in test specific remediation, and licensure exam results. Descriptive statistics provided means for standardized test scores, time spent on test specific remediation, score improvement, and licensure success on first attempt. Analysis of Variance (ANOVA) and correlation analysis were used to explore relationships among graduation year, and student success on licensure exam with standardized test scores and time spent in test remediation that accompanied the standardized exam.

Results: The results of the study demonstrated several important relationships for consideration in planning curricula and student preparation for licensure examination. When comparing mean test scores from students who passed (86.6%) versus those who failed (13.4%) the licensure exam on the first attempt, statistically significant differences in means scores were found for custom comprehensive exam scores ($F = 26.44$, $df = 1, 362$, $p < .001$) and exit exam scores ($F = 31.61$, $df = 1, 365$, $p < .001$). The exam most strongly correlated with licensure exam passing was the first administration of the exit exam in the spring of the senior year ($r_{pb} = .282$, $p < .001$), followed closely by the first custom comprehensive exam administered at the beginning of the senior year ($r_{pb} = .261$, $p < .001$). Time spent in test-specific remediation was positively, weakly correlated with test score improvement ($r = .173$, $p = .001$) in the fall semester, but remediation time in the spring semester (between the first and repeat administrations of the exit exam) was not associated with exit exam score improvements. Interestingly, over the three year period, we saw a significant increase in student time spent on test-specific remediation (1 hr 44 minutes in 2014 to 3 hrs 48 minutes in 2016) while mean test score improvements remained relatively stable as did licensure pass rates on the first attempt.

Conclusion: The results of our study are significant to educators interested in preparing pre-licensure students for licensing examinations. Identifying at risk students early on, developing a plan for addressing knowledge gaps and building confidence in their test taking skills may help them be more successful on their first attempt at the licensing exam. We incorporated curricular changes aimed at helping students to synthesize both current and previous knowledge in the hope that we would improve critical thinking skills. Originally, courses like this were only included in our senior year curriculum. Expanding the course concept to the junior year was an attempt to help students be more successful in testing throughout the nursing program.

The use of standardized exams has allowed us to help build student's comfort level and confidence with test taking. Students in the first semester of their senior year take an exam that is very similar at the beginning and end of the semester. This is a purposeful curricular design to help students identify gaps in knowledge, remediate on test specific concepts, and retest. Students who use this opportunity wisely are successful. The statistical correlation in this study demonstrates that a significant majority of our students were able to increase their score.

Time spent in test specific remediation is a small part of what we do to help prepare students for test success. It is a measurable variable that allows us a glimpse of how much time students spend preparing for testing. There are limitations to measuring time spent on remediation: although we can quantify time spent remediating through computerized tracking, we have no clear idea of the quality of the remediation. Additionally, students have the option to download study materials and study them at a later time. Therefore it is possible that we are not capturing all of the time spent on test-specific remediation. Another limitation is that we only looked at time spent on the custom comprehensive and exit exam remediation. Students were encouraged to spend some time remediating in other exams depending on their weak areas.

The fact that we had a limited number of students who were unsuccessful on licensure pass on their first attempt is good. However, this small number makes it much more difficult to identify what makes the difference for student success on licensure pass rates. This leaves us to speculate on what we, and nursing faculty in other programs, can do to truly ensure licensure exam success. We implemented a curricular change that incorporates a constellation of strategies to synthesize knowledge, build test taking comfort and confidence, identify areas of weakness, and develop a plan for remediation. This study allowed us to discover the impact of a few of those changes and to begin to ascertain the areas in which the time is well spent. Going forward, we will continue to motivate students to spend time in course specific remediation throughout the senior year as opposed to only in the fall semester. We will also keep the custom examination in the fall semester, as it has a strong correlation with student success. Identifying this correlation also allows us to implement additional efforts aimed at students who perform poorly on this exam to help them continue to prepare for licensure exam success.

P 10 - NCLEX Success

Nursing Students and NCLEX-RN® Success: Impact of a Standardized Review Course on Outcomes

Rosema Pine, PhD, RN, BC, USA

Barb Schreiner, PhD, APRN, CPLP, USA

Abstract

Purpose: Success on the NCLEX-RN® has widespread ramifications for students, nursing schools and employers. The stakes are high related to first time pass rates and review of the literature verified that student preparation for entry into practice is of great concern to nurse educators and schools nationally and globally (Wells, 2003; Higgins, 2004; Crow et al 2004; Davenport, 2007; Siffert & McDaniel, 2007; and Carrick, 2011); graduating seniors, and employers (Beeman, P., & Waterhouse, J., 2003; Spencer, J., 2006; Pine, 2007; Silvestri, L., Clark, M. & Moonie, S., 2013; Atemafac, J., 2014).

The purpose of this retrospective correlational pilot study was twofold. The first was to determine which characteristics of a standardized NCLEX –RN® Review Course impact NCLEX-RN® success. Are the characteristics, class size, course placement, mandatory attendance, and confidence level associated with NCLEX-RN® success? The second purpose was to describe the positioning within the curriculum of the standardized NCLEX Review Course and its relationship to the timing of the Exit Exam. Findings contribute to the identification of those variables that contribute to success on NCLEX-RN® when participating in an NCLEX® Review Course. Knowing which factors may contribute to success is helpful to schools of nursing in the formulation of innovative curriculum design to support nursing student success in the NCLEX-RN®.

There is limited research on the effect of standardized review courses on successful NCLEX-RN® or standardized exam outcomes. Success is a complex phenomenon. Corrigan-Magaldi, Colalillo, & Molloy, (2014); Crow (2004) and Ashley and O'Neill (1991) found review courses to be one of the statistically significant interventions for NCLEX® success. Requiring mandatory attendance at review courses seems to be a successful strategy (Mills, et al, 2001; Norton, et al, 2006). Ross, et al, (1996) identified that low participation at optional attendance standardized review courses resulted in lower standardized test scores. Lack of confidence was cited as a factor influencing NCLEX failure (Farquhar, 2014) while high self-efficacy expectations showed a positive correlation with NCLEX success (Silvestri, 2010; Silvestri, Clark & Moonie, 2013). While it is difficult to isolate class size from other variables, such as ineffective teaching methods and impact on grades or achievement, the educational literature suggests mixed results on class size and impact on grade or achievement (Robb, 2012; Hattie, 2009; Kokkelenberg, Dillon, & Christy, 2008; Arias & Walker, 2004; Mitchell & Beach, 1990).

Methods: This exempt study was approved by the IRB of Texas Woman's University Protocol #17690. A retrospective correlational research design was used and the DV was measured by first time passage of NCLEX-RN®. The independent variables included: a) required attendance at a standardized review course, b) class size, c) positioning of standardized exit exams (E2), d) timing of the course in relation to graduation, and e) confidence. The standardized NCLEX-RN® Review course emphasizes memory retrieval by reviewing key concepts related to commonly occurring disorders and health needs. It highlights mental rehearsal by helping the students practice critical thinking and test taking strategies and analysis and builds confidence through faculty/student interaction and repetition to support retention. In order to achieve these purposes, the students who attended the standardized NCLEX-RN® Review Course answered a post-course questionnaire measuring satisfaction and confidence. Deans or Directors were invited to respond to two questionnaires: demographic and scoring tool.

Results: Results revealed that mandatory attendance is associated with statistically significant higher scores on a standardized E2 ($p < .01$). A chi-square test of independence demonstrated no difference in NCLEX success between those required to attend a LRC and those who were not required ($X^2(1, N=746) = .1783, p = .674$). Students attending courses with smaller class sizes (<60 students) scored significantly higher on the Exit Exam ($X = 919.1$) than those attending larger classes (>60 student) ($X = 831.5$). There

was no difference in NCLEX outcomes. The percent of students passing NCLEX was the same regardless of class size ($X^2 = .003$, $p = .958$). Students passed NCLEX at statistically higher rates when the standardized exams were offered after the review course rather than before the review course ($p < .01$). The timing of the review course conferred benefit on NCLEX outcomes. More students passed NCLEX when the course was offered 1-9 weeks prior to graduation compared to students who attended a review the week of graduation or 12 weeks before graduation (1, N= 497) ($X^2 = 29.22$, $p < .01$). There was a statistically significant improvement in self-reported confidence among students enrolled in the standardized review course.

Conclusion: While limited research is available to determine the effectiveness of strategies used to improve NCLEX-RN success, a comprehensive standardized review course is appropriate to help students understand the testing process, develop test-taking skills, increase content knowledge, improve critical thinking abilities, and gain confidence. Future research is recommended on identifying confounding variables associated with class size and intent to prepare post-graduation

Feasibility of a Breast Health Education Intervention for Vietnamese-American Immigrant Women

Connie Kim Yen Nguyen-Truong, PhD, RN, PCCN, USA

Nisreen Pedhiwala, MS, BA, USA

Vananh Nguyen, MPH, CPH, USA

Cang Le, BS, USA

Tuong Vy Le, MS, BS, USA

Christine Lau, MA, CACDI, USA

Junghee Lee, PhD, MSW, USA

Frances Lee-Lin, PhD, RN, OCN, CNS, USA

Abstract

Purpose: The purpose of this pilot study was to assess the feasibility and acceptability of an adapted education intervention with targeted cultural and health belief messages (Early Care for Health – Vietnamese Women’s Breast Health Program [Early Care for Health]) to increase mammography screening among Vietnamese American (VA) immigrant women. The study was approved for human participation by the university institutional review board.

Asian Americans are a heterogeneous group and come from over 50 different countries and speak more than 100 languages (Gomez et al., 2013). VA immigrant women may have different cultural health beliefs and practices than other racial ethnic groups that significantly influence cancer risks and outcomes (Solanki, Ko, Qato, & Calip 2016). Previous researchers’ findings support the need to study groups separately. During the last 15-20 years, while breast cancer rates are declining in non-Hispanic American women, unfortunately, the rates are increasing among Asian-American women (Gomez et al., 2013). Furthermore, the incidence rates are significantly increased among VA immigrant women at 1.2% (95% CI = 0.1 to 2.2) per year (Gomez et al., 2013); and mammography screening rates (64%) are well below the national Healthy People 2020 (n.d.) goal of 81.1% (Pourat, Kagawa-Singer, Breen, & Sripipatana, 2010). VA immigrants encounter language, cultural, and economic barriers to preventive health care (McCracken et al., 2007). For example, VA immigrant women believe that breast cancer is only a concern when symptoms arise (Nguyen, Barg, Armstrong, Holmes, & Hornik, 2007). In addition, VA immigrants believe that looking for problems will invite new troubles into their lives. These suggest that VA immigrants need a compelling reason to seek a health care provider. Nguyen and colleagues (2010) found that VA immigrants were less likely compared to White and African Americans to report engaging in cancer information seeking. Researchers found that multiple intervention strategies that were culturally tailored were more likely to be effective at increasing mammography screening rather than singular non-tailored interventions among VA immigrant women (Lu et al., 2012). However, intervention intensity was difficult to determine because exposure to each of the multiple strategies was not tracked consistently. Therefore, the long-term sustainability is questionable (Lu et al., 2012). We previously developed and tested Early Care for Health (formerly known as the Targeted Breast Health Educational Program) among Chinese American immigrant women (Lee-Lin, Menon, Leo, & Pedhiwala, 2013; Lee-Lin, Nguyen, Pedhiwala, Dieckmann, & Menon 2015). The multi-component culturally targeted approach, which included targeted cultural and health belief messages delivered in an interactive education group that used power point media followed by individual counseling, was effective at increasing mammography screening at 3 months in a pilot study and at 6 and 12 months in a randomized controlled trial (n= 300) (Lee-Lin et al., 2013; 2015).

Methods: In our one- group pre- and post-test design, we recruited 40 VA immigrant women, aged 50 years and older, who had no personal history of breast cancer, had not had a mammography screening within the past 12 months, could understand and read Vietnamese or English, and were associated with/recruited from one Asian community-based organization as well as from the VA community in the Portland, Oregon metropolitan area, United States of America. We followed the American Cancer Society (ACS) 2015 screening guidelines (Oeffinger et al., 2015) since the ACS is most commonly followed by health care providers (Kwon et al., 2013). The Asian community-based organization is a trusted place

“...where health and other information is sought and given” (Lee-Lin et al., 2013, p 363) and this recruitment approach has been successfully used by others (Nguyen and colleagues, 2010). In keeping with the exploratory nature, we based our sample size on our previous similar exploratory pilot study with Chinese American immigrant women (80% power and alpha level of 0.1). We adapted and modified Early Care for Health, which consists of two parts: an interactive group teaching (discussion) that used power point media followed by individual counseling session after 10 days to help women to overcome barriers to mammography screening. Topics for the interactive group teaching included: breast cancer incidences and mortality rates, risks for breast cancer, the process required/used to obtain mammography screening, perceived benefits of obtaining a mammography screening, and how to overcome perceived common barriers, and perceived cultural barriers, to obtain mammography screening. The materials also contained culturally relevant graphics such as photos of older and younger VA women having a mother, daughter, and grandmother conversation and Asian landscapes, and a breast cancer survivor story. We translated health messages into Vietnamese using a translation team approach. This was similar to our previous translation team approach (Nguyen-Truong et al., 2014), which included VA bilingual and bicultural community members and an academic investigator who first translated independently, and then discussed translation decisions as a team to resolve ambiguities. The translation team approach successfully captured meanings within the context of the discussion versus a strictly literal translation. A baseline survey included questions on mammography screening and breast cancer knowledge and measures on the following independent variables: perceived susceptibility, perceived benefits, perceived common barriers, and perceived cultural barriers (crisis orientation, modesty, use of Eastern/Asian medicine, family support). This information was collected from participants prior to the interactive group teaching, and again 12-weeks post-intervention. At baseline, we also asked each participant to identify major barriers that prevented her from obtaining mammography screening within the past 12 months. At 12-weeks post-intervention, we asked participants about mammography screening completion and determined if they were at the pre-contemplation, contemplation, or action stage (outcomes variables). We used a paired t test to compare mean differences and performed logistic regression analysis to determine related independent variables with the outcome variables.

Results: Of the 69 VA women who were eligible for the study, 40 agreed to participate, for a response rate of 58%. The sample ranged from aged 50 to 80 years old (mean = 67 years old), mean age of 53 years old (SD = 11.7) when immigrated to the United States, and a mean of 14 years (SD = 9.2) having lived in the United States. Most participants are currently married (58%, n = 23); with some high school education (33%, n = 13); not employed (78%, n = 31); have a total household income less than \$15,000 (72%, n = 28); have health insurance (75%, n = 30); and do not speak English (38%, n = 15). Most participants have a regular health care provider (78%, n = 31). Thirty-nine women attended the interactive group teaching intervention. Participants identified the following reasons as top barriers to mammography screening: no reason (n = 17) followed by had no insurance or because of cost (n = 7), perceived they did not need to have a mammogram because they were over age 60 (n = 5), and did not have symptoms or did not think they would develop breast cancer (n = 3). Post-intervention survey results were encouraging: 75% (n = 30) of participants reported having obtained a mammography screening (action stage), of which 20% (n = 8) were in the pre-contemplation stage and 55% (n = 22) were in the contemplation stage at baseline. Of the 25% (n = 10) of participants who did not complete a mammography screening, one participant improved one stage from pre-contemplation to contemplation, seven remained the same stage, and one moved backward one stage from contemplation to pre-contemplation. The attrition rate was low with only one woman (3% of sample) lost to follow-up for a 98% (n = 39) completion rate. Ninety percent of participants judged Early Care for Health to be acceptable (e.g., cultural appropriateness of the content). Mean scores for the following variables significantly increased at post-test: breast cancer knowledge (t[39] = -14.72, p < .001), perceived susceptibility to developing breast cancer (t[39] = -2.69, p < .05), perceived benefits to mammography screening (t[39] = -4.39, p < .001), and perceived breast cancer and mammography benefits (t[39] = -4.09, p < .001). We found that crisis orientation towards mammography screening in pre- to post-test score difference was significantly positively associated with mammography screening completion (OR = 12.59, 90% confidence interval [CI] = 1.38-115.16) and stage in improvement (OR = 11.03, 90% CI = 1.34-91.05), whereas, older age was significantly negatively associated with both outcome variables (OR = .71, 90% CI = .57-.90; OR = .76, 90% CI = .62-.94 respectively) as well as modesty (OR = .04, 90% CI = .00-.45; OR = .04, 90% CI = .00-.45 respectively).

Conclusions: We achieved good feasibility, a good response rate, and very low attrition (Bowen et al., 2009). We also achieved acceptability of the program (Wahab, Menon, & Szalacha, 2008). Our pilot study findings are relevant to the congress themes and objectives because it is on health promotion and cancer disease prevention; based on theory and evidence-based research; a multi-component, culturally targeted educational program, which used power point media technology to deliver an interactive group teaching followed by individual counseling to improve access and remove barriers; and a strong interprofessional research team. This promising intervention can also be adapted for other Asian groups.

P 11 - Patient Education in Oncology Patients

Innovative Use of Electronic Tablets for Newly Diagnosed Cancer Patient Education

Patricia L. Petroulias, PhD, RN, USA

Abstract

Purpose: The purpose of this study was to test the use of an electronic tablet as a tool to provide coaching to newly diagnosed cancer patients for peripherally inserted central catheter (PICC) maintenance to minimize infection and occlusion complications. PICC occlusion and infection often occur because of poor maintenance techniques, specifically inadequate aseptic techniques when manipulating the line, failing to flush lines properly, and/or not using the locking solution recommended for a specific device. (Ferroni et al., 2014). Using the pulsatile flushing technique with normal saline is a simple and effective technique to create turbulence inside the line to prevent catheter occlusion and decrease bacterial colonization (Camp-Sorrell, 2011, Ferroni et al., 2014, INS, 2016). Effective patient and caregiver education is necessary to ensure infusion therapy safety and decrease the risk of PICC-related complications (INS, 2016). Patients and caregivers must be able to perform the tasks of PICC maintenance and know when to contact a healthcare provider if complications arise. Management of PICCs, as well as patient and family education using electronic tablets, is in the scope of nursing practice and the standards of practice for the Oncology Nursing Society (ONS) and Infusion Nurses' Society (INS). The INS (2016) recommended guidelines for patient/caregiver education for PICCs include device description, reason for placement, aseptic technique, basic device flushing, dressing and injection cap change, level of discomfort the patient may experience, site assessment for adverse outcome symptoms, potential complications, along with prevention and management of complications. As healthcare costs continue to escalate and home care benefits are being reduced, this study has significance to nursing. Patients who learn about self-care at home, away from the distractions of the healthcare environment, can be more involved in their care. By shifting the learning environment to the patients' homes or environments of choice, the intervention can take place in a patient-controlled environment. Integrating technology into healthcare practices can provide an innovative way to assist patients and nurses manage complex health conditions. Because of the volume and complexity of the information, patients have described self-care education as unhelpful, excessive, and frightening (Coffey et al., 2016). Patients feel overwhelmed and, therefore, their retention of this critical information is severely limited (INS, 2016; Coffey et al., 2016).

Methods: This study proposed a new strategy for patient and caregiver education – a comprehensive educational intervention using electronic tablets to reduce the incidence of PICC line occlusion and infection in the adult outpatient population. Combining technology and educational theory can provide repetition and self-paced learning for patients who are learning self-care techniques to manage their PICC lines. Using an electronic tablet to detail the steps required for flushing their PICC lines could help patients master the process better than receiving the standard method of patient education. The researcher had created the video for flushing PICC lines and uploaded it to YouTube. Therefore, the intervention for this project was a coaching session with the researcher who is an infusion nurse, along with providing the patient with a video on an electronic tablet that outlined the steps of flushing. The tablet was taken home to provide a demonstration that could be replayed as needed. In addition, a nurse could use voice and audio calls, such as *Facetime* or *Skype*, to coach the patient through the process. It was believed that as patients became more proficient at flushing their PICC lines, the negative outcomes of occlusion and infection should be minimized. To determine the efficacy of using electronic tablets as an instructional delivery method for patient and caregiver education, a pilot study was conducted.

Results: A sample of 11 newly diagnosed cancer patients were asked to participate in the study. The ages of the subjects ranged from 38 to 88 years old, with a mean age of 66.64 ($SD = 13.37$) years. Four participants (36.4%) were female and seven (63.6%) were male. Of the 11 patients who were initially enrolled in the study, leukemia was the most frequent diagnosis (3), ovarian (2) and pancreatic (2) cancers and 1 participant each with breast, bone, stomach or lung cancers. After reviewing the informed consent form with the researcher, they completed a short demographic survey. The patients and their

caregivers met with an infusion nurse who provided the standard education on flushing their PICC lines. They then met with the researcher who instructed them on using a tablet to access YouTube and Facetime applications. Each patient was sent home with an electronic tablet. Shortly after, the researcher contacted the patient/caregiver to provide interactive coaching on flushing their PICCs. The patients/caregivers were encouraged to contact the researcher if they encountered any difficulties when flushing their PICC lines. The infusion nurses at the clinic where they were receiving treatment monitored the infection and occlusion rates for the 11 patients. None of the patients experienced infection or occlusion complications with their PICC lines, although one patient experienced thrombophlebitis, which required removal of the PICC line. There were no occlusive outcomes in the pilot study participants. The national reported PICC occlusion rates varied from 14 to 36% (Barrier et al., 2013; Dougherty, 2014). There were no PICC line associated infections in the pilot study participants. The national reported PICC line associated infection rate in outpatients was 0.5% (Chopra et al., 2013). The outcomes for occlusion and infection in the study population were better than outcomes in national samples.

Conclusion: Previous research has demonstrated that electronic platforms for patient education improve interactive capabilities and support communication needs beyond the outpatient setting (Sawyer et al., 2016). The pilot study of oncology patients with newly inserted PICC lines demonstrated the positive effects of the use of technology to provide remote patient education and coaching in decreasing adverse patient outcomes of PICC occlusion and infection. Developing applications for electronic tables and smart phones to help with patient education can help overcome some of the visual and auditory problems associated with printed materials. The use of an electronic tablet to provide this type of education while the patient and caregiver are in their home environment can provide opportunities for coaching, reviewing, and reinforcing self-care treatments that can improve health outcomes.

P 12 - Preventing Injury and Infection in Resident Care

Urinary Incontinence in the Nursing Home Resident: Exploring CNA Caregivers' Attitudes and Beliefs Regarding UI

Roxellen Anntoinette Auletto, DNP, RN, MSN, MLA, ANP-BC, PNP, USA

Abstract

Purpose: The primary objective of this qualitative study was to elicit the attitudes and beliefs of CNA's towards UI in a long term care facility. A greater understanding of how CNA's view UI in this patient population can then position both nursing and CNA's to effectively identify, prevent, and coordinate plan of care for the reversal of UI.

Methods: Focus group methodology was utilized to answer the research question, "what are the attitudes and beliefs about urinary incontinence among a sample of CNA's working in a long- term care facility?" Data collection was in the form of semi-structured focus group interviews. Interviews were audio taped and transcribed verbatim. The group facilitator served as note taker capturing observations of the group during the interviews, noting body language, facial expressions and group interactions. The researcher served as the moderator, focusing on group dialogue, dynamics, and participation utilizing the semi-structured interview questions as prompts to facilitate and maintain CNAs engagement in the focus group.

Results: Five themes emerged from the data. 1) "We're stretched too thin"; 2) "No one asks our opinions, but we are the ones who know what's going on"; 3) "Incontinence: It's just what happens when you get old"; 4) "Some of them do this out of spite," and 5) "Preventing incontinence: It's everyone's job." Although research exists examining differences in attitude and understanding regarding UI among registered nurses, licensed practical nurses, and certified nursing assistants working in skilled nursing homes before and after study interventions, studies focusing solely on CNAs could not be found.

Conclusion: Although the five themes identified during the study may not seem novel or surprising, they represent the feelings of a growing body of healthcare providers whose voices can no longer be ignored. CNAs role in long term care will continue to require more responsibility, education, and leadership. It is unrealistic to think that their involvement can be limited to caregiving alone. If we are to address the issues of understaffing, feelings of unimportance in their role as CNAs, and lack of understanding as to why the elderly become incontinent, active engagement of the primary caregivers is essential.

P 12 - Preventing Injury and Infection in Resident Care

Describing Avoidable Transfers and Decisions to Transfer Residents From Long-Term Care to Emergency Departments

Judith Spiers, PhD, RN, Canada

Rowan El-Bialy, MSc, Canada

Kaitlyn C. Tate, BScN, RN, Canada

Patrick B. McLane, PhD, MA, Canada

Greta G. Cummings, PhD, RN, FCAHS, FAAN, Canada

Abstract

Purpose: Long term care residents (LTC) are typically frail elderly, who can suffer from iatrogenic effects of unnecessary or avoidable transitions to the emergency department (ED). Although most transfers of LTC residents via ambulance to the ED are necessary, our prior research shows that healthcare providers consider around 20% of transfers to be potentially avoidable. The purpose of this two-phase, mixed-methods study was to: define avoidable transitions, identify factors that influence decisions to transfer or not, and identify modifiable attributes of avoidable transitions.

Methods: Phase 1 involved in-depth individual and focus group interviews in 6 LTC facilities in Alberta, Canada. The sample consisted of 71 Registered Nurses (RNs), Licensed Practical Nurses (LPNs), Healthcare Aides, managers, and family members of LTC residents, in addition to 9 regional Emergency Medical Services (EMS) Personnel. Thematic analysis of 25 interviews and 19 focus groups followed. In Phase 2, an online survey was administered to staff and physicians in 18 LTC facilities and regional EMS personnel (N=351) to verify the findings of Phase 1. Descriptive analysis was undertaken of the survey data completed by the working sample: 50 RNs and physicians in an ED; 137 paramedics and EMTs; 142 RNs, LPNs, and administrators in LTCs; and 22 LTC Medical Directors.

Results: The results led to an inductively developed conceptual definition of avoidable transfers. The identification of primary factors contributing to avoidable LTC-ED transfer decisions included: healthcare providers' lack of familiarity with residents, a shortage of diagnostic and treatment resources in LTCs, limitations in the staff-family relationship, and varied interpretations of the Advance Care Planning policy. Emergent themes included: fear of liability; staff & family relationships; interpreting Goals of Care Designations; knowing the resident; healthcare provider's critical thinking & response to ambiguity; limited diagnostic & treatment options in LTC; access to a second opinion.

Conclusion: The implications of these findings lead to recommendations for changes to policies and the development of decision-making guidelines regarding LTC-ED transitions.

P 13 - Creating Nursing Competence Using Simulation

Use of Standardized Patients (SPs) With Disabilities in an Undergraduate Nursing Program

Bette A. Mariani, PhD, RN, RN, USA
Suzanne C. Smeltzer, EdD, MS, RN, ANEF, FAAN, USA
Colleen Meakim, MSN, CHSE, USA
Jennifer G. Ross, PhD, RN, CNE, USA
Elizabeth Petit de Mange, PhD, RN, FNP, USA

Abstract

Purpose: People with disability (PWD) report having negative encounters with nurses due to a lack of knowledge, negative attitudes, and a lack of communication skills necessary to interact effectively with PWD. Generally undergraduate programs dedicate little to no attention on the care of PWD. This research team addressed this gap through the integration of a program of simulation across the curriculum where PWD were used as standardized patients. The purpose of this study was to explore undergraduate nursing students' attitudes towards people with disability and their feelings about their interactions with PWD before and after participating in a program of simulation using standardized patients with disability.

Methods: A pretest-posttest mixed methods design was used to answer the following questions: 1) Will participating in a program of simulation including standardized people with disability (SPWD) influence students' attitudes toward people with disability; 2) Will participating in a program of simulation including standardized people with disability influence students' perceptions of their interactions with people with disability; and 3) What was students' experience with standardized patients with disability. After consenting to participate, students completed a brief demographic survey, the Attitudes Towards Disabled Persons (ATDP) Scale, (Form A) and the Interactions with Disabled (IDP) Persons Survey in their freshman year, prior to participating in simulations with SPWD, and then again just prior to graduation after completing the program of simulation with SPWD. The posttest survey also included five open-ended questions to allow students to comment on their reaction to the simulations, the value of the experience, and their recommendations on continuation of the program of simulation with SPWD.

Results: There was no statistically significant difference in the pretest and posttest results on the Attitudes Towards Disabled Persons (ATDP) Scale (Form A) and the Interactions with Disabled (IDP) Persons surveys for undergraduates who participated in the program of simulation with SPWD; however, analysis of the open-ended questions resulted in four categories of themes and subthemes, which were: cognitive, emotional, behavioral, and interpretive themes.

Conclusions: While the surveys did not reflect statistically significant differences, in the open-ended questions, the students overwhelmingly indicated that they valued this experience of interacting with SPWD and recommended continuing the program. This study contributes to a gap in nursing education in improving healthcare experiences for PWD.

P 13 - Creating Nursing Competence Using Simulation

Does a Culturally Infused High-Fidelity Human Simulation (HFHS) Scenario Accurately Depict the Culture?

Ruth E. Irwin, PhD, RN, USA

Abstract

Purpose: The United States (U.S.) is rapidly becoming a multi-cultural, pluralistic society. The U.S. Census current U. S. Census (2010) reported that 72% of the US population origins were from White European ancestry, 14% from African ancestry, 17.3 % from Hispanic Ancestry, 4.8% from Asian Ancestry and 0.9% Native American ancestry. The U.S. Census (2010) projects for the year 2020, 53% will be from White European decent and there will be a threefold increase in the Hispanic American and Asian American population. Providing culturally competent care in the 21st century is critical to excellent patient outcomes. This study sought to determine the outcomes of teaching a culturally infused nursing process to Foundation of Nursing students in an Associate Degree Nursing program. Nurse Educators usually write simulation scenarios to teach patient care and procedure skills. Opportunities to expose students from predominately white communities to cultural variations varies with in the US. Simulation scenarios with a cultural component provide a valued learning experience for students. The U.S. Department of Labor, Bureau of Labor Statistics (2016) reports that 81.9% of the 3 million licensed Registered Nurses identify themselves as white. The American Association of Colleges of Nursing (AACN) Enhancing Diversity in the Nursing Workforce (2015) recognizes the need to recruit people from diverse backgrounds into the nursing profession to educate our students in diversity and culture. Nurse Educators need to employ qualitative methods to evaluate the cultural component, ensure the objectives of the simulation are met, and disseminate their findings. The need for inclusive educational practices will also be congruent with the National League for Nursing (NLN) Outcomes and Competencies for Graduates of nursing programs (2010) recommendations for education programs graduate outcomes for inclusion of "the uniqueness, dignity, diversity, freedom, happiness, and holistic well-being of the individual within the larger family, community, and population. The nurse helps the individual in efforts to reclaim or develop new pathways toward human flourishing" (pg. 33). These data support the need to incorporate culturally infused human simulations into nursing program curriculums. However, Nurse Educators need to change the processes of writing and the evaluation of the culturally infused simulations. Representatives from the culture need to be participants in the development and evaluation of simulations to ensure a true representation of the culture or ethnic group.

Methods: A quantitative, quasi-experimental, 2 x 2 factorial design was used to measure two points in time with a pre-test and post-test to measure student performance on the use of the nursing process in one point in time and at the end of the course. Four groups of students were randomized and taught the nursing process: Group #1 - case study and concept mapping; Group #2 - case study, concept mapping with a pocket reference; Group #3 - case study, two hours HFHS, concept mapping with a pocket reference; or Group #4 - four hours of HFHS, concept mapping with a pocket reference. The Simulation Design Scale (SDS) was used to measure the perceptions of the four student groups for the design elements.

Results: The National League for Nursing (NLN) PAX-RN entrance examination had a significant correlation with students' passing onto the second semester in a nursing program ($p < .001$). The four-hour group (Group #4) mean was significantly lower on both the importance of the objectives and information and importance of fidelity design elements ($p < .05$). This suggests that as time in a simulation increases more attention to these elements is required. There was not a significant difference between the four study groups on the Nursing Process or the Assessment Technology Institute (ATI) RN Fundamentals 2010 Assessment Form B examinations individual scores. Two sub-categories on the ATI were significant. Planning was significantly higher for fall 2012 (Groups 2, 3, and 4) cohort ($p = .024$) and analysis/diagnosis was almost significant for fall 2011 (Group 1) cohort ($p = .054$). The results for Factorial Groups were not significant. The ATI results of students were the same without regard to the Factorial Group assigned in relation to instructor employment status of full time versus part time.

Nurse Educators are challenged to provide students with opportunities to care for diverse ethnic populations when the community and student population are predominately white (Irwin, 2013). Consideration was given in this study for recognizing differences in patient populations (National League for Nursing, 2010). The simulation exposed students to a patient situation requiring them to care for a migrant worker, from Mexico with English as a second language. A professional fluent in both English and Spanish recorded the vocals for the simulation. The patient was a field worker with heat exhaustion who was of Mexican heritage. The occupation is irrelevant. What matters is he is a migrant worker, from Mexican heritage. The importance is the simulation gave beginning nursing students the opportunity to experience the "other" by infusing culture into the scenario. Textbooks that describe culture were used to develop the scenario. Students were required to use listening skills and etiquette to understand the patient's responses based upon this textbook information. Cultural considerations were included that anticipated response to the assessment questions students might ask (Zoucha & Zamarripa, 2008). However, the researcher did not recognize the need to evaluate if in fact the simulation was correct for the Mexican culture. Representatives from the portrayed culture were not included in the evaluation process. This discovery sheds new light on the way Nurse Educators are composing cultural simulations.

Conclusion: It is not sufficient to just make changes in a nursing curriculum without a plan to evaluate the impact on program outcomes. However, this study was focused on learning of the nursing process and the presence and importance of the design elements of simulation. In reflecting back on the study, the researcher identified a missing element: the need to evaluate the simulation for the cultural presence or accuracy of portrayal using qualitative research methods. This discovery could influence how Nurse Educators proceed in the development of culturally infused simulation scenarios. No evidence of this concept was found in the nursing literature. This researcher is recommending Nurse Educators have representatives of the cultural group being portrayed in the simulation to participate in the development and evaluative phases of writing the simulation.

Exploring Water, Sanitation, and Hygiene Practices in Gatteau, Haiti

Diana Lyn Baptiste, DNP, MSN, RN, USA

Teresa A. Pfaff, MPH, MSN, BSN, BA, RN, APHN-BC, CPH, USA

Sabianca Delva, BSN, RN, USA

Casey McCormick, MPH, USA

Evi Dallman, MSN, BSN, RN, USA

Ruthly François, BS, MSPH, USA

Abstract

Purpose: Haiti is the poorest country in the Western Hemisphere. Located in the Western Caribbean, Haiti is populated by more than 10 million people, sharing the island of Hispaniola with the Dominican Republic. More than 75% of Haitian residents are living on less than two dollars a day and almost 56% on less than one dollar a day. Haitians have limited access to resources such as health care, food, and clean water. The country lacks adequate infrastructure and is highly dependent on non-governmental organizations (NGOs) for public health, schools, and roads. Every year, Haitians die from diseases associated with inadequate water supply, especially with the high prevalence of cholera with mortality rates ranging from 19.1 to 39.4/1,000 person-years between 2010-2011 from the cholera epidemic.

The Gatteau villages in Haiti are composed of several communities in the southwestern mountainous region, where access to basic resources such as food, durable shelter and clean drinking water remains scarce. With only 69% of the population having access to an improved water source, Haiti is the most underserved country in the western hemisphere in terms of water and sanitation infrastructure. The purpose of this presentation is to describe the current state of water sanitation and hygiene (WaSH) in communities surrounding Gatteau, to identify gaps in knowledge for researchers, and to inform feasible interventions to improve water sanitation for residents these areas.

Methods: Our multidisciplinary team, consisting of faculty and students from a school of nursing, public health, and a water institute, have been working collaboratively with a local NGO and community members to address two critical components to community health: sustainable sanitation and water resources. Our team has initiated a three-pronged approach to review the literature surrounding hand washing treatment, hygiene and sanitation. We have conducted data collection through community assessments to better understand some of the barriers and opportunities for sustainable WaSH projects to improve health. All of these initiatives are expanding on the work that the local NGO has been conducting with their Sanitation Community Development Project. Currently the NGO that serves the Gatteau villages has a community promoter program in operation. In this program, two members from each community receives training and reinforcement in basic WaSH practices based on the Center for Affordable Water and Sanitation Technology (CAWST) education materials. All community promoters reside within the communities they serve. The promoter program employs the "train-the-trainer" model for community education. Promoters attend classes at the NGO headquarters where they receive instruction on the 32-page booklet, written in 5th grade level written in their native language of Haitian Kreyol.

Results: After visiting seven water sources in the Gatteau villages, we discovered that small streams were the only type of water sources supplying the villages. One stream would serve as the main water source for up to five communities. Water came from various sources, most of which were not clean. Most started at the side or opening of the river and few rivers were full enough to create a current. There seemed to be three designated functional sections for the water sources. At the top of the stream, women and children collected water with jugs and buckets. Some were washing their feet, bathing and laundering in the inferior section. Cattlemen would allow their livestock to urinate and defecate from the same water source even though they are fenced off to prevent eutrophication and pollution.

Conclusion: We found that water sources in this area are scarce. Community members, usually women and children, commute anywhere from 15 minutes to one hour from their home to retrieve water multiple times a day and transport jugs and heavy containers on their heads. Research has shown that domestic

water carrying is associated with detrimental health effects. During the assessment, we rapidly discovered a connection between poor water access and WaSH practices in Gatineau including: common (and uncommon) water treatment methods, and sanitation and hygiene beliefs and practices among Haitians living in these rural villages. Further research is necessary to improve water quality, sanitation, and health in low-resource countries like Haiti.

Evaluating the Use of an Evidence-Based Test for Tuberculosis Screening

Gema M. Morales-Meyer, DNP, MSN/MPH, RN, CRRN, APHN-BC, CNS, USA

Abstract

Purpose: According to the World Health Organization, tuberculosis continues to be one of the top ten leading causes of death around the world. The Tuberculin Skin Test (TST), developed in the early 1900s, has been the primary test for Tuberculosis (TB) screening throughout the world. Despite its long term use, the TST has long been known for having its limitations. One limitation is the high number of false positive results due to an interaction with Bacillus-Calmette-Guerrin (BCG) vaccine, reactions to non-tuberculosis mycobacterial infections and interpreter bias while reading the results. A second limitation is the need for two visits to obtain results. Compliance due to poor patient follow-up for skin test readings is especially problematic among high risk populations such as the homeless.

In 2006, a new blood test for TB screening called Interferon Gamma Release Assays (IGRA) was developed and identified by the Centers for Disease Control as an evidence based practice in screening for tuberculosis. The sensitivity of the IGRA test ranged from 76% to 90% compared to a TST which showed a sensitivity of 63% to 71%. A greater difference was demonstrated in the specificity of IGRA which ranged from 92% to 100% compared to the TST which ranged from 66% to 88%. As a result of the higher specificity, screening with an IGRA results in having fewer false positive results because there is no interpreter bias, no interaction with BCG and it does not respond to non-tuberculosis mycobacterial infections. This results in more accurate screening, clinical efficiencies and improved patient outcomes. Despite the research, adoption of IGRA for tuberculosis screening has been limited by a number of barriers including cost, lack of education of the new test and lack of nursing adoption.

Methods: Promoting the transformation of knowledge and practice to advance global health and nursing is a critical component to ensuring evidence based screening for Tuberculosis. This presentation will report the evaluation of the implementation of IGRA in a large metropolitan public health department as evidence based practice for public health nursing. The ultimate goal was to improve secondary prevention screening for tuberculosis, create efficiencies and ensure better patient outcomes. The evaluation was made up of three components: a) usage of IGRA in the field, b) comparison of latent TB infection rates pre and post IGRA implementation with chi square analysis and c) cost analysis including an impact of cost for screening with TST and IGRA.

Results: Usage of IGRA tests in the field setting were overall successful and showed a steady monthly inclined trend from 68 tests in January 2014 to 589 tests in the month of December 2014. Upon a more detailed review the results showed a trend of 5 sites who were slow to adopt the new evidence based practice. Barriers to implementation were primarily based on nursing staff knowledge, attitudes and behaviors and included: staff perception in safety of administering the test, lack of experience in venipuncture and refusal to change practice. The second component of the evaluation showed a statistically significant decrease ($p < .0001$) of Latent Tuberculosis Infection (LTBI) rates from 21.7% in 2012 where there was no use of IGRA compared to a 13.1% in 2014 when IGRA was implemented. This reduction in LTBI rates resulted in cost savings to the organization of \$21,288 for every 1,000 contacts screened due to a reduction of persons needing chest x-ray and 9 month preventive treatment for LTBI.

Overall, the evaluation showed that adoption of evidence based practices can vary in different settings and barriers need to be identified and addressed in order to ensure compliance. TB infection rates decreased after IGRA implementation providing improved patient outcomes and cost effectiveness occurred during the screening process through a reduction of LTBI treatment as less false positives occurred.

Conclusion: Evidence based practice is an essential component of improving nursing practice and improving patient outcomes. Despite its benefits, nurses have struggled to implement evidence based practices and an evaluation component proved critical to ensuring adoption of this practice across all

settings. Implications for the nursing profession include the ability to effectively implement an evidence based practice that will screen patients with an evidence based test for tuberculosis and therefore ensure accurate results for improved patient outcomes.

P 15 - Sleep Disturbances

Prevalent Sleep Disordered Breathing and Obstructive Sleep Apnea (OSA) Despite Treatment for Acromegaly

Christine G. Yedinak, DNP, MN, BSN, RN, GradDipEd, FNP-BC, USA

Abstract

Purpose: Acromegaly is a rare disease usually associated with a pituitary adenoma which secretes excess growth hormone. Characteristically, this results in hypertrophy of pharyngeal soft tissue, craniofacial deformations, macroglossia and thickening of the upper airway predisposing the patient to sleep disordered breathing (SDB) and obstructive sleep apnea (OSA) (Ramos-Levi & Marazuela, 2016). Estimates vary, but 40-80% of patients diagnosed with acromegaly have also been found to have OSA compared to 5% of the general population (Galerneau et al., 2016). SDB has been associated with cardiovascular disease (Powlson & Gurnell., 2015) which is the most common cause of mortality for patients with acromegaly carrying a mortality risk 4.6 times higher than that of the general population (Mestron et al., 2004; Sherlock et al., 2014). Patients with sleep apnea report decreased quality of life associated with daytime sleepiness, fatigue, mood disturbance and depression and decline in cognitive function and executive functions (Devita et al., 2016; Silva et al., 2016; Nutt et al., 2013).

Acromegaly is an insidious progressive disease that often goes unrecognized for an estimated average of 4-10 years (Melmed, 2009). A diagnosis of SDB and OSA frequently occurs well in advance of a diagnosis of acromegaly but goes unrecognized as etiologic for OSA. However, sleep apnea may also go undiagnosed or untreated both prior to and post treatment of acromegaly. Although theoretically soft tissue hypertrophy is reversible post treatment (Powlson & Gurnell., 2015), there is little data to support the prevalence of resolution or the persistence of SDB or OSA post normalization of growth hormone levels.

This study was to evaluate the prevalence of a diagnosis of OSA versus the prevalence of patients meeting criteria for SDB or OSA pre and post treatment for acromegaly who presented to a single institution.

Methods: Fifty two patients diagnosed with acromegaly (23 Males/29 Females) were interviewed pre and post treatment of acromegaly as per clinic standard of practice. Patients were identified who had an historical diagnosis of obstructive sleep apnea. Patients without a prior diagnosis were evaluated to determine if their current symptoms would meet criteria for further assessment for obstructive sleep apnea using the STOP BANG questionnaire and the Epworth Sleepiness Scale with scores in the moderate to high risk range. This process was repeated post treatment when growth hormone levels were normalized. This may have occurred after either or both surgical and medical treatments. Statistical analysis included descriptive analysis, paired and independent *t* test, cross tabs analysis (Chi squared, likelihood ratio and linear by linear association) using PASW 18. This study was IRB approved.

Results: Of the 52 patients meeting criteria for acromegaly, 17 patients (32.7%, 7 Females/10 Males; mean age 51.2 years) presented with a diagnosis of sleep apnea prior to being diagnosed with acromegaly. However, a further 15 patients (28.8%, 9 females/6 males; mean age 44.5 years) met criteria indicating moderate to high risk for SDB or OSA. Together, a total of 35 patients (61.5%) met criteria for SDB or OSA. Post-treatment, 6/17 patients (35.3%, 4 females/2 males) reported resolution of OSA diagnosis after disease remission. One of the 6 patients, a female, continued to meet criteria for OSA. Of those patients meeting criteria for OSA pre-treatment, 4 were newly diagnosed with OSA after treatment and 4 continued to meet criteria for OSA and were referred for polysomnography. Linear by linear association indicated increasing age was associated with a higher likelihood of meeting criteria or having a diagnosis of OSA ($p=0.04$) but age was not a significant factor in those diagnosed with OSA at either time-point. There was no significant difference between genders for patients diagnosed with OSA at presentation (χ^2 , $p=0.19$) however, males were more likely to have a diagnosis of OSA after treatment for acromegaly ($p=0.04$). There was no gender difference with respect to those meeting criteria for OSA after treatment.

Conclusion: Both genders are known to be equally affected by acromegaly (Melmed 2009). In the general population males with higher BMI have been found to have more severe OSA (Galerneua et al., 2016). Among patients screened for both OSA and acromegaly in a large cohort of 775 patients Galerneua et al found a 0.35% incidence of undiagnosed acromegaly. However, this study suggests that younger age patients presenting with OSA may be at higher risk and perhaps should be screened for acromegaly.

Given the morphologic changes to the airway associated with acromegaly, it seems reasonable to assume that in contrast to the general population, males and females with acromegaly would be equally affected by OSA. Likewise there is no reason to believe that the regression of soft tissue swelling with disease remission should occur differentially by gender. Although this study found no gender difference in those diagnosed with OSA at presentation, post treatment there were significantly more males than females with persistent OSA. However, overall there was no significant difference in the prevalence of OSA or those meeting criteria for SDB or OSA despite 'cure' of acromegaly. Persistent risk may be associated with factors such as increased BMI post normalization of IGF-1 or other factors yet to be determined.

Both males and females should be evaluated for sleep apnea during physical examinations. The diagnosis of SDB or OSA may be a symptom requiring further etiologic evaluation particularly in young and female patients. Patients diagnosed with acromegaly, both males and females, regardless of age should be reassessed for SDB and OSA post treatment for acromegaly despite normalization of growth hormone levels. Further validation of these findings in larger acromegaly patient populations is needed.

P 15 - Sleep Disturbances

Sleep Disturbances Experienced by Military Burn Survivors

Linda H. Yoder, PhD, MBA, RN, AOCN, FAAN, USA

Patricia A. Carter, PhD, RN, CNS, USA

Abstract

Purpose: Military men and women may suffer from burn injuries because of their military duties. Due to advances in burn care, many service members survive their injuries. Following discharge, military burn survivors continue to experience sleep disturbances; however there is a lack of understanding of sleep disturbances in this population after discharge from the military burn center. The purpose of this study was to examine subjective reports of sleep disturbances as experienced by military burn survivors over time.

Methods: In this descriptive longitudinal study, data were gathered at 5 time points: burn center discharge; 3, 6, 12, and 18 months post-discharge. Sleep specific data were collected from questions on the: Burn Specific Health Scale-A (BSHS-A; 1 item), Post-Traumatic Distress Check List- Military (PCL-M; 2 items), and Center for Epidemiologic Studies Depression Scale (CESD; 4 items); participants also completed demographic and clinical history forms. Data were analyzed using measures of central tendency and repeated measures ANOVA. Cronbach's alpha was used to determine reliability of the sleep questions as a "measurement tool." The sleep questions also were factor analyzed using exploratory principal components analysis (unrotated).

Results: Seventy-eight service members enrolled in the study with 64 remaining at 18 months-for a total of 349 participant surveys collected over time. The participants were primarily Army (74%), enlisted service members (96%) with an average of 62 months of military service. Most service members were Caucasian (69%), males (n=97%) with a mean age of 25 years, at least a high school education or GED (56%); 45% were married and they had an annual income of \$40,000 or less (78%). They presented with thermal burns and polytrauma resulting from combat injuries and accidents with a mean total body surface area burned = 24%; the average length of stay in the burn unit was 44 days (median = 17 days). Patients reported persistent sleep disturbances that included: nightmares (50%); insomnia (71%); hypersomnia (31%) and excessive daytime sleepiness (63%). These sleep disturbances continued during the 18 month post-discharge period. There were no statistically significant improvements in their sleep over time. Cronbach's alpha for the sleep questions was .87 and when the seven sleep questions were factor analyzed, all seven questions loaded on one component, Sleep, which explained 60% of the variance (eigenvalue 4.169). The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy was .83 and Bartlett's Test of Sphericity was significant ($p < .000$; $df = 21$).

Conclusions: These patients were relatively young and in good physical health prior to sustaining a burn injury. Participants' sleep disturbances remained relatively consistent over this 18 month study post-discharge. This lack of improvement indicates a need for interventions that can improve sleep, decrease nightmares, and decrease excessive daytime sleepiness. Understanding burn patients' sleep disturbances assists with interpretation of burn rehabilitation progress and psychosocial needs. The seven questions used to measure sleep in this sample came from instruments commonly used with military and civilian patients. The reliability and factor analysis results indicated that these seven questions can be used to measure sleep without needing to use another instrument specifically designed for sleep measurement. This ultimately decreases the clinical and research burden for the patients.

Grant Information: This study was funded by the TriService Nursing Research Program.

P 16 - Technologies to Influence Palliative Care

A New Kind of Team! A Nurse-Led Technology-Enabled Interprofessional Palliative Home Care Model

Lorie Donelle, PhD, MA, BA, BScN, RN, Canada
Sandra Regan, PhD, MScN, MA, BScN, RN, Canada
Richard Booth, PhD, MScN, BScN, RN, Canada
Mickey Kerr, PhD, Canada

Selma Tobah, MSc, Canada

Abstract

Purpose: Community-based care is an important area where innovative models of practice may assist patients to remain in their home rather than being admitted to institutional-based care. This is particularly important in addressing the growing number of older adults who wish to “age in place” (Special Senate Committee on Aging, 2009). As health human resource shortages continue, difficulty recruiting and retaining community-based providers are impacting the delivery of home care services (Zeytinoglu et al., 2009). Innovative use of technology may transform how healthcare workers communicate and practice together within home care settings; improve equitable health care delivery for clients and their families; and shape policy and planning of health human resources.

In response to the shortage of nurses available to provide palliative home care, the home care provider in South West Ontario, Canada, led an innovation team comprised of service provider organizations, a software / technology provider, and health care providers in the development and implementation of a new model of palliative home care – the eShift model of palliative home care (eShift) (Ralph et al. 2016; South West Community Care Access Centre, 2011). The eShift model combines communication and documentation technology with novel utilization of health human resources to meet patient needs for palliative care in the home. The core of the eShift model of care is the pairing of a remotely located directing registered nurse and personal support worker in the technician role in the home along with the eShift technology and supported by a large team of healthcare and technology providers. *The aims of this study were to:* 1) develop a theoretical framework explaining the structure, process and outcomes of the eShift model of care; 2) identify and measure the process and outcomes of care; and 3) conduct an economic analysis of the model.

Methods: We conducted a three-year mixed methods study (Creswell & Clark, 2011) of the eShift model from pilot to full scale-up across the region. We conducted 29 individual interviews and five focus groups with 31 participants for a total of 60 nurses, personal support workers, physicians, nurse practitioners, allied health, and decision-makers. A content analysis of the interviews was conducted using NVivo 10 qualitative software program which informed the development of a theoretical framework based on Donabedian’s structure, process, outcomes of care (Donabedian, 2005). We then began to test the model and developed an online survey using both standardized instruments and researcher developed questions to measure the structure, process and outcomes of the eShift model. The online survey was conducted with all nurses, personal support workers and care coordinators working in the eShift model (n= 143). Data were analyzed using SPSS 20 and descriptive and inferential statistics were generated.

Results: This presentation will specifically focus on the findings related to perspectives on team within the technology-enabled model of home care. The technology in this model was positioned as an enabling factor for team work within the eShift model. The focus on patient care practices enabled by the implemented technologies was thought to facilitate the transformative changes to palliative care in the home setting. While the core members of the eShift health team were the remotely located directing registered nurse and the personal support worker in the home, the larger health care team reflects the evolution of technology enabled palliative home care which includes the visiting nurse, primary care

providers (physician, nurse practitioner), palliative care specialists, the care coordinator, and information technology support and design personnel. Participants described the importance of the collaborative relationship with the technology provider from early model development right through to implementation of the model of care. The eShift model of care has been influential in transforming team work. The eShift model of care supported the development of a strong virtual relationship and coaching and mentoring between the directing registered nurse and the personal support workers. We used the Interprofessional Socialization and Valuing scale (King et al. 2010) to measure self-perceived ability to work with others. Mean scores for nurses (m-54.1; SD -7.29) and personal support workers (m- 55.8; SD-6.1) were high; findings also indicate high job satisfaction, high empowerment, and high work engagement.

Conclusion: Overall the eShift model supported enhanced interprofessional collaboration through technology enabled communication and documentation systems. Findings suggest that the technology provider can play an important role in the interprofessional team; a finding absent in the current literature. Nurses and personal support workers reported high rates of interprofessional collaboration, mentoring, and feeling valued. Rather than hinder care processes, technology was seen as an enabler to communication among the team and contributed to enhanced relationships among and between providers of care.

P 16 - Technologies to Influence Palliative Care

Utilizing Clinical Decision Support Within the Electronic Health Record to Screen for Palliative Care

Tanja Baum, PhD, RN, USA
Ruth A. Bush, PhD, MPH, USA
Caroline Etland, PhD, RN, USA
Cynthia D. Connelly, PhD, RN, FAAN, USA

Abstract

Purpose: Timelier referral to palliative care services (PCS) within the acute care setting is a health care priority. End-of-life consumes a disproportionate share of healthcare dollars with studies indicating PCS can save hospitals approximately \$1.3 million annually, for every 500 consults completed. Strategies to increase timelier referral are needed. Integration of electronic clinical decision support and utilization of triggers to identify individuals who may benefit from palliative care, using an algorithm embedded with the electronic health record (EHR) may facilitate this identification, but lacks empirical support.

The purpose of this research was to utilize variables available in the electronic healthcare record (EHR) of palliative care patients receiving PCS in the acute care setting to identify triggers which could be used to identify individuals who should be referred for PCS.

Specific Aims:

Aim 1: Characterize EHR data related to palliative care consultations among severely and chronically ill patients in the acute care.

Aim 2: Examine the relationships between the list of clinical EHR data, select demographics, in a sample of palliative care patients

Methods: A descriptive, correlational study using de-identified retrospective data, collected from January 1, 2013 to December 31, 2015. An institutionally derived list of variables was used to provide a foundation for clinical decision support and patient identification integrated into the Cerner EHR system. Data were derived from three hospitals of a large multi-community healthcare system in San Diego County. Descriptive and inferential statistical analyses conducted using SPSS version 23.

Results: A randomized sample yielded 694 palliative care patients seeking acute care treatment at one of the three hospitals. Of these 51.7% were male, 65.4% White, 36.7% Christian, 80.8% English speaking, 49.7% Medicare recipients, 51.4% declared themselves as a 'do-not-resuscitate' and 97.6% were seen by a palliative care nurse. Significant associations were found between race/ethnicity/code status ($X^2 = 11.311$, $p .02$), language/presence of advance directive ($X^2 = 13.845$, $p .008$), and change of code status/loss of responsiveness ($X^2 = 15.129$, $p < .001$).

Conclusion: Using a large sample, a number of statistically significant demographic, physiologic, and clinical variables were found that to identify individuals suitable for timely referral to palliative care services. The integration of an EHR-based trigger system can aid not only nursing, but the interdisciplinary team to identify and refer potential palliative care patients in a timelier manner. The findings lay an important foundation for increased refinement of electronic clinical decision support within the EHR.

P 17 - The Student/Faculty Relationship

Academic Factors That Contribute to Nursing Students' Persistence: Pre-Program Support

Cecil Flores, PhD, RN, CNE, USA

Abstract

Purpose: In the first decade of the 21st century, Texas experienced a 20.6% increase in population growth (Texas State Data Center, 2012). If the projections for 2020 are correct, another three to eight million people will reside in Texas, straining the infrastructure of the state and having an impact on the need for nurses and healthcare providers. Nationally, the need for registered nurses (RNs) is expected to grow by more than 500,000 (American Association of Colleges of Nursing, 2014)

While the need to educate RNs is apparent, the persistence rates for nursing students in enrolled pre-licensure RNs programs have remained relatively constant at 69% from 2007 to 2011 (TCNWS, 2012). Many contributing factors have been identified as predictors to program success (Jeffreys, 2012; Shelton 2012). Few researchers have focused solely on academic factors that impact nursing student persistence (NSP). The purpose of this study was to identify academic factors associated with support provided prior to nursing school admission and NSP

Methods: Descriptive correlational. The 14-item Academic Factors that Impact Nursing Student persistence survey was emailed through a Qualtrics link to 93 deans and program directors of Texas RN programs. Inclusion criteria included completing nursing school within the Texas Higher Education Coordinating Board persistence guidelines. Pre-licensure student characteristics were described and odds ratios were calculated to determine the association between academic support and pre-licensure NSP.

Results: 39 deans/directors participated (41.9% response rate) with 33% completion rate (n=31). Positive associations were found when introductory courses were taught: Students were 2.9 times more likely to persist (OR=2.9; 90% CI: 2.79 -3.01) when math skills were taught and 2.54 times more likely to persist (OR= 2.54; 90% CI: 2.46, 2.63) when study skills were taught. When academic advisors were available to assist students, students were 2.3 times more likely to persist (OR= 2.31; 90% CI: 2.36-2.36).

Conclusion: Pre-program support was associated with NSP. Of the five pre-program support items, four were associated with NSP. When students had access to academic advisors and were provided with introductory courses that taught math skills, study skills, and critical thinking skills, they were more likely to persist and graduate at the 85% benchmark. Identifying factors that promote NSP, then providing students with these resources may increase the number of registered nurses.

P 17 - The Student/Faculty Relationship

Exploring Faculty-Student Relationships and Their Implications for Persistence in African American Senior Nursing Students

Yolanda M. Nelson, EdD, RN-BC, USA

Abstract

Purpose: This research explores the lived experiences of African American female nursing students and examines how faculty-student interactions may influence persistence of minority students. Little research exists which examines the interaction between faculty and their African American female nursing students. Combined with the current research and the lack of diversity within the profession of nursing, it is critical to unlock the mysteries as to why there is an inadequate representation of African American nurses within the profession of nursing. Utilizing the lens of the Black Feminist Thought perspective in conjunction with Tinto's Theoretical Model of Student Retention, the focus was to gain further insight into and to discover if a relationship exists between faculty involvement and the persistence of African American female nursing students. Improved awareness regarding persistence will empower educators to direct future efforts toward interventions that positively influence and facilitate successful program completion for minority nursing students (Loftin et. al, 2012).

Methods: This study used a phenomenological approach to analyze faculty-student interactions as well as student responses from journals, focus groups, and interviews. Applying a phenomenological approach seeks to describe the meaning attributed to several individuals regarding their lived experience(s) of a concept or phenomenon (Creswell, 2013). This particular approach attempts to understand people's perspectives and understanding of a particular situation (Van Manen, 1990). This study focused on the aspects which all participants have in common. The study consisted of three phases: Phase I entailed observing a heterogeneous group of baccalaureate nursing students and nursing faculty in order to document behaviors. Phase II contained interviews of African American senior nursing students to learn about their lived experiences. Lastly, Phase III consisted of a focus group discussion and follow-up interviews with a heterogeneous group of nursing students. A qualitative analysis of the transcribed focus group and interview data was utilized to identify themes discovered among the statements given by participants. Review of the interview transcript in its entirety was completed and the interview transcript was read a second time prior to coding.

The components were grouped into thematic categories. In addition, textual, verbatim examples from the interview and focus group's transcribed texts were included to highlight and clarify key concepts. All relevant data were coded throughout the document, which allowed the categories to emerge freely from the interview and focus group discussion data. The thematic categories were generated through the identification of similar types of responses. The final step involved a comprehensive review and interpretation of the data to provide the conclusions of the analysis. NVivo 10® qualitative analysis software was used to aid in the coding and the emergence of themes and patterns from the data by assisting in the classification, sorting and arranging of information, and tracking the frequency of occurrences across the interview and focus group data.

Results: The researcher used findings from the observations, interviews, and a focus group. The themes that were identified were the following: personal perseverance, supportive network, caring attitude, mentorship, and faculty-student interactions. The reactions regarding current faculty-student relationships were mixed. In describing their overall experiences with faculty, student participants used words ranging from approving terms like "positive," "friendly," and "helpful," to more negative ones like "initially intimidating," "cold," and "discriminatory." Some described having a personal connection with a professor while others noted that the professors lacked any personal connection with their students. Some participants also witnessed faculty favoritism towards certain students. Interview and focus group participants noted how imperative it was to have a support team that included advisors, mentors, and role models. Participants also stressed the importance of developing a faculty-student relationship. Some interview participants elaborated on this faculty-student connection, saying that helped them to feel less isolated or intimidated and actually boosted their self-confidence. This validates Fries-Britt & Turner's

(2002) notion that educators must create institutional support systems, so that African American students may have the opportunity to develop the personal confidence that will “propel them toward academic pursuits” (p. 326).

Conclusion: While shortages have occurred in health care throughout history, experts are discovering that the rising nursing shortage is uniquely serious (nd., 2011). Not only is there a shortage, but there is a major concern with the lack of diversity within the profession of nursing. The following recommendations are essential for consideration: (a) the incorporation of mandatory training with nursing faculty to incorporate and define a faculty-student relationship; (b) the inclusion of workshops to help faculty become mentors to various ethnic backgrounds; (c) annual evaluations of faculty regarding their professional relationships with students; (d) forming a yearly “get to know” workshop for students and faculty; (e) mandating that students have a weekly 1:1 meeting with an assigned nursing faculty member; and lastly, (f) providing workshops to African American nursing students that would feature African American leaders as guest speakers who can offer insight into leadership, advancement, and keys to success.

Moreover, this research can assist the nursing profession as well as higher education institutions in the development of faculty-student relationships to empower the success of African American nursing students. Additionally, this research can allow institutions to reflect, make needed changes regarding faculty-student interactions, and assist in promoting and retaining African American nursing students. Nursing faculty can be positive influences on students who seem to be discouraged or overwhelmed. Faculty can shape new, positive mental models by illustrating a welcoming approach towards students (Bull, Fitzgerald, & Veal, 2012). It is essential to create a safe learning environment in which students communicate in ways that respect diverse views and are appreciative of students as individuals (Bull, Fitzgerald, & Veal, 2012). Interactions between faculty and students have enduring effects on learning as well as professional development.

Q 07 - Global Perceptions of Pain Management

Clinical Decision-Making Regarding the Management of Pain: Differences Between Novice, Intermediate, and Expert Nurses

Igal Zlatkin, MA, BA, RN, Israel

Yulia Gendler, MSc, BA, RN, Israel

Abstract

Purpose: Nursing pain management is closely related to decision making-process, which includes continuous estimate, intervention, monitoring the effect of treatment, identifying the need for changes and alternative treatment. It is generally assumed that education and practical experience increases accuracy in decision-making. Benner presented an extensive theory that suggests five levels of proficiency that nurses pass in acquisition and development of skills from novice to expert. However, this theory does not examine strategies of decision making during these stages. The purpose of the study: (1) to identify the cognitive processes used by nurses when making pain management decisions and the factors which have an influence on these processes. (2) to examine the difference between novice, intermediate and expert nurses, in their decision making about pain management.

Methods: The subjects constitute a non-random sample of 65 registered nurses working in surgical wards in two academic teaching medical centers located in Israel. The study received approval from both hospitals' institutional review boards. The study is based on three tools: the self-assessment questionnaire of participants' pain management knowledge and skills; vignettes describing common situations which require nurse's decision making followed by questions examining basis of the decision; script concordance test evaluating decision making in common clinical situations. The tools were designed by the researches and validated by expert judgment.

Results: The decision regarding pain management of expert nurses were mostly based on their experience and intuition, while novices and intermediates relied on guidelines or colleagues' advises. In comparison to novice, expert nurses reported that the decision making process was easier for them ($\alpha=0.013$). Significantly better decision making was found among the nurses with Master degree ($F=7.15$, $\alpha=0.005$) and among nurses who have participated in pain management educational programs ($\alpha=0.02$). No association was found between seniority in a surgical ward and accuracy in decision making. The findings were consistent with vignettes and script concordance test.

Conclusions:

There is a substantial difference in the decision making regarding pain management between novices, intermediates and experts, both in quality of the decision and the cognitive process of the decision making. Well-developed guidelines may assist no novice to improve their decision making skills. The script concordance test seems to be an effective tool in evaluating nurses' clinical decisions. This study emphasized the benefit of nurses' higher education and participation in clinical educational programs

Q 07 - Global Perceptions of Pain Management Knowledge, Attitudes, and Practices of Nurses on Pain Assessment and Management in Manila, Philippines

Florence Roselle B. Adalin, BSN, Philippines
Josefina A. Tuazon, DrPH, MN, RN, USA
Misha Louise A. Delariarte, BSN, RN, Philippines

Abstract

Purpose: Nurses' knowledge and attitude on pain greatly affect their ability to assess and manage it. The Pain Society of the Philippines recognized the inadequacy and inaccessibility of data on the knowledge, skills, and attitude of nurses about pain management in the country. This study aims to describe the level of knowledge and attitude (KA), and current practices of nurses on pain assessment and management; and determine the relationship of nurses' KA with years of experience, training on pain management, and clinical area of practice.

Methods: A survey research design was employed. Four hospitals were selected through purposive sampling. Coordination was done among the two public and two private hospitals to gather data from Medical-Surgical and Intensive care unit (ICU) nurses. A total of 235 nurses participated in the study. The tool was a combination of the Nurses' Knowledge and Attitude Survey Regarding Pain (NKASRP) and Acute Pain Evidence Based Practice Questionnaire (APEBPQ), with self-report questions on non-pharmacologic pain management. The data obtained was analysed using descriptive statistics and two sample T-tests for the clinical areas and training; and Pearson product correlation to identify relationship of level of knowledge and attitude with years of experience.

Results: The mean knowledge and attitude (KA) score of the nurses was 47.14%. Similar studies such as that of Yava et al (2013) from Turkey had a reported mean correct answer rate of 39.65%, and 50.5% in Taiwan (Lai et. al, 2003). Majority answered 'most of the time' or 'all of the time' on 84.21% of practice items on assessment, implementation of non-pharmacologic interventions, evaluation and documentation. Three of 19 practice items describing morphine and opioid administration in special populations were only done 'a little of the time'. Non-pharmacologic interventions used were deep breathing exercises (79.66%), massage therapy (27.54%), and ice therapy (26.69%). There was no relationship between knowledge scores and years of clinical experience ($p = 0.05$, $r = -0.09$). Moreover, there was not enough evidence to show a difference in nurses' knowledge and attitude scores in relation to presence of training ($p = 0.41$) or areas (Medical-Surgical or ICU) of clinical practice ($p = 0.53$). This study showed a homogenous sample in terms of years of experience; therefore, no generalizations may be derived from the population.

Conclusion: The nurse's role in effective pain management is significant. Nurses are expected to possess adequate knowledge and attitude and adhere to evidence-based practices in pain management. With pain controlled and managed accordingly; the patient's quality of life is preserved. Findings of the study suggested that the level of knowledge and attitude of nurses on pain assessment and management is suboptimal. There was no relationship between nurses' knowledge and attitude and years of experience in this study. Nurses were also noted to use non-pharmacologic interventions in adjunct to pharmacologic treatment. Inadequate pain management is related to lack of knowledge, apprehension on side effects, restricted opioid use, and absence of pain management in the curricula of medical and nursing schools in developing countries (IASP, 2011). In this study, the results may have been influenced by non-prioritization of pain management in the Philippine Health Care Setting as noted by Tamalayan in 2012.

Further research may seek to determine the relationship of training, clinical area, and other variables such as pain perception and experience among nurses. It is recommended that further studies look into in the nursing curriculum on pain education, formulate culture-specific pain management protocols, and create a matrix for assessment for knowledge and attitudes; and implementation of evidenced- based practices in the country.

Q 08 - Innovative Teaching Strategies

Utilization of Innovative Teaching Strategies Following a Nursing Education Certificate Program in Guyana

Deborah Salani, DNP, PMHNP-BC, ARNP, NE-BC, USA

Mary E. Mckay, DNP, ARNP, CNE, USA

Abstract

Purpose: The purpose of this presentation is to showcase the utilization of non-traditional teaching strategies by Guyanese nursing tutors after the completion of a hybrid nursing education certificate program. The country of Guyana has been struggling with a severe nursing shortage; hence, the government expanded the enrollment capacity for the Guyana Schools of Nursing. The Guyanese nursing students' success rate in passing the national licensure exam has been less than optimal. In an effort to improve the nursing shortage and success rate on the board exam, the Guyana Ministry of Health, Pan American Health Organization, and the World Health Organization formed a collaboration with the School of Nursing and Health Studies to provide a Nursing Education Certificate Program for the nursing tutors. This dynamic program provided tutors with the skills and knowledge to facilitate lifelong learning to educate nursing students in the classroom and clinical settings. The program provided focused coursework in the areas of educational learning theory, curriculum and instructional design, teaching strategies and evaluation of student performance and instructional design. In Guyana, nursing students have been educated using traditional methods. This program emphasized the use of innovative teaching strategies such as simulation; case studies and gaming or on-line application that faculty may use to promote learning. Traditional pedagogies used in the classroom often creates passive learning (Tedesco-Schneck, 2013), however, usage of innovative strategies support critical thinking and encourages students to become more involved in the learning process (Gipson, 2013). Simulation is an educational strategy used by many nursing programs. According to Aebersold & Tschannen (2013), simulation is an effective method for improving competency in an area. Simulation may be utilized to educate nurses for new procedures, communication processes, and skills. Simulation may include a life size doll, role playing or usage of high-fidelity and virtual simulator. Case study teaching methods have been extolled for promoting student engagement and critical thinking skills (Freeman Herreid & Schiller, 2013). Another effective teaching strategy is the use of games. Gaming encourages student involvement, active learning, and critical thinking. Games are often used in combination with lecture to highlight important information (Xu, 2016).

The evaluation of student knowledge and skill acquisition is a critical aspect of the nurse educator role. Tutors were taught how to develop and utilize grading rubrics and to communicate with the students about grading expectations. Rubrics are an objective measure to provide clarity regarding expectations so students may complete the assignment successfully (Kirkpatrick & DeWitt, 2012). Another strategy to assess outcomes of learning is teacher-developed tests. According to Tarrant & Ware (2012), many nurse educators do not have the knowledge base or education to develop exam questions. Therefore, tutors were provided theory on test construction and item analysis.

Methods: The Certificate in Nursing Education Program was composed of four graduate level courses which were offered as a hybrid program. Weekly online classes were held along with virtual office hours. In order to provide support, consultation and mentorship, faculty visited Guyana on 4 different occasions. These courses were designed to meet the needs of the tutors and the various schools of nursing. All assignments were tailored to address their needs and to assist them in improving their curricula. Courses covered included teaching and learning theory in nursing education, methods of nursing education, practicum in nursing education and evaluation. All assignments were customized to address the tutors' needs and to assist them in making improvements to the curricula. Topics covered included teaching and learning theory in nursing education, methods of nursing education, and evaluation. Assignments included simulation scenario development, creation of an innovative learning strategy such as a game, table-top exercise or application, and case studies. Assessment and evaluation assignments included the development power point presentation, grading rubric, and skill or simulation evaluation tool. Tutors were

also required to write 10 test questions from more than one level of Bloom's taxonomy and provide a peer review.

The design utilized was a pre/post mixed method. Upon receiving approval from the university institutional review board 26 participants were requested to complete the survey before the start of the program and following the completion. All of the participants were tutors from the various schools of nursing in Guyana both public and private. Data collected included demographics, tutor teaching responsibilities, teaching and evaluation methods utilized in the clinical setting, expectations of the program, self-reported confidence and competence regarding teaching in the classroom, clinical and simulation setting, curriculum development, and qualitative open-ended questions.

Results: Pre-post scores found an increase in tutor use of simulation as a teaching modality (25% and 66 % respectively). Pre-post scores found an increase in tutor use of case presentations (59% and 83% respectively) and technology in the classroom (66% and 78% respectively) with a subsequent decrease in the use of traditional lectures (89% and 77% respectively). Pre-post scores found an increase in the usage of clinical competency skills checklist by tutors (46% and 65% respectively). Pre-post scores found an increase in tutors development of exam questions (88% and 94% respectively) with a subsequent decrease in the use of commercial test question banks(69% and 61%).

Conclusion: Upon completion of the Nursing Education Certificate program the Guyanese tutors demonstrated an increase in the utilization of innovative teaching strategies and evaluation measures. The participants reported an increase in the use of non-traditional teaching methods including simulation, case presentations and technology - based activities. Participants utilized clinical skills checklist as a formal evaluation measure at a greater rate following the program. Study limitations include a small sample size and self reported data. However, these results offer promise for future offering of the program. Innovative teaching strategies may promote an increase in student engagement and learning.

Q 08 - Innovative Teaching Strategies

Case-Based Learning in a Flipped Classroom to Promote Critical Reasoning

Noel Holly Santa, MSN, RN, CCRN, USA

Abstract

Purpose: The aim of this project was to determine if case-based learning in a flipped classroom model promoted critical reasoning in senior level nursing students enrolled in an undergraduate Baccalaureate Nursing program.

Background: There is an ever-growing need to change the pedagogy of nursing education to meet the demands of highly-technological and dynamic healthcare systems with more complex, diverse and higher acuity populations (Kaddoura, 2011). Nurse educators are challenged to bridge the theory-practice gap to ensure that new nurse graduates are well-equipped with the skills to critically reason through patient situations that require sound clinical judgment (Benner, Kyriakidis, & Stannard, 2013; Kaddoura, 2011). In meeting these challenges, nurse educators must transform the classroom, shifting teaching and learning paradigms (Benner, Kyriakidis, & Stannard, 2013; Nilson, 2016, October 24). The classroom environment must promote and support student engagement through deeper, more meaningful learning that foster critical reasoning (Kaddoura, 2011). A flipped classroom creates an environment in which students actively engage with content, thereby stimulating and encouraging higher level thinking (Honeycutt, 2016). The use of case scenarios promotes the development of critical reasoning through open-ended and unfolding situations that require students to interpret, analyze and synthesize the most salient patient data to support clinical decisions (Kaddoura, 2011; Nilson, 2016, October 24). Case scenarios also provide a format for students to explore alternatives, describe rationales that support their decisions, receive feedback from their peers and faculty, and promote a greater awareness of their own cognitive reasoning (Kaddoura, 2011; Nilson, 2016, October 24).

Methods: Case-based learning within a flipped classroom model was used to teach critical care content to senior level nursing students. Quantitative data was compiled using a pretest-posttest design with student results from Assessment Technologies Institute (ATI) Medical-Surgical Proctored examination before and after a senior-level critical care course. Qualitative data was also analyzed through student evaluations at the end of the course.

Participants: Convenience samples from four different cohorts (total n=48) in pre-licensure Baccalaureate Nursing programs were used to evaluate student learning outcomes.

Results: A pretest-posttest was performed from ATI Medical-Surgical Proctored examination percentages before and after the critical care course. The t-test results indicated statistical difference in students' performance for all four cohorts with *t* values ranging from 2.24 to 5.38. The resultant *p* values were less than 0.05. Themes from student comments in course evaluations ranged from wanting "more lecture" to "challenging" and "Hard work but very rewarding."

Conclusion: Quantitative and qualitative data suggests that integrating case-based learning within a flipped classroom model may be effective in promoting deeper and more meaningful learning to enhance critical reasoning.

Q 09 - International Research Collaborations

Challenges and Opportunities in Conducting International Research Study: Family-Witnessed Resuscitation in Two European Countries

Natalia Sak-Dankosky, MSN, BSN, RN, Finland

Paula R. Sherwood, PhD, MSN, BSN, RN, CNRN, FAAN, USA

Pawel Andruszkiewicz, PhD, MD, Poland

Tarja Kvist, PhD, MSN, BSN, RN, Finland

Abstract

Background: Conducting international nursing research has been recognized to be crucial in advancing professional healthcare practice (Opollo et al. 2014). Besides providing opportunities for building cultural competences and enhancing effective multi-cultural collaboration, international research projects have been found to have significant implications for research, education, policy and practice (Opollo et al. 2014, Fronda & Alhusen 2016). Its importance for the ethical aspects in critical care has been emphasized after the European Resuscitation Council recognized a need for unification of national legislations and improved application of ethical principles in CPR across Europe (Bossaert et al. 2015, Mentzelopoulos et al. 2016). It is therefore important to conduct research which include samples from different countries, what will contribute to the enhanced understanding of barriers preventing from implementing evidence-based nursing practices globally.

Purpose: The purpose of this presentation is to describe practical experiences in conducting international multisite study aiming to understand the barriers to family-witnessed cardiopulmonary resuscitation practice implementation in two European countries, Poland and Finland.

Methods: A multisite international study using a mixed-method descriptive-explanatory research design was conducted (Author citation 2015, Author citation 2016). Challenges, opportunities, and solutions to the encountered barrier were discussed.

Results: The international study we conducted was divided into two main phases: (1) a quantitative part in which we used a survey questionnaire to explore critical care and emergency nurses and physicians' experiences and attitudes related to in-hospital family-witnessed CPR, and (2) a qualitative part in which we interviewed critical patients' family members to explore and understand their views regarding family-witnessed CPR option. Despite many opportunities such as more diverse and larger sample, enhanced intercultural collaboration, presence of different cultural contexts and thus better understanding of the studied phenomenon, we faced multiple challenges related to in-between country differences which resulted in study protocol changes and adjustments. Translating the data collection instrument, different policies regarding ethical approval application, availability of the sample and culturally-determined willingness to participate in a research study were the main challenges we experienced during the design, empirical and analytic phases of the research process. Strategies such as adjusting the recruitment and data collection strategies, extending data collection time frames, unification of study variables, and analysis of the context and organization of care were used in order to address the encountered barriers.

Conclusion: Despite the generally recognized importance of international nursing studies, their planning, conducting, and implementing can be challenging especially when exploring an ethically sensitive phenomena. Critical issues related to the philosophical, methodological, practical, ethical and financial aspects need to be addressed during every phase of the international research process. Available strategies can help the researchers to overcome encountered challenges. Sometimes study protocol adjustments need to be made, to successfully conduct and meet the research aims of a multinational nursing research.

Q 09 - International Research Collaborations

Multinational Research Collaboratives, Interaction Costs, and Time to Productivity: An Empirical Model to Support Success

Betty A. Rambur, PhD, RN, FAAN, USA

Abstract

Purpose: To illuminate promising practices in multinational research collaboratives that may guide research initiatives that range from interprofessional, to multi-site, to international.

Research to effectively address complex global problems may require the composition of equally complex, diverse, multidisciplinary research teams. Indeed, collaboration among professions, disciplines, institutions, and nations may offer a means to address society's most vexing problems. Although intuitively attractive, collaboration also creates intricate interplays of personal and scientific values, norms and expectations. This research was undertaken to better understand promising practices in the potentially most complicated research collaboratives, those that span nations.

Methods: Because individuals in different regions of the globe may experience the same constructs in unique ways, a qualitative, inductive exploration of the perspective of those leading or managing research collaboratives that span nations was undertaken. A snowball sample of 15 cases drawn from research-intensive institutions in four continents served as exemplars for further exploration. Open-ended exploratory interviews were done to elicit narrative data. A grounded theory, constant comparative methodology was used for data analysis.

Results: Five distinct domains of collaboratives emerged, along an axis of progressive complexity at the operational interface, each with increasing time to research productivity. Identified domains were: parallel facility sharing; data sharing; bridging peers; differing scientific languages and academic cultures; and human subjects or politically/culturally sensitive themes. Each of these domains reflected increasing interaction costs that impeded productivity, with productivity slowed not by the complexity of the research per se, but the complexity of the interface between individuals and organizations. Notably, in the last two domains, differences were often not fully understood until research was well underway, thus creating compounding complexity and challenges. Thus, on further analysis, these five domains could also be further categorized in a simplified dichotomy of "deceptive differences" and "deceptive similarities." In the former, collaboratives were among institutions in which there appeared to be great differences due to geography or other factors, but initiatives were framed within similar scientific cultures and expectations. Distinguishing characteristics were comparatively little risk to the individual scientist, with risk held at the institutional level. Funds were an effective catalyst to spur productivity, and an administrative champion was essential. In contrast, collaboratives characterized by "deceptive similarities" were more unstable and reliant on individual connections, with resulting risk to the individual researchers. Funds were not a reliability effective catalyst and an administrative champion typically had little influence.

Conclusion: Such interaction costs may contribute to Hsiehchen, Espinoza, and Hsieh, (2015) findings that the growth of multinational clinical trials has remained "stagnant" in the last two decades. Implications for research collaboratives that range from those with teams within a single discipline to multinational efforts are detailed, with an emphasis on necessary supports for broad collaboratives spanning nations and diverse perspectives. Issues for consideration in proposal development inclusive of essential activities before the perceived beginning of the research are detailed

Q 10 - Novice Nurse Faculty

Developing Novice Nurse Faculty: Finding an Authentic Leadership Voice

Barbara J. Patterson, PhD, RN, ANEF, USA

Laura C. Dzurec, PhD, RN, PMHCNS-BC, ANEF, FAAN, RN, PMHCNS-BC, ANEF, FAAN, USA

Gwen Sherwood, PhD, RN, FAAN, ANEF, USA

David Anthony (Tony) Forrester, PhD, RN, ANEF, FAAN, USA

Abstract

Purpose: to describe the impact of a 20-month mentored leadership development program for new nurse faculty with less than five years academic experience.

According to the American Association of Colleges of Nursing's (AACN, 2015) 2014-2015 report, *Enrollment and Graduations in Baccalaureate and Graduate Programs in Nursing*, nursing schools in the U.S. turned away 68,938 qualified applicants from baccalaureate and graduate nursing programs in 2014 in part due to faculty shortages. A 2014 AACN special survey regarding faculty vacancies reveals a vacancy rate of 6.9% that year.

Anecdotally, some new nurse faculty members find the transition to academic life challenging and leave academia within 2-5 years, extending a shortage of nurse faculty. Further contributing to the existing shortage, the average age of doctorally prepared nurse faculty by rank (professor, associate professor, assistant professor) is 61.6, 57.6, and 51.4 years respectively. With a dramatic wave of retirements expected, fewer faculty will be available to fill the shortage, resulting not only in further shortage but in less experienced faculty, overall.

These factors raise questions of whether nurse faculty are adequately prepared for academic leadership. Research indicates that faculty and administrators in nursing programs in the United States resist accepting positions with greater administrative responsibility; faculty who do accept formal leadership roles are often thrust into positions with insufficient experience or leadership preparation (Young, Pearsall, Stiles, Nelson, & Horton-Deutsch, 2011). The quality of academic leadership sets the stage for the health of the overall work environment (Brady, 2010), which in turn affects faculty satisfaction and retention.

Formal mentoring offers one solution to addressing issues of gaps in leadership skill and numbers of faculty. Mentoring may be one way to facilitate leadership development and increase retention of new nursing faculty. However, despite broad recognition of the importance of mentoring, formal mentoring programs and empirical evidence is limited.

The Nurse Faculty Leadership Academy (NFLA) of Sigma Theta Tau International offers an intense, mentored leadership development experience to faculty with fewer than 5 years of full-time teaching experience. Based on the Kouzes and Posner Leadership model (2012), the NFLA is designed to foster academic career success, promote nurse faculty retention and satisfaction, encourage personal leadership development, and cultivate high performing, supportive work environments in academe. The NFLA is a 20-month mentored leadership experience through which scholars participate in two leadership development workshops, conduct in-depth self-assessment, and design an individualized leadership development plan guided by a Leadership Mentor from another academic institution and a Faculty Advisor from the NFLA core faculty. Together, Scholar, Mentor, and Advisor form a triadic mentoring relationship. Scholars also create, implement, and lead a team project to advance nursing education through which they develop their leadership skills and host two site visits for the triad with their local administrative team.

Methods: The design for the study was qualitative description with human subjects protection approval. Descriptive statistics were employed to describe characteristics of the Scholars, whose responses on their final NFLA report were reviewed and analyzed by four NFLA faculty to identify common patterns and

themes. The research team used comparative analysis to reach consensus on the results of their analysis, and an audit trail was maintained to ensure credibility of the findings.

Results: The sample of 14 Scholars comprised 12 females and 2 males with a mean age of 49 years (range 33-58 years). Average number of years in scholars' current teaching positions was 2.6. The majority of scholar respondents (86%) were Assistant Professors. The over-arching theme emerging from the data was "Finding an authentic leadership voice". Four sub-themes emerged to characterize this theme: Identifying inner strengths and weaknesses; Increasing focus on others, Increasing self-confidence; and Clarifying aspirations.

Conclusion: The findings of this study contribute to the advancement of the science of nursing education globally by providing empirical evidence for mentored leadership development programs. A greater emphasis on leadership development is needed for nurse faculty during graduate education and in the early years of an academic career. Results from this 20-month program also support the usefulness of a leadership model to guide mentored experiences. Leadership observers in the local institution helped facilitate scholar development by developing self-awareness and situational awareness of others and the environment.

Leadership is an essential component of the academic nurse faculty role. Leadership development is an on-going journey rooted in reflective practices to increase awareness of self, others, and context. For the Scholars in this NFLA cohort, the guided mentoring from NFLA programming contributed to behavioral changes in their leadership trajectory and helped clarify their faculty role amid expanding responsibilities. Finding their authentic voices was a major developmental step in contributing to the organization, learning to work with other faculty, and speaking up to help lead initiatives.

Q 10 - Novice Nurse Faculty

A Structured Mentorship Program to Support Expert Clinicians in New Roles as Clinical Faculty

Lisa A. Seldomridge, PhD, RN, USA

Judith M. Jarosinski, PhD, RN, CNE, USA

Abstract

Purpose: The international shortage of qualified nursing faculty has been identified as a key factor in the inability to educate additional students to become registered nurses (Nardi & Gyurko, 2015) and was a focus of the 2010 Sigma Theta Tau International and International Council of Nurses summit (International Summit, 2010). Because the faculty shortage is the result of multiple, decades-old problems, solutions must be coordinated and comprehensive (Kowalski & Kelly, 2013).

One solution to the nurse faculty shortage is the recruitment, training, and mentoring of expert clinicians to become part-time clinical teachers (Hinderer, Jarosinski, Seldomridge, & Reid, 2015). The aim of this program, the Eastern Shore Faculty Academy and Mentorship Initiative (ES-FAMI), was to develop a diverse group of new clinical faculty and support them through the transition from clinician to educator. The Academy provided a foundation in educational theory, legal aspects of clinical teaching, methods of providing formative and summative feedback, and strategies for dealing with difficult students using a variety of face-to-face, online, and simulation activities. Upon completion of the Academy, a year-long structured one-to-one mentorship experience was offered to graduates. Mentoring opportunities that are laissez-faire provide little structure for the mentee, whereas formalized mentoring experiences with clearly defined goals are far more beneficial to novice educators (Cunningham, 2016; University of Melbourne, 2012). By pairing novice teachers with expert nursing faculty from one of the three area nursing programs, additional support and professional development was provided to assist the novices through their first teaching assignments. The purpose of this research was to evaluate various aspects of the structured, comprehensive, one-to-one mentorship experience.

Methods: A review of the literature was undertaken to identify best practices for structured mentorship programs. Using this information, the team developed a web-based Mentorship Resource site containing all training materials, survey instruments, and resources needed for the program. After approval by the University Committee on Human Research, prospective mentors and mentees completed several instruments to assist in the matching process. Mentors also completed an online training module and 2 hour face-to-face training. Mentees completed a 1/1/2 hour orientation to the mentorship program, expectations, and responsibilities. Mentor-mentee pairs completed a mentorship agreement stipulating their goals, meeting arrangements, and expectations for confidentiality and feedback. Data were collected on the focus and method of each contact. Information on mentor and mentee satisfaction with the mentorship experience were collected after 6 months and again at 1 year.

Results: Data from 12 matches support a need for careful matching of mentors and mentees, separate training of mentors and mentees to prepare them for the mentorship experience, flexibility in meeting the expectation for twice per month contacts, development of separate resource websites for mentors and mentees, and open communication with program participants to problem-solve along the way.

Conclusion: A structured, comprehensive mentorship program is a necessary component of the preparation of expert clinicians as new nursing faculty and can be implemented in any nursing program regardless of geographic location. Since it takes one full-time faculty to produce six graduates per year who in turn provide \$704,000 in annual health care services (Kowalski & Kelly, 2013), assuring a successful transition to the role of clinical teacher is a sensible investment. Though it requires time and effort to develop, implement, and evaluate, an extended mentorship experience may be the missing link in supporting new clinical teachers through their first teaching assignments. This new model for professional development can add to the number of available nursing faculty and enhance "nursing's capacity to meet global healthcare needs" (Nardi & Gyurko, 2013, p. 324). The role of mentoring is vital in

the advancement of individual nurses as well as the advancement of the profession as a whole (Institute of Medicine, 2010).

Q 11 - Cooperative Simulation Learning

Cooperative Learning Versus Independent Learning and the Haptic Intravenous (IV) Simulator

Lenora McWilliams, PhD, RN, USA

Abstract

Purpose: Inserting an intravenous (IV) catheter is a complex and critical skill taught in nursing school. Haptic IV simulators provide opportunity for students to practice IV skills repeatedly in a safe environment without harm to a patient. Haptic IV simulators provide tactile feedback including palpation of a vein and resistance during venipuncture. Cooperative learning is an active learning strategy where students work together to complete a task. The basic elements of cooperative learning include: positive interdependence, promotive interactions, individual accountability, social skills and group processing. The aim of this study was to evaluate the effectiveness of cooperative based as compared to independent learning when used with nursing students who are learning intravenous catheter (IV) insertion using a haptic IV simulator.

Methods: A convenience sample of 180 nursing students were randomized into positions which indicated who was to attempt the simulation first, second or third within the cooperative learning group and the independent learner. Positions (1st, 2nd, 3rd learner and the independent learner) were then randomized into IV simulation groups. IV simulation groups determined the date and time to complete their IV simulation. A posttest only experimental research design was used to compare the effectiveness of cooperative based learners versus the independent learners on the haptic IV simulator based on the dependent variables. The two dependent variables were the initial performance score and the number of attempts to earn a passing performance score on the haptic IV simulator.

Results: Results of the ANCOVA for the initial performance score was significant and indicated that 36% of the variance was related to position in their group while less than 2% was related to IV experience. Results of the ANCOVA for the number of attempts to be successful was significant and indicated that position in their group accounted for 53% of variance while 10% was related to IV experience. Results were confirmed using a non-parametric Kruskal-Wallis test.

Conclusion: Cooperative learners' performance scores were higher while needing fewer attempts on the IV simulator compared to independent learners. The use of cooperative learning groups provide empirical evidence that students learn as a result of observing and working together. This study supports the efficacy of using simulators as a means for students to learn a psychometric skill.

Q 11 - Cooperative Simulation Learning

iHuman Project: Implementation and Evaluation of Cloud-Based, Virtual-Patient, Case-Based Simulation

Elaine D. Kauschinger, PhD, MSN, ARNP, FNP-BC, USA

Abstract

Purpose: The purpose of this study was to investigate how feasible and effective will it be to integrate simulation-based learning modules, delivered via the i-Human Patient virtual learning platform, into online graduate nursing courses, where feasibility is indicated by level of student and faculty satisfaction; effectiveness is determined by analysis of data generated from the i-Human cases that students completed. An additional interest was related to the students level of satisfaction with using a virtual patient case simulation.

Methods: During a 7 week period, students in an online graduate nursing course volunteered to complete 3 virtual patient cases. Students advanced through the virtual patient case simulations while the cloud-based system captured and tracked their clinical decision-making processes. Student participants also attended three WebEx-supported live debriefing sessions to have an opportunity to share their learning experiences with the virtual cases. Additionally, students completed an anonymous survey at the end of the course that assessed their level of satisfaction with the virtual patient simulation.

A second group of students in another online graduate nursing course were required to participate in the i-Human patient simulation as part of a graded activity over a 7 week period. Students selected and completed 4 out of 6 possible cases. Their clinical decision-making processes were also tracked and recorded via i-Human learning platform. Students completed an anonymous survey at the end of the course that assessed their level of satisfaction with the virtual patient simulation.

Results: Overall, both groups report that they were satisfied with the virtual stimulation experience and that they liked the interactive ability of the case simulation, stress-free learning environment and the clinical experience of patient care. Students disliked not receiving credit for questions they perceived were asked during the case, organization of options and the time it took to complete cases. Data from both groups provided insights to the faculty regarding students progress and performance on cognitive competencies as well as choices that impact clinical decision making. Overall, students in both performed better or equal to the previously completed cases. Exception reporting allowed faculty to be aware if students fell below a certain threshold in one or more areas of the case(s). Trend analysis identified certain questions or topics that students are not getting correct or topics that all the students are weak

Conclusion: Cloud-based virtual patient case simulation was an effective and feasible inclusion in online graduate nursing courses. Students and faculty using the virtual patient case simulation tended to be satisfied with the learning experience.

Q 12 - Creative Therapy Methods to Enhance Clinical Reasoning Poetry, Paintings, and a Short Story: Humanities Foster Success in Developing Clinical Reasoning Skills

Josette Brodhead, PhD, MSHS, CNE, RNC, USA
Patricia M. Burke, PhD, CNE, RNC, USA

Abstract

Purpose: Implementing humanities-based teaching/learning strategies can support the development of clinical reasoning skills in pre-licensure nursing students. The ability to function effectively in a dynamic, culturally diverse healthcare environment requires both critical thinking and clinical reasoning skills. The American Association of Colleges of Nursing (AACN, 2008) recognizes the importance of humanities in the baccalaureate nursing curriculum. The purpose of this quantitative study was to examine the use of humanities-based teaching/learning strategies on nursing students' critical thinking and clinical reasoning skills.

Methods: A quasi-experimental, nonrandomized pretest-posttest study examined the impact of humanities-based teaching/learning strategies on the development of critical thinking and clinical reasoning skills among BSN students enrolled in a maternal/newborn nursing course. Participants were selected from two private, faith based colleges, one in the mid-west and one in the north-east. The educational interventions were threaded throughout the course; a total of 9 students from each site completed the study. A lesson plan with scripted questions was provided to each instructor to ensure consistency and the researcher was available for consultation regarding implementation strategies. The humanities-based teaching/learning strategies that included the analysis of a poem, three paintings, and a short story provoked emotional and somatic responses, thus stimulating inner reflection. The collaborative sharing nature of open discourse encouraged students to view the unique perspectives of their peers. The use of educational strategies that evokes emotional and cognitive dissonance provides the platform for transformative learning to occur (Clifford & Montgomery, 2015; Haber-Curran & Tillapaugh, 2015). At the end of the activities, the value of uniqueness and differences was reinforced providing a new frame of reference to see the world. Participants completed the California Critical Thinking Skills Test (CCTST) to assess differences in critical thinking (Insight Assessment, 2015). The Self-Assessment of Clinical Reflection and Reasoning tool (SACRR) was used to assess changes in clinical reasoning (Royeen, Mu, Barrett, & Lubben, 2000). Both the Watson's theory of caring (Watson, 2008) and transformational learning (Cranton, 2006) philosophical underpinnings were used to develop the framework, to implement the educational interventions, and to interpret the results of the study.

Results: The findings indicated that the humanities-based teaching/learning strategies did significantly impact the development of clinical reasoning skills ($p < .05$). However, there was no significant difference between pretest and posttest scores ($p > 0.5$) for critical thinking skills.

Conclusion: The humanities-based teaching learning strategies did positively impact clinical reasoning skills. Although critical thinking scores did not significantly improve, one site did show growth. Further exploration of the research questions is warranted.

Q 12 - Creative Therapy Methods to Enhance Clinical Reasoning Reflective Practice Journaling and Clinical Reasoning: A Qualitative Inquiry Study

Debra Scardaville, PhD, RN, CPNP-PC, USA
Joyce A. Wright, PhD, MSN, BSN, RN, CNE, USA

Abstract

Purpose: The purpose of this presentation is to report the results of an IRB approved qualitative descriptive research study exploring the use of reflective journaling as a pedagogical strategy to evaluate the attainment of clinical reasoning among a targeted population of diverse RN-BSN students in a residency program at a public university in the United States. The following qualitative research question is answered in this presentation: What is the RN-BSN residency students' experience and perception of involvement of clinical reasoning and clinical judgment through the process of reflection and reflective journal writing? Purposive sampling of seven RN residency program students were obtained through informed consent.

Emerging complexity in healthcare practice settings inclusive of global arenas for care and the mandate for a stronger collaborative interdisciplinary nursing practice (Ironsides, 2015) have significantly contributed to the need for sustained exploration of educational paradigms in nursing practice preparation. Educational paradigms must be aimed at the development of not only technical skills but the ability to critically identify a holistic foundation for nursing practice, based upon different forms of knowledge or ways of knowing (Carper, 1978). Engagement in reflective practice is noted to facilitate the development of multiple ways of knowing in nursing practice (Sherwood & Horton-Deutsch, 2012), leading to the development of critical thinking (Zori, 2016). Research encompassing a variety of transformative educational strategies designed to address contemporary educational needs is evinced in the literature. However, despite advances in the epistemology of nursing knowledge and practice, continuing research into educational preparation modalities records evidence of a widening theory-practice gap (Hickerson, Taylor & Terhaar, 2016; Epp, 2008). Significantly, this disparity lends to a diminishment of safe, quality patient care. Therefore, contemporary educational practices must address these concerns.

A review of the literature notes the significance of the model of residency nursing education and reflective practice in the development of an epistemology founded upon multiple ways of knowing in nursing practice. Residency programs, described by the American Association of Colleges of Nursing [AACN] as a model intended to provide supplemental education within the context of the workplace through the provision of mentored, individualized clinical experiences, have demonstrated to provide benefits through a variety of ways including overall improvement (Rush, Adamack, Gordon, Lilly, & Janke, 2013); additional attainment of knowledge through skills training, debriefing, and hands on self-care knowledge (Pine & Tart, 2007); and culturally congruent care based upon evidence (Letourneau & Fater, 2015).

Evidence of the use of reflection as pedagogical strategy is well documented over decades in the nursing literature. Many models of reflective practice exist. Reflective practice, "a means of self-examination that involves looking back over what has happened in practice to improve or encourage professional growth" (Ruth-Sahd, 2003, p. 488) is cited as a conscious, dynamic process of thinking about, analyzing, and learning from an experience that gives one insights into Self and practice (Freshwater, 2008; Kim, Lauzon, Burbank & Martins, 2010; Asselin, 2011) and is an essential element of evidence-based practice through questioning (Thompson & Burns, 2008). Reflective practice allows a forum for opening to a holistic nursing practice through the embracement of diverse arenas of knowledge. Evidence of this is noted in the seminal work of Benner (1984) which documented a lessening of the theory-practice gap through the development of personal knowledge with technical or empirical knowledge and more recently though aiding in the internalization of ways of thinking (Kennison, 2012). Guided reflective journaling is one strategy frequently employed to assist in the development of reflective practice. Most recent evidence for the use of reflective journaling as an effective teaching-learning strategy in the development of clinical judgment is offered by Brussard (2015a, 2015b).

An extensive review of the literature entailed exploration of critical conceptual definitions as well as an examination of evidence-based educational strategies using reflective journaling. Succinctly, the theoretical basis for this study is noted within the conceptual analysis of the significant concepts of critical thinking, clinical reasoning, and clinical judgment. For the purpose of this study, critical thinking is maintained as a precursor to both concepts of clinical reasoning defined “as a complex cognitive process that uses formal and informal thinking strategies to gather and analyze patient information, evaluate the significance of this information and weigh alternative actions” (Simmons, 2010, p. 1155) and clinical judgment described as, “an interpretation about a patient’s needs and/or the judgment to take action (or not), the use of standard approaches or modification of standard approaches or improvising of a new one as deemed appropriate to the patient’s response” (Tanner, 2006, p. 204). The evidence of application and identification of a variety of forms of nursing knowledge, noted in the seminal work of Carper (1978) and further refined and expanded upon by Chinn & Kramer (2014) provided additional theoretical foundations in this study.

Methods: Methodology in this qualitative descriptive study utilized reflective journaling as an educational strategy created through active reflective dialogue with research faculty investigators through an anonymous secured electronic journaling platform. Following journal submissions, written insightful electronic feedback was created by each researcher independently, allowing for diverse reflective insights to the study participants. Cue questions inviting deeper reflection were created using the Johns (1995) model of structured learning to reveal multiple ways of knowing and learning (Carper, 1978). The Johns (1995) model promotes exploration of four fundamental patterns of knowing: ethical, personal, aesthetic, and empirical, adding an additional pattern of knowing, reflexivity, that assists the writer in knowing about themselves in the experience. Additional cue questions using emancipatory knowing (Chinn & Kramer, 2014) further reflecting contemporary nursing practice roles and identities, were also constructed.

Results: Rigor of data analysis process, was maintained utilizing the framework of Lincoln and Guba (1985). This framework incorporates methods to address rigor through the review of data credibility, transferability, dependability, and confirmability, in which the qualitative thematic analysis of journal entries was independently ascertained by the two researchers following the study completion. Following independent analysis, researchers met to compile mutual evidence of clinical reasoning as revealed in reflective journaling. A thematic analysis was structured around the framework of patterns of nursing knowledge (Carper, 1978; Chinn & Kramer, 2014). Study findings noted authentication of all ways of knowing embodied in student reflective journals. A continuum of expansion of the framework of nursing knowledge is distinguished by the involvement of the study participants’ reflective journaling from the technical or empirical ways of knowing in nursing practice as a single, foundational way of providing nursing care toward the attainment of emerging emancipatory thinking and nursing practice as corroborated through the emancipatory concepts of an opening to voice, vulnerability, holism, community of caring, and disparity.

Conclusion: Results of this study further indicate the significance for curricular and educational implications of reflective journaling and reflective narrative explorations as a warranted pedagogical strategy. The importance of this strategy is noted through the reflective journal of one participant in which a true “seeing” of the community of nursing was facilitated in this study (Study Participant, 2016). This pedagogical strategy, as based upon active constructivist learning theories and models of education and feasibility of use, continue to be validated for applicability of use in contemporary nursing education in global arenas. Models of clinical learning for the novice nurse in conjunction with reflective journaling offer many potential implications for safe, quality patient centered nursing practice.

Q 13 - Emergency Situations

Development and Implementation of a University Active Shooter Drill Using Cross-Sector Collaboration and Nursing Leadership

Shannon Lee Woods, DNP, RN, CNOR, CNE, USA

Abstract

Emergency and disaster preparedness is a modern day theme and has changed with increasing technology and the ability to predict natural disasters. Manmade disasters have provided little opportunity to mitigate outcomes except with robust emergency and disaster plans. Hospitals have been good at developing policies, procedures, and protocols in emergency management. Healthcare workers, particularly nurses, practice emergency management and mitigation naturally within the course of their daily work. With this strong skill, nurses are positioned to be a natural leader in higher educational settings' response plans as emergency and disaster preparedness becomes more common. The purpose of this proposal is to discuss the process and nursing skills used to provide expertise to a diverse group of individuals with a common focus on safety and emergency management.

Tabletop exercises can provide a tool to measure emergency management plans (Veenema, 2013). A tabletop exercise is a good starting point when developing an active drill. The use of tabletop exercises is not new to nursing. Tabletop exercises can be likened to simulation that better prepares the learner for real-world action in a comfortable and non-threatening environment (Rega & Fink, 2014; Wittman-Price, Godshall, & Wilson, 2013). Just as simulation allows the learner to make mistakes and then learn from them so does a tabletop exercise. This further develops a comfort level for immediate response to difficult situations of all involved (Jacobs, 2014; Wittman-Price et al., 2013). Learning occurs through finding gaps that exist in the emergency plan and expands the knowledge level of the learners. The interactions during a tabletop exercise enhances the learning experience as the participants glean knowledge from each other and learn where action is needed to make the emergency plan more successful (Rega & Fink, 2014).

Active drills are different in that the entire stakeholder group could potentially be engaged; whereas, in a tabletop drill the participants can be chosen and the drill can be more controlled (Veneema, 2013). Active drills follow a written script with moment-by-moment responses that change based on the actors that become part of the script unknowingly. Skill sets are practiced which include communication, action, interaction, and reaction. Designated observers monitor length of time in communication and response. A hot wash will typically occur at the end of an active drill where the main stakeholders assess and evaluate the witnessed responses. The evaluation includes recommendations and a plan of action to improve the emergency operation plan (Veneema, 2013). Active drills are shown to create continuity between community entities both in the U.S. and globally (Dausy & Moore, 2014).

In a small private university in South Georgia the president of the university appointed as chair to the Safety and Security Committee a nursing faculty member who had previous emergency and disaster experience. The university president tasked the committee to develop active drills to promote safety and mitigate disastrous outcomes. During the first two years the emergency operations plan was updated and tabletop exercises focusing on natural disasters occurred within the committee. Then the tabletop exercise was provided for participation of the administrative team.

After the natural disaster tabletop exercise with administration the committee chair contacted local law enforcement and the local fire chief and garnered support to develop a plan for university education on fire and active shooter safety. After many meetings with community emergency responders the first combined educational endeavor was mandatory training of university faculty and staff that was provided by the Safety and Security Committee, the local Fire Chief, and the local lead Lieutenant of The Special Weapons and Tactics (SWAT) division. Using best practices the training included fire safety, escape routes, fire extinguisher use, active shooter safety, and university reassembly areas (Interagency Security Committee, 2015).

With a foundation for combined educational endeavors the committee chair garnered support for an active shooter drill. An active shooter tabletop exercise was developed and initiated with the lead of the committee chair and SWAT team Lieutenant. Local community agencies and the university administrative team participated. After revising the safety plan, based on the tabletop findings, an active shooter drill was developed by the committee chair and SWAT team Lieutenant. This successful drill took place with comprehensive planning efforts that included inter-professional university divisions and cross-sector community collaboration.

The outcomes of the drill identified the opportunities for improvement within the emergency safety plan of the university and created a working knowledge of the roles of various individuals along with group effort initiatives clearly delineated. As identified in the literature, communication is the most essential component of emergency preparedness success (Veneema, 2013). Lessons learned by the university (and the committee chair) included the vast amount of communication efforts that must occur in developing, initiating, and deploying participatory drills. Other lessons learned included the use of technology for directing a drill including reverse calling systems to notify the public of drill dates and information, perimeter security, signage, campus involvement, and the use of media in conveying messages. Partnering agencies were beneficial in creating a more secure campus with the sharing of up-to-date floor plans that are part of the SWAT teams' computer based program, community partner drilling for acquisition of knowledge of layouts, and evaluation of processes from experts with thorough recommendations that can be evaluated and re-evaluated for functional use. The role of the committee chair as an effective and empowered nurse leader shows that nursing has a way to use clinical expertise in far-reaching ways that impact society positively and create not only inter-professional collaboration but cross-sector collaboration as well.

Q 13 - Emergency Situations

Differences and Similarities in Emergency Department Crowding Between a Developing Country and a Developed Country

Naomi van der Linden, PhD, Australia

M. C. (Christien) van der Linden, PhD, ACNP, CEN, RN, Netherlands

Abstract

Purpose: Emergency department (ED) crowding is an international crisis affecting patient care. ED crowding is associated with delays in treatment, diminished quality of care, and increased inpatient mortality. The problem of ED crowding has been extensively described in hospitals in the USA, Canada, Australia and Europe. However, the problem is not limited to developed countries. Although no comparison has been made between crowding issues in developed versus developing countries, lower amounts of resources may result in more severe crowding in developing countries. In this study, patient flow was compared between a hospital in a developing country, and a hospital in a developed country. Identifying key issues and bottlenecks affecting ED patient flow and analyzing the relative importance of contributing factors may provide insight into promising solutions.

Methods: An IRB-approved mixed methods study was conducted at two EDs, both urban Level 1 Trauma Centers. First, a 1-year (August 2014 – July 2015) retrospective cohort study was performed, comparing patients' conditions (including acuity level and final disposition) and crowding measures (including length of stay). Acuity level was registered according to the 5-level triage scales used at the EDs, in which acuity 1 has the highest priority and 5 the lowest priority. To investigate differences and similarities in the quantitative data between the hospitals, we used two-tailed *t* tests, Mann Whitney U tests, and χ^2 tests where appropriate. Statistical significance was assumed at a level of $P < 0.05$.

Second, participant observation and 18 face-to-face interviews were conducted in August and September 2015, focusing on the causes and consequences of ED crowding. Hospital administrators, ED staff, nurse managers, and emergency physicians were questioned individually about what they considered to be the main causes and consequences of ED crowding, using open-ended questions. Observation notes and interviews were transcribed within 12 hours. A member check technique with ED management was used to verify the accuracy and validity of the observations. Qualitative content analysis was used to summarize the views of the interviewees regarding causes and consequences of ED crowding into input-, throughput- and output issues. Analysis of the observations continued with triangulation from other sources (including scientific articles regarding ED crowding).

Results: At the ED in the developing country 58,839 visits (160 patients/day), and at the ED in the developed country 50,802 visits (140 patients/day) were registered. Patients' conditions and ED crowding were worse in the developing country compared with the developed country. Median patient length of stay at the ED of the developing country was significantly longer (279 minutes vs. 100 minutes, $P < 0.001$). Length of stay exceeded 6 hours for 37.9% of the patients at the ED in the developing country, vs. 3.3% of the patients at the ED in the developed country ($P < 0.001$). Almost 17% of the patients of the ED in the developing country were assigned acuity level 1, while only 1% of the ED patients in the developed country were assigned acuity level 1. There were higher admission percentages (35% vs. 21%, $P < 0.001$) and higher mortality rates (1.4% vs. 0.1%, $P < 0.001$) at the ED in the developing country compared with the ED in the developed country.

According to the interviewees from both EDs, crowding occurs on a daily basis. Interviewees mentioned similar reasons for constraints to the patient flow: high patient volumes, long treatment times, and poor availability of inpatient beds. An important reason for long length of stays at the ED of the developing country was the delay in reaching a decision to admit the patient or send the patient home. At both hospitals, delays in the admitting process, mostly due to a shortage of inpatient bed capacity, were mentioned. Solutions to ED crowding in the developing country should focus on improving ED throughput as well as ED output, while at the ED in the developed country the output issues are more important.

Conclusion: Despite differences in patient populations (more severely sick at the ED in the developing country), and in the state of crowding (worse at the ED in the developing country), the causes of ED crowding were the same in both EDs: high volumes, long treatment times, and poor availability of inpatient beds. ED crowding in the developing country can be reduced by more efficient processes in the ED and by increased capacity within the hospital. At the ED in the developed country, the outflow should be improved.

The impact of new interventions to improve patient flow through the ED should be considered carefully. Monitoring the patient flow during a longer period of time allows assessment of the extent to which these interventions foster constructive change.

Q 14 - Public Safety

Using Community Engagement and Multisectoral Collaboration to Address Health and Public Safety

Amber P. Williams, DNP, APRN, FNP, RNC-MNN, USA

Abstract

Problem: Carbon monoxide (CO) is the leading cause of poison related death in the United States, claiming over 400 lives and causing more than 20,000 emergency room visits annually (CDC, 2012). Carbon monoxide is a colorless, odorless, tasteless, and silent gas produced by fuel burning appliances, earning it's name as the silent killer. It is only detectable with CO detectors. Common fuel burning appliances that most Americans use include cars, heaters, ovens, grills, generators, fireplaces, and more. Yet, CO detectors are not required by law or code in many states leaving families, residents, travelers, shoppers, or diners unaware and unprotected where they work, live, play, pray, eat, shop, or learn. In essence, this is a public health concern requiring action from multiple fronts...where no single player is solely accountable for improving outcomes (Kindig & Isham, 2014).

Nurses have always been instrumental in health promotion activities. As a profession, nurses are well suited to lead collaborative community engaged public health activities. Collaboration is an essential driver of community health promotion with the ability to improve population health outcomes (Harper, et.al., 2014). According to Roberts and Jumpper-Black (2016), inclusion of key community stakeholders is critical in all level of the collaborative process. To address CO awareness, a nurse advocate gathered community stakeholders to discuss possible interventions. Multi-sectoral participants included the state fire marshal office, fire chiefs and educators from surrounding communities, the American Red Cross, local legislators, retail restaurant owners, academic nurse faculty, and a non-profit foundation. Together, a plan was developed to address public awareness and home safety related to carbon monoxide. To implement this shared vision, continued collaboration as well an engaged community would be necessary over the next 1-2 years. Communities, due to their intimate character, have the capacity to promote, accept, and sustain health initiatives (Simoes and Sumaya, 2010).

Methods: "Empowered groups and communities plan, enact, and evaluate interventions that affect their collective groups" (Roberts and Jumpper-Black, 2016, p88). Multiple organizations and six communities collaborated to implement a blitz program to assess homes, inform residents, install CO and smoke alarms where necessary at no cost, and protect residents. Each of the six cities' fire chiefs were surveyed for their CO needs. Funding was gained to support equipment and educational materials through grants and donations. Each community pooled its resources and networks to perform a 6 separate one-day blitz events in targeted neighborhoods to install 1000 CO alarms. Community networks included fire departments, fire marshals, sororities, civic organizations, neighborhood associations, Boy Scouts of America, American Red Cross volunteers, public safety officials, city administrators, nurses, police, food retailers, family members, the governor's office, home supply retailers, and many more.

Evaluation: Since CO detectors were not required by law in homes, there is no data on CO detector usage, knowledge, or effectiveness. To address this, a brief survey was included for each home that was entered to gather information. Basic demographic information was gathered regarding number of persons living in the home and their ages. Information about the home included: type of home, type of heat used, number of levels, and number of CO alarms installed.

Additionally, 4-6 months after installation, follow up surveys were conducted on 25% of the homes where CO detectors were installed to evaluate the education provided about carbon monoxide.

Results: During the one-day blitz events, 420 CO alarms were installed. Each of the communities continued to assess homes and install the remaining CO alarms at no cost. Follow up surveys revealed that all homes still had working alarms and respondents knew what to do if it alerts. 1000 families are now CO aware. Communities remain engaged in addressing awareness to prevent poisonings and deaths.

Q 14 - Public Safety

Effects of Insecticide Exposure Prevention Program on Exposure and Blood Cholinesterase Levels in Thai Farmers

Sukanda Worapitpong, MSN, RN, Thailand

Noppawan Piaseu, PhD, RN, APN/NP, Thailand

Abstract

Purpose: The present study aimed at investigating the effects of an insecticide exposure prevention program on exposure and blood cholinesterase levels of farmers.

Specific research objectives were: 1) to compare insecticide exposure levels between the experimental and the control groups after the program 2) to compare blood cholinesterase levels in the experimental group before and after the program and 3) to compare blood cholinesterase levels in the experimental and the control groups after the program.

Methods: This Quasi-experimental research aimed at investigating the effects of insecticide exposure prevention program on exposure and blood cholinesterase levels of farmers. The conceptual framework was guided by Donabedian and the RAMA Model including four components: Raising Awareness at the individual, family and community levels, Aiming at target outcome, Mobilizing change and innovation, and Assuring synergy for home visits and assessments by health teams. Through convenience sampling with inclusion criteria, the sample included 49 radish farmers exposed to Organophosphate consisting of experimental group (n=25) and a control group (n=24). The experimental group participated in a 12-week insecticide exposure prevention program. **The Raising Awareness** included group process at the individual and family levels, and focus group with community leaders, stakeholders, supporters, and healthcare team. **Aiming at target** outcome included community participation aimed to determine problem and set a mutual goal to protect insecticide exposure in community. **Mobilizing change and innovation** consisted of group activity aimed to promote a use of protective equipments, demonstrate role model, encourage a positive reinforcement and exchange of experiences to prevent insecticide exposure. The innovation emerged in this study was the insecticide exposure prevention strategies and environmental safety regulation in the community. **Assuring synergy** involved home visits by health team, prevention of insecticide exposure toward the community rules, and management of the problem. Unexpectedly, during the data collection process, the experimental group experienced the insect outbreak, therefore, they used insecticide more frequently. The control group received a guide book for farmers and routine nursing care. Data were collected from April to July, 2016. Data were then analyzed using descriptive statistics and inferential statistics including Chi-square test, Paired t-test, Independent t-test, Mann Whitney U test.

Results: Results revealed that mean age of the experimental group was 37.04 years (SD = 6.74) and that of the control group was 37.71 years (SD = 9.90). There were more male farmers in the experimental (72%) and the control (70.8%) groups. The insecticides used by the farmers were organophosphate, avermectin, pyrazole, phenylpyrazole, and chloroacetamide. Most of the samples had been using these insecticides for 6-10 years, 3-4 times a week. The subjects' characteristics were not statistical different between the experimental and control groups.

Since the mean scores of insecticide exposure between of the experimental (38.52) and the control (40.83) groups were significantly different before the program ($t = -2.135, p = .038$), mean differences between the experimental and the control groups were compared using Independent t-test revealing that mean difference of insecticide exposure was higher in the experimental (9.72) group than the control (2.63) group ($t = 6.612, p < .001$). The experimental group had insecticide exposure levels at 38.52 before and 28.80 after the program. The Paired t-test showed that after the program, the experimental group had less insecticide exposure level when compared to that before the program ($t = 10.924, p < .001$).

The experimental group had blood cholinesterase levels at 7.01 before and 6.59 after the program. The Paired t-test showed that after the program, blood cholinesterase levels of the experimental group were

not significantly different when compared to that before the program ($t = 1.315$, $p = .201$). Blood cholinesterase levels between of experimental (6.59) and the control (7.46) groups. The Independent t-test showed that after the program, blood cholinesterase level in the experimental group was not significantly different from the control group ($t = 1.343$, $p = .186$).

Conclusion: The results suggest that community nurse practitioners apply the principle of Raising awareness, Aiming at target outcome, Mobilizing change and innovation as approaches for insecticide exposure prevention program in the “farmers’ health clinical”, along with outcome monitoring for sustainability.

Q 15 - Smoking Cessation Interventions

Effect of RCT Testing on a CBPR-Developed Cessation Intervention for Culturally Diverse, Low Socioeconomic Women

Jeannette Andrews, PhD, RN, FAAN, USA

Martina Mueller, PhD, RN, USA

Susan Newman, PhD, RN, CRRN, USA

Gayenell S. Magwood, PhD, RN, FAAN, USA

Karen Kane McDonnell, PhD, MSN, RN, OCN, USA

Janie Heath, PhD, RN, FAAN, USA

Martha S. Tingen, PhD, RN, FAAN, USA

Abstract

Purpose: There are an estimated 4.8 million households living in US government subsidized housing, with the majority of these households led by single African American women. The smoking prevalence of African American women in US subsidized housing neighborhoods is two to three times higher than the African American women in the general population (40-60 % vs. 19 %). The convergence of individual, social, and neighborhood factors for women in subsidized housing creates an environment in which smoking is a social norm.

The purpose of this presentation is three fold: 1) to describe the effect of a recently conducted, CBPR developed, multi-level smoking cessation intervention among African American women living in subsidized housing neighborhoods in the Southeastern US; 2) to compare the results of this randomized controlled trial (RCT) with previous pilot work with these underserved, high-risk communities; and, 3) to analyze the barriers and challenges of sustaining relationships and research efforts with culturally diverse, low-socioeconomic communities over 15 years, scaling up CBPR pilot studies to randomized controlled trials, and social and environmental barriers with communities burdened with fiscal, environmental and social inequities.

Methods: For the recently conducted RCT, a total of n = 409 women in 14 subsidized housing neighborhoods in two Southeastern US states were enrolled in a group randomized controlled trial. Government subsidized neighborhoods (e.g., public housing and Section 8) were included that had at least 100 households in a clustered site and that had not been used in previous studies. Of the 34 subsidized housing neighborhoods in these two regions, the study was implemented in the 14 neighborhoods that met eligibility. Seven matched pairs were formed of the 14 subsidized neighborhoods based on size and geographical location and randomly assigned one neighborhood in each pair to either the treatment condition (*Sister to Sister*) or a delayed control condition. Neighborhoods included in the study ranged in size from 100 to 352 households, with 27-32 participants enrolled in each neighborhood. Intervention neighborhoods received a 24-week multi-level intervention (AKA *Sister to Sister*).

Women in neighborhoods randomized to the *Sister to Sister* intervention received individual, peer group, and neighborhood level strategies. Individual-led strategies were led by paid community health workers (termed “coaches” in the field). The community health workers provided 1:1 contact with participants to reinforce educational content and behavioral strategies from the group sessions, social support with the quitting process, and enhanced self-efficacy with cessation attempts. The community health workers met with participants’ in their homes or a designated place in the neighborhood (i.e., community center) weekly for 12 weeks, every other week for 4 weeks, and every 4 weeks for 8 weeks. A certified smoking cessation counselor led behavioral group sessions in each intervention neighborhood using the *Sister to Sister* handbook based on the Public Health Service Guidelines. The weekly group sessions were initiated during the 1st week of the intervention, with a total of 6 group sessions over a 6-week period. An 8-week supply of transdermal nicotine patches were offered to participants who set a quit date (targeted at week 2 of the intervention) with weekly to bi-weekly supplies administered after the group sessions. Within the 24-week study period, the neighborhood tenant association, in partnership with study staff, implemented at least two neighborhood level anti-smoking activities, such as a memory walk for family members who died from smoking-related illnesses, neighborhood health fair, and/or neighborhood

cookout with anti-tobacco educational handouts. Control neighborhoods received written cessation materials at weeks 1, 6, 12, 18 and a delayed intervention after the 12 month data collection. The primary outcome evaluated in the study was biochemically verified 7-day point prevalence abstinence from smoking assessed at 6 and 12 months.

For the longitudinal analyses, random coefficient models were used to account for the group-randomized trial design.

The previous pilot study conducted 6-8 years earlier, used a quasi-experimental design, with a similarly designed, multi-level intervention (AKA Sister to Sister). A total of 103 women from 2 neighborhoods completed this intervention study. Process evaluation, focus group data, and researcher/community feedback informed barriers and challenges and lessons learned over this 15 year period.

Results: In both the RCT and the investigators' previous pilot work, recruitment and retention (> 90%) goals for participants were met. In the RCT, approximately 86 % of the sample were African American, 34 % had not completed high school or equivalency, and 78 % reported household incomes less than \$20,000/year. At baseline, women, on average, smoked 12.7 cigarettes per day. Although 12 month smoking cessation outcomes in the RCT (12% vs. 5.3%, $p=0.016$; intervention vs. control) were similar to other biochemically validated outcome studies by other investigators in similar communities, the cessation outcomes were lower than the previous pilot study (39 % vs. 11.5 %, $p=0.008$; intervention vs. control) conducted by this investigative team. In both the pilot and RCT, intervention participants who kept community health worker visits, attended group sessions, and used nicotine patches were more likely to remain abstinent from smoking.

There were two major differences observed in the pilot and the larger, scaled RCT: time in the neighborhood and readiness of neighborhoods.

Conclusion: A CBPR developed study with culturally diverse women in subsidized housing showed promise with recruitment and retention in a large randomized controlled trial. While the cessation outcomes were less promising than previous pilot studies conducted by our team, women made serious quit attempts, quit smoking and/or reduced daily smoking over the study period. This landmark study demonstrated the benefits of a CBPR approach to reach, recruit, and engage this highly vulnerable population, however, effectiveness in promoting lifestyle behavior change in environments burdened with poverty and social inequities remain a challenge. Investigators, community partners, and especially funders, must consider and ultimately support the time and resources necessary for the processes of building relationships, trust, and co-ownership with marginalized, culturally diverse groups. Further, as a society, addressing the social determinants of health continue to be a priority in promoting behavior change with these high-risk communities.

Q 15 - Smoking Cessation Interventions

Tribal College Students' Access to and Use of Mobile Communication and Technology for Health Information

Jo Ann Walsh Dotson, PhD, MSN, RN, USA
Lonnie A. Nelson, PhD, USA

Abstract

Purpose: The purpose of this study was to assess the availability and use of cell phones for health education and promotion purposes in two tribal college communities in Montana. The study was completed in preparation for an intervention study examining the effectiveness of a text message delivered tobacco cessation program for tribal college students. The text messaging program was a modification of a successful program developed and implemented in New Zealand (Rodgers et al., 2005). Mobile communications technology is increasingly used for health education and promotion and as a mechanism to support healthy activities. In 2014 it was reported that 90% of the population in the U.S. have cell phones ("Mobile Technology Fact Sheet," 2014). Undergraduate college students in the U.S. are among the most "connected" worldwide, with 92% owning personal laptops and/or cell phones and 98% having internet access (Smith, Rainie, & Zickuhr, 2011). There is limited data about the availability of cell phones and networks in Indian Country and the acceptability of electronic media for health promotion purposes by American Indian college students.

Methods: This project was designed as a descriptive study. The research universities and tribal colleges' Institutional Review Boards determined to study to be exempt. The inclusion criteria were that participants had to be self-reported American Indian, at least a part time student at the TCU and 18 years of age or greater. The twenty two multiple choice questions queried respondents regarding their access to, use of, and preferences regarding cell phone use for health education and promotion purposes. Participants were recruited at the tribal college by student workers and researchers. Participants were given \$10 after completion of the survey. 200 paper/pencil surveys were gathered from two tribal college sites.

Results: Approximately 36% of tribal college students reported smoking. The mean age for tobacco use initiation was 15.7 years, with a range of 8 – 30 years. 98% of students had access to a computer, although less than 60% had access every day. 91% had a cell phone, but not all had unlimited text. Half of the respondents stated they would be interested in participating in a smoking cessation study using cell phones. Variations in characteristics of students and responses was assessed by RUCA code and statistically significant differences identified. Results of the surveys were reviewed and approved by tribal college presidents.

Conclusion: Tobacco use in rural and tribal communities continues to be high, making the development of tobacco cessation strategies that can effectively reach rural populations a priority. Students at tribal colleges in rural settings had less access to mobile communications and technology than students in universities and community colleges. Internet and cellphone use and access varies based on system infrastructure and community placement. Effective development and deployment of health education and promotion requires knowledge of the access to and acceptability of content by priority users.

Q 16 - Technology and Learning Strategies

Active Learning Strategies for Course Enhancement: Monitoring Adverse Event Reporting in Twitter

Janet Thornton, PhD, MS, RN, USA

Abstract

Purpose: Adverse drug event surveillance systems suffer from under-reporting and lags in data-processing (Freifeld et al., 2014). Meanwhile, patients are using Twitter social media to describe adverse drug events, real-time (Bian, Topaloglu, & Yu, 2012). Nursing students with limited clinical experience learn about real-world drug use and side effects from Twitter postings, while learning common pitfalls encountered when working with data. The purpose of this pre-test/post-test experimental study was to evaluate the impact of active learning strategies designed to appeal to six student learning styles: competitive, collaborative, avoidant, participant, dependent, and independent.

Scientific advances, new technologies, and volumes of big data are strong forces influencing the role of nurses, calling for new ways of thinking and teaching. Innovative educational models are needed to prepare safe, beginning practitioners to provide evidence-based care in a complex, rapidly changing healthcare environment. Broad-based skill sets are needed as advances in science and technology continue to emerge. In this Foundations of Research & Evidence Based Practice [EBP] undergraduate course, students learn principles of the research process and gain foundational competencies for EBP, as described by Melnyk & Fineout-Overholt (2015). Using a flipped classroom approach, students apply principles of the research process by comparing Federal Adverse Event Reporting System [FAERS] data and Twitter posts, reinforcing knowledge being learned in a patho-pharmacology course where they are concurrently enrolled.

Methods: Sophomore undergraduate students (N=65) enrolled in this course completed the 60-item Grasha-Riechmann Student Learning Styles Survey to identify the most and least preferred student learning styles. During week 1, a general (Pre-test) scale was used to assess attitudes and feelings toward courses taken up to that point in college. During week 14, students were instructed to assess attitudes and feelings toward the current course after exposure to active learning activities, using a specific (post-test) scale. Students were asked to use a 5-point Likert scale to rate attitudes and feelings (e.g., 1=strongly disagree; 5=strongly agree). Paired sample t-tests were used to compare the mean scores. Cohen's d was calculated to magnitude of the intervention's effect on six learning styles. Students collaborate in groups to create a basic research question involving a drug, evaluate the level of concordance between Twitter posts mentioning adverse events and reports received by the U.S. Food & Drug Administration Adverse Event Reporting System (FAERS) and generate a visual display of data (e.g. bar chart). They conduct a modified integrative review of literature and create a professional poster. Posters are displayed at the School of Nursing; faculty members vote on best posters. The winning group(s) are awarded a ribbon and invited to submit abstracts to present their poster at the College of HHS Student Research Day. Mined Twitter data was compared to data available in the FAERS dataset, to determine if events found on Twitter were consistent with adverse events reported in FAERS. At week 14, they were asked to answer three questions: *what I learned*, *what I most enjoyed in this class*, and *what I would do differently if I took this course again*. Professional posters were developed from an integrative literature review drawn from the PICOT question, following tips for better visual elements in posters and podium presentations .

Results: The average time taken to complete this electronic survey was 5.8 minutes. There were statistically significant decreases on the *Independent*, *Dependent*, *Competitive*, and *Participant Style* scores. The Independent Style results were: Time 1 (M=3.38, SD=0.36), Time 2 (M=3.21, SD=0.41), $t = 2.22$ (63 df), $p < .05$; Cohen's d (0.42) indicating a moderate effect size. Dependent Style results were Time 1 (M=3.81, SD= 0.35), Time 2 (M=3.61, SD=0.34), $t=3.46$ (60 df), $p<.001$; Cohen's d (0.57), indicating a large effect size. Competitive Style results were: Time 1 (M=2.66, SD=0.50), Time 2 (M=2.43, SD=0.53), $t=2.34$ (60 df), $p<.05$; Cohen's d (0.43) indicated a moderate effect size, and Participant Style results were: Time 1 (M=3.96, SD= 0.38), Time 2 (M=3.75, SD=0.44), $t=2.63$ (62 df), $p<.05$; Cohen's d

(0.50), indicating a large effect size. There was a statistically significant increase on the *Avoidant Style* score as follows: Time 1: (M=2.56, SD=0.54), Time 2 (M=2.87, SD=0.58), $t = -3.17$ (60 df), $p < .05$; Cohen's d (-0.56) indicating a large negative effect size. No significant differences were noted for the *Collaborative Style* of learning.

Key themes emerging from the question *What I learned* were: drug adverse events on Twitter are not always the same as those reported in the FAERS data, importance of teamwork, professionalism, and time management, and new skills (APA formatting, Excel, Zotero, One-Drive, Microsoft online, using GroupMe for communications, conducting literature searches, mining databases). *What I most enjoyed*: learning the importance of EBP in nursing and how it will help me in my role as a professional nurse, working in small groups, flipped classroom and active learning methods (as opposed to lectures), trying out new software, creating a professional poster. *What I would do differently*: change or revise my PICOT question, proofread for details, follow instructions more closely, time management skills, delegation in groups, read more of the assigned readings, start sooner to create the poster and literature tables.

Conclusion: Findings from this study have clear implications for nursing faculty who desire to try active learning strategies in the classroom and are ideally suited to those teaching evidence based practice courses. The cost-effective active learning techniques used in this course were designed to help students to become savvy consumers of research, while improving student engagement and satisfaction. Skills learned in this course may be transferred into subsequent courses (e.g. Leadership & Management), serving as a foundation for higher level coursework. Posters can be presented at upcoming university Undergraduate Research Event, showcasing what nursing students are learning. Students found the projects meaningful, interesting, and of importance for their future role as professional nurses and meeting graduate-level expectations. Using Twitter, the publicly available FAERS dataset (which also includes international event reporting), and working in group projects was a popular way to reinforce knowledge needed by nurses around the world (e.g., teamwork, delegation, basic data analysis, awareness of consumer issues, time management, awareness of adverse events, including off-label use of drugs).

Q 16 - Technology and Learning Strategies

Using the "Kahoot.it" Game to Enhance Undergraduate Nursing Students' Learning

Jane M. Kurz, PhD, RN, USA

Frances Kinder, PhD, RN, CPNP, USA

Abstract

Gaming wasn't formally included in nursing education until 75 years ago as an alternative to the traditional lecture method. Today, games as pedagogical platforms are becoming more popular in all areas of education.. These strategies engage the learner in a stimulating manner, appeal to many, and support learning. Individuals of different abilities can play together emphasizing participants' strengths. Feedback is immediate. Group cohesiveness can develop as a result of peer cooperation and team interactions. Nevertheless, educators might be inclined not to use games for a variety of reasons. They tend to be noisy, chaotic and less controllable than lecture presentations. Producing a game and planning for potential problems is time-consuming and labor-intensive. There are articles that describe various games that an educator could use (Bessinger, 2015). However, there has been little research that lends support for game use in improving students' knowledge level. One might ask the research question is: do undergraduate nursing students exposed to gaming in a nursing course have higher final exam scores than students who were not exposed to gaming. Although there are articles that describe various games, there are very few articles that provide empirical evidence to support use of games in the classroom (Davidson & Candy, 2016) . This quasi-experimental study addressed that gap.

Purpose: The purpose of this study was to explore if the "kahoot.it " game was associated with improved final exam scores with undergraduate nursing students. Kahoot.it is a free platform for learning that is engaging and fun. Players answer questions which are created by the faculty. They answer on their own devices and the lesson is shared on a screen in the classroom. Feedback is instant and the game is very competitive. Students can play in teams or as individuals. Adult Learning Theory provided the theoretical foundation for the use of gaming as a teaching strategy (Curran, 2014).

Methods: All 77 senior baccalaureate program students were enrolled in the required 15-week UG Nursing care of Children and Adolescent course. Students ranged in age from 20 to 22 years. All received the same lecture and class discussions but the research group (N=37) played Kahoot.it game in four 20 minute sessions during the semester. The control group (N=40) had no games during their classes. All students had the same final exam at the end of the semester.

Results: Independent t-tests showed that the research group had higher test scores. ($t=4.75$, $p=.01$) than the control group.

Conclusion: This study provided empirical evidence that gaming did make a significant difference in exam scores at the end of the course. Educators should incorporate this game strategy into their planned teaching modalities. Researchers should repeat this study with larger groups of students and test the number of games that need to be played within a single course to influence exam scores.

Q 17 - Theory Into Practice

Factors Influencing Undergraduate Students' Intention to Use Evidence-Based Practice (EBP) After Graduation

Mary-Anne Ramis, MPhil, BN, RN, AFHEA, MACN, Australia

Anne M. Chang, PhD, RN, FRCNA, Australia

Lisa Nissen, PhD, BPharm, AdvPracPharm, FPS, FHKAPh, FSHP, Australia

Abstract

Purpose: EBP education has historically been aimed at teaching EBP knowledge and skills to health professionals to effect a change in clinical behaviour (Young, Rohwer, Volmink, & Clarke, 2014), however, professional registration criteria in nursing and across many health disciplines now requires undergraduate students to be competent and capable of incorporating EBP into their clinical practice upon graduation (Bloom, Olinzock, Radjenovic, & Trice, 2013; Melnyk, 2013; Tilson et al., 2011). Despite this mandate, little research has been undertaken to identify factors which are influential toward student's uptake of EBP in their respective clinical environments. Using Bandura's self-efficacy construct (Bandura, 2012) as a framework, this research aimed to develop and test a model of factors influencing undergraduate health student's intention to use EBP following graduation.

Methods: Variables for inclusion in the model were determined from the theory, current literature and a systematic review of modeling studies predicting student intention to use EBP following graduation. A protocol for the systematic review was registered on the PROSPERO International Prospective Register of Systematic reviews (ID number: CRD42015029263). For the second stage of the research, data were collected via online survey from second year nursing and paramedicine students using validated measurement scales for each variable, to fit the hypothesised model. Structural equation modelling using path analysis methods were used to identify relationships between the dependant and outcome variables.

Results: Variables of student EBP self-efficacy, sources of EBP self-efficacy, EBP beliefs, EBP outcome expectancy and EBP use were found to be correlated to the outcome variable of intention to use EBP and subsequently were included in the model. Data from the first episode of data collection were entered into the modelling software however, the initial model was a poor fit for the data. After modification according to the parameters as suggested from the initial analysis report, the model was tested again using Maximum Likelihood analysis. The model fit indices (Blunch, 2012) for the modified model indicated a good fit ($\chi^2 = 9.04$, $df = 6$, $p = 0.171$; $GFI = 0.982$; $AGFI = 0.936$; $Standardized\ RMR = 0.0451$; $RMSEA = 0.046$), identifying undergraduate health student's intention to use EBP as being directly influenced by EBP beliefs, with the overall model identifying 25 % of variance of intention to use EBP.

Conclusion: Positive attitudes and beliefs that EBP is relevant and beneficial impact significantly on student's intention to use EBP, which has particular relevance to EBP educators. A high correlation between EBP expected outcomes and EBP self-efficacy was identified suggesting students do expect improved outcomes for the steps of the EBP process, however, this did not directly influence their intention to use EBP. Further research will be conducted to validate the model with a separate cohort of undergraduate students as well as further analysis of factors' influencing health undergraduate's current use of EBP.

Q 17 - Theory Into Practice

Strategies to Promote Student Publication in an Evidence-Based Practice Course

Margaret Harvey, PhD, APRN, ACNP-BC, USA

Abstract

Purpose: The purpose of this session is describe innovative teaching strategies used to enhance student manuscript preparation, submission, and publication of scholarly work completed during an EBP course.

Methods: Students enrolled in a graduate, evidence based practice course completed a pretest/post-test survey assessing their knowledge, skills, and attitudes regarding various teaching strategies designed to enhance student scholarship and manuscript preparation. Students were assigned to work in small groups based on their clinical practice area and develop a relevant PICOT question. Keywords were identified, appropriate databases were queried, and articles meeting selected criteria were critically appraised. Students registered for the free web based citation manager and imported all selected references to their respective group folders. Once an appropriate journal was selected, students prepared a systematic review using the specified submission guidelines for that journal. The course faculty mentored each group, reviewed, edited, and submitted the manuscript as the corresponding author. Students also submitted an abstract of their findings as a group poster presentation to a selected national conference.

Results: A 12 item survey was developed to assess the knowledge, skills, and attitudes of student's attitudes toward scholarship and ability to prepare and submit a manuscript based on a clinically relevant PICOT question. The tool was found to have a moderate degree of internal consistency with a Cronbach alpha 0.76. Seven of the 12 survey items addressing student confidence in appraising the literature, effective team work, and ability to translate research in to evidence based protocols were statistically significant (Paired t test, $p < 0.05$) There was no difference in scores related to future plans to submit posters and manuscripts or improved ability in using the web based citation manager. Of the seven manuscripts, five were submitted for publication, two were rejected, two were accepted for publication with minor revisions and one was accepted pending major revisions. All of the abstracts were accepted by national conferences for poster presentation.

Conclusions: Employing a small group approach with faculty guidance can enhance student manuscript preparation and publication. There were some technical issues with the web based citation manager that limited its usefulness. Major obstacles were found during the revision process for those manuscripts originally accepted due to time restraints and faculty work load issues. Submitting only one exemplar manuscript for publication and focusing on poster development and presentation is a more strategic and effective learning strategy in this setting.

R 02 - Experiences of Pregnant Women

Improving Care of High-Risk Obstetrics Patients By Creating an Evidence-Based Nurse-Driven Process

Holly A. Barbella, MSN, MBA, RN, USA

Grant C. Walter, BS, BS, USA

Ann F. McFadden, BSN, RN, USA

Abstract

Preterm birth complicates one out of every eight pregnancies in the US. A rural health system in north central Pennsylvania wanted to evaluate the most effective treatment modalities in trying to reduce preterm births. A collaborative interdisciplinary healthcare team, under nursing leadership was created to explore options. One additional aspect was the lack of process when identifying eligible high risk patients who might be eligible for intervention/treatment.

An evidence based practice (EBP) project utilizing the John's Hopkins Model of EBP was initiated. The goal of the project was to evaluate the overall effectiveness of 17-P (an injectable progesterone medication initiated between 16-20 weeks' gestation and given weekly until 37 weeks) as well as which high risk obstetric patients should receive the medication and its effectiveness at difference stages of the pregnancy. In addition, the project evaluated how to best reduce delays in treatment initiation. Literature was evaluated, specifically considering articles and publications that referred to clinical guidelines, clinical trials, medication information, and committee/expert opinions. All research articles and literature were evaluated per the Hopkin's Model. **Results** demonstrated that use of 17-P does reduce preterm deliveries in varying degrees depending on gestational age of initiation and patient medical history. Additionally, the EBP project confirmed patient eligibility criteria included prior spontaneous, preterm, singleton delivery.

Based on results from the EBP project, the nurse led collaborative team was continued and the following additional goals were developed: administer 17-P at 16 weeks, educate staff and patients as to the benefits of 17-P and streamline a nurse driven process utilizing the Electronic Medical Record (EMR). Three screening questions were developed incorporating recommendations from findings identified from the EBP project and embedded in the EMR. The process also included nurses screening all new obstetric patients with the questions at the initial new OB visit. If the screening questions identified an eligible patient, providers then received an electronic notification alerting them of an at risk patient in order to provide counseling, order the 17-P and begin the precertification process for insurance. Staff communication, the development of staff and patient education, use of team meeting updates, and formal Grand Rounds were utilized.

To evaluate the patient identification process (nurses completing the screening questions) a monthly report was created. The report showed screening compliance by each department and was distributed to the nursing and leadership staff for evaluation. This feedback was marginally successful - raising overall system compliance from 40% to over 60%. It was determined that more targeted data was needed, and a report was additionally developed that provided individual nurse compliance with the screening process. This report was also electronically distributed on a monthly basis. Step by step instruction of how to properly perform and document the screening questions was also included as process reinforcement. Process compliance dramatically increased from 60% to over 85% in only a few short months.

In addition to screening compliance, initial injection data for eligible patients was also tracked. Before a screening process was created, the average gestational age for the first injection was 22.5 weeks, which was well over the recommendation of 16-20 weeks. Administration data from the latest quarter in 2016 shows the average initiation is now at 17.5 weeks' gestation.

During reflection of the entire EBP project, the need for standardized work processes that are reliable across large service areas and multiple practices was recognized as the key for the improvement in outcomes. Transparent data shared regularly that were attributable to individuals provides a driving force

for increased compliance. In addition, recognizing high performers and sharing success stories with other teams empowered team members to remain focused on improving patient outcomes.

The poster or oral presentation will explain the EBP project and results, the electronic and process improvements, details of education accomplished, graphs showing interventions and follow-up, and how other nurses/healthcare facilities could integrate the same project.

R 02 - Experiences of Pregnant Women Differences Between Chinese and American Women and Their Experience of Stress Urinary Incontinence in Pregnancy

Jinguo Helen Zhai, MSN, RN, RM, China
Lynda A. Tyer-Viola, PhD, RNC, FAAN, USA
Joseph Hagan, PhD, USA

Abstract

Purpose: Stress urinary incontinence (SUI) is a common health problem for childbearing women with a prevalence rate that varies between 30-60% (Fozzatti et al., 2012). Although known to be prevalent in women during pregnancy and postpartum, urinary incontinence is associated more with women during the menopausal stage of life. Urinary incontinence can create health problems such as chronic skin breakdown and urinary tract infections as well as social isolation and decreased physical activity (Gandheri & Oskouei, 2014). Recognizing the presence and significance of SUI during pregnancy may be key to preventing exacerbation of SUI later in life. The lack of understanding of the relationship between pregnancy related SUI and its effect throughout the life span may affect long term quality of life. Due to the social stigma of the problem, nurses are uniquely positioned to care for these women. The health system can either provide support or be seen as a barrier to women expressing this care concern. Examination of SUI in a multi ethnic population of pregnant women cared for in the same health system revealed significant differences related to ethnicity (Bo, Oglund, Sletner, Morkrid, & Jennum, 2012). How SUI is perceived by different ethnic groups of women, cared for in two unique health care systems has not been explored. Treatment options require engagement with an array of health professionals such as a nurse, physical therapist, and/or behavioral health provider. Treatment can include medication, physiotherapy, and lifestyle behavioral therapy combinations (Ghaderi & Oskouei, 2014). The choice of treatment may be guided by culture and healthcare system beliefs. The purpose of this study is to explore the experience of severity of stress urinary incontinence during pregnancy, its prevalence and associated risk factors, acceptance of treatment options and its effect on quality of life.

Methods: A descriptive cross sectional design was used at two care sites: Guangzhou China and Houston Texas. A total of 356 postpartum women in China and the United States of America (USA) responded to an in person survey between September 2014 to September 2016. Primigravida women were enrolled during the postpartum period to assess their perceptions of SUI during their index pregnancy. One researcher collected data in both sites. All women completed a short demographic survey and two known validated measures: The Incontinence Impact Questionnaire (IIQ) and the International Consultation on Incontinence Questionnaire Short Form (ICIQ-SF).

Results: There were significant differences in demographics between the two groups. American women had less health problems prior to pregnancy ($p = .01$) and had higher education ($p = .00$) whereas more Chinese women were married ($p < .001$) and worked outside the home ($p = .00$). American women rated their state of health postpartum significantly greater than Chinese women ($p = .00$). Overall, 37% of women experienced urinary incontinence with Chinese women having experienced more incontinence than American women ($p = .0001$). More Chinese women experienced an episiotomy than American women. More women in China would consider prevention and treatment during pregnancy ($p < .0001$). Chinese and American women both exercised before and during pregnancy with differences noted related to time and intensity ($p < .001$). There are significant differences between acceptable prevention and treatment interventions ($p = .00$). All women would welcome pelvic floor conditioning with few opting for medication or surgery. There are no differences between Chinese ($M = 1.22$ $SD = 0.58$) and American ($M = 1.23$, $SD = 0.72$) women between the ICIQ-SF scores. There were significant differences related to the IIQ impact of incontinence on quality of life measure ($p = .001$).

Conclusion: There are significant differences between Chinese and American women related to prevalence, the presence of the risk factors and acceptable prevention and treatment interventions. Matching women's beliefs and understanding with acceptable treatment in relationship with the culture of

the society and health care system, may improve care over time. Nurses in both cultures are viewed as supportive care providers that could assist with prevention and care for women who experience SUI.

R 02 - Experiences of Pregnant Women

Experiences of Women With Physical Disabilities Related to Pregnancy

Suzanne C. Smeltzer, EdD, MS, RN, ANEF, FAAN, USA

Monika Mitra, PhD, MA, USA

Lisa I. Iezzoni, MD, MSc, USA

Linda Long-Bellil, PhD, JD, USA

Lauren D. Smith, MPH, BS, USA

Abstract

Purpose: The purpose of this IRB-approved study was to explore the pregnancy-related experiences of women with physical disabilities by obtaining their descriptions and perceptions of their experiences during the perinatal period as well as their recommendations for obstetric clinicians to improve perinatal care of women with physical disabilities. This study is significant because generations of women with disabilities have experienced barriers to health care, including in accessible offices, problematic interactions with health care providers and negative responses related to pregnancy and childbearing from health care professionals and others (Iezzoni, Wint, Smeltzer & Ecker, 2015; Mitra, Long-Bellil, Smeltzer, & Iezzoni, 2015).

Methods: This qualitative descriptive study (Colorafi & Evans, 2016), which is part of a larger mixed-method study of pregnancy-related experiences of women with physical disabilities, was conducted through telephone interview. Women with physical disabilities were recruited for the study through a variety of social media sites and contacts with community-based disability organizations. Thirty-one women responded to the invitation to participate. Following screening, 25 women who met the inclusion criteria of having delivered a newborn within the last 10 years, having a mobility limitation, and being between the ages of 21 and 55 at the time of the study were interviewed by phone.

Individual interviews were conducted by two members of the research team using a semi-structured interview guide based on literature, a preliminary focus group, and the results of the researchers' previous research and experience working with women with disabilities. Among other topics related to perinatal experiences, women were asked about their interactions with obstetric clinicians (obstetricians, nurse midwives, nurse practitioners, nurses) during pregnancy; they were also asked for recommendations for clinicians about how to ensure positive perinatal experiences for women with physical disabilities. Traditional content analysis was used to analyze the transcriptions of the interviews. The transcriptions of the interviews were independently read by members of the research team to identify salient points. The research team then used those salient points to identify categories of concerns related to interaction with clinicians and recommendations related to those concerns made by women for the health care providers. The transcriptions were again reviewed to identify specific examples of their interactions and the recommendations provided by the women. Codes were continuously revised and final themes with supporting examples of women's quotes were identified.

Results: The mean age of women in the study at the time their youngest child was born was 37.4 + 7.0. Fifteen women reported that their pregnancies were planned and ten reported unplanned pregnancies. Women reported diverse disabling conditions causing physical disability. Three themes emerged from analysis of the interview data: 1) clinicians' lack of knowledge about pregnancy-related needs of women with physical disabilities; 2) clinicians' failure to consider knowledge, experience and expertise of women about their own disability; and 3) clinicians' overall lack of awareness of reproductive concerns of women with physical disabilities. Women provided specific recommendations related to each of these themes and warrant attention by clinicians who interact with women of childbearing years who live with physical disabilities.

Conclusion: Women experienced problematic interactions with clinicians related to pregnancy and childbearing. They identified specific recommendations for clinicians to address those problems with the goal of improving perinatal health care for women with disabilities. These recommendations, if followed have the potential to improve the health of women with disabilities during the perinatal period

R 03 - Promoting Evidence-Based Practice

A Systematic Review of the Factors Influencing Healthcare Managers' Engagement in Evidence-Informed Practice

Pamela E. Baxter, PhD, RN, Canada
Sarah J. Hewko, MHA, RD, Canada
Kaitlyn C. Tate, BScN, RN, Canada
Patrick B. McLane, PhD, MA, Canada
Carly A. Whitmore, BScN, RN, CPMHN(c), Canada
Greta G. Cummings, PhD, RN, FCAHS, FAAN, Canada

Abstract

Purpose: Provision of quality care is dependent on both the progressive application of evidence-based medicine and the adoption of evidence-based management practices, which create the capacity for an organization to effectively standardize evidence-based care (Shortall, Rundall & Hsu, 2007). Despite general support among health care leaders for evidence-based approaches to clinical practice, many have been slow to approach their managerial practice with a similar lens (Hewison, 1997). We know relatively little about the knowledge practices of healthcare managers, particularly as it relates to the application of research evidence in their management practice (Lomas 2005). To fill this gap in the literature, we have conducted a systematic review of the international literature with the goal of isolating factors predictive of research use in the management practice of healthcare leaders.

Methods: This review was conducted concurrently to a related review examining interventions to enhance healthcare managers' use of research evidence in their management practice (Tate et al. *In Preparation*); we conducted a single search and filtered studies to one review or the other (or both) as appropriate. Inclusion and exclusion criteria, set *a priori* by the complete research team (n = 7) were applied independently by two reviewers at both the title and abstract review stage and the full-text manuscript review stage. Included studies must have reported on a primary study of healthcare managers, in which the goal (at least in part) was to identify factors related to healthcare managers' use of research in their management practice. *Healthcare managers*, for our purposes, were defined as persons employed in a formal management/leadership position at any level in a healthcare delivery organization (e.g. vice president, director, executive, manager). Studies were excluded if the subjects were primarily policy-makers, if the focus was on clinical decision-making, or if, in the study, knowledge use was defined so broadly as to include non-research evidence. *Research evidence*, for our purposes, was defined as researcher-produced evidence that had been developed in accordance with standard scholarly practices.

An academic librarian specializing in health sciences aided the research team in developing a comprehensive search strategy. We conducted our search in ten electronic databases including (but not limited to): CINAHL, MEDLINE, PsycINFO, Cochrane Database of Systematic Reviews and Business Source Complete. Key search terms included "decision-maker/making," "research use/utilization" and "healthcare managers/management."

For all studies meeting inclusion criteria, we extracted relevant methodological details and results into a standardized data extraction template. Each extraction was completed by one member of the research team and validated by another. Each included study also underwent quality appraisal, conducted independently by two team members. We appraised all qualitative papers using Letts, Wilkins, Law, Stewart, Bosch and Westmoreland's Critical Review Form – Qualitative Studies (Version 2.0) and all quantitative using Cummings et al.'s (2008) tool, which has been employed in multiple reviews to appraise cross-sectional, correlational and exploratory studies. Studies containing both qualitative and quantitative results were evaluated using both appraisal tools. Studies at all quality levels (low, medium, high) were included in the synthesis of results.

In order to organize and subsequently analyze the findings we used the PARIHS framework (Rycroft-Malone, 2004). This framework contains three core concepts: context, facilitation and evidence (Rycroft-

Malone, 2004). These three concepts were used as the initial rows for a matrix which were applied to the data. Each study was read and reread by PB, new themes and subthemes were added to the matrix as required (not captured by the three categories) under each of the themes. Additional rows were added as needed. An 'x' was placed in the matrix when a theme or sub-theme was identified in a study. Once the final themes and sub-themes were agreed upon by the research team, a final matrix was developed and applied to all included articles, which resulted in the final synthesis.

Results: From the data, we identified three major influencing factors; context, facilitators, healthcare manager characteristics. The evidence strongly suggests that organizational context plays a key role in determining whether or not the healthcare manager uses evidence to support/inform his/her practice. Factors within the organizational context include; the level of commitment within the organization to support and implement evidence-informed management practices, the amount of value placed on evidence-informed practice by the organization, organizational expectations related to the use of evidence in practice, the presence of organizational policies and mandates that support and/or promote evidence-informed healthcare manager practices, and the organization's philosophy related to the use of research evidence. Facilitators of evidence informed healthcare manager practice include having access to adequate human and non-human resources. Human resources included; adequate library services (librarian, library technicians) and support, knowledgeable staff (as it relates to research and evidence-informed practice), and other organizational leaders who could promote and support those wanting to implement evidence into practice. Non-human resources included; time to search, read, and apply research evidence to management practices, access to data/resources and a technical infrastructure capable of supporting evidence-informed practice. Healthcare manager characteristics also played a significant role in influencing whether or not he/she used research evidence in their practice. The lack of understanding of what evidence-informed practice is, the lack of training in research and/or the lack of personal research experience all limited the manager's use of evidence in healthcare manager practice.

Conclusion: Without a supportive environment and the necessary resources (human and non-human) within that environment health care managers (with or without knowledge of evidence-based practice) are much less likely to engage in evidence-based practice. More attention must be paid to supporting healthcare managers (using a variety of strategies) to engage with the research evidence to inform healthcare management practices.

R 03 - Promoting Evidence-Based Practice

Influence of Nurse Social Networks on Evidence-Based Practice (EBP): Results of an Exploratory Study

Nan M. Solomons, PhD, MS, USA

Judith A. Spross, PhD, RN, FAAN, USA

Gerri Lamb, PhD, RN, FAAN, USA

Abstract

Purpose: Nurses' adoption of and adherence to evidence-based practice (EBP) has been an ongoing concern for more than four decades (Eaton, Meins, Mitchell, Voss, & Doorenbos, 2015; Squires et al., 2011). Efforts to improve nurses' EBP adoption and adherence rates have demonstrated few results (Hanrahan et al., 2015; Thorsteinsson & Sveinsdottir, 2014). Findings by Benner et al. (1997), Pravikoff et al. (2005), and Estabrooks et al. (2005) suggest that nurses prefer to obtain clinical information through communication with colleagues, that is, their social network. Even though research on quality improvement and EBP suggest that relationships and communication are relevant, few studies have used social network methods to examine the role communication may play in the effective adoption of and adherence to EBP (Chambers, Wilson, Thompson, & Harden, 2012; Cunningham et al., 2012). The purpose of this presentation is to examine the relationship between nurses' communication patterns (who talks to whom) and their perceptions of the quality of that communication, concepts integral in understanding nurses' adoption of EBP. The findings here were part of a larger study exploring how communication patterns and communication quality were related to use of evidence-based transitional care practices.

Theoretical model: The model developed for this study was informed by diffusion of innovations theory (Rogers, 1995), social network theory, quality improvement and EBP literature, and relational coordination theory (Gittel, 2002). Rogers' diffusion of innovations theory is one of the most common frameworks for EBP research. His emphasis on the role of communication in spreading innovation provided an important bridge to social network theory and research. Many of Rogers' concepts like communication channels and boundary spanning have been elucidated and operationalized in social network research (Cunningham et al., 2012; Valente, 2010). Social networks are comprised of nodes (people or groups) and ties, the connection between nodes. Ties are characterized as strong or weak. Strong ties have a common background and possess the same knowledge whereas weak ties do not share a common background and have different sources of knowledge (Burt, 2007). Social networks comprised of strong ties are more interconnected and inwardly focused (Granovetter, 1973). Key social network scientists like Granovetter and Burt have demonstrated that the strength of the relationship and the position of the individual within the social network can influence the quality of the communication. Social network concepts operationalized in this study include density, fragmentation, and centrality.

Conceptualization of the quality of communication and its impact on care quality draws from the quality improvement and EBP literature. In a national ICU study, Shortell and colleagues (1992) reported that ICUs with high communication scores had better patient outcomes. High performing ICUs were not only more likely to be communicating within their unit but also communicating regularly with other units within the hospital and with the administration, more so than lower performing units. Two factors reported by Shortell and colleagues (1992) were the importance of open and accurate communication. Similarly, findings from the EBP literature report that nurses often obtain information from each other (Eaton et al., 2015; Thorsteinsson & Sveinsdottir, 2014) because it is relevant and timely (Estabrooks et al., 2005).

Relational coordination theory (Gittel, 2002) provides support for the link between the relational aspects of communication flow and communication quality identified by Shortell et al (1992). Gittel (2002) found that initially the relationship was the primary influence on communication quality; over time she found that influence was bidirectional: communication influenced the relationship and the relationship influenced communication.

Diffusion of innovations theory often informs EBP research (e.g. Eaton et al. (2015) and Hanrahan et al. (2015)). The addition of social network theory and methods allows a more granular examination of the roles of relationships and communication in EBP adoption and adherence.

Methods: A convenience sample of 10 adult medical-surgical units from six hospitals, five home care agencies, and six long-term care facilities was used. A total of 273 hospital staff (nurses, discharge planners, supervisors and Certified Nursing Assistants) and 69 post-acute (home care and long-term care) staff were surveyed. Analysis and discussion of post-acute data are outside of the scope of this presentation.

Hospital staff completed surveys about two communication patterns, one for patient care and one for patient discharge; communication quality; relationship quality; and demographic characteristics. Post-acute care staff completed a similar, abbreviated survey.

Communication patterns Nursing and discharge planning staff were asked to indicate their frequency of communication over a 30-day period for each staff person. Frequency was measured using a 5-point Likert scale, ranging from 1, not at all to 5, daily. Higher values of frequency corresponded to greater tie strength.

Communication quality Communication quality was measured using the ICU Nurse-Physician Questionnaire (Shortell et al., 1992) within-group communication scale, comprised of three subscales: (a) within-group openness (four items), (b) within-group accuracy (four items), and (c) within-group timeliness (three items). Items were measured using a 5-point Likert scale ranging from 1, strongly disagree to 5, strongly agree.

Results: The level of analysis for this study was at the unit level. Social network measures described the communication patterns across the unit. Statistical significance was set to .10 due to the exploratory nature of the study. Each communication pattern variable was correlated with each communication quality variable. Non-parametric correlation was used because social network data do not have a normal distribution (Borgatti, Everett, & Johnson, 2013). Before describing the results, it may be helpful to define the social network variables.

Density is a measure of overall cohesiveness among nodes in the social network; when density is high there is greater cohesiveness within the social network. *Fragmentation* is a measure of the presence of cliques or subgroups within the social network (Wasserman & Faust, 1994); when fragmentation is high there is low cohesion overall and a greater number of subgroups within the social network. *In-degree centralization* is a measure of hierarchy (Freeman, 1978). When in-degree centralization is high then communication is centralized among a few nodes; in contrast, when in-degree centralization is low, communication is decentralized within the social network. The results and the interpretation are reported by communication quality variable.

Communication Openness: Density and in-degree centralization were both strongly, negatively, and significantly associated with communication openness ($r_s(10) = -.80, p = .005$; $r_s(10) = -.57, p = .083$, respectively). The strength and direction of these associations in this study suggest that highly interconnected social networks with centralized communication may not be conducive to innovative ways of thinking. In contrast, the third social network variable, fragmentation, was strongly, positively, and significantly associated with communication openness ($r_s(10) = .72, p = .018$). The strength and direction of this association in this study suggests that EBP adoption is more likely to occur within small groups rather than larger groups.

Communication accuracy: Density was strongly, positively, and significantly associated with communication accuracy ($r_s(10) = .56, p = .093$). The strength and direction of this association suggests that social networks which have greater interconnectedness are more likely to believe that the information received from other members in the social network is correct. In contrast, fragmentation was moderately and negatively associated with communication accuracy ($r_s(10) = -.49, p = .15$), a finding that approached significance. The strength and direction of this association suggests that communication received from

other groups is not perceived to be as accurate as the communication from within the group. In-degree centralization was moderately and negatively associated with communication accuracy ($r_s(10) = -.34$, $p = .334$). The moderate strength and direction of this association suggests that there may be another unmeasured variable such as leadership style, teamwork, or demographic variables that would contribute to a hierarchy among unit staff.

Communication timeliness: There were no statistically significant relationships between the social network variables (density, fragmentation, and in-degree centralization) and communication timeliness ($r_s(10) = .06$, $p = .868$; $r_s(10) = .36$, $p = .343$; $r_s(10) = -.08$, $p = .828$, respectively). It is possible that the social network variables dropped from analysis—diameter, core-periphery, and average path length—may have led to different findings, given the role of these variables in the model.

Limitations: In general, social network analysis requires at least a 50% response rate, especially for measures that represent distance (core-periphery, diameter, average path length) (Borgatti, Carley, & Krackhardt, 2006). Response rates among some units in the sample were less than 50%; therefore, measures of distance were removed from the analysis. Other social network measures such as density, fragmentation, and in-degree centralization maintain reliability at lower response rates (Borgatti et al., 2006) and were included in the analysis.

Conclusion: The research question arose from findings in the EBP literature that nurses turn to each other for information, a finding that has been deemed at least puzzling and perhaps even concerning (Squires et al., 2011). The model and findings from this study suggest that understanding nurses' social networks may help us understand this reported phenomenon and why and how nurses' social networks contribute to or impede adoption of EBP. Implications for design and implementation of future research will be discussed.

R 03 - Promoting Evidence-Based Practice

Driving Evidence-Based Practice Through Remote and/or Mobile Applications

Kim Tharp-Barrie, DNP, RN, SANE, USA

Tracy Williams, DNP, RN, USA

Abstract

Purpose: The pilot study investigated the efficacy of a mobile application designed to facilitate critical thinking and clinical reasoning at the bedside, specifically related to nurse-sensitive quality indicators and core measures, or more specifically those healthcare acquired conditions we are all charged with managing and eliminating from our organizations. The mobile web application pilot provided resources in the navigation and management of one nurse-sensitive quality indicator Catheter Associated Urinary Tract Infection (CAUTI), and two core measures, Acute Myocardial Infarction & Stroke (AMI, STK).

Methods: Use of mobile application devices were coupled with the use of Remote Management for rapid response within system and to all designated “partners” (i.e. nursing home, LTAC, etc.) via tele-monitor and/or teleconference with facility prior to patient transfer. Center to be staffed with 24/7 Acute Care APRN. Traveling/On call APRNs to respond either remotely or on site to view and review all patients requesting and /or requiring transfer to acute care.

Results: The pilot included: one healthcare acquired condition (CAUTI), two core measures (AMI, STK), and a medication calculator. Early feedback from the participants prompted few changes in algorithms. An overwhelming interest indicated a need for adding more nursing sensitive indicator bundle and core measure algorithms. Seamless updates to the mobile web application are planned to remain current with the latest evidence-based practice recommendations established by regulators such as the Centers for Medicare and Medicaid Services (CMS) and The Joint Commission and national experts such as the Agency for Healthcare Research and Quality (AHRQ).

Conclusion: Hospitals are increasingly developing policies and procedures to restrict the use of mobile devices in the clinical arena. Caution should be exercised before instituting policies that will limit point of care nurses from accessing valuable resources, devices, and methods required to optimize the acquisition, retrieval, and use of information in health to inform clinical decisions—the very purpose of informatics in healthcare. To date, seven additional core measure sets have been added, four additional nurse sensitive quality/safety indicators have been added, an icon was placed on nursing workstations for easy access to the point-of-care bedside mobile application, and continued collaboration with leadership on allowing cellular devices in patient care areas is on-going.

R 04 - Quality Improvement Outcomes

Implementation and Sustainability of Quality Improvement (QI) in Home and Community-Based Service (HCBS) Settings

Kathleen Abrahamson, PhD, RN, USA
Heather Davila, MPA, USA
Christine Mueller, PhD, RN, FAAN, USA
Greg Arling, PhD, USA

Abstract

Purpose: Home and community-based services (HCBS), defined as receipt of support services in one's own home or other community setting, have been expanding rapidly since the 1980s, when the United States (US) Congress enacted section 1915(c) of the Social Security Act. Continued growth and expansion of HCBS and efforts to better integrate health and social services have sparked national interest in improving the quality of community-based services. Increasingly, QI processes are promoted by US agencies seeking to improve the quality "value" received from monetary investment. Within healthcare, the majority of QI efforts have taken place within hospitals, nursing facilities, and other institution-based care delivery environments. Across settings, nurses are often involved in leading QI efforts. Little is known about the implementation of QI in HCBS settings and it remains unclear whether QI principles can be effective within the variable, diffuse, individual-focused organizations that comprise the HCBS delivery network.

The objective of this study was to explore HCBS providers' perspectives of organizational readiness for QI in regards to motivation, structure, capabilities and QI experiences early in the project implementation phase. Additionally, follow-up data was collected from HCBS providers six-months after project completion to gather provider perceptions of project impact, sustainability, and availability of resources to maintain improved processes and outcomes.

Multiple models of innovation uptake and change processes note organizational readiness as a key component in the success of organizational change efforts. The current analyses examine readiness at the organizational level using the constructs of organizational readiness: motivational readiness (perceived need for improvement and training, pressure to change from internal or external forces); institutional resources (adequacy of space, staffing, training and technology); staff attributes (efficacy, influence, adaptability and desire for growth among employees); and organizational climate (clarity of mission, staff cohesiveness, autonomy, stress, openness to change and open communication).

Methods: The sample for this study were participants (52 respondents within 27 provider organizations) in a state-sponsored QI program, the Minnesota Home and Community-Based Services Performance-Based Incentive Payment Program (HCBS PIPP), which funded QI projects developed by HCBS providers. The number of respondents per organization ranged from 1-4, with a mode of 2 per organization. Projects that were selected for funding through HCBS PIPP aimed to improve the quality of life of older adults and people with disabilities in a measurable way; improve the quality of services in a measurable way; and/or deliver good quality services more efficiently. Fifty-eight agencies applied for HCBS PIPP support and 27 projects were funded. Funded agencies varied considerably, ranging from large home care agencies with a wide consumer base to small social service agencies serving a narrowly defined population. Projects were funded initially for one year; 17 agencies completed their work in one year and the remainder received extensions of 3 to 12 months. The HCBS PIPP provided a unique opportunity to examine provider perspectives of organizational readiness for QI within a diverse set of HCBS organizations.

A pencil and paper survey addressing 17 domains of QI capacity, readiness, implementation and impact was administered to participants attending a conference for HCBS PIPP participants in January, 2015 (about 6 months after the HCBS PIPP-funded QI projects started). The survey was designed to capture a comprehensive view of HCBS PIPP providers' perspectives of their organization's capacity for QI. Each of the 17 domains contained multiple survey items. Survey items were presented in Likert-scale format. At

least 6 months after project completion a follow-up survey was delivered on-line to HCBS-PIPP funded organizations. This latter survey addressed perceptions of project impact, sustainability, and factors that were barriers and/or facilitators to project success.

Descriptive statistics and frequencies were calculated for each survey item. Independent t-tests were used to determine significant differences in means based on organizational characteristics. A p-value of ≤ 0.05 was considered to be significant. For purposes of analysis, organizations were coded based on five major characteristics: residential services delivery (versus non-residential services), population served (older adults versus not specifically older adults), amount or level of prior experience with QI, structure (multiple participating sites versus a single site), and project size (>100 consumers or < 100 consumers affected or served by the project). Analyses were performed using SPSS version 23.

Results: The three factors most frequently noted as essential for QI participation were support from top leadership, having someone to write the HCBS-PIPP proposal, and having someone available to lead project planning. Top apprehensions surrounding participation in HCBS PIPP were choosing the right area for QI, coming up with a “really good” project, measuring quality, meeting project goals, and sustaining the project after funding. Primary resources needed by respondents to support QI included staff members who are trained in QI techniques and processes, as well as existing structures within the organization to manage QI implementation. Almost half of respondents reported making good progress in areas that were not yet fully established in their organization such as having a written description of their QI program (46%), and having a means to obtain consumer input (47%). Conversely, only 17% of respondents reported using a QI model such as the PDSA cycle or LEAN to guide their QI efforts and only 23% had a fully established evaluation plan for their QI project. It is notable that three fourths of respondents reported not having an established evaluation plan despite the HCBS PIPP projects being underway at the time of initial survey administration.

Respondents from organizations that provided residential services reported significantly less experience with QI implementation, greater use of root cause analysis, and increased use of internally-generated data reports to aid QI efforts than respondents from organizations providing only non-residential services. Respondents from organizations that served primarily older adults reported significantly more experience with QI implementation, greater use of root cause analysis, higher average organizational designation of someone with responsibility for QI, and less established identification of a set of quality areas that the organization wanted to monitor than those serving younger consumers. Additionally, respondents from organizations that served more than 100 consumers reported significantly more experience with implementing QI and more frequent designation of someone with responsibility for QI. Representatives from larger organizations (those serving > 100 consumers) noted connecting with other organizations to share ideas as a significant weakness and meeting the basic needs of consumers so there is more time to think about QI as a significant strength, in comparison to smaller organizations.

The follow-up survey addressing project sustainability, administered at least 6 months after project completion, revealed that most projects used project funds to hire a project coordinator, additional staff members, or to purchase/rent equipment. Most providers perceived significant improvements in quality within the project focus area, consumer quality of life, and consumer satisfaction. Although most noted that most of the project remained intact after completion of HCBS funding, funding project coordinator time and additional staff was a challenge. Turnover of staff and training newly hired staff was an additional concern. Those who were able to sustain parts of the project noted budgetary support from top leadership and redirection of resources toward the project to be successful strategies.

Conclusion: Internal resources available to support QI varied widely between participating organizations, with differences observed between smaller and larger agencies, as well as between provider types and populations served. Project funds were often used to provide additional staff, staff training and equipment. Directing funds toward tangible items became a challenge to project sustainability when funding concluded. Providers listed multiple innovative approaches to sustaining QI impacts after funding, and these approaches will be discussed in the presentation. Although implementing QI was perceived by respondents to have some sustained positive impact on organizational processes, follow-up research

could explore the impact of QI implementation on the capacity of organizations for ongoing QI, as well as the influence on organizational climate in order to inform and direct future HCBS QI initiatives.

R 04 - Quality Improvement Outcomes

A Description of Work Processes Used By Clinical Nurse Specialists (CNS) to Improve Patient Outcomes

Janet S. Fulton, PhD, RN, ACNS-BC, ANEF, FAAN, USA

Ann M. Mayo, DNSc, RN, CNS, FAAN, USA

Jane A. Walker, PhD, RN, USA

Linda Urden, DNSc, RN, CNS, NE-BC, FAAN, USA

Abstract

Purpose: The purpose of this qualitative descriptive study was to identify common processes used by clinical nurse specialists (CNS) working in a variety of practice settings and specialties to advance nursing practice and achieve improved clinical outcomes.

Background/Significance Around the world, health care environments are increasingly holding nurses accountable for outcomes. Advanced practice nurses with graduate-level nursing preparation are expected to contribute to improved patient outcomes. Nursing in the U.S.A. recognizes four advanced practice roles – clinical nurse specialists (CNS), nurse practitioners, nurse midwives and nurse anesthetists. Each role contributes to improving outcomes; however, the CNS role historically has led large scale nursing practice initiatives to advance excellent nursing care for specialty populations (Fulton, et al., 2016).

System-level structural and process factors are known to influence CNS practice (Kilpatrick, et al., 2016); however, little is known about the specific processes by which CNSs achieve improved clinical outcomes. Greater understanding of how CNSs achieve outcomes will provide insight into mechanisms for improving health care and capturing CNS practice outcomes in this volatile time of dramatic health care reform.

Methods: *Design:* Qualitative descriptive methods described by Sandelowski (2000) were used to identify the elements of how CNSs work and processes used by CNSs in implementing clinical improvement projects. CNSs are guided by professional practice competencies, therefore it is logical to assume that CNS work experiences have common meanings and associated behaviors, and that shared elements of the work process can be explored through the descriptive method.

Ethics: The study was approved by human subject institutional review boards of the investigators' universities.

Sample/Setting: A purposive sample was used to assure a diverse group. Participants were selected from among National Association of Clinical Nurse Specialist Conference juried abstract presentations describing project-related outcomes. It was believed that the abstract authors, having submitted their work for public presentation, would be willing to discuss how they achieved the outcomes. Each abstract author was recruited via e-mail.

Procedures: Participants attended one of two 60 minute focus groups. A funnel approach was used; the most open ended question was asked first. Participants shared stories about the process of achieving project outcomes, focusing on the thinking and decision making that guided them in working through the project. Responses were probed for details about decisions and actions; similarities and difference in experiences were explored. Discussions were audio-recorded and transcribed verbatim; transcripts were reviewed for accuracy.

Analysis: Qualitative descriptive methods were used to analyze the narratives. Qualitative description can be used to obtain a rich description of the common experiences of a group to obtain straightforward answers to questions (Sullivan-Boai, et al., 2005). Moderated structured interview with low-inference content analysis, all of which were used in this study, are common in qualitative description (Sandelowski, 2000).

A standard content analysis process (Neuendorf, 2002) was used. The team members read the transcripts several times. Transcripts were then divided among the team members and relevant sections (text units), were coded independently. The text units were compared and contrasted and grouped into subcategories independently. Team members revised and labeled the subcategories. The quality of the findings (Miles, et al., 2014) was enhanced by use of all researchers to code and categorize data and a consensus procedure (documented by audit trail) to resolve discrepancies. Demographic data were collected and analyzed using descriptive statistics.

Results: Seventeen CNSs participated (8 and 9 in each focus group); average 24 years (range:11 - 39) as a registered nurse; average 8.6 years (range: 1.5 to 23) worked as a CNS; average age 49.6 years (range:35 to 62 years); 82% held master's degree, 18% had a doctorate (DNP or PhD); specialty included 53% adult, 24% acute/critical care, 6% perinatal, 6% pediatrics, 11% other; 15 participants (88%) held advanced certifications including adult (35%), acute/critical care (18%); wound/ostomy(6%), and 6% other.

Findings involved descriptions of CNSs engaged in intricate interactions across a diverse workforce of health professionals and others with varying expertise and interests. The CNS carefully balanced a long term goal with more immediate challenges. The descriptions included detailed accounts of how the CNSs moved a project forward from initial problem identification to the endpoint of success, sustainability and disengagement. **Situating Work** was the category that emerged to describe the process of fitting the work to context, as each team, unit or division was a unique context requiring adaptations. Situating work included beginning with the end in mind, garnering resources, aligning evidence/data, managing tasks, tailoring strategies, managing the team, developing skills in staff, energizing forward movement, monitoring progress, and removing barriers/meeting the challenges of resistance. Descriptive categories of processes surrounding situating the work included: **Identifying a Problem** by using staff input and CNS knowledge and expertise; **Engaging Stakeholders**, which involved identifying stakeholders, conducting preparatory steps for engagement, and onboarding stakeholders; **Forecasting**, such as reading situation dynamics, seeing possibilities and being open to revisions; **Providing Feedback** by communicating, providing support and encouragement, and seeking feedback from others; **Interfacing with the System**, such as connecting with administration, bridging interdisciplinary teams and connecting within the system, and; **Disseminating** reports throughout the system including determining what needed to be reported to whom, when and how. These processes were embedded in personal attributes common and essential to CNS practice. **Building Trust** was described as earning trust of others, using purposeful strategies to build trust, and being trusted in the present and as capital for the future. **Having Self-agency** included rich descriptions of foundational characteristics representing a culmination of education, experience, and emotional intelligence creating a sense of self-reliance that lead to a willingness to take responsibility and to lead through influence. Self-agency also included nuanced and textured descriptions of how the participants took ownership of and responsibility for advancing nursing practice in their clinical settings.

Conclusion: Discussion: CNSs are responsible for identifying clinical problems and initiating system-level interventions to prevent or improve management of the problems (Whitman & Pervis, 2015). CNS practice competencies include leading change for improved clinical outcomes (Fulton, et al., 2016). This study provided insight into how CNSs practice and the processes used by CNSs in achieving clinical outcome improvements. The patient-centered activities of CNS have been studied (Norton et al., 2012), the activities related to system-level clinical leadership have been described (Elliott et al., 2012), and the importance of CNS leadership in for the sustainability of a project has been evaluated (Babine et.al, 2016). However, these studies provided limited insight into how CNSs work.

CNSs are clinical nursing experts, and the better expert work is done, the less visible it is (Wears, 2012). As CNSs become more engaged in supporting system-level practices of the healthcare team, the more invisible they become (Kilpatrick et al., 2016). The concept of "invisible work" was created to bring sociological attention to work that was unrecognized or undervalued (DeVault, 2014). This study provides insight into the very real but often invisible work processes used by CNSs in supporting and leading

healthcare teams and improving outcomes. Much of the supporting and leading of CNS work is articulation work; unacknowledged management of awkward intersections among the social worlds of people, technology and organizations (Hampton & Junor, 2005). For CNSs, this articulation work was facilitated by self-agency. A landmark document (NACNS, 2004) described core CNS professional attributes that included personal integrity, mastery of emotions, positive self-regard, willingness to take risks, knowledge of abilities, openness to self-review, and appreciation of diversity. These attributes were interwoven through the participants' stories and were central to successful system-level articulation work.

Conclusion: The findings of this study provide insight into CNS practice processes, lend credibility to the CNS's leadership abilities, and help explain why the CNS role and practice is often considered invisible and ambiguous.

Limitations: Participants were from North American health care systems (USA and Canada), and while structurally different they are similar in the level of health care delivered, thus the findings may not reflect CNS processes used in project work occurring in other systems in different countries. Participants were recruited from among those CNSs reporting successful improvement project outcomes, therefore little can be deduced about processes that were not successful.

Implications for Practice: Regardless of country, CNS-led clinical improvement projects are central in advancing nursing practice and improved outcomes. CNS practice is situational and contextual; processes used by CNSs to gain trust, solve problems, and communicate with other disciplines are essential to CNS practice. CNS education should incorporate these processes into curricula; new CNSs should be mentored in mastering these competencies and developing self-agency. Administrators need to support these critical, though often invisible, CNS work processes because CNS-led improvement initiatives will enhance the CNS role across specialties and settings, support individual CNS job satisfaction, and ultimately improve patient care outcomes.

Future research should provide closer examination of clinical and fiscal outcomes of CNS practice related to improvement projects. Also, studying this phenomenon in other countries where CNSs practice might validate the findings in this study, or reveal other unique characteristics that foster CNS success in achieving health care outcomes would be valuable.

R 04 - Quality Improvement Outcomes

The Influence of Multimorbidity on Rehabilitation Outcomes in Stroke and Amputation

Bianca Ivonne Buijck, PhD, MScN, RN, Netherlands

Abstract

Purpose: Multimorbidity is highly prevalent in older patients who rehabilitate in skilled nursing facilities (SNFs). In these SNFs, nurses have an important role in the rehabilitation process of patients. Although the high prevalence of multimorbidity, studies aimed at identifying determinants of outcome in elderly patients with multimorbidity that rehabilitate after stroke or lower limb amputation (LLA) in SNFs, are scarce. Therefore, this study aimed to investigate the influence of multimorbidity on rehabilitation outcomes in stroke and LLA.

Methods: The Geriatric Rehabilitation in AMPutation and Stroke (GRAMPS) study is a prospective, multicentre, cross sectional study in 15 SNFs. Univariate, and multivariate logistic and linear regression analyses were used to identify multimorbidity as independently related determinant of rehabilitation outcomes, such as postural imbalance (for stroke), and prosthetic use and timed-up-and-go test (for LLA).

Results: 186 patients with stroke and 46 patients with LLA were included in the study. Multimorbidity was present in 34% of the stroke patients and 53% of the patients with LLA. The stroke patients with multimorbidity differed from the patients without multimorbidity with respect to age, proprioception, and vibration sense, but not for any of the cognitive tests, muscle strength, or sitting balance. Patients with multimorbidity had, on average, lower scores on outcome measures. In linear regression analyses, both balance and walking abilities were best explained by multimorbidity, muscle strength, and the interaction between muscle strength and static sitting balance (overall explained variance 66% and 67%, respectively). In LLA patients multimorbidity was not independently related to prosthetic use. Being able to ambulate independently, and having a transtibial amputation (rather than a higher level of amputation), without phantom pain, determined prosthetic use ($R^2=56\%$), while cognitive abilities, low amputation level, and pre-operative functional abilities were independently associated with the timed-up-and-go test ($R^2=82\%$).

Conclusion: Multimorbidity was independently related to postural imbalance after stroke in patients admitted for rehabilitation in SNFs, but surprisingly multimorbidity had no significant role on rehabilitation outcomes of patients with LLA, even though other authors found an association between multimorbidity and prosthetic use. However, multimorbidity was evenly distributed between patients with, and patients without, a prosthesis. Therefore, it could not give an independent contribution to prosthetic use. Because the presence of multiple chronic diseases influences the performance of stroke and LLA patients during rehabilitation in het SNF, it is important that nurses have insight in rehabilitation outcome.

Abstract

Purpose: To further our understanding about relationship influences that impact health literacy, the purpose of this study was to characterize the perspectives of a culturally diverse group of people living with HIV (PLWH) toward their health care providers. Health literacy is the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate decisions related to their health. Low health literacy is associated with poor health outcomes. Use of preventive services, knowledge about medical conditions and treatment, rates of hospitalization, health status, and health care costs are all linked to health literacy. Although low health literacy can occur in any population, the burden of low health literacy disproportionately affects racial and ethnic minorities and individuals with low income levels. For PLWH, lower health literacy is associated with lower CD4 cell counts, higher viral loads, and a decreased likelihood of taking antiretroviral medication. Adequate health literacy is critical for treatment adherence and for promoting healthy behaviors in the daily lives of PLWH. In order to achieve and maintain HIV viral suppression, adherence to HIV treatment regimens requires a constant, near-perfect medication adherence rate for many medications. Further, the ability to seek and sustain treatment is contingent on one's ability to navigate a complex health care system. Proficiency in health literacy skills is critical to this process.

Methods: Twenty-eight focus groups consisting of people living with HIV were conducted in eight sites representing multicultural backgrounds in the United States, Puerto Rico and Botswana. Responses from audio-recorded focus group interviews were analyzed using content analysis.

Results: Five themes emerged from the data that exemplified characteristics and relationship qualities valued by the participants living with HIV in their health care providers – partnership, knowledgeable health care provider, understandable language, respect, and knowing the person. Participants valued respectful partnership relationships with a knowledgeable health care provider who used understandable language and regarded them as a person of worth.

Conclusion: Relationship quality between patients and health care providers was central to facilitating and enhancing the health literacy of PLWH and likely their retention in care.

R 06 - Provider Perceptions of the HIV Patient Barriers and Facilitators of Couples' HIV Testing and Counseling: Providers' Perceptions From an HIV Epicenter

Natalie M. Leblanc, PhD, MPH, RN, USA

Abstract

Globally, it is estimated that half of those who are HIV infected are in a relationship with someone who is not (1). Since the beginning of the HIV epidemic the literature has demonstrated that among women, including women of color in the United States, partner attributes heightened risk for infection (2, 3). In the United States, it is estimated that there are ~200,000 heterosexual serodiscordant couples, estimated by the proportion of HIV infected women in a relationship (4). Further modeling studies have identified intimate partnerships as a significant source of infection among gay men (5, 6, 1). These findings warrant HIV prevention in the U.S. to directly address interpersonal risk.

Couples HIV testing and counseling (CHTC) is a dyadic approach to HIV primary prevention that aims to address interpersonal risk for HIV (7, 8). It has been well developed globally, but only recently has been introduced for adoption in the United States (7). The World Health Organization (WHO) has recognized that there is a need to enhance identification of serodiscordant couples to prevent new infections and therefore they have developed guidelines for CHTC. These guidelines recommend that providers' support for CHTC and for HIV prevention in serodiscordant couples will be critical to the success of such services, and that providers' attitudes and views must be considered when planning orientation and training for CHTC (1).

So far, studies which have assessed the acceptance of CHTC in the United States has demonstrated its applicability and feasibility predominantly among male couples (10, 11, 12). The literature is lacking in demonstrating the role of providers in the promotion of CHTC within healthcare facilities and among varying patient populations. Therefore, a need remains to understand provider perspectives that may enhance or impede implementation of CHTC in the U.S. within a clinical setting.

Purpose: Miami-Dade County is the leading jurisdiction for HIV incidence in the United States, with a rate of 45.3(13). Several factors contribute to this high incidence including state public health and health institutional policy, a large immigrant population, interpersonal risk factors and geographical vulnerability (proximation to high incidence countries and location within a high prevalence US. Region; 13). As part of a broader study to describe healthcare provider knowledge, attitudes and perception of couples' HIV testing and counseling (CHTC) in Miami-Dade County, Florida, a qualitative descriptive design (14) was used to also explore provider's perspectives about CHTC in a clinical setting. The focus of this abstract is to describe provider perceived facilitators and barriers to CHTC implementation.

Methods: A two-tiered purposive sampling approach was used to recruit providers with experience of engaging people into the HIV care continuum. In-depth, semi-structured interviews among healthcare (clinical and non-clinical) providers (N=22) recruited among 4 healthcare facilities in Miami-Dade County, Florida were conducted from December 2015 to March 2016. Data collection involved use of a topic guide that allowed for open ended responses and that was informed by the literature on provider motivation to engage patients into the HIV care continuum. A content data analysis was conducted to develop codes, categories and themes. This was followed by a thematic analysis to explore more latent content and underlying themes from the narratives (14, 15).

Overall healthcare providers possessed a favorable attitude toward CHTC and believed it to be warranted among their patient population. Content analysis revealed that provider's perceptions were influenced by their personal ethos and experience, their knowledge of the local context including the context of their patient vulnerabilities. A thematic analysis revealed four themes among the narratives: 1) Whom is this strategy for?; 2) Balanced engagement; 3) provider experiences, practices and preferences; and 4) the model of care and the health problem.

Results: Providers perceived couples' HIV testing and counseling (CHTC) to be for couples who aim to establish commitment or monogamy. They perceived the strategy allowed for the reconceptualization of health promotion within couples and approaches between patients and providers. Providers perceived CHTC to balance engagement between themselves and the individual patient(s) and between partners within the couple. Providers described CHTC as a strategy that allows the couple to avoid any confusion regarding joint results and mitigate any anxiety or potential blame regarding the couple's diagnosis. Adoption of CHTC indicated for some providers not only an evolution in HIV screening approaches, but in how individuals perceived personal well-being to allow for a reconceptualization of individual health.

Current provider practices and preferences were believed to either facilitate or impede CHTC. Many providers spoke of having high levels of comfortability to engage patients in HIV screening, and conversations regarding sexual health. In addition, some of these providers reported experiences engaging couples in a wellness or health visit, or facilitating disclosure between their HIV infected patient/client and their sexual partner. Therefore, to implement CHTC was simply the next step in their personal practice.

Although overall clinical providers reported a willingness to engage couples, some noted that some of their colleagues may not be capable or willing to do so. Some providers reported that the prospect of having a seropositive patient or a serodiscordant couple may be a deterrent for providers. Others perceived some provider's lack of knowledge, training and ultimately capacity to even manage a couple and/or HIV infected patients would make them unwilling to adopt the practice of offering CHTC. It was also believed that some providers are not amendable to having frank with patients about their sexual health.

Provider induced stigma was reported as an important problem. Healthcare providers reported that certain clinical providers possess biases against and can be judgmental toward certain patient populations. This stigma was demonstrated through implicit or explicit biases which potentially deterred patients from screening and engaging into subsequent HIV care for those in which it's indicated.

Some providers also spoke about patient attributes as potential barriers to CHCT. Underlying mental health issues and poor coping skills were salient concerns regarding vulnerability of patients. These concerns dominated all populations discussed in the narratives and by extension perceived to be an important consideration for CHTC. The contexts of patients' lives were also perceived to be potential barriers to uptake. These contexts include concerns regarding insurance, lack of time and transportation or lack of partner willingness to engage in the strategy. Despite this context, prior patient demands and current inquires for CHTC among the patient population and the community were perceived as facilitators to begin offering CHTC at primary care facilities.

Providers perceived that the current U.S. healthcare system does not adequately support HIV primary prevention and therefore this may be a barrier to including partners in HIV screening in a clinical setting. The lack of health insurance among male partners of female index patients within couples, in tandem with provider commitment to the index patient was perceived as a barrier to CHTC. Providers reported that the clinical provider has to be able to bill for their services and delineate who is the patient, in addition to whether the partner of the index patient is registered at the facility, all indicative of perceived barriers.

Providers narratives described the organizational setting and program policies which would facilitate CHTC or was perceived to be potential barriers to CHTC. Providers in favor of clinically-based CHTC noted that federally qualified health centers (FQHC's) and primary care clinics would be best suited to implement CHTC because of the population they serve and the belief that these settings were family/community oriented. Providers used elements of their workplace setting as the model of care that could implement CHTC. Many reported that their organization has the space to accommodate another person in a consultation room to be screened, that they provide free HIV screening on-site, have personnel who can conduct rapid tests and a model of care that incorporates routinized HIV screening, elements which were all perceived facilitators of CHTC. Providers also identified that the scope of practice within their facility allowed for partners to be screened for sexually transmitted diseases including HIV infection and hence can logistically facilitate CHTC.

Conclusion: All but one provider expressed their willingness and capability to implement CHTC. However, providers expressed the need for a multi-level paradigm shift in the U.S. so that the model of care addresses the health problem of interpersonal risk. One level involved a need for clinical providers to be better trained in interpersonal relationships with their patients and improved tolerance for diverse populations. It also involved more cross-training of skills among non-clinical providers and a model of healthcare that was more interdisciplinary to address diverse patient needs. Specific recommendations included the need for provider and patient's education regarding interpersonal health risk and a need to streamline existing health care services so that partners are able to be screened for HIV if present with the index patient.

R 06 - Provider Perceptions of the HIV Patient Quality of Care at Primary Healthcare Facilities: Perceptions of Tuberculosis and HIV Co-Infected Patients

Deliwe Rene Phetlhu, PhD, MHS, BA, RN, RM, South Africa
Siphokazi Mngcozelo, BCur, RN, RM, South Africa
Million Bimerew, PhD, MN, BN, RN, South Africa
Joliana Selma Phillips, PhD, MSc, South Africa

Abstract

Purpose: Tuberculosis (TB) has been declared a global emergency and in South Africa a national emergency over two decades ago. TB is the leading opportunistic infection worldwide and the primary cause of mortality among people living with Human Immunodeficiency Virus (HIV). Tuberculosis and HIV combined are responsible for the deaths of over 4 million people annually and more than 65% of individuals diagnosed with TB in South Africa are co-infected with HIV. Providing quality health care services is therefore of utmost importance in improving South Africa's poor health outcomes in addition to restoring patient and staff confidence in the health system. The South African health consumers (patients) are increasingly becoming aware of their rights to quality care and their met or unmet expectations of quality services are directly linked to issues such as treatment adherence and patient retention. This could be a contributing factor in the increase in the TB/HIV co-infection rate in South Africa. Therefore, the purpose of this research was to explore and describe the perceptions of patients co-infected with TB and HIV regarding the quality of care at primary health care facilities in the Eastern Cape Province of South Africa.

Methods: Data collection commenced after ethical approval was received from the university's ethics committee and the provincial health department's research committee. The setting of the study was a sub-district that had primary health care facilities in rural, semi-rural and urban areas. Purposive sampling was used to select participants who then gave consent voluntarily after the study aim was explained to them and all other ethical concerns were addressed. Semi-structured interviews were conducted and data saturation was reached after the 18th participant was interviewed. The transcripts of the interviews were analysed thematically and a consensus meeting held to confirm and agree on common themes.

Results: Two main themes were generated, that is; satisfaction with delivered services and impediments to quality of care. The sub-themes of the satisfaction theme were: positive nurse-patient relationship; non-discrimination; health promotion; and availability of resources. The sub-themes of the impediments theme were: lack of privacy and confidentiality and prolonged waiting time.

Conclusion: The findings indicated that the participants' perception of quality of care were closely linked to their perception of nurses' behaviour and the systemic dynamics. It is therefore important for nurses to be respectful and responsive to the patients' individual needs to enable them to provide quality patient-centred care. The importance of nurses' knowledge regarding TB and HIV and their role in providing health education to patients are also highlighted.

R 08 - Using Simulation in Nursing Education

Hands Off: Student Experiences in Objective Data Collection in Virtual Clinical Simulation

A. J. Kleinheksel, PhD, CHSE, USA
Francisco Jimenez, PhD, MA, MA, USA
Aaron Kotranza, PhD, USA

Abstract

Purpose: The purpose of this study was to investigate the impact of professional nursing experience on student satisfaction and perceived efficacy of virtual patient simulation in baccalaureate nursing curricula.

The increasing adoption of simulation in undergraduate nursing curriculum is motivated by the National Council of State Boards of Nursing simulation study (Hayden, et. al 2014) which supports replacing up to 50% of clinical hours with simulation. While the NCBSN study was limited in scope to physical and high-fidelity computer-assisted simulation (e.g human patient simulators) and pre-licensure undergraduate nursing programs, virtual simulation, including virtual patient simulation, is an additional tool for educators augmenting or replacing clinical placements with simulation. Virtual simulation can be as or more effective than physical simulation for teaching diagnostic reasoning to pre-licensure nursing students (Duff, Miller, and Bruce, 2016). Virtual patient simulation has been adopted to teach medical students communication and diagnostic skills (Cendan and Lok, 2012). However, the adoption of virtual simulation for “hands on” curricular components such as physical assessment may be limited by the lack of physical contact with the simulated patient. Particularly for post-licensure students, who typically have practical nursing experience, the lack of physical interaction may limit student satisfaction and the perceived efficacy of the simulation, presenting a barrier to curriculum integration.

To illuminate the potential for implementation of virtual patient simulations in physical assessment curricula, the researchers evaluated pre- and post-licensure baccalaureate nursing students’ attitudes towards curriculum-integrated virtual patient simulations that teach and evaluate physical assessment.

Methods: Participants: The participants in this study were BSN and RN-BSN students at 20 nursing schools across the United States. A total of 5,774 students were enrolled in courses during the spring 2016 semester. Sample exclusion criteria was identified based on the specific assignment and courses configurations that would most likely result in unreliable student data: students enrolled in courses in which instructors allowed multiple attempts or reopening of the assignments and assignment attempts in which students spent less than 10 minutes with the virtual patient. The assignments sampled for this study were Digital Clinical Experience (DCE) Focused Exams (FE) that included a newly released objective data collection feature. A final sample of 1,028 student attempts for the FE assignments of the DCE were selected for the study: 480 for the Respiratory FE (46.7%), 323 for the Cardiovascular FE (31.4%), and 225 for the Abdominal FE (21.9%).

Materials: Three assignments of DCE Undergraduate Health Assessment simulation product were selected for the study: the Respiratory FE, the Cardiovascular FE, and the Abdominal FE. In the Respiratory FE, students perform a focused examination of a 8-year-old male pediatric patient who is having a persistent cough. In the Cardiovascular FE, students perform a focused examination of a 58-year-old postoperative male patient who is presenting with chest discomfort. In the Abdominal FE, students perform a focused examination on a 68-year-old female patient who comes to the ER with abdominal pain. Each virtual patient case and associated performance assessment instruments were previously validated for nursing accuracy and learning value by several subject-matter experts.

The new objective data collection feature allows students to use the Exam Menu interface to perform physical assessments (e.g., inspection, percussion, and auscultation). As they perform each assessment, the Objective Data Collection tab automatically opens in the EHR allowing students to report on the respective assessment dimensions. For example, when students inspect the patient’s abdomen to assess for abnormalities, the dimensions students can report on are symmetry (symmetric or asymmetric),

contour (flat, rounded, protuberant, or hollowed), and appearance (e.g., rash, striae, distension, bruising, etc.). When students leave the virtual patient's room, the system alerts them to any assessments that they have not yet reported. When they submit their assignment to their instructor, students receive a score several aspects of their performance, including Objective Data Collection.

Measures: The researchers developed a survey containing eight Likert-type items and one open-ended question to measure students' attitudes towards the new objective data collection feature. The Likert-type items were "Overall, I feel that this assignment was a worthwhile learning experience", "I feel that the patient's body images and visuals allowed me to select the appropriate findings in the EHR", "I feel that the patient's body sounds allowed me to select the appropriate findings in the EHR", "I feel that the process of reporting objective findings improved my clinical reasoning skills", "I feel that the duration of this assignment was appropriate", "I feel that the score I received on objective data collection was a fair representation of my performance", "I feel that this assignment was too challenging for me to complete", and "I feel that this assignment helped me identify physical exam skills that need improvement". These items were evaluated on a scale of 1 to 5 where 1 = Strongly Disagree, 2 = Disagree, 3 = Neutral, 4 = Agree, and 5 = Strongly Agree. The open-ended question was "How satisfied were you with the experience of selecting a physical exam from the menu, and then reporting the objective data in the EHR?".

Procedure: Each FE assignment had a post-exam activity that included a link to the survey instrument. In the survey instructions, students were told that their answers would be confidential and that participating or opting-out of the survey would not interfere with their patient exam assignment in any way. In order to ensure anonymity, identifying information, including demographics, were not collected in the survey.

Analysis: The data included in this study employed both quantitative and qualitative elements in a mixed-model design (Johnson & Onwuegbuzie, 2004). We conducted independent samples t-tests to compare RN-BSN and BSN student responses to the Likert-type items. Responses to the open-ended question were first coded for distinct concepts and themes in each student group separately. Then, responses were counted within each of the identified themes to obtain frequencies of occurrence.

Results: Quantitative analysis: In the Respiratory FE assignment, compared to their BSN peers, RN-BSN students reported significantly higher levels of agreement to the items "Overall, I feel that this assignment was a worthwhile learning experience", $t(460) = 3.274, p < .05$, and "I feel that the duration of this assignment was appropriate", $t(449) = 4.123, p < .05$. In the Cardiovascular FE assignment, RN-BSN students reported significantly higher levels of agreement to the item "I feel that the duration of this assignment was appropriate" compared to their BSN peers, $t(319) = -3.095, p < .05$. Similar to Respiratory, in the Abdominal FE assignment, RN-BSN students reported significantly higher levels of agreement than their BSN peers to the items "Overall, I feel that this assignment was a worthwhile learning experience", $t(222) = 2.353, p < .05$, and "I feel that the duration of this assignment was appropriate", $t(223) = 3.095, p < .05$.

Qualitative analysis: Over 75% of the RN-BSN and 80% of the BSN students who responded to the open-ended question included in each FE reported that they were satisfied or very satisfied with the experience of selecting a physical exam from the menu, and then reporting the objective data in the EHR. The main themes emerging among responses from RN-BSN students were: 1) the need for better art and sound assets to identify abnormalities (e.g., it was difficult to distinguish if patient was flushed or not, or the quality of the auscultation sounds made it difficult to report the finding), 2) the expectation that the EHR would auto-populate with the correct dimensions selected without having to select them, and 3) using the open-text Nursing Progress Notes tab in the EHR to summarize objective findings implied additional work and time. The main themes emerging among responses from BSN students were: 1) the activity was challenging or difficult to complete, 2) the workflow of the assessment was appropriate (i.e., having to perform the assessment and then record on the EHR, or EHR opening simultaneously with performing the assessment, or being able to report findings from various dimensions available), and 3) the idea that better instructions were required to complete the activity.

Conclusion: Due to persistent shortages of clinical placements and faculty, nursing programs are in an increasing need of a variety of simulation modalities to achieve their learning objectives assessment outcomes. Virtual patient simulations presents a viable, flexible, and standardized option for faculty. This study found that students of both learning populations find value and realism in virtual patient physical assessments. This study also found that significantly more RN-BSN students found virtual physical assessments to be valuable and appropriate than their pre-licensure counterparts. This difference, which surprising at first glance may be explained by the high level of fidelity of the virtual environment, which experienced students recognize, and/or the complexity experience presented by the deep patient narrative, which is more realistic to a real person. The findings of this study can be used to add additional evidence to case for using virtual patients in nursing education, but more importantly, it can be used to help faculty better frame the design, use, and value of virtual patients for their different student populations.

R 08 - Using Simulation in Nursing Education

The Impact of Clinical Simulation on Beginning Nursing Students' Self-Efficacy and Learning

Lucy R. Van Otterloo, PhD, RNC, CNS, USA
Cathleen Deckers, EdD, RN, CHSE, USA

Abstract

Purpose: The use of simulation as an educational tool is becoming increasingly prevalent in nursing education (Yuan et al., 2012). Simulation-based education has been shown to improve communication skills, collaboration, and critical thinking (Bond et al., 2004; Norman, 2012), as well as increase self-efficacy and competency (Bambini et al., 2009). In fact, the National Council of State Boards of Nursing recommends substituting high-quality simulation experiences for up to half of traditional clinical hours (Alexander et al., 2015). Although published studies show improved learning with simulation compared to traditional education, there are few attempts to determine simulation effectiveness in building self-efficacy prior to beginning the clinical experience and/or in the obstetric setting. While all nursing courses adhere to a similar nursing practice basis, the care of the childbearing family is unique in its need to understand normal physiologic functioning as well as the effects pregnancy has on these normal functions. The purpose of the study was to compare the effectiveness of two educational delivery methods for the clinical setting, traditional lecture and high-fidelity human simulation on beginning level nursing students' self-efficacy. The aim was to determine if a simulated experience would increase self-efficacy of students preparing to enter the obstetrics clinical setting thereby improving the students' confidence and maximizing learning outcomes.

Methods: A control/experimental design was used for this study. Students enrolled in the clinical courses were either placed in the traditional lecture or simulation group. A pre/post-test was utilized to assess knowledge and a validated self-efficacy instrument (Obstetric Nurse Self-Efficacy) specific to the obstetric setting was used to determine level of confidence. Assessments were linked using specific participant ID numbers and entered into SPSS for analysis.

Results: A total of 150 students participated in the study (control=64, experimental=86). No significant difference was noted in knowledge acquisition between the two groups as expected, but the simulation group had slightly higher confidence scores. Significant difference was noted in groups where faculty followed a standardized procedure during the simulation between all groups and the control/experimental groups ($p=.034$). Qualitative data collected from students in the simulation group indicated that they felt better prepared to initiate care for the laboring patient, were less anxious about "not-knowing", and adapted to the new unit quickly. Faculty noted a positive difference regarding students' initiation of and confidence in care with those in the simulation group.

Conclusions: Novice students are noted to incur increased anxiety when entering the obstetric course with limited knowledge and skills needed for the care of the obstetric population. Furthermore, patient safety concerns with this vulnerable population limits actual hands-on experience to learn the necessary new skills. The results of this study support the use of simulation to assist in enhancing undergraduate students' self-efficacy in dealing with obstetric patients as well as their satisfaction with learning. Although simulation may be costly, programs should consider the appropriate, adequate, and timely use of simulation in nursing education and develop policies for standardization throughout the curriculum.

R 08 - Using Simulation in Nursing Education

Validating Targeted Behavioral Markers for Baccalaureate Nursing Student Teamwork Performance Outcomes in Simulation

LeAnn Chisholm, PhD, RN, USA
Rose A. Harding, MSN, RN, USA
Keili L. Peterman, MSN, MBA, RN, NEA-BC, USA
Mary E. Ford, MSN, RN, USA
Lisa Donnelly, MSN, RN, USA
Theresa A. Rhodes, MSN, RN, CPN, USA
Kelli M. White, MSN, RN-BC, USA
Kacie S. Calloway, BSN, RN, USA

Abstract

Background: Patient safety is a global priority for nurses and healthcare providers alike, yet medical errors are not decreasing. The Agency for Healthcare Research and Quality (AHRQ, 2014f) indicates that one out of seven Medicare patients in the United States will be the victim of a medical error. James (2013) concluded that medical error accounts for 200,000 to 440,000 deaths per year, with many of these errors related to ineffective teamwork and communication (AHRQ, 2014f). In an effort to improve teamwork and communication in healthcare, the United States Department of Defense and AHRQ developed the Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPs®) Instructional Framework to facilitate teamwork education and evaluation. TeamSTEPPs® evaluation instruments include the Teamwork Attitudes Questionnaire, Teamwork Perceptions Questionnaire, and the Teamwork Performance Observation Tool (TPOT). The TPOT (AHRQ, 2014a) was designed to objectively measure teamwork performance but has not been sufficiently studied. The AHRQ encourages nationwide implementation of these essential teamwork concepts in order to decrease morbidity and mortality associated with medical error.

Significance : Teamwork principles can be implemented in every high-fidelity simulation according to Clapper and Kong (2012). The NLN's Vision for Simulation in Nursing Education emphasizes the imperative for nurse educators to purposefully integrate simulation throughout curricula to promote clinical reasoning and good judgment (NLN Vision statement, 2015). Learning outcomes from these experiences need to be evaluated using reliable and valid instruments especially when these experiences replace clinical time (NLN Vision Statement, 2015). The ultimate goal of nursing education, despite teaching pedagogy, is for students to translate learning into clinical practice (Adamson, Kardong-Edgren, & Willhaus, 2013).

Zhang (2015) applied the Event Based Training (EBT) methodology to teamwork education and the development of Targeted Behavioral Markers (TBMs) which are scenario specific and reflect teamwork behaviors from the Team Performance Observation Tool (TPOT). With EBT, simulation scenarios are embedded with events which trigger an expected response creating an objective evaluation and facilitating feedback for improvement (Dwyer, Oser, Salas, and Fowlkes, 1999).

Purpose: The purpose of this research study was to analyze psychometric properties of the Teamwork Performance Observation Tool (TPOT) enhanced with Targeted Behavioral Markers (TBM) using a methodology by which validation can be efficiently accomplished and replicated.

Methods: This presentation will discuss a methodological study which sought to demonstrate the viability of the Team Performance Observation Tool enhanced with Targeted Behavioral Markers (TBMs) as a sensitive and valid measure of teamwork performance and a superior approach to teamwork assessment without TBMs. This study provides psychometric data for TeamSTEPPs® Teamwork evaluation instruments and a discussion of interrater reliability concerns, including implications for future studies using observational instruments.

Research Design: The study employed a quasi-experimental Multitrait-Multimethod (MTMM) design to investigate construct validity of the TPOT with TBMs. It compared methods of evaluation and traits being evaluated to determine if the evaluation method affects the outcome of testing. In this study, instruments with established reliability (TPOT, T-TPQ, T-TAQ) and varying methods of evaluation were utilized to evaluate teamwork along with newly developed TBMs which identify scenario specific teamwork behaviors. The Teamwork Nomological Network was developed for this study to illustrate theoretical relationships between the concept of teamwork, individual traits and outcomes, and associated measurement instruments. The Multitrait-Multimethod Correlation Matrix is a numerical expression of the Teamwork Nomological Network.

Aim and Research Questions: The aim of this research was to assess the convergent and divergent validity of the Team Performance Observation Tool (TPOT) enhanced with Targeted Behavioral Markers (TBM) as a valid measure of teamwork skill and performance acquisition in simulation training.

RQ 1: What is the relationship between TPOT, TPOT with TBMs, and the T-TPQ, T-TAQ, and the NLN Simulation Checklist (assesses convergent validity)?

RQ2: What is the relationship between the TPOT, TPOT with TBMs, and the Clinical Skills Self Efficacy Scale (assesses divergent validity)?

Sample, Setting, Recruitment: The study used a convenience sample of senior level baccalaureate nursing students enrolled in a clinical capstone nursing course (n=57) at a medium sized University and within a ten bed high fidelity Simulation Center. After Institutional Review Board (IRB) approval was obtained, the PI explained the purpose and design of the study, answer questions, invited clinical capstone students to participate, and obtained their voluntary written consent. Students were eligible to participate in the research study if all prior course work was complete. No student enrolled in the capstone course was excluded from the study since all students were expected to participate in the final clinical experience and were expected to successfully complete the nursing program. Participation in the study involved completing surveys and analysis of observational data. Choosing to participate or not participate in the study did not affect the student's grade for the course.

Rater Training: Three baccalaureate nursing students, who are not in the study sample, were recruited to participate in testing the simulation scenario and create a video for conducting interrater reliability among study raters. These volunteers received the TeamSTEPPs® teamwork education workshop but did not complete study surveys or demographic forms. The volunteer simulation was realistic and revealed technical issues in the scenario implementation, pre-scenario instructions and checklists which needed to be made prior to the study. Five faculty and two TeamSTEPPs® Master Trainers participated in a four hour faculty development workshop conducted by the PI (TeamSTEPPs® Master Trainer) in order to review the simulation, study instruments, and obtain baseline interrater reliability. Baseline interrater reliability of 80% was established for the observational instruments.

Data Collection: Five nurse faculty members each evaluated and scored three or four teams consisting of three nursing students using the observational instruments. Each team participated in the same simulation developed by the National League for Nursing (NLN) and Laerdal®. The PI viewed all simulations and rated each group on the observational instruments. The two TeamSTEPPs® Master Trainers viewed and rated 50% of the simulations and participated in the faculty development workshop. Ratings from the five faculty members, PI, and two TeamSTEPPs® Master Trainers were compared and interrater reliability was examined. Participating students completed the Clinical Skills Self Efficacy Scale, the T-TPQ (teamwork perceptions) and T-TAQ (teamwork attitudes) using anonymous Blackboard® surveys after the simulation.

Data Management: Data consisted of individual Likert style individual student surveys (Demographics, Clinical Skills Self Efficacy Scale, T-TPQ, T-TAQ) as well as group team performance evaluations (TPOT, TPOT with TBMs, NLN Simulation Checklist) and recorded simulations. Each student was assigned an individual identification number, team identification number, and faculty identification number. A code book linking subjects with their individual, team, and faculty evaluator identification numbers was maintained on the PI's laptop computer which was maintained in a locked office and password protected

along with videos of the simulations. Team raw scores and mean scores were calculated for the individual surveys in order to analyze relationships between survey data and teamwork observational data.

Data Analysis: The data was analyzed using the Statistical Package for Social Science (SPSS) version 22. Preliminary analysis included demographics, reliability statistics for each instrument, and Intraclass Correlations to analyze interrater reliability between raters on the observational instruments. Pearson correlations were calculated and placed in the Multitrait-Multimethod Correlation Matrix for interpretation. Pearson Correlations were calculated between the TPOT without TBMs, TPOT with TBMs, T-TPQ, T-TAQ, and NLN Simulation Checklist and entered in to the Multitrait-Multimethod Correlation Matrix. Moderate correlations (.4 - .6) indicate convergence while high correlations (.6 - .9) may indicate that the concepts are very similar. Pearson Correlations for the TPOT, TPOT with TBMs, and the Clinical Skills Self Efficacy Scale were also calculated. Low correlations (<.4) between self efficacy, team performance measures, and outcomes indicate divergence.

Results: Correlations between the TPOT and TBMs ($r^2=.87$, $p < .01$) and between the TAQ and TPQ surveys were significant and high ($r^2=.47$, $p < .01$). However, correlations between observed teamwork performance (TPOT and TBM), teamwork attitudes (TAQ), and perceptions (TPQ) overall scores were weak in this study ($r < 0.4$). No study was identified for comparison. Unexpected findings may be related to rater training, faculty teamwork knowledge and simulation experience, ambiguity of behavioral markers, contamination of TPOT results by exposure to TBMs, and varying student performance. Conversely, self-efficacy with clinical skills demonstrated low correlations with teamwork attitudes and perceptions as predicted, but unexpected high correlations with observed teamwork scores. High correlations between clinical skill self-efficacy and observed teamwork performance scores ($p < .05$) may indicate that clinical skill self-efficacy influences teamwork performance. Additional study of these relationships using fully crossed designs for interrater agreement are needed in order to clarify the MTMM Correlation Matrix and provide a framework to assess future teamwork behavioral markers.

Conclusion: Teamwork education and evaluation in nursing education is essential to promote patient safety. Assessment of teamwork perceptions and attitudes can be used to indicate the effectiveness of teamwork education (Brock et al., 2013); however, attitudes and perceptions do not always translate to clinical practice. Established rigorous methods for determining reliability and validity need to be applied to testing objective teamwork performance instruments. Findings from this study provide much needed psychometric data for the TPOT and unexpected findings regarding the relationship between the TPOT, TAQ, and TPQ.

Finding Meanings: Using Photovoice to Explore Smoking in Rural Low-Income Women

Star Mitchell, PhD, RN, CCRN, USA

Abstract

Background: High rates of smoking-related chronic disease in low-income rural women and limited access to and use of quality health care has created a challenge to tobacco cessation efforts. These factors support the international call for creative and targeted research approaches that offer new insight and meaning into the relationship between smoking and social determinants of health (Garrett, Dube, Bann, & McAfee, 2015; World Health Organization, 2008). Research has provided a clear picture of how many people smoke, who smokes, and how much they smoke. Unanswered questions remain that are relative to *why* certain demographic groups of people continue to smoke and *how* to effectively reduce cigarette use in populations that embrace smoking. Smoking rates in low-income rural women are stagnant while rates in non-poor and non-rural populations continue to decline, disproportionately increasing the tobacco-related disease and health burden of rural communities when compared to other sectors of society (American Lung Association, 2012; Centers for Disease and Control, 2014).

Purpose: This study explored the meaning of smoking from the perspective of rural low-income women and its effect on the relationship to social identity, sociocultural factors, and smoking behavior. Using photovoice from a relativist's perspective, the purposes of this study were to (a) explore cultural and social factors that give meaning to being a smoker in rural low-income women and (b) explore the relationships between social support, social networks, social identity, and the meaning of smoking in rural low-income women's decision to smoke and attempt smoking cessation.

Methods: This is an interpretive focused ethnography using photovoice as the primary method of inquiry to collect data from low-income rural women residing in three homogeneous and neighboring counties located in the mid-Atlantic portion of the United States. Counties selected for recruitment presented high rates of poverty, smoking, and unemployment with similar cultural, economic, geographic, and social characteristics. This naturalistic approach to inquiry included community assessments and individual photo elicited interviews. Participants completed an initial interview focusing on their current smoking behaviors and smoking history. After completing self-produced photographs of smoking experiences, a second individual interview was conducted using the photos as a mechanism to elicit deeper discussion and gain insight into what it means to smoke and be a smoker. Demographic data were recorded and analyzed for similarities and nuances. Transcribed narratives and photographs were analyzed for the complexity of participants' stories, focusing on the phenomenon of smoking in various aspects of their lives, including identity development and the socio-cultural meaning of smoking (Goodall, 2000; Saldana, 2013). ATLAS.ti was used to support descriptive, thematic, and theoretical coding of transcripts and photos to facilitate identifying variations and patterns reflective of the women's experiences, relationships, social and cultural beliefs, and behaviors within the social context of smoking.

Results: Of the 17 women enrolled in the study, 13 completed both interviews and submitted photographs, which resulted in 26 interviews and 196 participant-produced photographs for analysis. For these 13 women between the ages of 25 and 63, social characteristics showed all participants living as single women, most with dependent children, a common history of drug or alcohol abuse, current or previous domestic violence, and exposure to community violence in their current living conditions. All the women wanted to find a job. Seven themes evolved from analysis of the data which add to our understanding of what it means to be a smoker within the social context of low-income rural women: (1) feelings of isolation (2) struggling day to day (3) it's relaxing (4) looking good and the sense of empowerment (5) family support and expectations (6) being a good mother (7) hope for a better life. Although the interview questions did not specifically ask about rural life, patterns and themes disclosed during narratives and review of the photographs related to social engagement, social identities, and the meaning of the women's social relationships within the context of rural living. Feelings of isolation were associated with the geographic nature of rural living and further amplified by the stigmatization

encountered when identified as a smoker. Prominent narrative themes include relationships between smoking and their roles associated with family membership, being a good mother, and their need to feel empowered within their social environments. As established in previous smoking studies, women in the current study described smoking as a tool for relaxation and stress relief.

Conclusion: Photovoice is an effective and creative method for expanding our knowledge of the relationship between smoking and social determinants of health. Findings presented in this study add to our understanding of cultural and social factors that give meaning to smoking in rural low-income woman; and explore the relationships between social support, social networks, social identity, and the decision to smoke or attempt smoking cessation in this marginalized population of smokers that have not responded to current smoking cessation interventions. This knowledge will be useful in the design of smoking cessation interventions that target low-income women living in disadvantaged rural areas and supports the use of this creative research approach in future studies that target disadvantaged or marginalized populations.

Photovoice Empowerment Activity: Engaging High-Risk Youth in Civic Engagement and a Leadership Program

Ainat Koren, PhD, RN, USA

Abstract

Purpose: High risk youth have few opportunities to engage in the community and have their voices heard. Photovoice is a creative community-based participatory research methodology that has been successful in giving marginalized populations leadership roles in assessing their environment and advocating for positive change (Catalani & Minkler, 2010; Hergenrather, Rhodes, Bardhoshi, 2010; Israel, Eng, Schultz, & Parker, 2015; Wang 2006).

Research has established the positive impact of community service, community and school engagement, positive youth and adult relationships and enhanced self image on reducing youth risk behavior. The purpose of Photovoice is to (1) to enable individuals to record and reflect their community's strengths and concerns, (2) to promote a dialogue and knowledge about important issues through discussion of photographs, and (3) to reach key stakeholders in the community. The ability to digitally communicate their identities, the context of their lives, and express changes that they believe need to be made on individual and societal levels has given these teens a voice. This presentation will share results from a photovoice activity and a program evaluation of high risk teens participating in a civic engagement and leadership program.

Methods: An exploratory qualitative method was employed to examine the impact of photovoice combined with civic engagement and leadership program participation on eleven high school students in Southern Massachusetts. An interview guided focus group was audio recorded and transcribed verbatim. The data was coded and themes were summarized. In addition, photographs from the photovoice project and their accompanied narratives were coded and summarized into themes.

Results: Focus group analyses showed that teens experienced concerns about gender and race discrimination. They were also concerned about the crime rates in their community. The teen experienced empowerment, identity awareness, and community awareness through the workshop and photovoice activity. Participants expressed their desire for civic engagement. In addition the teens expressed short and long term plans for education attainment, graduation and productive life goals. At the end of the year the group is planning an exhibition of their photographs in their high school and community library, to raise the consciousness of the community and key stakeholders to their view and vision for their community.

Conclusion: This study has implications for professionals and researchers engaging with high risk minority teens in the community. Photovoice methodology can complement any program that has teen empowerment among their goals. Photographs acquired through a photovoice project have the potential to promote participatory action by allowing participant to have a voice.

R 09 - Using Photovoice in Healthcare

Curling and Rural Women's Health in Canada: A National Photovoice Study

Beverly D. Leipert, PhD, MSN, BSN, BA, RN, Canada

Lynn Scruby, PhD, MS, BN, RN, Canada

Heather Mair, PhD, Canada

Robyn Plunkett, PhD, MScN, BScN, BSc, RN, Canada

Abstract

Purpose: Purposes of the Study were to:

- 1) Explore effects of curling on the health and community life of rural women;
- 2) Determine how health, sport, and recreation can be understood within the contexts of rural gender and community change; and
- 3) Assess the utility of photovoice, an innovative, participatory qualitative research methodology and method, in advancing research with rural women.

These purposes were set for the following reasons. Sport and recreation play important roles in rural life in Canada. Determinants of health such as physical activity and social inclusion are key to the health of rural residents and essential for rural community life (Kulig & Williams, 2012). More than 28% of Canadian curlers live in communities with fewer than 10,000 people (Canadian Curling Association, 2008). Yet, rural women have few opportunities to experience the social and health benefits of sport and recreation, as rural communities tend to favor men and boys in sports, to the exclusion or minimizing of women and girls, for example in sports such as hockey. In addition, little research has been conducted on the significance and effects of sport and recreation for rural women (Morrow & Wamsley, 2013).

Rural communities in Canada are becoming feminized aging communities (Leipert, Leach, & Thurston, 2012). In these rural communities, few health and recreation resources exist (Mair, 2007), and rural people are less healthy and have shorter life expectancies compared to urban residents (Canadian Institute for Health Information, 2006; Kulig & Williams, 2012). Thus, it is vital that research focus on rural women and recreation to enhance understanding and nursing practice regarding sport and the health of rural people in general, and rural women in particular.

Methods: The methods of this study were guided by two methodological approaches: rural ethnography, and photovoice. Rural ethnography, in its exploration of ways in which the world is experienced and understood in the everyday lives of people, acknowledges the centrality of gender, power, process, and complexity in rural life (Hughes, Morris, & Seymour, 2000). Photovoice, with its novel use of photographs and oral and written methods, elicits rich data about contexts and social and health-related experiences (Wang & Burris, 1997). Thus, both of these methodologies were suitable for this study.

Sample and Setting: Fifty-two women and girls, ranging in age from 12 to 75 years with an average age range of 50-60 years, in seven rural communities in Nova Scotia, Manitoba, Ontario, and the Northwest Territories participated in the study. Inclusion criteria were that participants self-identified as present or past female members of rural curling clubs. Curling experience ranged from one to 16 or more years with most participants having several years of curling experience. Rural was defined in this study as populations living outside the commuting zone of areas with more than 10,000 residents (du Plessis, Beshiri, & Bollman, 2002).

Data Collection: Prior to beginning the study, ethical approval was obtained from Western University, the University of Manitoba, and Dalhousie University. Then, in a camera orientation session, participants were provided with cameras and log books and asked to take photos and record data that depict roles that curling clubs play as sport and community places for rural women and how curling and curling clubs influence the health of rural women. After two weeks the cameras and log books were retrieved, and copies of the photos were made for the participants and the researchers. These photos were returned to the women in focus group settings, where each participant selected two photos to title and discuss. Further data collection occurred as the researchers observed in rural curling rinks and engaged in

conversations about physical and socio-cultural aspects of the rink, such as the roles of women and others, how the rink is used by women, men, children, and the community, and the effects of use on the social lives and health of rural women. These researcher observations and perspectives were recorded in field notes and included in the data of the study.

Results: Study participants in the four provinces took 955 photographs, recorded in 52 log books, and participated in two group interviews in their rural location. All of the data from these sources were analyzed by the researchers with some analysis also done by and with the participants. Results reveal that curling enhances physical and mental health and resiliency, facilitates vital social and community connections, supports rural community life, and provides a valued and visible way for women to support rural community life. Photovoice was revealed as a significant enhancement to this research in its facilitation of the recruitment of participants of varying ages and backgrounds, and in the provision of rich, evocative, and insightful data, analysis, and findings. Narrative and pictorial data will be used extensively in the presentation to illustrate these findings.

Conclusions: This research significantly enhances understanding of how gender and recreation intersect to influence rural women's health, social capital, rural community change, and community development and sustainability. Important recommendations regarding nursing and other support and enhancement of girls' and women's sport and curling in rural communities will be offered based on the findings of this study. Recommendations regarding the utility of this research for nursing education, for example regarding learning about research methodologies and methods and rural nursing practice possibilities, are also evident and will be addressed in the presentation. Photovoice methodology significantly enriched recruitment, data collection, analysis, and dissemination activities, and its utility and suggestions for further rural and women's health research to enhance substantive, methodological, and nursing education and practice understandings will be offered.

S 04 - Creating a Culture of Patient Safety

The Development and Testing of a Measure for Turbulence in Intensive Care

Jennifer A. Browne, PhD, RN-BC, CCRN, USA

Carrie Jo Braden, PhD, RN, FAAN, USA

Abstract

Purpose: Nursing workload is a valuable measure of a nurses' work and is used to determine the needs of a unit and to bring some degree of standardization to staffing models and costs. Once a workload measure is in place, connections and correlations can be made between nurse staffing, performance measures and patient outcomes.¹ Gaining a better understanding of nursing work has become especially important as leaders attempt to balance diminishing healthcare resources and cost containment with a need to promote clinical outcomes and patient safety. (Berry & Curry, 2012; Myny, Van Hecke, De Bacquer, Verhaeghe, Gobert, Defloor & Van Goubergen, 2012).

While undertaking a model-building dissertation study, it became evident that the concept of workload did not describe all the activities nurses were performing. It was observed that some staff nurses with moderate to low workload assignments were exhibiting stress and were delayed with scheduled tasks. The nurses voiced frustration with work blockages such as incorrect medications delivered, missing supplies (i.e., wrong size ostomy bag) and equipment issues (i.e., broken bar code scanner). The activities undertaken to surmount barriers to completing patient care were not captured in standard workload measures. (Baernholdt, Cox & Scully, 2010)

Because the full extent of nurse activities could not be specified in the proposed model, a variable for turbulence was created in order to capture nurse activities not represented by workload. The purpose of this presentation is to report the completed validity and reliability testing of a measure for turbulence and, based on the identified characteristics, propose a turbulence definition. Recommendations for future research are influenced by the initial correlation findings between turbulence, workload and patient safety. Literature Review:

Environmental turbulence has been defined as "an interaction between individuals and their environment in response to instability and rapid changes in their internal and/or external environment affected by attributes of the individuals, groups and/or the organization with the potential to impact patient and nursing outcomes" (Bosco, 2007, p.13). Turbulence is inclusive of internal factors with a notion of ineffective buffering of any disruptive force that may intrude upon the nurses' ability to perform nursing practice and provide patient care. (Tillman, Salyer & Corely, 1997; Bosco, 2007).

Jennings (2007) characterized turbulence as a loss of control due to simultaneous demands; difficult, or unfamiliar work; heavy patient loads; and excessive responsibility. Turbulence attributes clustered into two themes: communication and workload. Unique stressors, exclusive to our conceptualization of turbulence were those items that grouped primarily under nursing communication: breakdowns, distractions, interruptions, loss of information during handoffs, cognitive stacking and impaired decision-making. (Salyer, 1995; Patterson & Wears, 2010; Rivera-Rodriguez & Karsh, 2010; Coiera, 2012; Hopkinson & Jennings, 2013; Park, Blegen, Spetz, Chapman & DeGroot, 2013).

Methods: This mixed methods study was conducted in collaboration with The American Association of Critical Care Nurses (AACN) and approved by The University of Texas Health Science Center IRB. A 15 item turbulence scale was developed from the literature and tested in a mixed methods dissertation pilot with our local chapter of AACN. Clinical experts in critical care helped determine content validity. Reliability was tested using an interrater approach with critical care nurse raters scoring unique workload and turbulence components

The turbulence items were then administered as part of a national survey interested in assessment of a Health Information Technology Workaround Model. A voluntary survey was sent to all members of AACN. Respondents were asked if any of the 15 listed activities were present or impacted work on their unit

during their workaround experience. Responses were on a Yes (1)/ No (0) scale. Workload was measured using acuity, staffing ratio, and the nurse's perception of their workload (light, moderate and heavy).

Results: A sample of 307 AACN RN members responded to an email survey consisting of items measuring nurse characteristics, workload, turbulence/ problems and patient safety risk (or event) and workarounds. Open ended questions solicited narrative descriptions of the problems, work activities and workarounds encountered or performed by the nurses. The respondents were 87% female, and the majority were 45 years old or greater. Almost 50% of the nurses had a bachelor's degree in nursing, and 20.6% an associate degree. Nurse experience was midway between proficient and expert. Intensive care specialties included adult, pediatric and neonatal. Patient acuity was reported as: 61.8% critical, 28.7% guarded. Workload of the nurse was reported as heavy (40%) and moderate (58%).

The distribution characteristics for the turbulence items will be presented. Sudden changes in acuity, interruptions and distractions were reported by more than half of the respondents. Other frequently selected turbulence items included administrative demands, communication breakdowns, information overload, noise, transfers in and out of the unit and staff having to leave the unit. Triangulation methods resulted in inter-method agreement of all 15 of the turbulence characteristics. There were no outliers or additional attributes identified.

The minimum amount of data for factor analysis was satisfied with a final sample size of 296 (> 12 cases per variable). Using completed study data, consistency for the total scale indicated a Cronbach's alpha of .75 ($p < .01$). The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy was .77, above the recommended value of .6, therefore exploratory factor analysis of the 15 items was examined. Based on principal component extraction with varimax rotation, the five factor solution obtained had Eigen values greater than one and factor loadings ranging from .53 to .82. The 5 factors explained 54% of the variance. The criteria for the factor solutions are consistent with conventional statistical recommendations (Polit & Beck, 2008). Based on the analysis, the definition of turbulence offered by this work is: The degree to which the interaction between a nurse and attention diversion, resource inadequacy, communication breakdowns, sudden acuity increases and interpersonal relationships affects the nurses' ability to practice or provide care.

Conclusion: Initial testing of a turbulence measure demonstrated reliability and validity and produced a preliminary definition based on essential attributes. Hyun, Bakken, Douglas and Stone (2008, p.8) state "staffing decisions that lack consideration of all relevant factors may result in poor patient outcomes". Workload, although widely used, does not tell the entire story and underestimates the totality of nurses' tasks and responsibilities. When considering workload and turbulence, a broader understanding of nurse activities might provide us with alternative solutions beyond "staffing". For example, workload (i.e., acuity, admissions and discharges) might be difficult to manipulate, but turbulence items, such as interruptions, loss of information, communication breakdowns and inadequate resources can be intervened upon. In the primary study we found that turbulence was most strongly correlated with safety hazards ($r = .41$, $N = 293$, $p = .000$) whereas the association between workload and safety hazards ($r = .16$, $N = 29$, $p = .005$) had the weakest relationship. The findings of this research will be presented and suggest that interventions aimed at turbulence reduction should result in better clinical outcomes and a reduction in safety risk.

S 04 - Creating a Culture of Patient Safety

Registered Nurses' Perceptions of Patient Safety Culture and Safety Outcomes in the Workplace

Elizabeth J. Murray, PhD, RN, CNE, USA

Abstract

Purpose: Patient safety presents a serious global public health issue (WHO, 2014). Health care organizations have worked to reduce errors, identify, and analyze near misses, and foster a patient safety culture for more than 15 years all over the world. Yet, estimates indicate that in developing countries one in ten patients is harmed by a range of errors or adverse events while hospitalized (WHO, 2014). In addition, recent studies suggest that close to 210,000 patients die in the United States from preventable errors (James, 2013) and at least 3.6% of hospital deaths in England are attributed to preventable errors (Yu, Flott, Chainani, Fontana, Darzi, 2016). Patient safety and patient safety culture are key components of quality health care. Keeping patients safe is inherent in nursing care. As the largest component of the healthcare workforce, registered nurses are viewed as “inseparably linked to patient safety” (IOM, 2004, p. 23). The aim of this study was to explore registered nurses’ perceptions of patient safety culture and safety outcomes in their workplace using the AHRQ *Survey on Patient Safety Culture*.

Methods: This study involved a descriptive correlational design using the AHRQ *Survey on Patient Safety Culture*. Is a 42-item survey that measures seven patient safety composites at the unit level, three patient safety composites at the organizational level, and four safety outcomes. The *Surveys on Patient Safety Culture* were mailed to a randomized sample of 500 registered nurses with active and clear licenses in a southeastern state in the United States using the Dillman Tailored Design Method (2000). The estimated sample size was calculated using G* Power 3. The results yielded a minimum of 67 nurses were needed for a medium effect size ($r = 0.30$), 0.05 level of significance, and the desired power of 0.80 (Faulstich, Erdfelder, Lang, & Buchner, 2007). Data collection took place from November 2014 to February 2015. Data analysis was completed using SPSS software for Windows, Version 23.

Results: A total of 108 valid surveys were returned resulting in a response rate of 24%. The percent of positive results were calculated for each survey item and each composite. Negatively worded items were recoded. Among the unit-level aspects of patient safety culture, *teamwork within units* had the highest average positive response (76.5%) and *nonpunitive response to errors* had the lowest average response (25.5%). Among the organizational-level aspects of patient safety culture, *management support for patient safety* had the highest average positive response (52%) and *handoffs & transitions* had the lowest average positive response (33.75%). Twelve percent of the respondents gave their workplace an overall grade of excellent while 14.9% rated their workplace as poor or failing. The average percentage of positive responses to the safety outcomes of overall perceptions of patient safety and the frequency of events reported were 46% and 50.33% respectively. Pearson correlation coefficient was used to examine the relationships between patient safety culture composites and safety outcomes. A significant positive correlations were found between *communication and openness* and the *frequency of events reported* ($p < 0.001$) and *supervisor/manager expectation & actions promoting patient safety* and *patient safety grade* ($p < 0.001$). A significant negative correlation was found between staffing and the number of events reported ($p < 0.001$).

Conclusion: There are several limitations to this study. A major limitation of this study is the low response rate, however, the sample was representative of nurses across numerous work areas. Another limitation is the self-selection of participants. Many factors could have influenced their responses such as recent exposure to safety training or adverse event in the practice setting. Finally, the survey was conducted in one state in the southeastern region of the United States and may not be generalized to the larger population.

The findings of this study have implications for nursing practice, nursing leadership, and future research. These results provide evidence for the need to further education of frontline nurses on the importance of

reporting errors and near misses. In addition, nurses must feel safe reporting errors and near misses and these findings suggest that there is more work to be done to ensure a non-punitive environment. Understanding nurses' perceptions will help the profession and nursing leadership to develop strategies that foster transparency in the workplace, support patient safety culture, increase safety outcomes, and improve error reporting systems.

Further research is needed to explore nurses' perceptions of patient safety culture, safety outcomes, and error reporting regionally, nationally, and globally. In addition, further research related to each composite on the AHRQ *Survey on Patient Safety Culture* is recommended.

S 07 - Cross-Country Health Systems

Making a Cross-Country Comparison of Health Systems: What Are the Possible Study Design Frameworks?

Cheryl Zlotnick, DrPH, MPH, MS, RN, Israel

Sue A. Anderson, PhD, MS, BSN, BS, AS, RN, FNP-BC, USA

Vanessa Heaslip, PhD, MA, BSc (Hons), DipHe, RN, DN, United Kingdom

Abstract

Purpose: Health care systems form the framework and context through which countries provide health care services to their populations. They are comprised of an amalgam of culturally- and often economically-driven structures (e.g., facilities, personnel, policies, processes) to attain optimal health outcomes. No single health system is precisely like another. However, when studies explore differences in population health status or outcomes across countries, often the comparison focuses solely on health outcomes, completely omitting the effects and influences of the health system. This omission is problematic, since as several health care provision models suggest, health care outcome inequities may be connected to or even originate from the health system's context and approach; but this topic has been explored by very few studies. With increasing globalization, nurses comprising the largest health professional labor force in the world must employ the most rigorous study design frameworks when conducting cross-country comparisons of health outcomes. Thus, the goal of this research project is to examine study design frameworks used to make cross-country comparisons of health care outcomes taking into account the health care system context.

Methods: To address this goal, this study examined study design frameworks using a scoping review methodology with the following steps: the identification of the domains of the health care system that must be explored; search and selection of relevant studies; charting the studies' findings; and summarization of the results.

Results: Study design frameworks for cross-country comparisons of health care outcomes within the health system context varied by: (1) use of country selection criteria as a basis for country selection, (2) use of a guiding theory to govern the elements for comparison, (3) the decision of the data type (i.e., quantitative, qualitative, mixed-methods), (4) ascertainment and validation of measurements, (5) synthesis of findings employed a wide versus narrow focus, (6) inclusion of countries' cultures and population composition, and (7) contribution to other countries' health systems.

Conclusion: A grid denoting a variety of cross-country study design frameworks depicts a variety of strengths and weaknesses. Countries' health care systems are culturally-linked, but criteria exploring or explicating cultural influences within the health system context were sparse or absent. Moreover, cross-country comparison frameworks were inconsistent in their abilities to delineate and define approaches that resulted in inequitable health service outcomes for different population groups. Design frameworks failing to include the cultural context limit our ability to fully examine differences in health care outcomes. Nurses and other health professionals must choose a study design framework that is systematic, comprehensive and sufficiently robust to meet the challenge of conducting cross-country comparisons so that study results are able to assist countries' policymakers and administrators to make improvements that promote better and more equitable health outcomes for their population.

S 07 - Cross-Country Health Systems

A Case-Oriented, Cross-Country Comparison of Three High-Income Countries' Health Systems and Healthcare Accessibility

Sue A. Anderson, PhD, MS, BSN, BS, AS, RN, FNP-BC, USA

Cheryl Zlotnick, DrPH, MPH, MS, RN, Israel

Vanessa Heaslip, PhD, MA, BSc (Hons), DipHe, RN, DN, United Kingdom

Abstract

Purpose: Located on different continents, the United Kingdom (UK), Israel and the United States (US) are high income countries differing in size, population size, and type of health care systems; yet, their general population's health outcomes are similar. This study used qualitative and quantitative information to gain insight on the health care systems and health care accessibility of vulnerable groups in the general populations of these three industrialized countries.

Methods: Using a case-oriented, cross-country comparison, this study uses the three factors of the Behavioral Model of Utilization (i.e., health system environments, population characteristics and health behaviors/outcomes) to examine health care accessibility for selected vulnerable groups in each of the three countries (i.e., Israel, UK, US).

Results: The health system environments and population characteristics differed dramatically. The health system of the United Kingdom had open access to all; Israel's health system provided basic healthcare to all citizens, yet citizens could opt for different levels of services. The fee-for-service system in the US resulted in barriers to healthcare access for vulnerable citizens. Regardless of the type of healthcare system and level of access to health care, all three countries experienced threats to health. All health systems showed features indicating their adaptation to the dominant or majority group of the country's general population. However, all three high income countries' health systems were inadequate at addressing vulnerable population groups (i.e., socioeconomically low income individuals, minorities, immigrants, non-citizens) as demonstrated by unmet need and inadequate health behaviors.

Conclusion: Despite the diversity of health system philosophies and approaches, none of the health systems were effective at addressing health care inaccessibility and or unmet need for vulnerable population groups. Health systems in high income countries must acknowledge that access to healthcare is an important component of a healthy population; knowledge development of specific strategies to improve health within communities is equally important. Health systems in the three countries lack strategies that proactively engage, reach-out to and facilitate health care access for vulnerable populations. Nurses must be fully engaged through their work and research within communities to strengthen health systems and improve the health of all.

S 08 - Effective Teaching Methods

Student-Centered Teaching Methodology in an Undergraduate Nursing Programme at Two Nursing Institutions in Kingston, Jamaica

Melissa Walker, MScN (Ed), BScN (Hons), RN, CertPaedNsg, CertNsgAdmin, Jamaica

Cavelle J. Allen, MScN (Dist), BScN (Hons), RN, Jamaica

Dawn Munroe, MA (CounsPsych) (High Hons), RN, RM, Jamaica

Rosain N. Stennett, MPH, BSc, Jamaica

Shaulene M. Stanley, MScN (Ed), BScN, RN, CertAdvNsgEd, Jamaica

Karozan S. Cascoe, MScN (Dist), BScN (Hons), RN, Jamaica

Abstract

Purpose: To determine the factors related to student-centred teaching methodology in an undergraduate nursing programme at two nursing institutions in Kingston, Jamaica.

Methods: This descriptive cross-sectional study was conducted among 129 randomly selected students and the 24 lecturers teaching this cohort. Data were collected using the Principles of Adult Learning Scale (PALS). The tool consists of 39 items with seven constructs namely: Personalizing Instruction, Relating to Experience, Assessing Student Needs, Climate Building, Participation in Learning Process and Flexibility for Personal Development. **Results** were analysed using the SPSS version 22. Pearson's Correlation Coefficient was used to determine the relationship between the demographic characteristics of the lecturers and the teaching methodology as well as the relationship between class size and the teaching methodology. Independent sample *t* test was used to compare means and determine the significance of observed differences.

Results: The study had a response rate of (79%) and (71%) for students and lecturers respectively. The results showed that 50% of the lecturers and students rated the degree of student-centredness as teacher-centred. There was no significant relationship between age and years of experience and the teaching methodology. However, there was a strong negative relationship between class size and the teaching methodology and this was statistically significant ($p < 0.001$). There was a statistically significant difference between the lecturers' and students' mean scores within the following factors: Learner Centred Activities ($t = -9.267, p < 0.001$), Personalizing Instructions ($t = 4.063, p < 0.001$), Assessing Students' Needs ($t = -6.24, p < 0.001$) and Participation in Learning ($t = -3.384, p = 0.001$).

Conclusion: There was no significant relationship between age and years of experience and the teaching methodology. However, there was a strong negative relationship between class size and the teaching methodology. Fifty percent of the lecturers and students rated the degree of student-centredness as teacher-centred. The findings of this study are extremely important to nursing education as it highlights the disjunction between the lecturers' rating of specific practices and the predominant teaching approach. Given the relationship between student-centredness and enhanced critical thinking skills, student engagement and motivation to learn, it is critical for the teaching/learning environment to be more student centred.

S 08 - Effective Teaching Methods

Leadership Initiatives: Challenges and Implications for a Remote Nursing Education Program

Dora Maria Carbonu, EdD, EdM, MN, BN, RN, Canada

Nancy A. Edgecombe, PhD, MN, BN, OPN, RN-NP, Canada

Amanda R. Parrott, BN, RN, OHN, CMSN(C), CCNE, Canada

Elissa Sakariassen, MN, BN, RN, Canada

Abstract

Purpose: The need for nursing education to facilitate the development of leadership skills has been recognized in the literature (Rosser, 2014; Galuska, 2015). Several collaborative and innovative activities have been incorporated into nursing programs, including peer mentoring both in the clinical and laboratory settings, service learning, promoting student attendance at leadership conferences, and facilitating active student-organizations (Foli, Braswell, Kirkpatrick and Lim, 2015; Ross, Bruderle and Meakim, 2015; Schoening et al., 2015; Tabloski, 2016). The Bachelor of Science in Arctic Nursing (BScN) Program is unique as it is located in Iqaluit in Nunavut Territory, a remote area of Canada's Arctic, which has implications on what activities and opportunities for leadership experiences are possible. This presentation outlines the challenges and implications of incorporating leadership activities into the BScN Arctic Nursing Program.

Methods: The Bachelor of Science in Arctic Nursing Program is delivered by Nunavut Arctic College (NAC) in Iqaluit, Nunavut in partnership with Dalhousie University in Halifax, Nova Scotia. A number of activities have fostered student leadership initiatives in the Program, including student attendance at conferences, focused assignments within the leadership course, and service learning experiences. One highly successful activity is the 3rd-Year nursing students' participation in a leadership activity prior to their six-week intersession clinical placement at Dalhousie University in Halifax. As part of the orientation experience for the Arctic Nursing students in Halifax, they participate in a two-day Leadership Boot Camp where, through learning experiences the students acquire theoretical and practical leadership strategies and skills. Upon completion of their clinical placement in Halifax, the students return to Nunavut, highly motivated and enthused about their acquired leadership knowledge and understanding. They express interest and willingness to take on a leadership role, and this interest has translated into a number of both formal and informal activities that have allowed the students to demonstrate leadership within the School of Nursing. Informal activities have included advocacy initiatives, such as submitting an article to the local newspaper to raise public awareness and to correct the myths about the BScN Program, and leading student-professional development forums. Formal initiatives have included incorporation of student leadership activities into several courses, such as peer mentoring of junior students by senior students.

Results: The success of the BScN (Arctic Nursing) Program leadership initiatives has resulted from three important environmental factors: (a) students feeling safe and challenged as a result of academic leadership activities, which enhance their sense of belonging; (b) clearly defined goals, objectives and tasks the students work together on; and (c) student-and-Faculty-groups being small and cohesive, and all contributing to the learning process. The students are individually accountable for their work, and the group-work as a whole is also assessed and evaluated.

Conclusion: Leadership learning experiences have promoted and enhanced the students' academic and clinical performance, and have resulted in increased confidence and satisfaction by capitalizing on achieving their goals and objectives. Students actively invest in their own learning, sharing their strengths and improving on their weaker skills, demonstrating respect for each other, and with improved interpersonal relationships among the student-groups and instructors. This innovative approach to teaching-learning remains an ongoing goal and a challenge, yielding highly achievable and positive academic results among the nursing-student-faculty population at Nunavut Arctic College.

Evidence-Based Practice Poster Presentations

EBP PST 1 - Evidence-Based Practice Poster Session 1

The Influence of Leader-Member Exchange and Structural Empowerment on Nurses' Perceptions of Patient Safety

Adam J. Morse, BScN, BSc, RN, Canada

Abstract

Reports have illustrated the lack of supportive and inclusive work environments is a causative factor of health related absences and nursing attrition. This has been reported to lead to increased risk to nurses' safety, patients' safety and poorer patient outcomes. The purpose of this study is to examine the impact of the four dimensions of Leader-Member Exchange (LMX) (contribution, affect, loyalty, and professional respect) of nurse managers and access to the four structures of structural empowerment (support, opportunity, resources, and information) on nurses' perceptions of patient safety climate. A cross-sectional survey is conducted using a random sample of 230 nurses across Ontario in acute care settings. *Leader-Member Exchange-MDM*, *Conditions for Work Effectiveness Questionnaire-II*, and *Patient Safety Climate Questionnaire* are used to measure study variables. Previously, no specific research has examined the influence of LMX, and structural empowerment, on patient safety climate. This study may uncover some of the processes by which each of these variables influences the next.

Leader-Member Exchange (LMX) theory focus is on the relationship between leader and follower, identifying key features of the relationship that are important to the development of trust and effective working relationships (Lunenburg, 2010). LMX can be used to examine leadership techniques that enhance patient and environmental safety, as well as organizational commitment when applied to performance outcomes (Higgins, 2015). High level of structural empowerment (SE) is shown to increase job satisfaction, and increase organizational commitment (Laschinger et al., 2009a). Previous studies show correlations between LMX and SE that have a positive influence on patient outcomes (Squires et al., 2010; Cai, & Zhou, 2009). SE is the degrees of access employees have to environmental structures including opportunity, support, resources, and information. Effective leaders play a key role in ensuring nurses have access to these structures.

Nursing leaders foster a work environment that supports staff and increases the patient safety climate (PSC) (Armstrgon et al., 2009). High PSC reduces adverse events from occurring and avoid harm to patients (Flin et al., 2006; Sexton et al., 2006a). Patient outcomes, workplace injury, and staff's intention to leave the unit are found to all be affected by the PSC (Hotmann & Mark, 2006). Researchers have proposed that positive link between effective leadership styles and continuous quality improvement (McFadden et al., 2015), however no direct link has been examined between the effects of both individual leadership styles and SE on how nurses perceive a PSC. Through LMX, nursing leaders may be better able to develop effective working relationships with nurses, increase SE and therefore create an atmosphere for a better PSC (Davies et al., 2011).

From the College of Nurses of Ontario registry, a random sample of 230 registered nurses working in an acute care teaching hospital within the province of Ontario has been selected from both rural and urban settings. Inclusion criteria is met if participants are currently employed for more than four months on their current unit, either full-time or part-time, to avoid the inclusion of data from individuals who are new and may not be familiar with their current manager and working environment. Participants must be directly involved in patient care with a superior in a leadership role who they are required to report directly to. Participants currently on leave or returned to work for less than four months will be excluded.

Three standardized self-reporting instruments will be used to measure the study variables (see Appendix B). Iden & Maslyn (1998) *Leader-Member Exchange-MDM (LMX-MDM)* will be used to measure the quality of relationships between the nurse managers and nursing staff. *LMX-MDM* is a 12-item scale that asks participants to what extent do they agree or disagree with a series of questions.

Nurses will not be guaranteed any direct benefits as a result of their participation in this study. However, this study will indicate the impact of Leader-Member Exchange of nurse managers and structural empowerment on nurses' perceptions of patient safety climate.

In addition, further knowledge can be acquired that will begin to identify the factors affecting patient outcomes in relation to the impact of individuals in managerial roles. As a result, this information can be used to enhance the working environments of nurses and increase patient safety in the future.

The results of this study primarily target nursing leaders in front-line managerial positions, possibly increasing their awareness of SE allowing them to develop a more positive working environment on their unit that may lead to increased productivity and increased patient safety. Managers in middle and upper management may also be interested in these findings as a means to examining positive influences to LMX and developing strategies and training to be provided to front-line managers to enhance a PSC. The abstract of this study will be submitted for presentation at conferences focusing on researching nursing leadership styles and research on influential factors related to patient safety.

Memory-Focused Interventions for People With Cognitive Disorders: A Meta-Analysis of Randomized Controlled Studies

Kuei-Ru Chou, PhD, Professor, RN, Taiwan

Abstract

Background: Cognitive disorder is a crucial global issue. Memory impairment is often considered an early and crucial clinical manifestation of cognitive disorder. Previous studies have shown that memory-focused interventions can effectively mitigate memory function decline. However, in previous studies, the research targets were mostly healthy older adults; few meta-analyses on patients with cognitive disorders have been performed. The purpose of the present study was to assess the effect of memory-focused interventions on cognitive disorder through conducting a meta-analysis.

Methods: According to a systematical literature search strategy, using keywords and the MeSH terms to identify studies related to memory-focused interventions and cognitive disorders. The online electronic databases used in this study were PubMed, the Cochrane Library, OVID-Medline, CINHALL, PsycINFO, and Embase (up to July 2015). Articles that met the inclusion criteria were included and a random effect model was used for a meta-analysis. The primary indicators were objective memory performance and subjective memory performance; the secondary indicators were immediate recall, delayed recall, global cognitive functions, and depression.

Result: A total of 19 research articles were included in this study. The results showed that memory-focused interventions had a medium–large effect on the objective and subjective memory performance of patients with cognitive disorders, a small–medium effect on delayed recall and global cognitive function, and a small effect on immediate recall (all $p < .05$). A subgroup analysis on objective memory performance that featured medium heterogeneity showed that the number of treatment weeks (≤ 5 weeks) could be adopted as a moderator variable for the effect of memory-focused interventions on objective memory performance. A metaregression analysis showed that various continuous variables were nonsignificantly correlated with effect size.

Conclusion: In this study, the meta-analysis results showed that memory-focused interventions effectively improved the objective and subjective memory performance of patients with cognitive disorders. Objective memory performance can serve as a reference for diagnosing cognitive disorders; the meaning of subjective memory performance and related factors is crucial for rapidly aging societies. We hope that memory-focused interventions can improve memory function and assist patients in overcoming their self-care problems resulting from memory impairment.

Implementing an Acuity Adaptable Care Model in an Existing Academic Medical Center

Gretchen Brown, MSN, RN, USA
Cyndi Parke, MSN, RN, USA

Abstract

Stanford Health Care has successfully implemented one Acuity Adaptable Unit (AAU) for neurosciences patients. The Stanford AAU model merges acute care patients and intermediate intensive care patients within one patient care unit. The nursing staff on the AAU are all trained and competent to provide varied levels of care to match each patient's clinical needs, which minimizes patient transfers between units and handoffs between clinicians, thereby decreasing demands on housekeeping and transport and improving patient safety. The current hospital expansion provides a unique opportunity to leverage this successful model of care and spread it throughout the organization, with the intent of improving the patient experience, minimizing disruptions to care, improving the staff experience, improving patient flow, and decreasing operational costs. We are currently 50% through our implementation in our existing hospital and will move the model to our new tower. This will be Stanford Health Care's new model of Nursing Care and a strategy to bring best practice to our patient centered care. This change in our existing Nursing mental model has truly been a change management initiative as well as an opportunity to look at quality outcomes from a new perspective. Patients will not move for technology and the added training allows nurses in the Acute Care and Intermediate Intensive Care areas to bring a higher level of critical thinking to their patients. Physicians and ancillary staff can now enjoy a team atmosphere and colocate their resources with their patients. Case Management has played a pivotal role in clarifying level of care, and Housekeeping and Transport are enjoying the decrease in effort since we are transferring patients less often. All of these efficiencies add to our cost effectiveness and lean perspective we have toward delivering exemplary care while being efficient. We will share some of our early metrics and lessons learned with the audience. We have learned valuable lessons along the way.

A Standardized Handover and Transport Process for Critically Ill Pediatric Patients: An Interdisciplinary Collaboration

Brigit VanGraafeiland, DNP, MSN, RN, CRNP,, USA
Cynthia Foronda, PhD, CNE, ANEF, USA
Sarah Vanderwagen, BSN, RN, USA
Laura Allan, BSN, RN, USA
Meghan Bernier, MD, USA
Jennifer Fishe, MD, FAAP, USA
Elizabeth Hunt, MD, MPH, PhD, USA
Justin Jeffers, MD, USA

Abstract

Background :The transfer and handover of critically ill pediatric patients from the pediatric emergency department (PED) to the pediatric intensive care unit (PICU) is a period of vulnerability associated with adverse events. The Institute of Medicine (IOM) has emphasized that multiple threats to patient safety exist during the transfer of patients due to the potential for delayed, incorrect, interrupted, or incomplete communications. Furthermore, delays in transfer and handover impact the time for the patient to receive definitive treatment.

Aims: Using a Systems Engineering Initiative for Patient Safety framework, the aims of this project were to 1) examine staff members' satisfaction with the current handover and transport process, 2) develop a new protocol and process for handover, and 3) evaluate staff satisfaction with the standardized, interdisciplinary, handover and transport process.

Methods: Focus groups were conducted to determine barriers and facilitators to the current handover and transport process. Using these data, a multi-disciplinary team convened to establish seven patient criteria for specialized transport as well as a standardized, interdisciplinary handover tool. The seven patient criteria were; 1.) Out of hospital witnessed arrest with return of spontaneous circulation, 2.) Status epilepticus, 3.) Complex cardiac patients with unstable vital signs, 4.) Intubation or ventilation requirements in the form of new BiPAP or CPaP, 5.) Shock physiology with vasopressor requirement, 6.) New Glasgow Coma Scale less than 10, 7.) High risk for acute compensation at the discretion of the attending physician. When patients met the established criteria, the PICU nurse and physician would come directly to the ED for team-to-team (the Pediatric Expedited Team) handover and physically assist with the transport to the PICU. The new process was piloted over a 6-month period, from September 2015 to March 2016. Staff satisfaction regarding the new process was examined pre and post-intervention using mixed methods.

Findings: Focus groups revealed five themes: need for improved communication, cultural dissonance among units, defects in system and processes, need for standardization, and ambiguity between providers regarding acuity. During the 6- month pilot period there were 370 PED to PICU transfers, 45 of which activated the PET Team (12.1%). Quantitative data were analyzed using cross-tabulations and descriptive statistics. Staff members reported improvements in their perceptions of satisfaction, safety, communication, and role understanding with the new process.

EBP PST 1 - Evidence-Based Practice Poster Session 1

The Utilization of a Nurse Manager Audit Toolkit to Re-Envision the Nurse Manager Role

Louise C. Rudden, MScN, RN, BScN, NP (Paed), Canada

Melody Hicks, BScN, Canada

Stephanie Lappan-Gracon, MN, BScN, Canada

Yogini Walli, MN, BScN, RN, Canada

Abstract

Managers are recognized as the lynchpins in sustaining organizational improvements. Over time, healthcare has evolved placing increased demands on the manager role. Factors influencing the scope of the role include increasing unit transparency and accountability, added corporate projects and protocols, increased focus on quality standards, Rising patient acuity and demand, and heightened use of technology. Managers are being pulled in different directions between operations and clinical tasks and have less time to focus on clinical leadership activities. A nurse unit manager role toolkit was utilized to re envision the nurse manager role in a pilot group of managers in a large ambulatory portfolio (The Advisory Board Company, 2015).

This was a two stage process and included restructuring the role and ensuring strategic prioritization. In the first stage, the group began by clarifying the role expectations of the manager and the executive. Using the toolkit, the first step was establishing the priority manager and executive areas of accountability. Once these had been identified a manager time audit was performed and results were compiled to identify the current state. Both these tools were key in determining the gaps between the current state and the ideal state and highlighted key areas to focus on when re-envisioning the role to meet organizational priorities. To do this in a systematic way, involved understanding manager activities to identify how to offload, delegate and eliminate low value tasks to allow managers to focus on more high value activities. Manager feedback was also incorporated to understand these activities.

In the second stage, ensuring strategic prioritization was imperative. This included securing daily efficiency gains such as strategies in delegating non-managerial work and developing expert partnerships. Protecting the important from the immediate was achieved with enhancing real time transparency and structuring each day around priorities. The toolkit was helpful in restructuring the manager role to allow managers to focus on more clinical leadership activities especially those which align with the strategic directions of the organization. Early results of the re-envisioning process are promising and will be shared. The limitations of a unit manager toolkit and the target audience for use will be discussed.

Discharging Patients Before 10:00 a.m.: A Pilot Study

Chiao-Wen Chang, RN, Taiwan
 Pi-Yu Chang, Taiwan
 Chiung-Ying Chang, RN, Taiwan
 Li-Mei Ou, BSN, RN, Taiwan
 Tsung-Hsien Lin, PhD, MD, Taiwan
 Yen-Hsu Chen, PhD, MD, Taiwan

Abstract

Background: Late afternoon hospital discharges are thought as a bottleneck for the emergency department (ED) patients admission to the ward. Currently, the discharge process is lack of generalized solutions. If admission patients discharges are earlier in a day, it might improve ED admission process, ED overcrowding, and increase satisfaction for both patients and staffs.

Purpose: The aim of this pre-/post-intervention retrospective analysis study is to increase the morning discharge percentage between 8am and 10am in a 1680 beds university medical center in Taiwan.

Intervention: The steering group create a Discharging Procedure Program (DPP) to enhance everyone's responsibilities for early discharge. We initiated several meeting rounds to explain the procedure and fully communicated with all participants. A next-day patients discharge list was created and a short message was sent at daily 8:00 am to notify physician and nurse practitioner to remind the scheduled discharge patients at the same day. We also created a website to monitor the patients expected to be discharged since April 2016.

Results: Total 21670 patients discharge was analyzed. The early discharge percentage increased from 15% to 19% over the 5-month intervention. The non-elderly (age < 65 year old) group has more earlier hospital discharges than the elderly group (age > 64 years old) ($p < 0.001$) (see Table one).

Conclusions: Our study demonstrates that increased patients early discharge could be possible by a team work. Future effort and investigation will allow for better early discharge and understanding of the difficulties on hospital discharges of the elderly.

Table one: Hospital discharges of the elderly

Variables	Discharge between 8am and 10am		Non-Discharge between 8am and 10am		X ² %
	N	%	N	%	
Age**					
age < 65 year old	2,654	18.7	11,545	81.3	0.001 _a
age > 64 years old	1,258	16.8	6,213	83.2

The Relationships Between Critical Care Nurses' Experience, Decision-Making, and Their Attitudes Toward Physical Restraint Use

Kristi J. Stinson, PhD, RN, MSN, APN-BC, USA

Abstract

The purpose of this descriptive correlational study was to examine the relationships between and among registered nurses' clinical experience, clinical decision-making processes, nursing practice issues with physical restraint use, and attitudes regarding physical restraint use in the critical care environment. The participants were 413 primarily white (91%), critical care nurses ranging in age from 19 to 68 (M=45.56) from across the United States. Participants were classified as experts based on Benner's (2001) classifications, in both experience in nursing in general (88%) and in critical care (82%) in particular. Participants were recruited through the American Association of Critical Care Nurses (AACN) and completed two online surveys (Jenkins' Clinical Decision Making in Nursing Scale (CDMNS) and The Physical Restraint Questionnaire – the Nursing Practice Issues with PR Use and Attitudes Toward PR Use subsections) via Survey Monkey™.

The results indicate that there is no strong correlation to explain any variance between attitudes toward PR use in critical care and clinical experience in nursing in general, clinical experience in critical care, clinical decision making, and nursing practice issues with PR use. This sample of nurses' mean scores on the CDMNS were higher than noted in previous research. A moderate correlation was found between clinical decision making processes and nursing practice issues with physical restraint use. There were no differences found in any of the Benner stages of clinical experience. Nurses at all of Benner's level from novice through expert had no significant differences in their attitudes toward PR use. Nurses with more clinical experience were more likely to have been taught content about PR use in their basic RN nursing curriculum than those with less clinical experience.

The results of this study suggest that there is a need to include education related to PR use in current nursing curricula which can lead to better clinical decisions and improved overall patient care related to PR use in critical care environments.

Career Maturity Characteristics of Mid-Career Japanese Nurses Working in Small and Mid-Sized Hospitals

Makiko Muya, PhD, RN, Japan
Kyoko Shida, MS, RN, Japan

Abstract

Purpose: Career maturity indicates the degree to which a person's thinking has matured regarding their way of living their professional and leisure life. The purpose of this study was to better understand the career maturity characteristics of mid-career Japanese nurses working in small and mid-sized hospitals.

Methods: Participants were 210 mid-career Japanese nurses with 5–15 years of experience working in hospitals with 299 or fewer beds. The survey questionnaire used was the Occupational Career Maturity Scale developed by Sakayanagi (1999). The scale consists of nine items each related to “career concern,” “career autonomy,” and “career planning.” The SPSS 22 was used to analyze the data to calculate descriptive statistics, Pearson's correlation, and t-tests. Ethical approval for the study was obtained from the Committee for Ethical Research for the Graduate School of Nursing at “A” University. Participants were provided with a written explanation that participation was voluntary and personal information would be handled and safe-guarded. It was assumed that consent was provided when a completed survey questionnaire was returned.

Results and Discussion: Analysis was performed on the responses obtained from 201 participants (response rate: 95.7%). Respondents' mean age was 33.9 ± 6.3 years and mean years of experience was 10.5 ± 4.3 years. Of the respondents, 119 or more than half (66.1%), intended to continue their careers (“I will continue to work in the nursing profession”). As for the mean scores for the factors on the Professional Career Maturity Scale, “career concern” was highest at 32.4 ± 5.4 , “career autonomy” was 30.6 ± 4.1 , and “career planning” was lowest at 27.4 ± 5.6 . Significant relationships between career maturity factors and intention to continue in the nursing profession were found for “career autonomy” ($r = 0.234$, $p < 0.001$) and “career planning” ($r = 0.233$, $p < 0.001$), but not for “career concern.” Dividing the data into two groups based on years of experience and performing t-tests showed a significant difference for “career planning” ($t = 1.33$, $p < 0.05$) between the mean scores for the 5–10 year group (27.8 ± 4.9) and 11–15 year group (26.6 ± 6.4). The low scores for “career planning” in this study showed that the participants found it difficult to plan their futures. In particular, the results indicated that career planning support for mid-career nurses with 5–10 years of experience is important, given the lower scores for that group. Related to continuing working in the nursing profession, autonomy and planning in the participants' professional lives were relevant to the same degree, suggesting that necessary future career support might explore options, such as fields of specialization appropriate to small and mid-sized hospitals while encouraging autonomy through fostering independence and a sense of responsibility toward the profession.

Nurses' Work-Related Fatigue and Related Factors

Chi-Hui Chuang, MS, RN, Taiwan

Yi Liu, PhD, RN, Taiwan

Abstract

Background: Fatigue not only is commonly seen in clinical patients but also prevails in healthy population. Fatigue can lead to poor performance, absenteeism, and medical adverse events. It is one of the main causes of nurses' intention to leave. Therefore, to explore the main factors associated with the work-related fatigue among nurses would help the establishment of fatigue reduction strategies.

Objective: To investigate work related fatigue and the related factors. **Methods:** A cross sectional study was conducted and a structured questionnaire survey was applied. The questionnaires were distributed to 11 wards in a district hospital and a medical center. A total of 276 valid questionnaires was obtained. IBM SPSS version 20 was used for data analysis.

Results: The main work related fatigue was acute fatigue among nurses. Physical work load, fatigue recovery, work overtime, work frustrations and work unit were significant predictors of acute fatigue.

Work overtime, recover are significant predictors. Overtime in nursing staff is generally discussed. Because of the implementation of electronic signatures, no overtime in this study sample. Because of overtime will reduce the rest time, reduce the nursing staff fatigue recovery.

According to the results of the study, the general medical ward work fatigue is higher than intensive care unit. According to the literatures, equipment in intensive care unit are more than general ward. Patients' condition with high complexity in intensive care unit. But the division in general ward is less specific. In Taiwan's general wards, 1 nurse take care of 8 patients, more at night shift. Each nurse at intensive care unit care take care of 2-3 patients.

Conclusion: Managers should implement strategies to limit overtime and performed self-scheduling method so that nurses can have more time for recovery. Based on different workload, manager reassign work to nurses/and regularly screen nurses'work-related fatigue. Be aware of the sources of nurses'work frustration and then make improvement on work environment.

Using Diverse Strategies to Enhance the Quality of Emergency Nursing

Hui-Ju Chung, RN, Taiwan

Hui-Ching Hsu, RN, Taiwan

Abstract

Purpose: As rapid economic development in Taiwan increases the living standard among the public, the needs for higher quality of medical services have also been growing, consequently gradually leading to more complaints about medical institutions. Enhancing the quality of medical services increases satisfaction and decreases the complaints from the patients. However, the enhancement of nursing quality on patients requires cross-sectional as well as longitudinal communication among medical staff, so as to effectively enhance patient-oriented nursing quality. Among those medical staff, nurses act as the coordinators between doctors and patients, and hold the key to cross-team resource integration. Nurses not only report opinions from patients and their families to medical teams, but also help medical teams to better understand thoughts and feelings of patients and their families. Therefore, this study aimed to, through clinical education and positive encouragement, enable nursing staff to identify feelings or understanding that hindered communication or caused misunderstanding in the process of doctor-patient communication in light of understanding, learning, practicing, discussing, and coordinating embedded in the communication theory. This study also attempted to help nursing staff to increase their self-awareness, and further develop emotion regulation, with good communicative skills utilized in medical teams to strengthen clinical nurse-patient communication and to enhance the quality of clinical nursing.

Methods: With the analysis of current situations and verification of previous literature for further unit complaint case analyses, project improvement based on factors related to complaints were as follows:

1. Holding relevant in-service educational courses
1. Communicative skills: error disclosure, conflict resolution, expression of sympathy, and apology conveyance.
2. Analyzing underlying reasons to verify the ins and outs as well as attributes of an event, and to propose relevant improvements.
3. Law regulations and basic knowledge related to medical disputes.
 1. Clinical practice – simulation
 1. Case discussion: Experiencing the feelings and understanding of the given communication and challenges in miscommunication between nursing staff and patients via simulations and role plays, allowing for angles and perspectives of reinterpretation.
 2. Demonstrating and explaining differences between negative and positive communication, reasons for success, and aspects that fit relevant theories.
 3. Discussing and practicing positive communication by probing into its challenges, reasons for success, and feelings/thoughts/behaviors embedded in a given communication.
 1. Ways of positive encouragement
 1. Setting up an honorary award: Publicizing patients' recognition of nurses' outstanding services.
 2. Awarding praise cards and gifts to nursing staff of outstanding services in ward meetings.
 3. Allocation of award fund: Superintendents allocated award fund to nursing staff of outstanding services.

Results: The project, with diverse strategies employed for clinical education and improvement measures, calculated numbers of complaint and praise in the Emergency Department from 2013 to 2015. The results revealed that cases of nursing complaints decreased (2 cases/year in 2013 to zero case/year in 2015), that praises of nursing services increased substantially (22 cases/year in 2013 to 97 cases/year in 2015), and that patients' satisfaction with nursing services was above 99%.

Discussions and conclusion: Medical practitioners and consumers all regarded the service attitude of nursing staff as one of significant indicators in medial service quality, and mentioned that service factors such as attitude and explanation were key to satisfaction. Nursing staff are normally in the forefront of serving patients and their families in medical institutions, thus service attitude and training of coping

capacity is vital in nursing. Nurse-patient communication is also an important factor affecting job satisfaction with nursing staff. A study probing into the effects of nursing staff's reception of communication training indicated that after the training of nurse-patient communication, the relationship between nurses and patients became closer and enhanced subsequent job satisfaction. In this project, diverse instructional methods were utilized, including communicative skills, analysis of underlying reasons, law regulations and basic knowledge related to medical disputes. Role play simulations that increased doctor-patient communication were also added, enabling participants to have hands-on experiences in doctor-patient communication in advance with diverse simulations. Ways of positive encourage for increasing the morale among nursing staff effectively lowered cases of complaints and greatly increased praises of outstanding services.

Does Nail Polish Have Significance on Pulse Oximetry Readings?: A Literature Review

Julie Titus, SN, USA

Omolara Adedimeji, SN, USA

Diandra Duncan, SN, USA

Abstract

Purpose: A patient asked “if I have nail polish on during labor and then have to go for an unplanned caesarian section does my nail polish need to be removed?” (St. Vincent’s Private Hospital Maternity Blog, 2013). In nursing, nail polish is routinely removed prior to surgery or a procedure, based on the hospital’s protocol. Patients are questioning this practice. The aim of the literature review was to discover if fingernail polish has a profound effect on the accuracy of the pulse oximeter readings.

Methods: A literature review was conducted using EBSCOhost database. Articles selected ranged from the year 2011 to 2016. Eight articles on SpO₂ and nail polish were reviewed. The five selected research articles focused on how different colors and brands of nail polish affect SpO₂ readings; articles omitted were those that accentuated other factors that didn’t include nail polish. Only subjects with SpO₂ at 95 to 100 percent were included. Results were grouped into factors studied, and were compared and contrasted with respect to their methodology and data. Research has been ongoing about the effects that nail polish can have on the accuracy of the readings.

Results: Desalu (2013) conducted a study on fifty non-smoking participants using the Lifebox pulse oximeter. Four fingers of each hand were painted with clear, red, brown, and black nail polish. One finger on both hands remained free of nail polish as the control. Colors found not significantly different from the control mean are clear and red nail polish ($p=0.378$, $p=0.427$). Only 12% of the black nail polish and 64% of the brown nail polish were able to provide readings. The mean oxygen saturation values for black and brown nail polish were significantly different from their control mean ($p<0.001$).

Jakpor (2011) of University of Southern California performed three separate experiments, one which tested six colors of nail polish on 23 subjects using the Nonin Onyx pulse oximeter and the Nellcor N-395 pulse oximeter. Each nail in this study was painted with two coats of the color nail polish followed by a clear top coat, with one nail left alone as the control. The brand used had been Avon Quick Dry Nail Polish with the colors white (Snowflake), red (Red Red), blue (Sizzling Sky), pink (Carnival), wine (Red Wine), and clear. According to Jakpor, there were small, yet clinically insignificant drops in the readings with the application of blue, pink, and white nail polish with the Nonin pulse oximeter.

Yont (2013) conducted two phases for this study on 40 healthy, nonsmoking females. The first phase of the study comprised of pulse oximeter readings (model MD300C1) simultaneously on both left and right nail beds without nail polish. The second phase consisted of using ten different nail polish colors: dark red, yellow, dark blue, green, brown, purple, black, metallic, brown and light pink of the same brand. One coat of nail polish was applied onto the left hand while the right hand remained free of nail polish. The colors found to show significance ($p<0.05$) when compared to readings on the right hand were metallic, pink, yellow, green, blue, purple, black, brown and white. Red however did not show significance ($p>0.05$).

Diccini (2011) from Paulista Nursing School at the Federal University of São Paola conducted a cross-sectional study testing four different nail polish colors on eighty healthy participants using a portable Dixtal DX-2405 pulse oximeter. The researchers used five colors on the left hand—plum on the thumb, red on the index finger, chocolate on the middle finger, coffee on the ring finger, and “coffee with milk” on the little finger—while the right hand was used as a control. It was discovered that the colors red and coffee showed much more significant differences in measurements than the controlled hand; as much as 0.19% and 0.22% respectively. Meanwhile plum, “coffee with milk”, and chocolate showed no significant differences.

Yeganehkah (2014) collected oxygen saturation readings from thirty healthy students with SpO₂ values from 95-100%. Each participant had sat on a chair at continuous resting position for ten minutes. Following this, baseline readings were obtained on all fingers as they remained unpolished. Ten different colors were then randomly selected for each participant, with the application of two coats on each nail. Once the nails were dried, SpO₂ readings were then re-measured. Nail polish colors, orange, pink, and purple did not have an effect on SpO₂, while the other colors did provide a statistical difference (p<0.05). These readings however were clinically insignificant with <1.2%.

Conclusion: The results of the reviewed articles showed a variation on the effect that fingernail polish has on pulse oximeter readings. Each study varied depending on the color of nail polish used, the brand of the pulse oximeter, and the number of coats applied. On extensive review of the selected articles, it was found that colors such as black, brown, blue, pink, and white had more of an effect on pulse oximeter levels than colors such as red and clear. Although, red is noted to have the least significance in most of the articles, it was discovered in one study that red nail polish had a greater effect than other colors such as plum, "coffee with milk", and chocolate (Diccini, 2011). The reason behind these contradicting results is not stated, however, may suggest that the color of nail polish is insignificant to pulse oximeter readings. Through review of these articles, differences were detected with colors that had the greatest impact on pulse oximeter readings. These differences, however, are clinically insignificant and not great enough to make a significant impact on pulse oximeter readings. Thus, it is concluded, through the extensive review of literature, that fingernail polish does not have a profound effect on the accuracy of pulse oximeter readings.

EBP PST 1 - Evidence-Based Practice Poster Session 1

A Method of Analyzing Defects in Preoperative Preparation Process Using a Computerized Control System

Maya Novikov, BS, RN, Israel
Liat Cohen, MA, RN, Israel
Tatyana Fishman, MA, RN, Israel

Abstract

Overview: Providing of qualitative and timely care to all patients is a critical goal of management in surgery departments. The significant role in achievement of that goal and in effective functioning of staff in surgical department is an accurate preoperative preparing of patients. Defects in preoperative preparation process often cause to delays and cancellations of operations which lead to such outcomes as: increase of patient risk factors, prolongation of patient waiting time, ineffective usage of operational resources, reduce of patient's satisfaction rate, etc. Effective analyze of those defects and applying appropriate steps have significant impact on improvement of preoperative preparation process in surgery departments.

Purpose: To assess effectivity of a method for reducing rates of defects in preoperative preparation process based on a computerized control system.

Method: The method was introduced in 2015 in a major medical center (1,500 beds, 120 wards, 2,500 nurses) located in Israel as part of initiative to improve the effectivity of operations department. The method provides a way of analyzing reasons of delays and cancelations of operations causing by defects in preoperative preparation process. The method consists of introduction of computerized control system for documenting and classification cases of inappropriate preoperative preparation of patients. The method enables to get summary reports by various criteria, for example, by defects causes, by departments, etc., and this allows to see the whole picture and identify "bottle necks". During the period of application of the method, the documenting of cases and sharing reports were performed by nurse of preoperative room of operating department. The reports were distributed daily to management of surgery departments and contained patients' data and details of inappropriate preoperative preparing. These reports enabled nurses in charge as well as nursing management to identify the most frequent defects in each surgery department and to correct the preoperative preparation process in those departments. The main advantages of this method are transparency and availability of information which facilitate the improvement of preoperative preparation process.

Results: During the period of application of this method in medical center was observed significant reduction at least 80% of the rate of defects in preoperational preparing of patients in compare to the previous year. In addition, during the same period the number of operations was increased at least by 10%. Also, this allowed to renew and improve the existing procedure of preoperational preparing of patients and ensure more safety and qualitative care to all patients.

Describing the Contribution and Value of Public Health Nurses to Health System Outcomes

Nancy Purdy, PhD, RN, Canada
Maureen Cava, MN, RN, FCCHSL, Canada
Joanne Crawford, PhD, RN, Canada
Cristina Catallo, PhD, RN, Canada

Abstract

Given that nurses are the largest group within the public health workforce, more effective use of PHNs would optimize the associated financial investment by improving the upstream prevention of illness and promotion of health (Meagher-Stewart, 2009). PHN roles have been vulnerable to cuts and replacement by other less expensive providers (National Advisory Council on Nurse Education and Practice, 2013). Building an effective Public Health Nurse (PHN) workforce requires an evidence base to articulate the contributions made by PHNs to the health outcomes of individuals and communities they serve (Underwood, 2010). Many aspects of PHN practice are invisible and need to be made explicit to the public and to administrators who manage public health programming and resources (Royal College of Nursing, 2016). The purpose of this study is to explore PHN and Nursing Leaders perspectives of their perceived value to health system outcomes.

The Nursing Role Effectiveness Model (Doran et al., 2002), based on systems theory, includes structural, process and outcome components that impact the quality of care. This framework will underpin the interview guide, as well as the identification of concepts relevant to PHN practice in relation to health outcomes. To understand outcomes unique to public health, the Ontario Public Health Standards (MOHLTC, 2008) will be used to reflect the five program areas (infectious diseases, family health, chronic disease management, environmental health and emergency preparedness).

A qualitative design will be employed and data collected using individual telephone interviews (up to 60 minutes). Purposive sampling with maximum variation will be used to ensure representation by the five programmatic areas of public health practice, the five regions of public health across Ontario (Canada) and a balance of PHN roles. Participants will be recruited via email distributed through the membership of two provincial PHN professional groups representing direct practice and formal leadership roles. A sample of 20 practitioners and 10 nursing leaders are sought (or more until saturation achieved). Interviews will be recorded, transcribed verbatim with personal identifiers removed. NVIVO 10 will be used to assist with coding. Inductive content analysis will be used to identify themes. Themes derived from the interviews will be used to identify concepts relevant to PHN practice in relation to contributions, value to the system, and group/community outcomes. The findings will be used to inform a systematic review of the literature to identify PHN-sensitive outcomes that can be used by administrators and policy makers to plan appropriate health human resources required for a robust public health system.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Evaluation of Comprehensive Screening to Support Initial Depression Diagnosis Among Military Adolescent Beneficiaries

Chelsea M. Cruz, BSN, RN, USA

Alicia Rossiter, DNP, FNP, PCPNP-BC, FAANP, USA

Catherine G. Ling, PhD, FNP-BC, FAANP, USA

Abstract

Problem Statement: Due to the unique life circumstances associated with military service, greater burdens are placed on a military member's family increasing stress and risk for mental illness, especially among pediatric dependents. Symptoms of adolescent depression vary by individual and often go undiscovered by those closest to the individual. 90% Of adolescents seen within primary care in the United States have an undiagnosed mental health illness (NAMI, 2016). when an adolescent is facing a mental illness or attempting suicide, it prevents our military members both stateside and deployed from completing their missions adequately. Adolescent patients who are presently seen at a Military Healthcare Facility for primary care are screened using the Patient Health Questionnaire- 2 (PHQ-2) only at annual visits and when presenting with a psychosocial chief complaint. The PHQ-2 is not a comprehensive questionnaire and is not required to be completed at all visits with the physician. With 80% of families visiting their primary care physicians throughout the year it is imperative that screening for depression improves (Arroll et al., 2011). In the absence of a routine comprehensive screening 50% of adolescent depression cases are being overlooked (Arroll et al., 2011). **Purpose:** The PHQ-2 presently promoted by military pediatric primary care providers is not identifying over half of adolescent military beneficiaries at risk and/or presently suffering from symptoms of depression. Clinical recommendation for this study is to screen all military adolescent beneficiaries with the comprehensive Patient Health Questionnaire-9 Modified on a routine basis to support identification and initial diagnosis of depression. This study will explore the use of a standardized comprehensive depression screening tool (PHQ-9 Modified) among military adolescents for initial suggestive diagnosis. **Methods:** A voluntary anonymous online survey will be available for completion by parents of military adolescent beneficiaries who are stationed at MacDill Air Force Base in Tampa, Florida. The scoring of surveys will be completed following required methods established by the PHQ-9 Modified and PHQ-2 questionnaires. Evaluation of the survey results will reveal a comprehensive screening assessment tool's ability to support initial diagnosis of military adolescents at risk for depression. This will be reflected through supported data of the comprehensive screening questions derived from the PHQ-9 Modified identifying more individual military adolescents scoring at risk for depression that were not found at risk using questions derived from the PHQ-2. **Significance:** Adolescent depression is a serious disorder which often goes undiagnosed and has the ability to lead to suicidal attempts. Despite this fact and numerous supporting studies, practice guidelines have not wavered and continue to diagnose less than 50% of adolescents with depression prior to adulthood, with less being diagnosed within the military adolescent population. Our goal is to identifying and support the need for a routine comprehensive screening tool. With this study's support, education initiatives will be provided to not only to clinical staff at MacDill Air Force Base but also to the United States Military's health care providers across the nation and worldwide so that not only the adolescents at MacDill are screened properly, but those overseas as well.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Nursing Student Simulation: A Three-Tiered Model Approach

Kristina L. Leyden, PhD, APRN, FNP-BC, USA

Nakisha S. Paul, MBA, USA

Katherine D. Simpson, MSN, RN, FNP, CNRN, CVRN-II, LNC, USA

Abstract

Introduction: Simulation has long been used as training in nonmedical facilities¹. In nursing, it has had many definitions. The oldest definition found is using models to teach basic skills¹. As simulation technology grows, changes, and improves, so does the need to clearly define terms and how we use them. Simulation, presently, includes varying degrees of interaction. Examples include low-fidelity models (LFM) which has limited function/interaction (task-trainer intravenous (IV) arms for IV insertion); medium-fidelity mannequin (MFM), (chest model illustrating heart rhythms); high-fidelity mannequin (HFM), (full-bodied mannequin, fully functioning, mimicking a living patient)^{2,3}; and standardized patients (SP), (live persons participating in a scenario)⁴.

Technologically-enriched learning through simulation lab activity enhances personal and professional confidence. Simulations promote teamwork through communication and collaboration⁵. Students stated they enjoy the simulation lab activity and prepares them for the real world clinical environment. Students enter their roles with explored senses of patient care needs, and clinical expectations. This produces confidence and decreases situational anxiety⁶. Patient safety has improved since the seeds of critical thinking skills have been planted and sprouted in the real clinical environment. Medication errors are identified and corrected during simulation learning⁷.

Usefulness of differing simulation mediums in student education needs to be fully explored, well-documented, and clearly defined. Recommendations for use of differing simulation methods are dependent on learning objectives and the level of the student⁸. The purpose of this research is to disseminate how one baccalaureate-nursing program in a highly diverse, liberal-arts university with novice simulation technicians and faculty defined various methods of simulation, students' response to various methods, and recommendations for use.

Background: Partnership with a senior baccalaureate-nursing program with expert simulation technicians and faculty occurred so lab facilitators/faculty could shadow simulations and explore laboratory function to enhance simulation development and experience with novice users. A hospital clinical rotation preparation simulation was developed in Fall 2015, it was well received by students; however, technical limitations warranted close examination for modifications. High-intensity simulations were used in Spring 2016. Categorization, definitions, and learning objectives for simulation was needed for clarity across the program.

Methods: Faculty developed an introductory simulation, Fall 2015 for the adult/older adult medical surgical course, in addition to already existing laboratory skills with LFM. Introductory simulation included students assigned to one-on-one care to HFM with adult/older adult medical/surgical scenarios. This simulation mimicked a general medical/surgical hospital unit. Objectives included hospital unit preparation, setting expectations, understanding the routine of a hospital unit, beginning clinical reasoning, and effective communication to facilitate patient care. One student acted as charge nurse, other students assessed, medicated, and called the "provider" if needed and performed many other tasks, critical thinking, and prioritizing orders. Students carried out orders, documented findings, called laboratory and radiology for results, if needed. Students performed this simulation over 6-hour periods with pre- and post-briefing. Debriefing included asking the students to describe how they can use this experience going forward to their clinical experience, discuss their perceived limitations, and their perceived needs for clinical success.

Faculty extended simulation Spring 2016 for the Pediatric course. This simulation was increased in intensity and performed in a shorter period in small groups of 2-3 students and completed in phases. This

simulation included two higher acuity patient scenario and a focus on clinical reasoning. Students participated in two scenarios. Pre- and post-simulation testing completed to measure effectiveness and meeting of learner objectives.

Students' positive feedback and request for more simulations prompted the faculty to develop a step-approach to simulation in courses. Resources and technological restrictions needed to be evaluated.

Limitations: HFM require the most consideration. HFM are manufactured and programed by commercial companies and try to resemble life-like situations. Battery life varies between brand, gender, and mass. Males are more efficient because of automated features. The power source is located below the waist. Females use more power. They are used for general simulations and maternity. In maternity simulations, automation requires total body manipulation which requires greater power. Longevity of the mannequin's battery life may determine scenario length. Learning objectives may depend on mannequin type.

Power source can be a great limitation, as well as varying sizes of simulation laboratories. When the lab size is small, the radioactivity space is limited. This causes a voided transfer of data between mannequins. This cancels programmed scenario data and will not allow use of multiple mannequins in one setting; this can create limited teaching capabilities at one time.

Instructors must monitor mannequin vitals at all times. If abnormal vital signs are set in a scenario and go untreated by the student, mannequins will decompensate like live patients would. Mannequins will overheat and shut down.

Facilitator knowledge and ability varies and facilitators must learn the technology in order to allow the student to gather the most benefit. This facility uses an ultraportable recording system, so the ideal simulation includes one-facilitator recording/annotating student observations, one facilitator changing mannequin settings, vital signs, one answering the students' questions as the "patient", and one facilitator acting as the provider on-call, laboratory, or other departments the student may need to call upon.

Implementation: In Fall 2016, faculty developed a three-tiered model approach to simulation for students entering the adult/older adult medical surgical clinical rotation in order to classify and define simulation exercises for students. The first tier, coined "Sim-Skill", included needed laboratory skills training. The second tier, "Sim-Shift", is an introduction into the hospital unit and patient care during a shift. The third tier, "Sim-Care", is a high-acuity patient scenario.

Sim-Skill included learning new skills on LFM. For example, nasogastric tube insertion, central line dressing change, and injections were a few of the skills learned. In addition, students view equipment orientation and procedures via faculty-made videos.

Sim-Shift included students assigned to HFM as if in a general medical/surgical nursing unit, like in the previous year. However, shifts were shortened to morning and afternoon sessions allowing for technical considerations, and the students to report to one another between shifts. Session changes allowed the students to develop their communication skills nurse-to-nurse while giving report on the patient. Students in both sessions reported to the class on the following day their experience. These changes allowed the mannequins to reset between sessions. Most importantly, it allowed the students to transfer patient care and learn what was essential in communicating for transfer of care. Students got a sense of what it is like to work on a medical/surgical unit, fully manage patient care, communicate for continuation of care, and be accountable to others for that patient. Furthermore, students were able to put into practice fundamental safety concerns. For example, if a student left a side-rail down, simulation facilitators would place mannequin on the floor for the student to find. Sim-Shift was useful in identifying immediate safety and prioritization student needs.

Sim-Care included HFM and SP (acting as mannequin's family member) with high-acuity adult/older adult and pediatric scenarios performed in groups of 2-3 students. Expectations included assessment, prioritization, and interventions appropriate to scenario stages. The simulated patient's family may also be in the scenario adding another dimension to the simulation. They were also expected to communicate

findings to the patient's provider. Learning objectives in this tier include synthesizing theory learned in classroom and skills learned in the previous tiers. In addition, faculty assessment of students included clinical judgment and critical indicators. Pre-/post-simulation testing occurred.

Results: Students consistently request more time spent in the lab to develop technique and facilitate practice for the clinical setting. Students report a freedom in lab practice without risk of causing harm to a live patient.

Students participating in Sim-Shift reported better understanding of clinical expectations/role and helped to link theory to actual patient care. They reported seeing symptoms displayed by mannequins helped make disease clinical manifestations concrete. Learning these elements in simulated environment helped students feel safe in practice when clinical began. Students especially liked mannequins who were placed on contact/respiratory isolation. This helped make aware of needing to prioritize and prepare nursing interventions. Students learned importance of communication and preparedness before talking to the simulated-provider of the patient in order to receive orders or request the patient to be seen. Students reported an over-all positive experience and a desire for more Sim-Shifts.

Students participating in Sim-Care reported positive, stressful experiences. Post-simulation testing improved knowledge base in 57% of students for both scenarios and 83% of students for one scenario. One student had poor performance in post testing of both scenarios. All students identified own needs in order to think, prioritize, communicate, and implement patient care. All students requested more Sim-Care scenarios to translate didactic content into practical environment.

Conclusion: Simulation definitions helped facilitators communicate needs and student expectations to faculty and students. In addition, the clear definitions helped students understand a step-approach to clinical preparedness. This three-tiered model approach assists faculty in deciding simulation levels appropriate to student ability of for meeting set objectives. Technical limitations help form simulation type, length, and intensity. Faculty will continue to use this three-tier model to facilitate learning.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Engaging Nurses to Promote Clinical Outcomes

Allison Kathleen Peters, DNP, RN, CNOR, NEC, USA

Abstract

In a profession where it is critical to be engaged, nurses are said to be the least engaged of all of healthcare providers. As reflected in the research reviewed for this scholarly project, patients cared for by engaged nurses have been shown to have positive outcomes in their care. It is crucial to understand the factors facilitating nursing engagement and how we can create the work environment needed for nurses to achieve and maintain high levels of engagement in their workplace. To better understand the basic factors that help facilitate a healthy work environment for nurses, the Maslow Hierarchy of Inborn needs was paired with a corresponding Maslow Triangle of employee needs to investigate the effects of evidence-based workshops on levels of nursing engagement. This quality improvement project was conducted in a large academic medical center that has 850-beds and a Level I Trauma Center in its third Magnet® designation status. The two top rated engagement challenges in the unit were identified through the National Database of Nursing Quality Indicators (NDNQI) survey. Selected staff development workshops were conducted along with the utilization of the evidence based Press-Ganey® Action Planning Tips Guide (Toolkit) which targeted specific engagement challenges. 32 nurses participated in this project. The effectiveness of the project and its impact on nursing engagement was measured by comparing responses pre- and post-workshops using Utrecht Work Engagement Survey (UWES). In addition the Practice Environment Scale of the Nursing Work Index (PES-NWI) was given post implementation of the project. Increases in vigor, dedication and absorption were measured and observed across all of the engagement benchmarks evaluated. Limiting factors included length of time project was in place and study size. As part of Magnet status, nursing satisfaction/engagement is required to be measured and maintained at a high level and this project supports that it is a potentially modifiable construct.

Fostering Nurse Renewal Through Compassion: A Model for Alleviating Nurse Workplace Stress

Marie M. Shanahan, MA, RN, HN-BC, USA
Gayle Novack, MAOM, BSN, HNB-BC, USA
Veda L. Andrus, EdD, Hn-BC, USA

Abstract

Nursing workplace stress is a known deterrent to nurse satisfaction with the work environment. (Cranick, Miller, Allen, Ewell, & Whittington, 2015) It can lead to compassion fatigue and burnout. It is a contributing factor to nursing turnover and decreased retention of a skilled workforce (Edmonson & Asturi, 2015). Nurse workplace stress is an element of the downward spiral in patient safety and quality. If left unchecked it creates a cascading effect that diminishes effective organizational functioning, costing millions and endangering patients' lives (Birmingham, Dent & Ellerbe, 2013). Sadly, it can rob nurses of the joy and fulfillment they derive from caregiving (Bauer-Wu, & Fontaine, 2015).

Nurse workplace stress is most often associated with perceived and actual stressful elements of the work setting. It can be caused by challenging professional or personal relationships, inadequate staffing, demanding clinical workloads, patient acuity, unresponsive leadership, unresolved moral distress, and weak psychological boundaries. Regardless of the cause, it threatens the nurse's ability to perform at peak levels. (Richards, 2014).

Because nurse workplace stress is closely related to patient outcomes, it is imperative that nurse leaders create realistic avenues for nurses to develop coping skills and build resilience on the job.

This 900 bed urban hospital nursing team recognized the signs of nurse workplace stress and opted to take on the challenge. The nursing leadership had set the stage by adopting Jean Watson's Caring Science theory as their guiding philosophy of care. It fit well with their mission of providing spiritually centered holistic patient care. Nurses were educated in the tenets of Watson's theory and sought to enact them in clinical practice. They quickly realized that while nurses strongly desired to practice more caring centered care, they were failing due to tremendous workplace stressors related to heavy patient workloads, persistent staffing shortages and pressure to respond to multiple organizational initiatives. Nurses were describing their workloads as 'unbearable' and 'overwhelming to the extreme'.

To address this problem, nurse administrators developed a pilot project. They created a renewal room on the women's health unit. The purpose was to have specifically designated spaces for nurses to rest and re-focus while they are on shift. (Bullen, 2016). It needed to convey a sense of tranquility and peacefulness where nurse could reflect and re-connect to their love of nursing. It also needed to be a place where nurses let go of their burdens for a short period of time and practice the art of self-care (Andrus, 2016). As part of this project, it was hoped nurses would find relief from their day to day stressors and develop greater resiliency with regard to their workload.

A room that held excess equipment was selected as the designated space. It was close to the nurses' station, too small to be a patient room and had a privacy lock on the door. The nurse manager quickly enlisted clinical nurses to transform the room into a tranquil and soothing space. Nurses donated a comfortable chair and foot rest. They decorated with soft lighting, pillows and an electric tea pot and cups. Soon other nurses provided a portable music player and relaxing music. Also added were uplifting reading material, inspiring sayings and a journal to share thoughts with other nurses.

The renewal room became an overnight success with nurses utilizing it to refresh and rejuvenate before, during and after their shifts. As the usage increased, nurses from other units began to request their own renewal room. Today there are 17 renewal rooms throughout this organization, including one in the nursing administration office. They are in all patient services areas including the emergency department and surgical services. All employees are permitted to use the rooms for the purpose of quiet reflection

and alleviating their stress. The rooms are not used for eating, sleeping, consulting, charting, or meeting. They are separate from nurse break rooms and patient-family meeting areas. One person at a time may use the room and electronics are strongly discouraged. Some rooms contain massage chairs and many have essential oils for aromatherapy.

Included in this poster is a communication from one nurse to another that poignantly captures the need and success of the project.

First entry: "My nurse manager took me to this room today because I had my first breakdown on the unit. She is making me stay here for 30 mins. So while she's caring for my patients...and I cry my eyes out...I am still worried about doing things for them ON TIME. Being a new nurse is so stressful. This chair is cozy, the tea is yummy and I feel like I failed today. When does that feeling go away? My patients need me :-)"

Second entry: "Hang in there, we were all once a new nurse! Each day focus on one thing that went smoother, time management takes organization and in time will come. Things will all come together. BREATHE . It helps to have support, ask for help, ask for tips from your TEAM. How they prioritize, time save. Sending you + thoughts for an easier day! I'm sure your patients can feel your kind spirit, let it shine through! Be yourself! :-)"

Nurses were confronting tremendous work stressors, robbing them of their joy and resilience. This organization was committed to addressing workplace stress for their nursing team and they did so in a creative and compassionate fashion. Learn how they improved nurse renewal and embedded self-care in their culture. Today the renewal rooms are part of their culture and have contributed to a caring nursing work environment.

Feasibility of Using Appreciative Inquiry to Improve Maternity Services in District Hospitals of Malawi

Zione Dembo, MSc, BSc, RNM, Malawi
Abi Merriel, MD, BSc, PGCertMedRsch, United Kingdom

Abstract

Purpose: In Malawi as demand for maternity services continues to surpass supply and overstretches frontline healthcare providers, it is important to improve the quality of maternity care to address the burden of maternal mortality and morbidity. Appreciative Inquiry (AI) is a method through which healthcare providers can make organisational change to improve clinical care and their working lives. It harnesses the energy and ideas of staff through a four-stage cycle: Discover (how it is now), Dream (of what it could be), Design (concrete plans) and Destiny (implement plans).

The purpose of the study was to assess the feasibility of implementing Appreciative Inquiry in three district level facilities in Malawi using participatory approach.

Methods: Between April 2015 and January, 2016 we adapted and implemented AI through participatory action cycle sessions.

Findings: We have successfully implemented AI with contributions from the entire ward team (patient attendants, nurses, clinical officers and clerks). Each team chose a different focus for their activities including 'team spirit' and 'infection prevention'. In two hospitals there have been some steps towards change, driven largely by key midwives team leaders. In one hospital the team have lobbied the management to have security guards to support their 'traffic control' policies in addition to successfully implementing the removal of shoes before entering the nursery and kangaroo wards. Another team has reduced the number of incidences of overfull sharps bins and waste in the incorrect bins on the ward. The main challenges faced were from constantly changing teams and the lack of time and resources to dedicate to the change process.

Conclusion: It is feasible to implement AI in maternity settings in Malawi when the care providers stay positive. However, the presence of committed champions seems important and health system challenges necessitate realistic goal setting; further study is needed to understand the effectiveness of the intervention.

Engaging Nurses in the Diagnostic Process

Kelly T. Gleason, BSN, RN, USA

Cheryl R. Dennison Himmelfarb, PhD, RN, ANP, FAAN, USA

Abstract

The dismal state of diagnostic errors in the medical world has recently been highlighted by the National Academy of Medicine's report, *Improving Diagnosis Healthcare* (The National Academies of Sciences, 2015). Each patient in the United States health care system faces a 5% chance of experiencing a diagnostic error every year. The first goal listed in the National Academy of Medicine's report is "Facilitate more effective teamwork in the diagnostic process among health care professionals, patients, and their families." The report specifically recommends interprofessional teamwork in the diagnostic process. Historically, medical diagnosis is considered solely a physician responsibility, and teamwork in diagnosis generally refers to physicians working together across specialties. There is a pressing need to adjust this antiquated view and enlist nurses to address diagnostic error. Interprofessional collaboration has been a key principle in successful efforts to reduce therapeutic errors (Goeschel & Pronovost, 2008) and, we believe, will be equally important to diagnostic safety efforts. While there are logistical, regulatory, and sociocultural barriers to engaging nurses and other allied health professionals on the diagnostic team that must be addressed, the potential benefits of engaging them are immense. (Newman-Toker, 2016) Achieving diagnostic safety is aligned with the core values of the nursing profession to provide safe, effective, and compassionate care. The purpose of this paper is to discuss necessary steps to address barriers to nurses effectively participating in the diagnostic process.

To change the view that nurses are not diagnostic team members, several steps must be taken:

- 1. Sociocultural barriers:** Nurses and physicians working together requires learned skills, including an understanding of roles and responsibilities, effective communication, shared values, and teamwork. Collaboration in practice results in better patient outcomes and healthcare processes (Zwarenstein, Goldman, & Reeves, 2009), and will be key achieving diagnostic excellence. There is a need for a paradigm shift in which nurses and physicians work together for the benefit of patient outcomes. Sociocultural barriers can be overcome through interprofessional education, multidisciplinary rounds, and understanding other health professionals' roles and responsibilities. Interprofessional education is required by licensing bodies of health professions and includes focus on interprofessional communication, understanding the roles of each discipline and collaborating as teams. Application of interprofessional principles should specifically focus on training opportunities related to the diagnostic process and the role of teams in achieving diagnostic accuracy. Creating structured opportunities for nurse to share observations and conclusions with diagnostic team may be a place to begin engaging nurses. Multidisciplinary rounds are increasingly common; including a discussion regarding the diagnostic process in multidisciplinary rounds would give the nurses an opportunity to present their observations and conclusions. Understanding other health professionals' roles and responsibilities is key to valuing the voice each health professional brings to the table. Nurses, physical therapists, and pharmacists are just a few allied health professionals that are not traditionally thought of as being members of the diagnostic team, though each brings an important perspective and knowledge to the diagnostic process.
- 2. Logistical barriers:** Logistical barriers exist in managing nurses' time in their already busy schedules to give them opportunities to present their observations and conclusions to providers. While providers and nurses may be open to nurses participating on the diagnostic team, the current routine in many hospitals has the diagnostic thought process taking part separate from the nurses. Logistical barriers can be overcome by working as a team to prioritize the diagnostic process in recognition that it is currently a major source of patient harm.
- 3. Regulatory barriers:** Regulatory barriers exist in the variable scope of practice regulations across locations. For example, within the United States, differences exist across states in nurse scope of

practice regulations. More effective and timely diagnoses can be enhanced if nurses practice to the full extent of their scope of practice. The Institute of Medicine's report "The Future of Nursing: Leading Chance, Advancing Health" (2010) highlighted the need for nurses to practice to the full extent of their education and training. Nurses play a critical role in monitoring the patient's condition, identifying and preventing diagnostic errors, care coordination, communication, and patient education. However, there is documented evidence that nurses are not currently practicing to their full scope of practice. Addressing regulatory barriers requires: 1) working with legislators to create universal scope of practice regulations that allow nurses to practice to the full extent of their training, education, and experience, and 2) nurses understanding scope of practice regulations in their specific area.

In conclusion, diagnostic errors are an urgent problem in health care. Achieving diagnostic excellence is impossible unless nurses contribute to the diagnostic process as an equal member of the healthcare team. Nurses have not traditionally been considered diagnosticians; we have a responsibility to own our role on the diagnostic team out of commitment to providing safe, effective, and compassionate care.

Reducing Preventable Transfers From Short-Stay Care

Carmen Potter, MSN, RN, USA

Abstract

Problem: Reducing hospital-acquired conditions and decreasing the number of potentially avoidable rehospitalization are targeted goals of the federal health care reform (Maslow & Ouslander, 2012). Vulnerable populations such as clients who are being cared for in skilled nursing facilities (SNF) are often subjected to unnecessary emergency room visits and rehospitalizations. One in 4 clients discharged to a SNF is readmitted within 30 days. (Neuman, Wirtalla, & Werner, 2014). The PICOT question for the practicum project is, "For the nursing staff on a short-term care unit, does the implementation of an evidence-based patient evaluation tool, INTERACT, lead to a reduction in preventable hospitalizations?"

Evidence: It is believed that two-thirds of the readmissions are preventable (Neuman, Wirtalla, & Werner, 2014). These interventions increase healthcare costs and the incidences of hospital-acquired complications. Increased morbidity and mortality rates occur as a result of preventable transfers to acute care facilities. If a substantial percentage of rehospitalizations can be prevented, billions of dollars in Medicare and Medicaid savings will result over the next several years (Ouslander, Bonner, Herndon, & Shutes, 2014; Bonner, Tappen, Herndon, & Ouslander, 2014).

Interventions to Reduce Acute Care Transfer (INTERACT) is a quality initiative implemented by many skilled nursing facilities in the United States, Canada, the United Kingdom, and Singapore. Consistent use of the program has been associated with a 24% reduction in preventable hospitalizations of nursing home clients over a six-month period (Ouslander et al., 2014; Toles, Young, & Ouslander, 2013).

Strategy: Interventions to be implemented at the skilled nursing facility are components of the validated INTERACT quality improvement program. INTERACT is comprised of several tools and does not require implementation of all tools to be effective in reducing preventable transfers to acute care facilities. The INTERACT Quality Improvement Program is designed to assist and guide front-line staff in early identification, assessment, communication, and documentation about acute changes in client condition. It includes clinical and educational tools and strategies for use in everyday practice in skilled nursing facilities. Skilled nursing facilities across the country have implemented portions or all parts of the INTERACT Quality Improvement Program and many facilities have been able to significantly reduce avoidable hospitalizations using these resources (Ouslander et al., 2014; Toles et al., 2013).

The tools chosen for the pilot provide structured information used for client assessment which can then be relayed to the healthcare provider appropriately in a structured format. All licensed nursing staff will use Care Paths. Care Paths is an educational and reference tool used in guiding the nurse with the evaluation of specific symptoms that commonly cause acute care transfers. Acute Change in Condition File Cards are used by licensed nursing staff and provide guidance on when to communicate acute changes in status to healthcare providers. Another tool from the INTERACT program is the Stop and Watch Early Warning Tool which is utilized by Certified Nursing Assistants. Regular evaluation of and recognition of changes in clients' condition and reporting changes to the nurse is enhanced with use of Stop and Watch. All licensed nursing staff will incorporate the SBAR Communication Tool and Change in Condition Progress Note to effectively evaluate and communicate acute changes in condition to healthcare providers. Documentation of evaluation and communications on the form allows this to be a permanent part of the client medical record. Finally, the fifth INTERACT tool to assist with documentation of unplanned acute care transfers data collection is the Acute Care Transfer Log.

Practice Change: The purpose of the proposed clinical practice change process is to determine if implementing components of the INTERACT program at the skilled nursing facility will reduce preventable transfer and hospitalizations of clients from the short-stay care unit. The project proposal provides an overview of how INTERACT is used to successfully decrease unessential rehospitalizations. Information

on the significance of the problem as it relates to a higher than national percentage of rehospitalizations associated with not using a quality program such as INTERACT is presented. Practice recommendations and the plan to implement the proposed change process will be discussed with the goal being preventing unnecessary hospitalizations when it is safe to do so (Maslow & Ouslander, 2012).

Evaluation: Outcome represents results that will be measured to examine the effectiveness of the proposed intervention. Validated outcome measurement tools relevant to the pilot are utilized. The outcome being assessed in the project is the number of avoidable hospital admissions after implementation of the INTERACT quality initiative tools. The long-term objective for the pilot is there will be a 2% decrease in client rehospitalizations from the short-care unit during the eight weeks of practice implementation.

Depression and Its Predictors in Hemodialysis Patients in Taiwan

Chou-Ping Chiou, PhD, RN, Taiwan

Abstract

Background. Depression is a common psychological problem in hemodialysis patients that affects their treatment compliance and lifestyle as well as their quality of life. Previous studies showed that depression and anxiety symptom in older HD patients were significantly higher than that of the age-matched controls. Social support is important for HD patients' treatment as it influences dialysis patients' health.

Aim. The objectives of this study were to investigate depression in hemodialysis patients in Taiwan and the important predictors for depression.

Methods. This study used a correlational cross-sectional design. Data for 150 hemodialysis patients were collected from one hemodialysis center in southern Taiwan. Measures included a demographic and clinical variables questionnaire, the Center for Epidemiologic Studies Depression Scale, and the Personal Resource Questionnaire 2000. Statistical analysis was carried out using multiple regression analysis.

Results. The results showed 55% of hemodialysis patients may be depressed. The social support level for hemodialysis patients was in the moderate range. Multiple regression analysis revealed that marital status, number of comorbidities, exercise behavior, and social support could significantly predict depression; total explanatory variance was 30.5%.

Implications for nursing practice. Hemodialysis patients have a high prevalence of depression. Risk factors influencing depression include lack of spouse, higher numbers of comorbidities, low levels of exercise, and low social support. The findings of this study can assist health care professionals in understanding factors that influence depression in hemodialysis patients. According to this study, exercise and social support are important factors that reduce depression and should be used in the care of hemodialysis patients. Exercise or regular physical activities are an integral part of life. Health care professionals can also help find an appropriate method of exercise and providing patients with concrete home exercise guidance. This study may serve as a reference when drafting future interventions to prevent or improve depression and enhance daily psychological and social care.

Personalized Bleeding Risk Score to Optimize Post Coronary Intervention Outcomes

Sivaranjani Ramamoorthy, DNP, MSN, RN, ANP, NP-C, USA

Abstract

Purpose: To examine the effect of implementing a standardized bleeding risk score in minimizing bleeding complications in adult patients undergoing percutaneous coronary intervention

Background: Bleeding is the most common complication after percutaneous coronary Intervention (PCI). PCI-related bleeding events are associated with increased mortality, morbidity, cost and length of stay (LOS). Based on the Centers of Medicare and Medicaid Services Acute Care Episode Demonstration Program, PCI-related bleeding is considered a quality indicator for PCI outcome. According to 2011 AHA/ACC PCI guidelines, all the patients undergoing PCI need to be evaluated for their bleeding risk prior to the procedure. Personalized bleeding risk score (BRS) can predict and prevent PCI-related bleeding complications. The National Cardiovascular Data Registry (NCDR) CathPCI bleeding risk score (BRS) is a validated bleeding risk predictor tool which is readily available however, it is underutilized in the clinical setting.

Methods and Results: A quality improvement study was proposed and implemented in a cohort of sequential patients (n=128 electively scheduled for PCI. Retrospective data of patients who were reported to have had bleeding complications requiring blood transfusion and extended length of stay (LOS) were retrieved electronically. Then, an educational intervention was instituted to implement the BRS assessment tool and to use an expanded PCI-specific bleeding definition to document post-PCI bleeding. PCI-related bleeding complications, prior to initiation of the CathPCI bleeding risk tool (n=64) was compared to those who had pre-procedural estimation of bleeding risk (n=64) before undergoing PCI. Pre-procedural estimation of bleeding risk has had significantly (p=0.00) reduced the rate of PCI-related bleeding complications. The use of a bleeding risk tool supported clinician's selection of the appropriate treatment modalities such as coronary artery bypass graft (CABG) vs. percutaneous coronary intervention vs. medical therapy; assisted in the selection of stent type, drug eluting vs. bare metal, helps in the choice of type and duration of antiplatelet therapy, aids in careful attainment of vascular access radial vs. femoral artery, and influenced the use of vascular closure device vs. manual compression to reduce a patient's chances of developing bleeding complications.

Conclusion: Estimating pre procedural bleeding risk guides clinical decision making to promote bleeding risk adjusted therapy and which achieves better clinical outcomes. The study concluded that implementing the NCDR CathCPI bleeding risk score and using an expanded PCI specific bleeding definition together have effectively reduced the number of blood transfusions and length of stay.

Predictors of Implementation of Evidence-Based Fall Management Among Nursing Staff in Geriatric Hospitals

Hyun Jeong, MSN, RN, Korea, Republic of (South)

Mihyun Lee, MSN, RN, Korea, Republic of (South)

Myonghwa Park, PhD, RN, Korea, Republic of (South)

Younghye Go, MSN, RN, Korea, Democratic People's Republic of (North)

Miri Jeong, MSN, RN, Korea, Democratic People's Republic of (North)

Abstract

Purpose: Falls are one of the most frequent critical health problems for elderly in long term care settings. Injuries are a significant cause of morbidity and mortality. Implementing preventive management to lower the incidence of falls would go a long way to improve the quality of care in long term care settings. Nursing staff play an active and essential role in falls prevention. Evidence-based practice is a key recommendation to improve patient care outcomes. Although the Institute of Medicine has set the goal that 90 percent of clinical decisions will be evidence-based by 2020, low rate of nursing staff deliver evidence-based practice. The purpose of this study was to identify predictors that influence nursing staff's implementation of evidence-based fall management in geriatric hospitals. **Methods:** This study consisted of 505 nursing staff from long term care hospitals in Korea. The survey was designed to investigate nursing staff's knowledge, belief, organizational culture, competency and implementation of evidence based practice regarding fall management. **Results:** The results of stepwise regression analysis indicated that the nursing staff' knowledge, belief, organizational culture and competency for evidence-based practice explain 54.9% of evidence based fall management performed in geriatric hospitals. Among these factors, the significant predictors were organizational culture of evidence based fall management ($\beta=.37$, $p<.001$) belief of evidence based fall management($\beta=.27$, $p<.001$), knowledge of evidence based fall management($\beta=.19$, $p<.001$) and competency of evidence based fall management($\beta=.18$, $p<.001$). Belief of evidence based fall management and organizational culture of evidence based fall management were found to be the strong predictors of evidence based fall management implementation among nursing staff in geriatric hospitals. **Conclusion:** The results of this study suggest that there is a need to develop a systematic program to enhance individual nursing staff's belief of evidence based practice at individual level and to foster innovative organizational culture toward evidence based practice at organizational level.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Effectiveness of Oral Sodium Phosphate Bowel Preparation for Colonoscopy: A Meta-Analysis

Hsin-Mei Ho, MSN, RN, Taiwan
Yueh-Yen Fang, PhD, RN, Taiwan
Shu-Chi Chen, MSN, RN, Taiwan
Chin-Han Hsieh, BSN, RN, Taiwan

Abstract

Purpose: Colon cancer is one of the top ten causes of death, and colonoscopy is one of the most commonly used diagnostic procedures. Effectiveness of bowel preparation is significant for the success of colonoscopy. The type and severity of bowel preparation side effects vary with the product used. Common adverse effects include nausea, vomiting, bloating, or abdominal pain. For the severe cases, kidney failure, heart failure or seizures might present. Though polyethylene glycol (PEG) is isotonic, the large volume used for bowel preparation and adverse events of nausea and abdominal discomfort may compromise patient compliance and increase the need for repeat procedures. Sodium phosphate (NaP) is used as an alternative for bowel preparation in current days. However, studies that compare the effects of bowel preparation between NaP and PEG are inconsistent. To validate the effect of NaP on bowel preparation for colonoscopy, this study compared the efficiency and adverse events of NaP and PEG bowel preparations.

Methods: We searched two Chinese databases (CEPS, and the Chinese Journal database) and four English databases (CINAHL, Medline, PubMed, and the Cochrane Central Register of Controlled Trials) to identify studies comparing the effects of bowel preparation with NaP and PEG. Evaluations of study quality were conducted by the 2011 Oxford Centre for Evidence Based Medicine Levels of Evidence and the Cochrane Collaboration's tool for assessing risk of bias. Meta-analyses were performed by the random effect model. Pooled effects of efficiency in bowel preparation and adverse events of NaP and PEG were calculated.

Results: Seventeen studies were included in the meta-analyses. Fourteen studies provided comparisons between NaP and 4-L PEP and the homogeneity was reached after 2 studies were excluded. The efficiency of NaP is significantly better than using the PEG (OR=1.55, 95% CI=1.15-2.09, $p=.004$). NaP and PEG did not differ in nausea, but NaP presented less vomiting responses than PEG.

Conclusion: Meta-analyses of efficacy in bowel preparation and related adverse events supported NaP as an effective strategy. Application of NaP in bowel cleaning will also provide patient comfort during the procedure.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Comparison of Oral Health and Oral QOL Among Community Residents and Patients With Renal Insufficiency

Hsueh-Erh Liu, PhD, RN, Taiwan
Jeng-Yi Huang, MD, Taiwan
Wan-Jing Ho, MD, Taiwan
Hui-Ting Lu, BS, RN, Taiwan
Hsiu-Fang Lee, MSN, RN, Taiwan
Li-Hua Wang, MS, RN, Taiwan
Yi-Hsuan Kuo, MD, Taiwan

Abstract

Purpose: The major purpose of this study was to assess and compare the oral health status and oral health-related quality of life of the community residents, CKD patients and ESRD patients from a medical center and neighborhood community located in northern part of Taiwan.

Methods: A cross-sectional study design was conducted. A total of 79 community residents, 120 CKD patients and 101 ESRD patients agreed to participate and completed all data collection. Instruments for data collection included: questionnaires (demographic information, oral hygiene habit, attitude and knowledge related to oral health, and geriatric oral health assessment index_GOHA) and oral inspection (done by a trained assistant).

Results: The comparisons of demographic data showed that samples in CKD group were more male and lower educated. In addition, the age in ESRD group was significantly older than the CKD and community residents groups.

In regard to the performance of oral health, results of comparison showed that community residents had better performance than the other two groups in general. Specifically, the ESRD group reported lowest ratio in tooth brush at “after breakfast”, “after dinner” and “after eating”. Also, ESRD group reported a higher ratio in “never receive teeth examination”. The comparison of knowledge related to oral health showed that CKD group was the one with lower level than the other two groups. In addition, the comparison of attitude toward oral health found that community residents group reported more positive than the other two groups.

The results of personal inspection showed that CKD group had less untreated dental caries whereas the ESRD group had higher ratio of untreated dental caries. In addition, ESRD group had higher ratio of “0-5 loss teeth” in upper jaw whereas the CKD group had higher ratio of “11-15 loss teeth” in lower jaw. In regard to the dentures, CKD group had a higher ratio of active dentures and the ESRD group had a less ratio of full dentures.

The comparison of oral health-related quality of life showed that CKD group reported less total score than the groups of community residents and CKD patients. The comparisons of subscales showed that the CKD group had lower score in the psychosocial impact subscale than the groups of community residents and ESRD patients. For the pain and discomfort dimension, the group of community residents reported higher scores than the ESRD and CKD group. In addition, subjects in ESRD group reported higher scores than patients in CKD group.

Conclusion: The oral health status in the community residents, CKD patients, and ESRD patients were no good, measured by both subjective and objective methods. And limited patients had searched for medical treatment actively. The health care professions need to pay more attention to the oral health status of these specific subjects and referred them to dentist timely. Thus a holistic care could be achieved.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Implementation of "Creative Joint-Defense Network" to Improve Nursing Quality for Endotracheal Intubation

Huang-Jen Shih, BSN, RN, Taiwan

Abstract

Abstract Introduction: According to 2014 statistics from the Ministry of Health and Welfare's Taiwan Patient Safety Reporting System (TPR), among various tubing incidents reported by hospitals, endotracheal tubing incidents are of highest percentage (representing 97.8%) that are "harmful" to patients. Therefore, to implement the management of patient safety incidents, to prevent unplanned endotracheal tube removal, and to improve nursing quality for endotracheal intubation are issues of significant importance.

Aims: According to the statistics unit, unplanned endotracheal tube removal rate increased abruptly from 0‰ to 4.24‰ from 2014 April to June, which is 1.2‰ higher than the unplanned extubation rate of Taiwan Clinical Performance Indicator (TCPI) in 2014. Not only does unplanned extubation cause further harm to patients, but also leads to self-blame and low morale among nurses. Ensuring patient safety and successful ventilator weaning are the unit's foremost priorities, thus the motivation to conduct an improvement project with the purpose of applying its results to improve nursing quality for endotracheal intubation, prevent unplanned extubation incidents and to ensure the safety of patients.

Methods: The project is divided into three stages – the planning stage, implementation stage and evaluation stage. **First Stage:** Establish project team, through interviews, literature review, cause and effect diagrams etc., reasons for unplanned extubation confirmed: 1. Neglect of corner beds and cross-sector nursing care 2. Inexperience in intubation healthcare 3. Lack of auditing system 4. Low compliance from family members 5. Misunderstanding of high-risk self-extubation patients. **Second Stage:** After discussion and using decision matrix to take feasibility, efficiency, cost and other factors into consideration, solutions are formulated and conducted according to results analysis: 1. Implementation of Creative Joint-Defense Network for corner beds and cross-sector nursing care. 2. Implementation of consensus slogan for the unit team's joint-defense communication: "Joint-Defense Human Figure Diagram". 3. Implementation of 3D tape three-dimensional fixing method. 4. Implementation of bed-side empowerment tape (wufendai) fixing tutorial. 5. Implementation of audit system for endotracheal intubation. 6. Health education accompanied by doctors for patients' family members with low compliance. 7. Organization of health education work-shop for "ping-pong-gloves". 8. Watch patients' 30% muscle strength's "UE Video". **Third Stage:** After project implementation, statistics collected from 2015 May to July showed that the unit's unplanned extubation rate was 0‰, and endotracheal intubation completion was 100%.

Results: With the implementation of the project, unplanned extubation rate decreased from 4.24‰ to 0‰, thereby achieving the purpose of the project. Through the results of this project, rigid regulations and technicalities have been integrated with creative approaches, easing rejection against defense regulation implementations, and effectively decreasing unplanned extubation rate.

Conclusions: During the project's implementation, there was resistance and rejection from doctors, and project members continued to discuss and negotiate with support and assistance from supervisors to successfully accomplish our goals. After implementing the creative joint-defense network concept, the unit's unplanned extubation rate dropped from 4.24‰ before improvement to 0‰, demonstrating that medical harm from unplanned extubation can be prevented and avoided. This article hopes to be provided as reference for relative units.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Personality Type and the Configuration of Online Learning Groups

Deborah Mandel, PhD, RNC-OB, USA

Mary Ann Dailey, PhD, RN, USA

Abstract

In nursing courses, 3 to 5 or more students are required to work within a group and complete assignments. Within a classroom environment, faculty and students are more aware of student personalities and their ability to work together within a group. However, in online courses, most students and faculty never meet in a face-to-face situation and students may not know their peers. For this reason, selection of students for a specific work group frequently occurs through random assignment, random selection, assignment by surname, or some other method selected by the faculty. Because group work is not favored by many students, the random process of group selection can cause individual and group dissatisfaction. Using a personality typology survey and making student assignments based upon the results of each student's 16 unique personality traits (i.e., beyond introversion and extraversion) could create groups that work more effectively and meet student learning outcomes.

The population selected for this research study was comprised of RN-BSN students enrolled in online courses within two nursing programs in two different universities, Slippery Rock University (SRU) and West Chester University (WCU), within the Pennsylvania State System of Higher Education. After obtaining IRB approval from both schools, students were asked to participate in the study for the fall 2016 semester. At the beginning of the semester, students enrolled in NURS 327 (SRU) and NSG 311-90 (WCU) were invited to participate in the research study using a "Generalized Announcement About the Research Project". Contained within this announcement was an explanation about the project and its purpose. If the student decided to participate in the research project, then the student was asked to complete the Informed Consent Form. Submission of the form demonstrated each student's willingness to participate in the research project. Following submission of the consent, students were asked to complete the Open Extended Jungian Type Scales 1.2 (OEJTS)TM survey, which took approximately 7-minutes. Results of the OEJTS 1.2 were used to create groups based upon complimentary personalities of each student member. Those students who did not wish to participate in the research project were randomly assigned to a non-study group to complete the assignments. Following completion of the group assignments, each student anonymously completed The Team Development Measure (a VA trademarked tool), which uses 31 statements to measure team characteristics. Within this study, data will be collected until December 19, 2016, the end of the semester.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Nurse's Self-Confidence of Family Presence During Resuscitation in Japanese Pediatric Emergency and Critical Care Field

Emi Masuda, MNS, RN, Japan
Kayuri Furuya, DNSc, RN, PHN, Japan

Abstract

Introduction: According to the 2015's JRC (Japan Resuscitation Council) guidelines, family members of children under going resuscitation should be given the option of presence at the bedside. And in order to do that, it is necessary to build a system to provide enough family support. However in general, the family is guided away from their loved one into waiting room during patient's resuscitation in Japan. Furthermore, it is found that the system to support the family is undeveloped.

In the literature, nurses who invited family into resuscitations reported significantly higher self-confidence in their ability to manage it those that did not. To date, no researches have yet examined this issue and how to support to improve their self-confidence in Japan.

Objective: The purpose of this study was to measure nurse's self-confidence of family presence during resuscitation and to identify assistance to increase their self-confidence in Japanese pediatric emergency and critical care field.

Methods: Design: The study was a cross-sectional survey using questionnaire. **Subjects:** Our study's subjects were Japanese nurses who work in pediatric emergency and intensive care unit. **Materials:** The questionnaire collected basic personal demographic data and each hospital facilities characteristics. **Scale:** Japanese-language version FPS-CS (Family Presence Self-Confidence Scale)

We request and granted from the original author to use the tool of Japanese version. After having done back translation, we evaluate the reliability and validity of the scale. As a result of analysis, Cronbach's α reliability was 0.94, and ICC was 0.85.

Analysis: We tested differences according to demographic, staff characteristics and facility characteristics using the t tests for two group comparisons. Analysis of variance was used to examine differences in scores on the FPS-CS on the nurses and facility characteristics. SPSS Statistics Version 22 was used for all analyses. Significance was set at $p < .05$.

Ethical considerations: This study was approved by University of Tsukuba Faculty of Medicine, Ethics Committee. A letter was sent to each participants containing an ethical consideration, and their consent was implied on return of questionnaire.

Results: Three hundred twenty six employed in 24 wards of 19 different hospitals completed the questionnaire (response rate was 65.1%), of which 57.8% of nurses provided the opportunity for the family to be present during the resuscitation procedure. Mean total score were 2.53 ($SD=0.62$) on the Japanese-language version FPS-CS. Self-confidence for family assessment and support score was 1.94 ($SD=0.64$), the lowest score.

Self-confidence for direct patient care was significantly greater in nurses who had experienced 10 or more resuscitation events ($p < .001$, $d=0.85$), had experienced family presence during resuscitation ($p < .001$, $d=0.68$), had experienced 5 years or more medical practice in emergency or intensive care unit ($p < .001$, $d=0.64$), or had experienced 5 years or more medical practice as a nurse ($p=.001$, $d=0.61$). Self-confidence for managing family presence during resuscitation had a similar result. In addition participants who work in hospital that had education of family care for after the bereavement ($p=.007$, $d=0.46$), and had a system of family support for after the bereavement reported significantly more self-confidence for family assessment and support.

Discussion: Similar to overseas study, more than half of participants provided the opportunity for the family to be present. However they reported 1 point or more low score of FPS-CS as compared to the previous researches. One reason for this finding could be the specific influence of Japanese culture. In addition, the presence of family by the bedside during resuscitation is uncommon in Japan. And this finding could be related to lack of guideline for family presence and family support systems.

Using a skill-based experience within simulation training could be developing nurse's self-confidence for direct patient care and managing family presence during resuscitation. The findings suggest the need for the development of family's support system and advanced education for nurses in each hospital to improve nurse's self-confidence for family assessment and support. Further, we need developing family presence facilitators who support the family and the staff providing direct care in Japan.

Does Completing a Post Graduate Advanced Clinical Assessment Paper Influence Nursing Practice: An Exploratory Study?

Deborah J. Somerville, MNurs, RN, New Zealand

Abstract

The purpose of this research was to explore the influence a post graduate advanced assessment and clinical reasoning nursing paper may have on a registered nurses clinical practice. The post graduate paper, 773, has been available to registered nurses doing post graduate studies at the University of Auckland for over fifteen years. In this time, over 3000 nurses have completed this paper as part of their post graduate studies. It is often the first or second paper that a registered nurse completes as 50% of a post graduate certificate and is a compulsory paper for a clinical nursing masters or nurse practitioner pathway. The paper has a strong focus on clinical examination and diagnostic reasoning and students are required to perform a clinical examination as part of the assessment process. In addition they are required to complete an exam which assesses their knowledge and clinical application on a variety of blood tests and ECG interpretation. Therefore to successfully pass the paper all students must be at a certain level in their ability to perform a clinical examination and interpret diagnostic tests. What is unknown from the paper however, is whether students are able to take the clinical skills and the diagnostic reasoning knowledge and apply them to their area of clinical practice. The aim of this study was to explore whether advancing a nurses clinical examination skill and knowledge actually transitions into clinical practice 3 months after completion of the course.

The first part of the research included a questionnaire given to students at the beginning of the nursing paper and the same questionnaire repeated at the end of the paper. A total of 61 nurses completed the first questionnaire on day one of the course and 51 nurses completed the repeated version four months later at the completion of the course. The questionnaire used a combination of Likert scales and descriptive phrases to identify where nurses rated their clinical examination skills, including interpretation of ECGs and blood results. This part of the study has been entered into a data base and will be analysed using a comparative approach to the two questionnaires.

The second part of the research involved 13 nurses in two focus groups. The participants were recruited three months after completing the advanced assessment and clinical reasoning paper and the criteria was that they must be working within a clinical nursing role. The focus group facilitator directed the communication around clinical practice following completion of the paper. Specific emphasis included the everyday practice of clinical assessment, identification of the deteriorating patient and overall confidence in clinical assessment, including interpretation of blood results and ECG. This part of the study is currently being analysed using a thematic analysis approach. An early indication from the analysis is the paper develops a nurse's confidence to perform clinical examination on a greater number of patients and to intervene earlier with appropriate care.

Personality Traits Are Important Predictors of Glycemic Control in Patients With Diabetes

Shu-Fen Lee, PhD, MSN, RN, Taiwan

Abstract

Background: A close relationship between personality traits and diseases. Most diabetic patients understand the importance of complying with the healthy lifestyle of drugs, but the actual implementation situation is not ideal, because the performance behavior of dominant personality is an important factor affecting your doctor compliances. Today, limited clinical diabetes health teacher time and manpower considerations, provide personal and exclusive knowledge of diabetes care in the limited time is quite high challenge, due, personality traits and self-efficacy and self-care with a high degree of correlation. Therefore, to understand the case of personality traits as the core of the case management of blood glucose hub.

Objective: To investigate the personality traits of their diabetes patients with different body composition and blood parameters of difference, and to identify associated factors affect blood glucose control.

Methods: In this study, patients with certain metabolic Branch of the teaching hospital for the study, a total of 219 accepted questionnaires, 214 valid questionnaires. The resulting data with SPSS 18.0 descriptive statistics, one-way analysis of variance, chi-square test, Pearson's product-moment correlation and multiple regression analysis.

Results: The results showed that (1) Personal property, sex, marital status, education level, work patterns, exercise phase, the presence or absence of chronic diseases, perceived health status and other variables have significant differences in glycosylated hemoglobin. (2) the impact of glucose control important factors including age, morbidity time (years), perceived health status unhealthy - Other, fasting glucose, triglycerides and nervous personality - other personality traits and other variables have a relationship with glycosylated hemoglobin, age the elderly, the lower the risk of poor glycemic control, and reached statistical significance ($B = -0.097$, $OR = 0.908$, $95\% CI = 0.833-0.988$) for each additional 10 years of age, the risk of poor glycemic control reduced by an average of 9.2% . The longer diabetes, poor glycemic control risk, the higher ($B = 0.181$, $OR = 1.199$, $95\% CI = 1.064-1.351$), each additional year an increase of 1.199 times the chance of poor glycemic control. Perceived health status is unhealthy healthy than those who consciously poor glycemic control its 40.44-fold increased risk. Fasting plasma glucose each additional 10mg / dl an increase of 59 per cent of poor glycemic control probability. And triglycerides each additional 10 g / dl increase 39 percent risk of poorly controlled blood sugar. Prudential risks personality ($OR = 0.646$, $95\% CI = 0.109-3.838$) and a friendly personality ($OR = 0.605$, $95\% CI = 0.123-2.988$) poorly controlled blood sugar is relatively low, but less significant. However, nervous personality as significant predictors ($B = 2.017$), compared to other personality personality nerve have 7.52 times the risk of poorly controlled blood sugar.00

Conclusion: The study confirmed that patients with personality traits diabetes control and have a direct relationship. Long-term implementation of health behavior in order to maintain a stable blood sugar, in this personality trait crucial influence. Theoretical concepts to determine personality traits and health status is an important cornerstone of a nursing care to enhance the quality, if the medical staff can indirectly predict and assess the relationship between personality traits through the interaction of their health behavior and disease, and to give according to the characteristics of the personality traits adaptive health education will be able to improve the quality of care nursing care.

The Effect of Elevating Head of Bed for Esophageal Cancer Patients With Nocturnal Reflux Symptom

Hui-Chen Huang, BSN, RN, Taiwan

Su-Ying Fang, PhD, RN, Taiwan

Abstract

Background: It has been demonstrated that elevating head of bed nocturnally can improve the symptoms of gastro-esophageal reflux disease by the mechanism of gravity to increase the clearance rate of removing acid-base digestion fluid. Our study base on this theory and previous researches to examine the effect of elevating head of bed for patients with esophageal cancer suffered from nocturnal reflux symptom after esophagectomy and reconstruction.

Purpose: The purpose of this study was to understand the effect of elevating head of bed by using the wedge form pillow on the gastro-esophageal reflux symptoms among patients receiving esophagectomy and reconstruction during the period of 14 days.

Methods: Cross-over design and block randomization was used in this study. First group were treated with proton pump inhibitors (PPI) at the first seven days, and started to use wedge form pillow combined with PPI using during eight to fourteen days. The second group used wedge form pillow and PPI at the first seven days and remove wedge form pillow and only use PPI during the second week. We used the questionnaire of The Dysfunction after Upper Gastrointestinal Surgery Cancer (DAUGS32) to follow their reflux symptoms by using telephone contact on 1st, 2nd, 3rd, 5th, 7th, and 8th, 9th, 10th, 12th, 14th day.

Inclusion criteria were above twenty years old, had been confirmed the diagnosis of esophagus cancer and finished total esophagus resection, gastric tube reconstruction and cervical anastomosis at least two months. If adjuvant radiotherapy and chemotherapy were intervened, we started the trial at least three months after operation. Participants who used materials other than gastric tube for esophagus reconstruction, accepted pyloroplasty or combined with others malignant tumor or recurrent status were excluded.

Result: Thirteen patients were recruited until now in which 7 were assigned to first group and 6 were in the second group. We used multiple mixed effect model to evaluate the improvement of symptoms of GERD. It had a significant effect ($p=0.034$) on the improvement of GERD symptoms in the first group while the period used wedge form pillow combined with PPI than the period treated only with medication. However, it did not show significant difference in the second group between wedge form pillow combined with PPI and PPI used alone ($p=0.054$). As a result of small sample size, we need to recruit more participants to .

Expect Result: The preliminary results of this study revealed that using wedge form pillow may improve the symptoms of gastro-esophagus reflux. We will keep follow the symptoms of all participants for at least three months and continue to recruit more patients into this study. If this management can decrease the time of reconstructed esophagus exposing in acid environment nocturnally, it can improve the patients' sleeping disorder and elevate their quality of life.

Development and Psychometric Tests of the Chinese Version of Patient Satisfaction With Nurse Practitioner Scale

Chuan-Yu Hu, MSN, NP, RN, Taiwan

Shu-Yuan Lin, PhD, RN, Taiwan

Wei-hui Hsiao, BSN, RN, NP, Taiwan

Abstract

Background: Patient satisfaction is a common indicator of patient care outcome. It has been included in the hospital accreditation standards by Taiwan Joint Commission since 2008. An instrument of patient satisfaction targeted to evaluate care outcomes that provide by nurse practitioners is rarely found in a review of literature.

Purpose: The purpose of this study was to develop and test psychometric properties of the Chinese version of patient satisfaction with nurse practitioner scale (C-PSNP).

Method: There were three phases of development in Chinese version of patient satisfaction with nurse practitioner scale. The first phase was to conduct literature review and focus group, that constructs the content of the questionnaire to measure patient satisfaction with nurse practitioner. The second phase was to test the construct validity of the C-PSNP scale. The third phase was to conduct a cross-sectional survey that used a convenience sample by recruiting 230 patients from four hospitals. The survey yield 230 validated questionnaires that collected from February to May, 2016. The data collected from the questionnaires had analyzed by SPSS 19.0. Statistical analysis including item analysis, Pearson correlations, exploratory factor analysis and reliability of Cronbach's α with the C-PSNP scale.

Result: The 20-item C-PSNP scale was developed, with a item discrimination CR (critical ratio) of 7.46–15.41 ($p < .001$), and item-total correlation of .61–.86 ($p < .001$). Exploratory factor analysis had extracted four factors, and they explained a total variance of 78.19%. Four factors were named as "communication and caring", "health information", "professional knowledge and skills", and "participation in decision-making". The Cronbach's α for the C-PSNP scale was .96. The Cronbach's α coefficients of four subscales were in an range of .88 - .94.

Conclusion: This study demonstrated the Chinese version of patient satisfaction with nurse practitioner scale is a valid and reliable tool that is recommended to use as an assessment tool for measuring the patient satisfaction with Taiwanese nurse practitioners.

An Innovative Interdisciplinary Response to CVC-Related Complications in TPN-Dependent Pediatric Patients: A Comprehensive Educational Initiative

Gloria Verret, BSN, RN, CPN, USA
Meghan Meehan, MSN, RN, CPHON, VA-BC, USA
Manisha Parikh, MSW, LCSW, USA

Abstract

Central line associated bloodstream infections (CLABSIs) are a significant cause of morbidity in medically complex pediatric patients who rely on central venous access for life-saving medications and nutrition. The financial burden of CLABSIs is also significant. It is estimated that each CLABSI-related admission has a mean attributable cost of over \$55,000 and a length of stay of 19 days (Goudie et al., 2014). Catheter damage and malfunction contribute to costs as they also necessitate hospital visits and admissions. The CDC estimates there are 30,000 CLABSIs each year in the United States and 1 in 4 patients die from those infections.

Our urban pediatric academic medical center cares for a large volume of patients whose therapy requires the placement of a CVC, such as Intestinal Rehab (IR) patients who depend on total parenteral nutrition (TPN) for nutrition, and those followed by the Complex Care Hospitalist Medicine team for additional issues such as Mitochondrial Disorder. Since the parents and caregivers of these patients are expected to manage these devices in the home setting, a basic CVC care and maintenance class is offered twice a week to provide education, time for questions and hands-on practice. This class occurs in the hospital's Family Resource Center (FRC) and is taught by experienced nurses. Depending on the type of CVC a patient has, parents are taught catheter hub access, flushing maintenance, dressing changes, cap changes and steps to take in an emergency. Nursing and medical staff reinforce education as needed throughout the course of therapy.

Despite education and reinforcement, certain patients were repeatedly admitted for CLABSIs, catheter damage and/or malfunction. In the second quarter of 2016, out of 56 patients, there were 21 admissions for line complications. At times, serious sequelae were occurring such as loss of viable vessels for new catheter sites, leading to invasive procedures such as vessel stenting. A review of four complex-care patients showed 30 line infections in the last two years. One patient had 18 infections. There were 8 ICU stays for sepsis and intubation required on 2 patients. Multi-organ failure occurred in 1 patient. Multiple members of the interdisciplinary teams who care for these patients saw a need to provide enhanced education to this subset of patients and their families to help minimize complications. Families are currently encouraged to re-attend the CVC class when their child is admitted for a line complication acquired outside of the hospital. However, we noted that the class content might be too basic for those caregivers who were seasoned in caring for CVCs. While a review of the basics is essential, many families need more detailed and creative solutions for managing their child's long-term CVC, giving consideration to their own unique set of challenges and home situations.

A multidisciplinary team was organized to develop an Advanced CVC Care Class curriculum for this subset of families. The group consists of a nurse champion who both cares for patients on the medical-surgical ward and serves an educator in the FRC, an IR physician, Child Life Specialist (CLS), Social Worker (SW), Occupational Therapist (OT) and CVC nurse consultants. Families who had successfully prevented CLABSIs were also invited to participate and share tips and ideas. As families are involved in the creation of the educational content of the class, it is hoped that parents will feel increasingly valued and respected. The overarching aim is to help families help themselves (Tallon, et al., 2015). This class will accomplish this by empowering and partnering with parents and caregivers to provide more tools, resources and strategies to successfully prevent CVC complications and thus strive towards zero preventable CLABSIs in and outside the hospital.

The class is currently in the final stages of the development process and will be launched as soon as it is completed. The content consists of a PowerPoint presentation and individual videos from an IR physician,

CLS, SW, OT and CVC nurse consultants. Each specialty will provide educational tips, resources, and evidence-based best practices, along with creative solutions and ideas from families. This format will allow the nurse educator to individualize each class by focusing on the CVC complication that lead to the patient's admission while also gearing it towards the child's specific developmental age. The videotaped content will be available in three languages in order to meet the diverse needs of our patient population.

A pre-class survey will assess attendees' concerns and questions, while a post-class survey will gauge the attendees' comprehension of class content. In addition to rating their level of comfort caring for a CVC pre-and post-class, caregivers will be asked to rate their level of understanding and provide written examples of tips and techniques that they could utilize with their child's CVC.

With hospital stays shorter and acuties higher, teaching families home care by partnering with them as they transition home is key to decreasing readmission (Chick, et. al., 2012). In a systematic review of thirty-eight studies or articles, it was found that nurses have a singular opportunity to enhance meaningful interaction, build confidence and promote a successful transition home Two cornerstones of family centered care are a focus on developmentally appropriate care and providing adequate instruction to caregivers responsible for providing complex home care (Dokken et al., 22015). Based on these objectives and a foundation in evidence-based practice, the mission of this innovative and family centered advanced class is a reduction in CVC-related complications and associated patient morbidity and hospital admissions.

Outcomes of an Innovative Evidence-Based Project: Building a Difficult Access Team in an Emergency Department

Barbara Maliszewski, MS, RN, USA
Madeleine Whalen, MSN/MPH, RN, CEN, USA
Heather Gardner, MS, RN, USA
Rebecca Sheinfeld, BA, CNE, USA
Diana Lyn Baptiste, DNP, MSN, RN, USA

Abstract

Background/Introduction: Emergency departments across the nation face challenges of longer lengths of stay due to increased volumes and patient acuity. Intravenous (IV) access is vital to emergency care, and a large proportion of patients seen in the Emergency Department have difficult venous access, resulting in patient care delays. Difficult venous access (DVA) is identified as a condition among individuals who most often require 2 or more attempts for successful IV access, leading to an increased length of time needed to obtain IV access, or may require special interventions to establish peripheral IV access.

Purpose/Objectives: The objective of this project was to determine if a dedicated difficult access team will decrease the number of attempts and amount of time for successfully obtaining IV access in difficult venous access patients.

Methods: The intervention included the implementation of a difficult access clinical technician team. The specialized team was initiated as a pilot to determine whether use of a specialized team would decrease number of attempts and amount of time for successfully obtaining IV access in difficult venous access patients. This study included convenience samples of patients visiting the adult emergency department with a provider order to place IV access. We compared the mean number of attempts and time it took for obtaining successful IV access for the pre and post- intervention periods, among two samples.

Results: Prior to the intervention, there were 3.8 (SD 1.18) mean number of attempts for obtaining IV access for (N=52) patients who were identified to have DVA. After the intervention, a mean number of attempts per DVA patient was reported at 1.2 (0.47). A significant difference ($p < 0.05$; CI 95% 2.25-2.94) was found between the pre intervention and post intervention mean number of successful attempts but no significant reduction in the time it takes to obtain successful IV access among these two samples.

Conclusion: IV access is an essential procedure for the assessment and treatment of patients seeking health care in the emergency department. It is important to consider a feasible solution for managing DVA among patients. Our findings suggest that implementation of a dedicated difficult access team can decrease the time and number of attempts necessary for obtaining IV access in individuals with difficult venous access. Further investigation is necessary to determine variables that impact increased time to obtain successful IV access in patients with difficult venous access.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Identifying Acute Cardiac Deterioration in a Critical Care Setting and Establishing a New Recognition Protocol

Sarah A. Power, BS, USA

Abstract

Background: The early detection of clinical signs indicating cardiac deterioration can reduce the risk of adverse outcomes (Jones et al., 2013). Worsening physiological symptoms can easily go overlooked or unmanaged, if professionals are not educated properly. When these symptoms are not addressed, patients can experience treatment delays and mortality (Preece et al., 2012). The early detection of cardiac deterioration's clinical signs can reduce the risk worsening condition, or death. Defining a unit protocol for nurses would allow a systematic way to evaluate patients and their health status.

Objectives: The purpose of an integrative literature review was to identify signs and symptoms that precede acute cardiac deterioration within a critical care setting, and to establish a new recognition protocol to ameliorate patient care outcomes. Cardiac deterioration is a major public health problem with over 350,000 in-hospital cardiac arrests happening each year in the United States (American Heart Association, 2016). Nurses need to be better educated on the signs and symptoms that antecede a cardiac arrest, and have a protocol to identify and to initiate intervention.

Method: An integrative literature review was conducted undergoing an extensive integrative search to identify acute cardiac deterioration within a critical care setting and recognizing protocol measures. Whittemore and Knaf's (2005) approach to amalgamate review writing was used as a framework to synthesize and organize the literature found.

Results: Vital signs, level of consciousness, lab values, EKG, and age were found to be the most supported symptoms, which lead to acute cardiac deterioration within a critical care setting (Soar & Subbe, 2012; Hodgetts, et al, 2006; Preece et al., 2012). It is unknown if the the current protocols for nurses to recognize these signs are effective in treating patients. Recommendations for a new protocol include the development of an early warning score system.

Conclusions: This review found five clinical symptoms related to cardiac deterioration; however, these symptoms in current nursing protocol programs are not well addressed. Thus, there is a need to develop an appropriate prevention program incorporating these symptoms to help decrease the risk for cardiac deterioration with the intensive care unit.

Green Care as Psychosocial Intervention for Depressive Symptoms: What Might Be the Active Ingredients?

Rebecca Elizabeth Salomon, MSN, BA, RN, PMHNP-BC, USA

Alison Duncan Salomon, BA, USA

Linda S. Beeber, PhD, PMHCNS-BC, FAAN, USA

Abstract

Background: Green care is an umbrella term for psychosocial interventions that integrate biotic and abiotic elements of nature to promote an individual's health and well-being (Haubehofer, Elings, Hassink, & Hine, 2010). Green care interventions include animal assisted therapy, therapeutic horticulture, care farming, and others (Sempik, Hine, & Wilcox, 2010). A variety of green care interventions are used in countries such as Finland, Norway, Japan, Germany, the United Kingdom, and the United States, indicating its capacity for cultural diversity and sensitivity (Annerstedt & Währborg, 2011; Haubehofer et al., 2010). Some green care therapies, such as community gardening, can be used as low-cost health promotion and disease prevention interventions in difficult-to-target and vulnerable populations; community gardening has been used as an intervention for displaced refugees and improves physical activity, mental health, and community development (Gerber et al., 2016).

Many green care interventions can be adapted to treat depression, which directly affects approximately 350 million and is the leading cause of disability worldwide (World Health Organization, 2015). Depression is under-diagnosed, under-treated, and recurs in at least 50 percent of patients who receive treatment (Schwenk & Terrell, 2014). Many people delay seeking treatment for symptoms, causing their depression to remain undiagnosed and untreated (Thompson, Hunt, & Issakidis, 2004). When individuals do seek help, they may encounter barriers in accessing treatment (Mohr et al., 2010). Finally, treatments are sometimes ineffective and fail to decrease symptoms by at least half (McPherson et al., 2005).

Green care interventions are novel and evidence based, offering many benefits in terms of access and cost because of their alternative delivery formats. Green care interventions are rarely clinic-based, making treatment more easily integrated into community settings (Sempik et al., 2010). Many green care interventions, such as animal-assisted therapy and horticulture therapy, vary significantly from traditional psychotherapeutic approaches in terms of their settings and format. Qualitative research shows that patients seeking green care do not feel as stigmatized in this type of therapeutic environment (Iancu, 2013). Additionally, green care interventions can often be offered in a group therapy format, which can be tailored to individual needs while providing social benefits (Sempik et al., 2010).

Multiple quantitative studies have found decreased depressive symptoms following green care therapies (Gonzalez, Hartig, Patil, Martinsen, & Kirkevold, 2011; Pedersen, Martinsen, Berget, & Braastad, 2015). Key elements identified by participants in qualitative and mixed methods studies include a positive and supportive atmosphere, social engagement, increased physical activities, and increased feelings of skill and competence (Elings & Hassink, 2008; Kam & Siu, 2010; Kogstad, Agdal, & Hopfenbeck, 2014; Nordh, Grahn, & Währborg, 2009; Pedersen, Ihlebæk, & Kirkevold, 2012).

Objectives: Through a systematic review of the literature, the researchers evaluated the evidence that social support, behavioral activation, and self-efficacy mediate improvement of depressive symptoms in a range of psychosocial interventions. The findings have been used to expand the consideration of green care as an evidence based therapy and provide insight into possible active ingredients.

Design: The researchers followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines and sourced English-language articles from PubMed, CINAHL and PsycINFO through July 2016. Database searches identified 159 unique articles. To meet inclusion criteria, all studies had to examine depressive symptoms, one of the three mediators of interest, and a psychosocial intervention for adults. With that in mind, the first and second author reviewed the articles separately, excluding 139 articles based on title and abstract. The remaining twenty abstracts were

reviewed and screened again by authors, excluding another eight articles after discussion and agreement. Upon full text review, six articles were excluded for the following reasons: five did not analyze the effect of the mediator of interest on depressive symptoms and one did not measure depressive symptoms after the intervention was completed. Two additional articles that were known to the primary author and fit the requirements for inclusion were added at this stage. After screening and exclusions, eight articles were included in the synthesis. Each article was extracted independently; the data were combined into a matrix and analyzed for thematic content.

Results: Two studies addressed the mediator of behavioral activation (Losada, Marquez-Gonzalez, & Romero-Moreno, 2011; Ryba, Lejuez, & Hopko, 2014), two addressed social support (Dour et al., 2014; Roth, Mittelman, Clay, Madan, & Haley, 2005), and four addressed self-efficacy (Backenstrass et al., 2006; Kavanagh & Wilson, 1989; Oman & Bormann, 2015; White, Kendrick, & Yardley, 2009). The studies were completed in a variety of Western countries: four in the United States, one in Australia, one in Spain, one in Germany, and one in England. Studies ranged in sample size from 23 subjects to 1004 subjects. A range of interventions were performed across the studies. Out of the eight studies, four interventions included some amount of Cognitive Behavioral Therapy, one was an unspecified combination of individual, family, and group psychotherapy, one was Mantram Repetition Therapy, one utilized Behavioral Activation therapy, and one was purely based on individual physical activity. The duration of each intervention also varied, ranging from six weeks in one study to one year in another study. Evidence from the studies support behavioral activation, social support, and self-efficacy as mediators of improved depressive symptoms in psychosocial interventions.

Conclusions: Green care interventions offer a portal for individuals of different depressive symptoms and severities to be treated alongside each other while being modified to meet the needs of each individual participant. Additionally, it offers the opportunity for interventions that target all three active mediators that could be harnessed by nurses at a variety of training levels as well as community health workers.

Lessons Learned in Creating Evidence-Based Electronic Oncology Care Plans

Meghan Coleman, DNP, RN CRNP-BC, AOCNP, USA
Karen J. Hammelef, DNP, RN, USA

Abstract

The delivery of patient-facing treatment summaries and symptom management care plans has been an important step forward in the provision of evidence-based, patient-centered cancer care. This has also been accelerated by the Institute of Medicine's recommendation to address the quality chasm in oncology care. Studies of the use of evidence-based electronic care plans in the cancer population have demonstrated an improvement in the overall patient care experience, decreased negative outcomes, and enhanced physician/patient communication. Electronic delivery of these plans can streamline the documentation process, provide an overview of the patient's care in one concise document, and enhance provider and patient communication through identification of goals of care. Despite this evidence, use of electronic evidence-based care plans remains low.

This presentation details a nurse-led process of creating electronic patient facing care-plans (responsive to unique patient-reported symptoms), that are supported by high level evidence and clinical practice guidelines. Lessons learned, barriers and facilitators to their development and clinical considerations for future products will be reviewed.

This electronic care plan addressed oncology patient needs at one of three phases of the cancer treatment spectrum: treatment planning, active treatment (including distress and symptom management), and survivorship. An over-arching goal of providing the electronic care plan was to reduce distress, improve the quality of patient cancer care, as well as improve patient involvement in care through patient action items supported by high level evidence. Nurse led electronic care plan development can enhance patient understanding and education, which can reduce patient distress. The novel care plan delivery fosters interdisciplinary involvement. Further analytics are needed to assess the effectiveness of reaching these goals.

Clinical nursing staff used the care plans to review common symptom experiences during the treatment planning, active and survivorship care periods. Development of evidence matrixes supported clinician and patient interventions in managing symptom experiences. These interventions were translated into an electronic patient care plan that provided symptom management strategies along with cancer-specific education, recommended referrals and potential treatment-related side-effects. The strength of the care plan content was in the rigorous evidence-based review process which included an expert panel review and consensus building for interventions with low-level supporting evidence. To facilitate implementation of the care plan readability of the content was reviewed by a health educator and targeted at a 7th grade level; plan length was monitored as was ease of electronic use (e.g. connecting to education documents through hyperlinks).

Barriers identified to the process include the continued burden of evidence review and content maintenance to ensure alignment with current best practices (a process facilitated by the electronic nature of this product). Additionally, obtaining resources such as national clinical practice guidelines and oncology experts' review required unanticipated fees, permissions and consents, resulting in the re-evaluation of the project budget and timeline.

Future nursing research efforts should focus on the electronic care plan's ability to improve provider-patient communication and document its impact on the patient symptom experience. With a standardized approach to literature review and a process to sustain current supporting evidence, the electronic patient care plan offers the opportunity to close the quality chasm through an effective and patient centered approach.

Compare the Traditional Brush Hand or Dry Hand Disinfection Methods: A Randomized Controlled Trial

Jui-Chen Tsai, MSN, RN, Taiwan

Abstract

OBJECTIVE: Effective perioperative hand antisepsis is crucial for the safety of patients and medical staff in surgical rooms. The antimicrobial effectiveness of different antiseptic methods including conventional scrubbing and waterless rubbing has not been well evaluated. **DESIGN, SETTING, AND PARTICIPANTS:** A randomized controlled trial (RCT) was conducted to investigate the effectiveness of the three antiseptic methods in surgical staff of Taipei Medical University-Shuang Ho Hospital. Each group enrolled 80 participants.

INTERVENTION: Surgical hand cleansing with conventional 10% povidone–iodine scrub, conventional 4% chlorhexidine scrub, or waterless rub (1% chlorhexidine gluconate and 61% ethyl alcohol).

Materials and methods: This study was a single-center, single-blind, randomized trial. Participants were recruited from the surgical staff members of Taipei Medical University-Shuang Ho Hospital between December 1, 2014 and January 31, 2015. This trial was approved by the institutional review boards of Taipei Medical University and registered with ClinicalTrials.gov, NCT02294604.

Outcomes and statistical analysis: Required Sample size was calculated based on an intermediate effect size of 0.25, power of 80%, and two-sided test with type I error of 5%. G*Power was conducted to carry out the calculation.²¹ Based on the abovementioned parameters, the estimated sample size was 231. The primary outcome of this study was the CFU count per plate of each participant before surgical hand disinfection, after surgical hand disinfection, and immediately after surgery. The centrality of continuous variables was expressed as the mean, whereas the degree of variations was presented as the standard error of the mean. Analysis of variance (ANOVA) was used to examine the group difference in the antiseptic effect at specific time points and for specific surgery durations. Within-group comparisons of CFU counts between time points were performed using the paired t test. To adjust for CFU counts before disinfection, analysis of covariance (ANCOVA) was used to compare the effectiveness of the antiseptic methods. Multiple linear regression was used to adjust for potential risk factors to determine the effectiveness of the antiseptic methods. The Statistical Analysis System (SAS), Version 9.4, was used for all statistical analyses.

RESULTS: The mean colony-forming unit (CFU) count were collected using the hand imprinting method before and after disinfection and after surgery. After surgical hand disinfection, CFU count of the conventional chlorhexidine (0.48 ± 0.22 , $P < 0.01$) and waterless rub groups (1.38 ± 0.74 , $P < 0.05$) was significantly lower than that of the conventional povidone group (4.29 ± 1.25). No significant difference was observed in the mean CFU count among the groups after surgery. Similar results were obtained when preexisting differences before disinfection were considered in the analysis of covariance. Furthermore, multivariate regression indicated that the antiseptic method ($P = 0.0036$), but not other variables, predicted the mean CFU count.

CONCLUSIONS: Conventional chlorhexidine scrub and waterless rub were superior to conventional povidone–iodine in bacterial inhibition. We recommend using the conventional chlorhexidine scrub as a standard method for perioperative hand antisepsis. Waterless rub may be used if the higher cost is affordable.

Collaborative Use of KDOQI Guideline to Improve Chronic Kidney Disease Care

Ann Hallock, DNP, APRN, NP-BC, CNN, USA

Abstract

Chronic kidney disease (CKD) is a silent yet deadly disease affecting millions of people worldwide. It is the gradual loss of kidney function, measured and stratified by estimated glomerular filtration rate (eGFR); it is often secondary to chronic diseases such as diabetes, hypertension, or intrinsic kidney disease. Risk factors for CKD are common problems in primary care such as diabetes, hypertension, chronic use of NSAIDs, low socioeconomic status, older age and ethnic minority. The National Kidney Foundation (NKF) estimates one-half of people with at least one risk factor for CKD have the disease, but few even know it. Research shows that early detection and intervention can save lives and costs associated with disease progression. Use of the NKF Kidney Disease Outcomes Quality Initiative (KDOQI) evidence-based clinical guideline for evaluation, classification, and stratification of CKD has been shown to be effective in identifying the disease early and slowing complications and loss of kidney function by screening annually and intervening early, especially in the primary care setting. Patients at a free nurse managed health center in the southeastern US were not routinely screened for CKD. Subsequently, the disease was going unidentified in a population with known high incidence of diabetes, hypertension, and low socioeconomic status. An interprofessional team at the nurse managed health center consisting of NPs, social worker, technical support manager, nurses, medical assistants, and community resources director agreed to work collaboratively to initiate a pilot project using the KDOQI guideline. The purpose of the project was to implement a change in the way patients at risk for CKD were identified and subsequently managed. The team worked to develop a routine clinical order set based on the KDOQI guideline that would trigger the assessment for risk factors and markers of CKD in all patients scheduled for a routine visit. The project goals were to increase the identification of those with CKD, reduce risk and progression, and improve the management of those with CKD by modifying treatment plans such as improved B/P control and halting the use of NSAIDs. All patients scheduled for a routine visit during a two month interval were evaluated for inclusion in the pilot. Inclusion criterion was clinical evidence of CKD, exclusion criteria was no clinical evidence of disease. Clinical Indicators of eGFR, blood pressure, evidence of urine protein evaluation, use of NSAIDs and ICD-9 coding for CKD were selected by the team as the measures to evaluate how effectively the NP providers applied the KDOQI guideline. Of the 200 patients screened in two months, 56 were identified with evidence of CKD, of these, 22 enrolled in the pilot. The 22 patients were managed per the KDOI guided order set for a period of 5 months. Post intervention data showed ICD-9 coding increased from 0% to 80% and urinary protein checks increased from 59% to 90% which was an expected result of the intervention. Uncontrolled blood pressure decreased from 59% to 40% and use of NSAIDs decreased from 32% use to 5% which was also an expected result. The baseline mean eGFR (69.94 ml/min) increased to 76.23 ml/min which was an expected result related to the improvements in blood pressure control and reduced use of NSAIDs. Use of the KDOQI guideline successfully changed the way this nurse managed health center evaluated for risks and presence of CKD in the pilot population. "Our project has changed the way I practice; I use my GFR calculator everyday now and I think twice before I prescribe an NSAID" (anonymous NP provider). In order to sustain the change the order set was imbedded into the electronic medical record. In addition, steps to further ensure the quality of the practice change included periodic review of CKD outcomes, continued review of the literature for best practice enhancements, continuing education of all providers, and development of nephrology referral network.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Therapeutic Hypothermia Improvement Project

Shiao-Pei Wang, MSN, RN, Taiwan

Abstract

Background: Therapeutic hypothermia (TH) is a standard care of post-cardiac arrest (CA), several studies have showed that TH can improve anoxia neurological outcomes. According to the evidence, TH should be initiated as soon as possible after CA. However, TH is a complicated and labor intensive treatment. Therefore, in order to enhance the efficacy of TH, we must shorten the time from return-of-spontaneous circulation (ROSC) after CA to initiation of TH and improve the integrity of nursing care process.

Methodology:

Improvement project:

1. Form a trans-unit TH team
2. Renew and propose TH operational process and nursing care practice standards
3. Put medical treatments into a doctor's order package
4. Develop a nursing care checklist include all nursing care activities
5. Held in-service education

Project implementation:

1. A trans-unit TH team was formed which included attending physician, residents, clinical nursing staff and administrator of emergency department and intensive care unit, one pharmacist also involved in this team. Team members met once a month and discussed the difficulties of TH in practice.
2. Renewed and proposed the TH operational process and nursing care practice standard, which approved by department and became a formal practice guideline. The shared decision making concept was applied into the process while physician explained TH to patient's family.
3. Put all medical treatments into a doctor's order package and made it more convenient when doctor prescribed TH orders and reduced missing.
4. Developed and integrated all nursing care activities into a nursing care checklist, avoiding incomplete nursing care.
5. ED and ICU physicians and nurses undergo at least one hour education about TH, and advocated the new TH protocol and nursing care practice guideline.

Results: The time from ROSC after CA to initiation of TH was shortened from 151 minutes to 122 minutes. The time from ROSC after CA to target temperature was shortened from 431 minutes to 316 minutes. Care completeness increased from 81.5% to 95%.

Discussion: Through the trans-unit cooperation, this improvement project shortened the time from ROSC to initiation of TH, time from ROSC to target temperature and improve care completeness successfully. Besides, medical staff had increased knowledge about TH. In the future, we should parallel promote TH protocol and care standard to other ICU.

Depression and Sleep Impairment Impact on Pain and Quality of Life for Sickle Cell Patients

Sheran Maxwell Simo, DNP, APRN, ACHPN, FNP-BC,

Abstract

Vaso-occlusive crisis pain is both an acute and chronic factor for patients with sickle cell disease (SCD). Many of the complications associated with SCD have some aspect of pain associated with them, beginning in infancy and continuing throughout the lifespan as a result of sickled red blood cells (Ballas, 2011; Ballas et al., 2012). Acute, recurrent, and unrelenting pain is often joined by other affective disorders that affect pain chronicity, and some patients with SCD have depression and/or sleep disturbances that may affect pain levels and quality of life (Ballas et al., 2012; Vichinsky, 2014). According to Treadwell, Barreda, Kaur and Gildengorin (2015), patients with SCD have a higher incidence of depression and anxiety compared to those in the general population, and these psychiatric conditions may develop as a result of unmanaged acute or chronic pain (Ballas et al., 2012).

The purpose of this quality improvement project is to improve the process of evaluation and treatment of depression and sleep disturbance in patients admitted with vaso-occlusive crisis. The five phases of the Stetler Model were used to guide the process of translating existing research regarding the impact of depression and sleep impairment on pain and quality of life, in patients presenting with acute sickle cell pain crisis, into evidence-based practice for this quality improvement project. An interdisciplinary sickle cell team created the *Guideline for the Evaluation and Treatment of Depression and Sleep Impairment in Sickle Cell Disease*, to guide the evaluation and treatment of depression and sleep impairment, and evaluate their impact on pain levels and quality of life. The sickle cell team initiated implementation of the guideline in August, 2016 as standard of care.

Patients are evaluated using four reliable and validated tools, that were incorporated in the guideline, appropriate for use in the assessment of depression, sleep impairment, pain and quality of life in patients with sickle cell disease. These tools include *The Patient Health Questionnaire (PHQ-9)*, *The Pittsburgh Sleep Quality Index (PSQI)*, *The Quality of Life Scale (QOLS)* and *the Numerical Rating Pain Scale (NRS)* and *Simple Descriptive Pain Scale (SDPS)*. Patients are initially assessed, then reassessed each time the patient is admitted for sickle cell pain crisis, regardless of the results of the initial evaluation, and treatments are offered, if appropriate, based on the guideline. A chart review will be conducted with patient informed consent to collect data on initial and follow-up evaluations, as well as any treatment provided.

Descriptive statistics will include mean, standard deviation and frequencies of depression, sleep impairment, pain and QOL. Pearson correlations and *t*-tests will be performed to examine the linear relationships between pain, depression, sleep and QOL scores. A random-effects time series regression model using a numbered patient identifier as a panel variable will be used to account for within-person correlation. A *p* value of less than 0.05 will be considered statistically significant. It is anticipated that outcome data collection and analysis will be completed by April 1, 2017.

The goal of this quality improvement project is to improve overall pain levels and quality of life for patients with SCD through efficient and effective evaluation and treatment for depression and sleep impairment. Persons living with SCD are at risk for many complications associated with both the acute and chronic effects of sickling red blood cells. Close attention to the physiological and biochemical aspects of the disease, as well as, the psychological aspects associated with it, is important in order to prevent increased morbidity and mortality in this vulnerable population.

Palliative care advanced practice nurses (APNs) provide support and symptom management to patients with life-limiting and serious illnesses, including patients with SCD, as a means of improving quality of life. This project has significance for APNs in both palliative care and specialty SCD/Hematology care as a means to translate existing research into evidence-based practice; as well as provide an efficient and

effective means to evaluate and treat depression and sleep impairment and their impact on pain and quality of life.

Follow-Up of the Joint Function and Quality of Life After Total Joint Arthroplasty

Pi-Chu Lin, EdD, RN, Taiwan

Abstract

As the population ageing, more and more patients suffer from joint disease in Taiwan. Joint replacement surgery performed in Taiwan is about 10,000 to 20,000 cases yearly. The purpose of this study was to investigate the Quality of life and joint functions of TKR (total knee replacement) and THR (total hip replacement) patients 6 weeks and 3 months after surgery. Convenience sampling was used and a total 126 patients were recruited. Average age was 72.75 (SD = 9.046). THR surgery was 21 (16.7 %) and TKR surgery was 105 (83.3 %). One hundred and twenty patients (95.2 %) lived with family and six (4.8 %) was lived alone. Mean score of perceived the convenience of home environment was 3.90 (SD = .74), with 18.7% of patients felt a little inconvenience or very inconvenience, 81.7% felt convenience or very convenience. The patients had moderate satisfaction about the surgery, with mean score 17.68 (SD = 2.13) 6 weeks and 17.75(SD = 2.55) 3 months after surgery. There was significant difference between TKR patients and THR patients on pre-operation ($t = 3.225, p < .05$) and 6 weeks after surgery ($t = 2.32, p < .05$) on EQ5D utility index. Repeated measures ANOVA was used to analyze TKR patients on joint function ($F = 61.38, p = .000$) and perceived health score ($F = 3.74, p < .05$) on pre-operation, 6 weeks and 3 months after surgery. Repeated measures ANOVA was used to analyze THR patients on joint function and perceived health score on pre-operation, 6 weeks and 3 months after surgery, it showed no significant difference ($p > .05$). Because of small sample size of THR patients, it May affect the results of inference. It is recommended to keep track of longer surgical outcomes, and increase the number of THR patients, to improve the results of inferential.

Effects of a Nursing Intervention on Illness Perceptions and Quality of Life in Injured Patients

Bih-O Lee, PhD, RN, Taiwan
Mei-fang Liang, BSN, RN, Taiwan

Abstract

Background. Illness representations and quality of life are important health outcomes for injured patients. A nursing intervention that utilizes cognitive behavioral therapy skills is increasingly being applied to improve injured patients' outcomes, but there is limited evidence of its effectiveness.

Objectives. This study evaluated the long-term effects of a nursing intervention in changing the illness perceptions and quality of life of injured patients.

Design. A prospective randomized controlled trial was used.

Settings. Data were collected at a medical center in Taiwan.

Participants. Participants were screened through the trauma database of the hospital's computer system. A total of 94 patients were randomly assigned either to the experimental group or the control group.

Methods. Data were collected from 2013 to 2015. Based on a self-regulatory theory, the intervention was conducted by trained nurse practitioners. In recording the outcomes, illness perceptions of injury were measured by the Brief Illness Perception Questionnaire, and quality of life was measured by the World Health Organization's Quality of Life questionnaire. Follow-ups on the experimental and control groups were conducted by telephone to complete the survey at 3, 6, and 12 months after their discharge from the hospital.

Results. The intervention positively changed patients' illness perceptions for "personal control" ($B = 1.26$, $P < 0.05$) and "treatment control" ($B = 1.50$, $P < 0.01$) 3 months after being injured, and it changed their "emotional representations" 6 months after being injured. The intervention also positively affected the overall illness perceptions 3 months ($B = -0.60$, $P < 0.05$) and 6 months ($B = -0.82$, $P < 0.001$) after the injury. The intervention also promoted the patients' quality of life in the "social domain" 6 months ($B = 1.38$, $P < 0.01$) and 12 months ($B = 1.38$, $P < 0.01$) after the injury.

Conclusions. The results indicated the intervention had positively changed the patients' illness representations and quality of life. This study adds new knowledge that proves nursing interventions have longer-term effects on injured patients. A multidisciplinary care plan and retesting of the intervention protocol are needed in the future.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Best Practices for Reducing Catheter-Associated Urinary Tract Infections (CAUTIs) in the Medical Intensive Care Unit

Joanna Marie Trinidad, BSN, RN, WTA-C, CCRN, USA

Abstract

Description: Recognize effective interventions to reduce CAUTI rates in the MICU through unit-based protocol formulation, aggressive staff education and hands-on simulation.

Purpose: The purpose of this unit-based study is to provide answers to the best practice question: "What are the best practices for preventing catheter-associated urinary tract infections (CAUTIs) in critically-ill adult patients?"

Significance: Findings from the 2014 NDNQI Data led the Medical Intensive Care Unit (MICU) Council to establish unit-based initiatives including MICU CAUTI Bundles and aggressive staff education and hands-on simulation. A review of the current literature and guidelines (Flodgren et al., 2013, Wald et al., 2012) led to the formulation of the unit-based protocol during the fourth quarter of 2014, including indwelling catheter indication, early catheter removal, bladder scanner utilization, and good nursing practice. Commencement of staff education during the first quarter of 2015 in the form of annual skills fair, monthly Unit Council meetings, and daily charge nurse huddles ensured fast dissemination of information and skills. Laminated badge cards specifying elements of the CAUTI Bundles are also distributed to the staff during this timeframe. Additionally, designation of a CAUTI Unit Champion for both day and night shifts monitored staff compliance and performed inpatient rounding twice a week.

Evaluation: From the first quarter of 2014, the MICU had 12.16 cases of CAUTI per 1,000 catheter days. A drastic fall in CAUTI rates starting in the first quarter of 2015 (0 cases per 1,000 catheter days) proved that evidence-based changes in nursing interventions are indispensable in preventing CAUTIs. Based on 2015 NDNQI data, MICU's CAUTI rate is well below the national benchmark. The utilization of the MICU CAUTI Bundles and aggressive staff education proved, and continue to be a success.

Implications for Practice: Nursing implications include assessment of catheter indication, early catheter removal, and continuing assessment of skills and knowledge of nursing staff to be successful indicators of decreased CAUTI rates (Wald et al., 2012).

EBP PST 1 - Evidence-Based Practice Poster Session 1

Developing a Guideline for Transferring Premature Infants From Incubator to Open Crib in the NICU

Ani Jacob, DNP, RN, RN-BC, RNC-NICU, USA
Joanne Casatelli, DNP, CNNP, USA

Abstract

In the neonatal intensive care units (NICU) achieving stable temperature in an open crib is one of the criteria for discharging premature infants. This physiologic criterion is attained by the premature babies at varying post menstrual ages (PMA) of a stable preterm in the NICU. For a stable preterm infant, majority of the NICUs across the nation recommend maintenance of an axillary temperature between 36.5-37.2 as the normal skin temperature (Barone et al. 2014; Knobel, 2014; Schneiderman et al. 2009; Zecca et al. 2010). Due to concerns over the thermal instability and poor weight gain, the traditional incubator weaning protocols have mostly been depended upon individual physicians' preferences and standard infant weights between 1600-2000 gm.

There are very few studies done to examine the weaning process of a stable preterm infant and policies and procedures vary between institutions. A few studies examined the feasibility of transferring preterm infants at varying birth weights, as low as 1600 gm. (Barone et al., 2014; Schneiderman et al. 2009; Zecca et al., 2010). Barone et al. (2014) conducted a study on early weaning process of infants at 1600 gm weight and concluded that early weaning decreases length of stay and PMA at discharge. Their study also showed an increased growth velocity of these infants compared to those infants who were weaned at 1800 weight or higher. Yet, a standard protocol or guideline regarding the weight, PMA, and/or incubator temperature prior to transfer to an open crib has not been established in transferring stable preterm infants from an incubator to an open crib.

The purpose of the study is to identify criteria for successful transfer of stable preterm infants from an incubator to an open crib maintaining the thermoregulation within the acceptable range of axillary temperature between 36.5⁰-37.2⁰ C. All the infants will be diapered, dressed in a t-shirt, cap, and wrapped in blanket during the transfer process.

Research Questions:

1. What is the optimal weight to have a successful transfer from an incubator to an open crib for a medically stable growing premature infant from 23- 34 6/7 weeks gestational age?
2. What is the appropriate gestational age to have a successful transfer from an incubator to an open crib for a medically stable growing premature infant from 23- 34 6/7 weeks gestational age?
3. What is the optimal axillary temperature to have a successful transfer from an incubator to an open crib for a medically stable growing premature infant from 23- 34 6/7 weeks gestational age?

Definition of terminologies:

Medically stable – the infant will have no episodes of clinically significant apnea, bradycardia, or desaturation during the weaning period 24 hours prior to transfer and 24 hours post transfer.

Successful transfer- the infant will be able to maintain his/her axillary temperature within the range of 36.5-37.5⁰ Celsius in the crib with standard swaddling (diaper, t-shirt, blanket, and hat) until discharge; able to take the entire feeding by mouth/tube and tolerate; and steadily gain weight daily without any lose.

All neonates admitted to the NICU at North Shore University Hospital (NSUH) from 1/1/2010 to 12/31/2015 between 23-34 6/7 weeks of gestational age will be eligible for the study. Other eligibility criteria include a minimum weight of 1500 gm, consistent weight gain for at least 5 days, and enteral nutrition prior to the transfer. Infants who were medically unstable such as ventilator assistance and apnea & bradycardia episodes at the time of transfer from incubator to crib will be excluded from the study.

A retrospective chart review will be conducted on all infants between 23-34 6/7 gestational ages at birth and who are medically stable at the time of transfer from an incubator to an open crib from January 2010-December 2015. These infants will be further stratified into 23-26 6/7 weeks, 27- 30 6/7 weeks and 31-34 6/7 weeks of gestational age. The data collection tool template is given in appendix I.

As the suggested study is a retrospective chart review, an informed consent is not sought for the study. No identifiable data will be extracted from the chart for study purposes. There will be no interventions or deviations from the current protocol. Currently the transfers are done based on individual attending physician's discretion.

This is a chart review, and the proposed sample size is based on feasibility and availability of resources, and not on a formal power calculation. The charts of all neonates meeting the inclusion/exclusion criteria from January 2010 to December 2015 will be reviewed. It is estimated that there are between 700 and 1000 such charts. Approximately 80% of such transfers are successful. Therefore, it is estimated that of the 700-1000 charts, between 700 and 800 will have been successfully transferred, and between 200 and 300 will have been unsuccessful. In order to obtain stable estimates when using logistic regression, approximately 10 events per variable are required. (ref: van Belle, *Statistical Rules of Thumb*, John Wiley & Sons, Inc, 2002). Therefore, the proposed sample size will be sufficient to examine models including 8 to 10 variables. (It should be noted that for purposes of this calculation, the "event" would be unsuccessful transfer, as that is the lower proportion).

The data collected will be based on the infants' PMA, weight at transfer, and the range of incubator temperatures. Then the data will be stratified based on the stratified age group of the study subjects-23-26 6/7 weeks, 27- 30 6/7 weeks and 31-34 6/7 weeks of gestational age. A normally distributed data will be analyzed as mean and standard deviation or as median and interquartile range if the normal distribution is unacceptable. The baseline characteristics will be expressed as numbers and percentages.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Evaluating the Effectiveness of a Community Partnership to Raise Toxic Stress Awareness in Early Childhood

Michelle A. Beauchesne, DNSc, RN, CPNP, FAAN, FAANP, FNAP, USA
Patrice Farquharson, EdD, CSDE, PC, USA

Abstract

Statement of Problem: The American Academy of Nursing (the Academy) has listed the reduction of toxic stress associated with adverse childhood experiences (ACEs) as a top priority for improving the health of the population (Mason & Cox, 2014). Exposure to ACEs or trauma in childhood places children at higher risk for developing both short-term and long-term negative physical and psychological health outcomes (Horner, 2015). Toxic stress is defined as the prolonged activation of stress response systems in the absence of protective relationships (Center for Child Development, 2016). Research has shown that children who have protective factors that promote resilience to such stress do not experience negative consequences (AAP, 2012). In 2016 the Academy issued a policy statement to encourage partnerships between health care professionals and other child and family organizations advocating for policies that strengthen and expand access to programs and services for families at risk for toxic stress to help promote optimal mental health and well-being, including enhancing protective factors (Gross et al., 2016). This project exemplifies such a partnership.

Purpose: The purpose of this poster is to share the evaluation of the effectiveness of a community partnership to raise awareness of toxic stress in early childhood and increase resilience and protective factors in children and families. The evaluation process uses the *Social Ecological Model* guided by the Center for Disease Control (CDC) *Six-Step Public Health Program Evaluation Framework*.

Setting: The Early Childhood Council and the Early Childcare Center, designated by the American Academy of Pediatrics (AAP) as a promising medical home, located in a suburban city in northeastern United States, partnered in this endeavor. The multi-strategy toxic stress awareness intervention implemented over a 12-month period is serving approximately 150 children ages 2-5 years of primarily low or moderate income working families from culturally diverse backgrounds. The team consists of a Pediatric Nurse Practitioner (PNP) consultant, a school nurse, a social worker, the executive director, teachers, staff, families and interprofessional university students.

Summary of Intervention: All staff received training in developmental assessment using the Ages & Stages Questionnaires (ASQ) with an emphasis on social emotional development. Family engagement is key to positive outcomes for children and families. Resources were created to ensure continuity of prevention education in the home, classroom and broader community utilizing social media. Families at risk meet with the social worker to develop individual family plans. A peer-mentoring program involving families as peer mentors is designed to reduce conflict, foster problem-solving skills, and promote healthy relationships within the family. Educational materials and learning activities are designed at all 4 levels of the *Social Ecological Model- child, family, school, and broader community* with emphasis on emergent literacy and current curricular threads on social emotional development and resiliency building in early childhood.

Outcomes: Indicators of success are evidenced against the performance standards of utility, feasibility, propriety, and accuracy. Multiple measures based on the six-step CDC process include parent and staff surveys, focus groups with key informants, curricular changes, and analyses of children's stories and drawings. The results of Ages and Stages Social Emotional Questionnaires (ASQ-SE) administered at recommended intervals to identify children at risk are discussed.

Implications for Practice: Distinguishing principles between research and program evaluation methodology are outlined. Outcome evaluations, future plans, and implications for public health are discussed. Strategies to assist professionals to support children and families meet the challenges of

addressing the effects of toxic stress and increasing awareness are explored. Suggestions on implementing similar comprehensive community program evaluation processes are shared.

Funding & Support: The National Center on Early Childhood Health and Wellness' (NCECHW): Early Childhood Education (ECE) /Medical Home Toxic Stress Learning Collaborative grant.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Impact of NICHE Preparation on Nursing Knowledge of Geriatric Patient Care

Tru Brynes, MSN, RN, CNL, CMSRN, USA

Abstract

The aging of the United States population has profound implications for nursing practice and health care costs (Capezuti, Bolt, Cline, Dickson, Rosenberg, Wagner, Shuluk, & Nigolian, 2012). Their health care utilization are three to five times more than younger patients, which accounted for \$444 billion or 23% of the health care spending in 2008 and 13 % of the U.S federal budget (Wier, Pfuntner, & Steiner, 2010). Research shows units that have implemented the Geriatric Resource Nurse (GRN) model have better patient outcomes in terms of preventing falls and fall related injuries, decreased restraint use, early recognition of confusion or delirium, and decreased hospital acquired infections (Boltz, Capezuti, Bowar-Ferres, Norman, Secic, Kim, Fairchild, Mezey, & Fulmer, 2008; Kim, Capezuti, Boltz, and Fairchild, 2009). 5 Tower, a post-surgical unit, experienced a shift in its patient population in 2015 after the addition of the telemetry monitors to the unit. Since then, there was an in-flux of a geriatric population with both medical and surgical comorbidities. 5Tower served 734 older adults in 2015 ranking the fifth highest unit within the Central Division (CMC-Main and Mercy). Recognizing the special needs of geriatric patients, 5T implemented the GRN model by training staff nurses to better understand the normal signs of aging and contraindications related to caring for the geriatric population to recognize and identify resources available within the community and anticipate risks associated with care of the geriatric patients.

Purpose: The purpose of this project is to increase the number of GRNs on 5T to better serve the geriatric patients.

Clinical Question: Will there be an improvement in nurses' knowledge related to the geriatric population after the completion of the Nurse Improve Care for Healthcare Elderly (NICHE) Geriatric Nurse modules?

Theoretical Framework: Using the King's Goal Attainment Theory guided this study. The Goal Attainment Theory is comprised of three major systems: personal systems, interpersonal system, and social systems. In this study, the personal system will be an individual nurse who recognizes the importance of self-growth in pursuing the advanced knowledge of the geriatric population with the desire of becoming a GRN. The unit will have a group of GRNs (interpersonal system) serve as a resource for the unit in order to help improve care for geriatric patients. The hospital administration (social system) provides a supportive environment and tools for staff to practice so they can better care for their patients.

Methods: Using the pre-test and post-test method to assess nurses' knowledge before and after they completed the NICHE GRN modules. A 25 item survey questionnaires related to geriatric patient care is used to assess nurse's knowledge about geriatric care before and after completing the modules. The modules cover 14 topics, which take about 20 hours to complete. There is a free 20 contact hours at the end of the 14 modules.

Result: The survey results will be analyzed using descriptive statistic. Aggregate mean of the pre-survey and the post-survey will be analyzed using pair t-test. The final result will be calculated when the project is completed in December 2016.

Conclusion/Implication: Geriatric patients have higher acuity, experience more hospital complications, and have longer lengths of stay; thus, resulting in an increase in health care cost and poor health outcomes. It is important for hospital to support and equip nurses with advanced knowledge to better serve the geriatric patients. This project not only help improve geriatric patient outcomes, but also help the nurses become a geriatric specialist. The next step after forming a team of GRNs, we will be examining geriatric patient outcomes, includes delirium screening, fall prevention, and discharge planning.

EBP PST 1 - Evidence-Based Practice Poster Session 1

In-Home Air Pollution is Associated With Respiratory Symptoms in Patients With Chronic Obstructive Pulmonary Disease

Su-Er Guo, PhD, RN, Taiwan

Abstract

Background: Ambient particulate matter (PM) has shown adverse effects of health on respiratory diseases. To date, although studies have demonstrated that PM was associated with increased morbidity, readmission rates, resource utilization, and the mortality in chronic obstructive pulmonary disease (COPD), few studies investigated the influences of indoor PM on respiratory symptoms, lung function, and acute exacerbations in patients with COPD. **Objective:** In this longitudinal study, we investigated the relationships between indoor PM (PM_{2.5} & PM₁₀), respiratory symptoms, lung function, and acute exacerbations in patients with moderate to very severe COPD. **Methods:** Indoor air quality (PM_{2.5} and PM₁₀ levels) was monitored by using an aerosol spectrometer (Model TSI8532) in the patients' bedroom, kitchen, living room, and front door at baseline and every two months until one year. At each home visit, the patients were asked to complete spirometry and questionnaire testing, including respiratory symptoms and clinical characteristics. Respiratory symptoms were evaluated using a modified version of the symptoms section of the St. George's Respiratory Questionnaire (SGRQ). Clinical characteristics included Charlson comorbidity index (CCI), FEV₁ at first visit, and length of COPD diagnosis in years. Exacerbations were assessed by chart review. Generalized estimating equation (GEE) analysis was used to analyze data. **Results:** The results of the present study ($n = 83$) showed that the level of wheezing was significantly higher in patients whose living room and kitchen had abnormal (higher than the maximum accepted) PM_{2.5} ($B = 0.80$; $B = 1.03$, respectively) and PM₁₀ levels ($B = 0.36$; $B = 0.38$, respectively). **Conclusions and clinical application:** Increased PM levels were associated with worse respiratory symptom and increased admission rate in patients with moderate to very severe COPD. Future investigations are needed to determine the effectiveness of environmental interventions or self-management programs to reduce PM concentrations and improve health outcomes in this susceptible population.

Implementing Project Echo: Complex Care Management, Using Technology to Support Primary Care Nurses

Mary L. Blankson, DNP, APRN, FNP-C, USA

Sarahi Y. Almonte, MS, RN, USA

Katie Ann Lainas, BS, USA

Abstract

Project ECHO is a telehealth model of knowledge transfer that connects expert faculty teams with primary care providers. The primary goal of Project ECHO is to improve health care outcomes through case-based learning. It aims to do so by equipping participants with the knowledge and skills needed to care for unique patient populations. While there are several established Project ECHOs specifically addressing the knowledge needs of primary care providers, Project ECHO Complex Care Management (CCM) is one of the first specifically targeting primary care nurses. It is uniquely designed to build nurse leadership and to directly support nurses as they engage in complex care management. A faculty team of multidisciplinary specialists advise the nurses on next steps to manage their patients with complex medical, psychosocial, and behavioral issues.

As part of a larger complex care management initiative at the Community Health Center, Inc. (CHCI), Project ECHO Complex Care Management (CCM) was uniquely designed to build nurse leadership skills and experience. The CHCI is one agency with 14 different integrated patient-centered primary care sites across the state of Connecticut. These sites provided care for uninsured and underinsured patients. The CHCI translated this provider-centric design using the Knowledge To Action framework to a model centered on nurses. Through twice monthly didactics and case presentations, nurses from all over CHCI's statewide network connect via videoconference to receive expert advice from a variety of specialists on how to care for their most complex patients. The faculty team is made up of a nurse practitioner and Chief Nursing Officer, a medical provider, behavioral health provider, pharmacist, registered dietician, certified diabetes educator, care management specialist and homecare nurse. The first thirty minutes of a session are focused on didactic education, and the latter 1.5 hours on case presentations by nurses. There is a standard presentation form that was designed to support nurses in organizing the case information as well as the questions they are requesting the faculty to address. Through videoconferencing and case-based learning, the faculty lends real-time support and supports nurses as they address the needs of their complex patients. Nurses are empowered to practice to the top of their license and provide patients with high quality, low cost care. Through case presentations nurses learn valuable care management skills and gain the confidence to develop their roles as leaders on health care teams.

Project ECHO CCM develops nurses as leaders and care managers in the primary care setting. It is an effective tool in training both new and experienced nurses as they transition into primary care roles that include a significant amount of care management. Project ECHO CCM is an important platform for improving nurses' knowledge and self-efficacy. Project ECHO CCM connects every nurse throughout the CHCI on a regular basis. It provides them with the chance to learn from one another, creating a knowledge network, and a stronger team dynamic. The opportunity to communicate in this way across each of the CHCI's sites would not be possible without Project ECHO. This technology has the potential to connect nurses without regard to geography, linking teams together to learn from each other, and to share best practices.

Operational data from Project ECHO CCM further demonstrates the impact through case analysis, and also general metrics of the % of nurses who have presented, as well as the number of continuing nurse education credits granted. As of July 2016, 42 cases have been presented, representing 35 discrete patients with 66% of nurses at CHCI having had presented at least one case, and 1 nurse having presented eight cases. This number will continue to rise and more and more nurses are likely to full engage in this intervention in the coming year. Topics covered during the didactic portion of Project ECHO CCM have included chronic pain, substance abuse, diabetes, asthma, COPD, self-management goal setting, motivational interviewing and even medical nutrition therapy to name a few. This poster will

be updated with the most current operational data to better describe the overall impact and global implications for Project ECHO CCM.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Text Message Quality Improvement Intervention Improves Influenza Vaccination Rate Among Pediatric Patients With Asthma

Elizabeth Sloand, PhD, RN, PNP-BC, FAAN, USA
Augusta MacQueen, BSN, RN, USA
Sarah Polk, MD, ScM, USA
Annie Holm, MSN, RN, USA

Abstract

Background: The Centers for Disease Control (CDC) and the World Health Organization (WHO) recognize that children with asthma are at an increased risk of severe complications due to influenza infection. The CDC highly recommends that all children with asthma, 6 months and older, receive an annual influenza vaccine. Clinicians are challenged to educate families about the recommendations and insure that these high risk children are vaccinated each year.

Methods: For the 2015-2016 influenza season (Year 1), a reminder text message campaign was implemented at an ambulatory pediatric clinic to improve influenza vaccination adherence rates among children with asthma. The majority of the clinic's patients have public insurance and are Latino children with immigrant parents. Using the electronic medical record, a list of children with asthma and their family's phone number was generated. A three-part text message in English or Spanish was sent with information about the vaccine, a link to an informational video for parents, and instructions for making an appointment to get the vaccine. The Year 1 campaign was evaluated and revised accordingly. The text-based campaign was relaunched for the 2016-2017 influenza season, Year 2, which will include October 2016 to April 2017. For Year 2, the text message was clarified and the text response options were simplified. Follow up phone calls were made as needed. Responses for each year were tallied. Results for both years were analyzed and compared.

Results: For Year 1, text messages were sent to 381 households, representing 399 clinic patients. The response rate was 11.5%. For Year 2, text messages were sent to 441 households. Preliminary results indicate an increase in both response rates and influenza vaccination rates. These early results from Year 2 will be further refined and analyzed in order to further improve the influenza vaccine program for next year.

Conclusions: The text message project showed that family responses and influenza vaccine rate improved from Year 1 to Year 2. This project sets the stage for future quality improvement research on text message reminder/recall systems to increase annual influenza vaccination rates in pediatric patients with asthma. Such text message interventions may increase population/family engagement and influenza vaccination rates, ultimately decreasing preventable, severe health complications in children with asthma. This is particularly important because of the inclusion of minority immigrant children, an under-represented population that is not routinely included in health outreach efforts.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Assessing Nurse Learners' Stress Using Technology to Measure Physiologic Adaptation Within Interprofessional Patient Care Simulation

Jill Van Der Like, DNP, MSN, RNC, USA

Lela Hobby-Burns, DNP, MSN, APHN-BC, USA

Eric Greska, PhD, CSCS, CPT, USA

Abstract

Background: Recent public reports find that communication-based errors contribute to medical errors as the third leading cause of death in America (Fikes, 2016; Kaiser Health News, 2016). Safe, efficient reporting of patient information is perplexing, especially for newly graduated nursing staff. Communication skills cannot develop through memorization and knowledge, but, rather, through practice and experience during the education process (Goh, 2016). Interprofessional communication is pivotal for patient safety as nurses accumulate patient information and transfer the important facts to physicians, psychologists, pharmacists, dietitians, social workers, technicians and other key team members. The Simulation (SIM) laboratory provides a safe, realistic setting for learners to become familiar with accommodating their stress while practicing teamwork and communication skills.

Nurses frequently report job dissatisfaction related to the stressful work environment. Current turnover rates among nursing staff are approaching 15%, which has led to a focus on retention strategies (AACN, 2016). Newly graduated nurses especially feel overwhelmed about a lack of team support when building their practice competencies (AACN, 2016; IOM, 2011). Simulation Interprofessional education (SIM-IPE) practice during the undergraduate learning process builds confidence in team communication, knowledge, and skills (AACN, 2016; Ruebling et al., 2014). SIM-IPE is an effective teaching strategy that facilitates learning while building confidence and reducing anxiety. During SIM-IPE, learners from multiple disciplines role-play decision-making to communicate vital information among team members. These SIM-IPE learning experiences promote familiarity with the complex roles and responsibilities among the healthcare team. New graduates use these foundational team skills from their first day and on as a member of the healthcare team.

The autonomic nervous system (ANS) regulates vital involuntary functions of the body. The system is divided into sympathetic nervous system (i.e., heart rate acceleration, blood vessel constriction, increase in blood pressure) and the parasympathetic nervous system (i.e., slows the heart rate, increases intestinal and gland activity and relaxes sphincter muscles). Current technology can measure the ANS response and indicate stress adaptation.

Methods: The purpose of this descriptive longitudinal study is to examine nurse learners' biological stress adaptation during SIM-IPE experiences. These adaptation indicators were monitored 8 times as learners (n=57) progressed through their first semester, and 31 times the second semester as junior-year Bachelor of Science in Nursing (BSN) students.

During the simulation sessions, students were fitted with a Bioharness (Medtronic, Annapolis, MD) physiologic module to monitor heart rate variability (HRV). Post-processing of the HRV data utilized KubiosHRV software (version 2.2, Kuopio, Finland) to assess the frequency domains during simulation participation and peer-to-peer debriefing sessions. The high-frequency domain is relative to parasympathetic (vagus) response, whereas the low-frequency domain measures a combination of parasympathetic and sympathetic (i.e., parasympathetic when respiration is below 7 bpm, otherwise sympathetic).

Sample and Setting: In the United States, the setting is a School of Nursing in a Florida mid-sized public university. The University's Nursing and Exercise Science faculty collaborated on SIM-IPE design and data collection. The nurse faculty conducted the SIM-IPE laboratory experiences, while the Exercise Science faculty set up, monitored and analyzed the data collected. SIM-IPE learners were informed of the research study details, and signed a university-approved IRB consent before participating. A convenience

sample of junior-year nurse learners (n=57) was selected in a prelicensure Bachelor of Science in Nursing (BSN) program. The SIM-IPE experience occurred in the nursing school's SIM laboratory, debriefing room, and Home Hospice SIM room. Learners were assigned one (1) of three (3) roles primary nurse, secondary nurse, and resource nurse. The primary nurse leads the care decisions with secondary nurse assisting, while resource nurse communicates important patient information to the team. Each participant completed 5 SIM-IPE experiences over 2 semesters, and the roles were randomly rotated per student volunteers. The nurse instructor briefed the learners with a nurse report of important patient information prior to care.

Data Collection: During the SIM-IPE briefing, Exercise Science faculty fitted learners with a Zephyr BioHarness™3 sensor that was worn next to learners' skin beneath their uniform shirt. This technology senses and records the physiologic indicators of stress (i.e., heart rate, heart rate variability, respiration rate, and trunk inclination level). The Zephyr BioHarness™3 sensor continuously monitors the learner's activity throughout the SIM experience and instructor's debriefing period. Exercise Science faculty monitored and used a time-stamp marker to define the learner's stress indicators during simulated patient care and debriefing. Learners' roles were carefully identified and recorded so faculty could analyze the real-time changes in stress adaptation. The data is automatically recorded and stored into a password protected laptop, and backed up by a university lab password protected intranet.

Results: The Zephyr BioHarness™3 sensor measured physiological stress indicators during each SIM nurse role and debriefing. Data was analyzed collectively to determine when stress adaptation were more prevalent. Findings revealed that during the semester's initial SIM-IPE sessions, nurse learners demonstrated an increase in stress indicators while involved in patient care activities. However, over time and after five (5) SIMs, stress indicators were lower, indicating learners adapted to stress, and, perhaps more confident when performing the patient care activities (i.e., sensor data demonstrated an increase in high-frequency relative power, with an equivalent reduction in the low-frequency relative power from the beginning to the end of the semester). This change in heart rate variability frequency bands demonstrates a change in neural influence from sympathetic to more parasympathetic controls, thus indicating stress adaptation. Learners, as the semester progressed, appeared to adapt to stress during SIM patient care activities. However, during all the post-SIM debriefing peer-analysis sessions, throughout both semesters, learners' physiologic stress indicators remained high.

Analysis of these debriefing sessions finds these same learners displayed no changes in their frequency relative power, indicating that stress, brought on by peer-to-peer accountability, still remained high. Learners' stress levels remained high, unchanged, when explaining their patient care and decision-making.

Conclusion: Conclusion: The IOM (2011) states that interprofessional collaboration and coordination should be the norm for quality patient care. This study supports the SIM-IPE environment as a safe learning environment to reduce stress and promote teamwork. The SIM-IPE environment provides nurse learners practice to adapt to the stress of patient care, and perhaps indicates more confidence of their patient care skills and interactions. However, these same learners continue to have unchanged stress adaptation levels during the peer-to-peer debriefing session.

More research is needed on learners' stress adaptation during peer-to-peer debriefing. SIM-IPE should be integrated across the learning continuum, where learners build knowledge, skills and positive attitudes across practice settings and professions (IPEC, 2011).

Development of Smartrek a Theory Driven Mobile App to Prevent Alcohol Use Among College Students

Donna Kazemi, PhD, MSN, CNE, FIAAN, USA

Abstract

Background Hazardous alcohol consumption use and its related consequences is a foremost global public health issue facing individuals, families, and society contributing to significant morbidity among youth college students. More than one third of college students report engaging in heavy episodic drinking (4+/5+ drinks in a single sitting for females/males) at least once in the past two weeks, and 8% (females) to 20% (males) consume at least twice on a binge (i.e., 8+/10+ drinks) Alarming numbers of college students drink heavily, often in binges, bringing negative consequences such as blackout, rape, HIV-related sexual risk-taking, academic failure, suicide and violence The most recent survey conducted by the 2015 National College Health Association found that among the 34,208 students who responded, 63% reported drinking in the last 30 days. Alcohol is the most commonly used substance, with one out of three young adults reporting binge drinking Binge drinking is associated with substantial negative consequences including annual rates of 646,000 physical assaults, 97,000 sexual assaults, 599,000 unintentional injuries, and 1,825 deaths. Excessive alcohol use is one of the greatest societal medical burdens with an annual cost exceeding \$250 billion per year.

Today's college students are the first generation raised in a media environment; known as 'Net Generation', they have always had access to digital technologies In the United States, 91% of adults use a mobile phone with over 50% owning Smartphones. Those in "Generation Z" who have extensive access to digital technology view communication using this technology. Technologies such as mobile apps, text messaging and online chat increase receptivity to new information and verbalization in this age group. Mobile apps represent a novel growing market, and environment in which to disseminate health behavior change interventions. App features are delivered as individual components (e.g., text only) or in combination. New technologies, such as smartphones, offer more efficient delivery to college students, who access their phones multiple times a day.

Given the familiarity and comfort that students have with mobile phones and their willingness to adopt new trends, there are exciting opportunity to use mHealth to deliver interventions. One approach to reducing high-risk drinking is Motivational Intervention (MI), a person-centered approach to strengthening motivation for change. MI is an empirically supported, evidence-based intervention for students aged 18-25 that uses a directive but non-confrontational approach with personalized feedback to resolve ambivalence and reduce alcohol misuse and its harms. A growing body of research demonstrates the effectiveness of computerized MI deliveries. Computerized interventions simulate face-to-face interventions by giving personalized feedback on characteristics related to behavior change. In addition, web interventions that incorporate personalized feedback and harm reduction strategies have shown some promise with mandated college students and could be of use with students during the summer months. The widespread use of evidence-based Brief Motivational Interviewing (BMI) on campuses has been hindered by logistical issues and the financial costs of implementation. Interventions have been developed to reduce alcohol use among student that would be related in real-life, real-time situations. There is mounting evidence that mobile-based technology is a promising approach for reducing substance use and warrants further investigation.

Objective: The objectives of this current study were 1) to translate the motivational intervention to mobile delivery, 2) based on the translations to design and develop a smartphone (SP) application (or "app") to deliver a modified intervention through mobile phones and use electronic communications (e.g., text messaging) for interactions and 3) once development of the app was completed, we then tested the app by conducting theater testing and field testing to determine acceptability with the college population. Thus we designed an innovative app by refining the original MI to address drinking by college students and tested college students' responses to and acceptance of delivery of our adapted app.

We aim to develop a mobile app intervention based on motivational interviewing that will 1) development of a mobile intervention that would be applied in real-life, real-time environments to reduce hazardous drinking amongst college students. We developed a smartphone (SP) application (or “app”) to deliver a modified intervention through mobile phones and use electronic communications (e.g., text messaging) for interactions. 2) Once modifications are complete, we examined the feasibility of the intervention by conducting theater testing and field testing to determine acceptability with the college population.

Methods: Using components of intervention mapping as a guide we designed a Smartphone app by translating Motivational Intervention techniques conducted in three phases, 1) first in phase 1 we adapted the MI constructs for mobile delivery and developed preliminary app designs, 2) then based on the preliminary designs we developed the app and system server, and 3) finally in phase 3 we tested the app by conducting theater and field testing ($n=20$) to determine feasibility and acceptability among college students.

Results: The components of motivational interviewing (MI) and MI spirit were integrated into the SmarTrek features (e.g., engaging, focusing, evoking, planning, acceptance, compassion, and partnership). A suite of mobile features was developed based on ME and EMI constructs which enable effective change of the students drinking behaviors. The mobile app features that were developed within this framework included integrated tools of surveys and assessments, personalized feedback reports, real-time email communication (Coach), motivational text messaging, and educational games. SmarTrek average overall usability score was 5.97 out of 7 (SD=1.20, Cronbach's $\alpha=0.916$). Looking at the three sub-scales, the usefulness of the APP was measured using 4 items and the average score was 5.68 (SD=1.06, $\alpha=0.781$). Ease of use was measured using 15 items and the average score was 6.03 (SD=1.24, $\alpha=0.951$). The satisfactory was measured using 7 items and the average score was 6.02 (SD=1.20, $\alpha=0.648$). 90% of the participants would like to recommend the APP to friends; 50% of the participants agreed/strongly agree that they drank less while using the APP; 60% at least agreed on a positive effect of the APP; 80% of the participants would like to continue using the strategies learned and 40% participants thought they were motivated to reduce drinking while using the APP.

Conclusion: SmarTrek was developed and tested with multiple features to deliver BMI to college students with risky alcohol behaviors. The integration of theory into SmarTrek a mHealth self-monitoring app provides support for future research to feasibly assimilate theoretical constructs into existing hazardous drinking among college students. This important work would best be accomplished by a global multi-disciplinary collaboration to include nurses, health service providers, computer scientists, mathematicians, internet technical specialists, government/community services, and public citizens.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Factors Associated With Development of Pressure Ulcers in Patients With Assist Device Tubes in ICUs

Li Chuan Chang, BSN, RN, Taiwan

Hui-Ju Chung, RN, Taiwan

Hui-Ting Kuo, MSN, RN, Taiwan

Abstract

Purpose of the study: Critically ill patients are a high risk group for pressure sores due to insufficiency of blood perfusion and oxygenation. Particularly, patients in the cardiovascular surgery department have a significantly higher incidence of pressure ulcers than those in other departments due to poor blood circulation in combination with physical constraints caused by assist device tubes. Patients with heart failure mainly need to be installed with the tubes of the following assist devices: intra-aortic balloon pump (IABP) and extracorporeal membrane oxygenation (ECMO) or ventricular assist device (VAD). Cardiac surgery ICUs provide care for patients after various major cardiac surgeries as well as IABP depending on the severity of the patient's conditions to reduce cardiac afterload and increase myocardial blood flow, or install ECMO for the patient's heart to recover and to gain time for treatment. Whether in the case of heart failure caused by sudden acute myocardial infarction, awaiting a heart transplant due to chronic heart failure, or acute heart failure following an open-heart surgery, ECMO and VAD can be used when IABP assist fails to bring about any improvement. Although both being machine-assisted circulation systems, IABP and ECMO differ in timing of use and effectiveness. Therefore, choices still depend on patient needs. Assist systems are relied upon to allow the patient's heart and lungs to rest and gain time to treat the patient's disease itself. The purpose of this study is therefore to investigate factors associated with development of grade 1-2 pressure ulcers in patients installed with assist device tubes in cardiovascular surgery ICUs.

Methods: This study was conducted using case analysis and review of medical records over the period between January 2012 and March 2016. The sample consisted of 139 patients who had experienced pressure ulcers in cardio surgery ICUs. An analysis table for causes of pressure ulcers was developed based on the proof from the literature. With the analysis table, 33 patients who were installed with the tubes of assist devices (IABP, ECMO and VAD) and developed pressure ulcers were selected for the investigation of factors associated with development of pressure ulcers in patients installed with assist device tubes and data analysis using SPSS.

Results: During the study, 33 of the 139 patients who had experienced pressure ulcers in cardiovascular surgery ICUs developed pressure ulcers due to installation of the tubes of assist devices (IABP, ECMO and VAD) required for their conditions, constituting an incidence of 23.74% (33/139). Factors associated with development of pressure ulcers in patients installed with assist device tubes include demographical variables, such as gender and age, surgical wounds, with males accounting for 84% and average age at 62, surgical wounds (90%). The analysis of associated factors reveals variables to be: cachexia (diabetes, kidney disease, anemia etc.) (75.7%), limb edema (81.8%), surgical wounds (90%), no and incorrect anti-pressure measures (33.3%). In the Braden Scale for Predicting Pressure Ulcer Risk, patients with pressure ulcers scoring equal to or greater than 16 account for 15.1%, those scoring 4 in sensory perception for 15.1%, and those with malnutrition for 48.4%.

Conclusions: This study shows that factors causing development of pressure ulcers in patients installed with assist device tubes are: cachexia, score of 4 in sensory perception, malnutrition, no and incorrect anti-pressure measures. Patients in cardiovascular surgery ICUs have a significantly higher incidence of pressure ulcers than those in other departments due to heart failure in combination with poor blood circulation, poor nutrition, pains from surgical wounds and physical constraints caused by the installation of assist device tubes on lower limbs or the chest. It is therefore suggested that further research should focus on enhancing education on preventive measures for pressure ulcers and knowledge of care associated with assist device tubes for medical staff and improving alertness in nursing staff for development of pressure ulcers in patients installed with assist device tubes to prevent this problem.

EBP PST 1 - Evidence-Based Practice Poster Session 1

Simulation Training for Obstetrical Emergencies: Improving Nurse's Clinical Skills During a Shoulder Dystocia

Katie SuAnn Caldwell, MSN, CNM, USA

Abstract

Introduction: Perinatal mortality and morbidity are a significant problem with the mortality rates attributed to antenatal and intrapartum complications. After reducing perinatal mortality and morbidity by way of good maternal health, obstetrical emergencies still can occur. To further decrease mortality and morbidity, health care professionals need to be properly trained to handle such emergencies.

Background and Significance: A pregnancy related maternal death has been defined as a death occurring during pregnancy or the year following the end of a pregnancy due to a pregnancy complication (CDC, 2014a). In 1987, there were 7.8 deaths per 100,000 live births, and in 2011 there were 17.8 deaths per 100,000 live births. Obstetrical emergencies identified as causing poor perinatal outcomes consist of shoulder dystocia, eclamptic seizures, postpartum hemorrhage, umbilical cord prolapse, and emergency cesarean section (CDC, 2014b).

According to the United Nations, approximately half of the mortality rate of children under five years old includes preterm birth complications and intrapartum-related complications (World Health Organization, 2016). Reducing intrapartum-related complications can be achieved by having adequately trained staff to handle the complications and evidence has shown that outcomes have improved by using simulation training programs of high and low technology (Cass, Crofts, & Draycott, 2011).

Review of Literature: From a global perspective, simulation is a common modality of training, which helps to train staff, and implement evidence-based practice (EBP) into perinatal care. The United Kingdom and Australia utilize the Practical Obstetric Multi-Professional Training (PROMPT) program using high technology simulators that mimic vital signs, fetal heart tones, uterine bleeding, etc., to simulate obstetrical emergencies ("Evidence based multi-professional training package for obstetric emergencies - Prompt Maternity," n.d.).

Cass et al. (2011) performed a meta-analysis, which described simulation training to teach necessary skills to handle shoulder dystocia, postpartum hemorrhage, eclampsia, and umbilical cord prolapse. The shoulder dystocia data showed that 42.9% of participants were able to successfully relieve the shoulder dystocia before the training session and 83.3% after the training session. In a systematic review by Meri n, van de Ven, Mol, Houterman, and Oei (2010), the effectiveness of multidisciplinary teamwork training in a simulation setting on adverse outcomes in obstetrical emergencies were shown to improvement of knowledge, practical skills, team performance and communication. Grobman et al. (2011) assessed outcomes that were associated with the implementation of a shoulder dystocia protocol/simulation that focused on team response, which resulted in a decrease in brachial plexus injuries from 10.1% to 4.0%.

Purpose of Project: The purpose of the EBP change project was to evaluate, educate, and demonstrate improvement of clinical skills necessary to handle shoulder dystocia emergencies. The project consisted of a pretest, posttest and simulation sessions for participants using information obtained from Gnosis OB by Advanced Practice Strategies (APS) educational platform (Advanced Practice Strategies, n.d.). The desired outcomes of the project is to show improvement in knowledge and clinical skills of participants regarding shoulder dystocia.

Methods: Project Description - The project consisted of a pretest and posttest using information obtained from Gnosis OB by Advanced Practice Strategies (APS) educational platform (Advanced Practice Strategies, n.d.). After the pre-test, a shoulder dystocia simulation was performed; followed by debriefing, an informational PowerPoint, second shoulder dystocia simulation, and finally a posttest. The

desired outcomes of the project were to show improvement in knowledge and clinical skills of participants regarding shoulder dystocia.

Participants and Setting - The individuals recruited for the EBP change project are Registered Nurses of all skill/experience level and level of education from the labor and delivery (L&D) unit at the clinical facility site. The facility where the EBP change project was implemented was a tertiary hospital located in Southwestern Pennsylvania. The hospital was the first to achieve Magnet Recognition status in southwestern Pennsylvania from the American Nurses Credentialing Center and Magnet re-designation.

Implementation Steps - The first step was the recruitment process, which consisted of flyers hung on the unit, emailed to nursing and posted on the unit Facebook page with instructions on how to sign up. There was a maximum of two participants per session and the date and time offerings were weekday, weekday evening and weekends to accommodate all schedules.

The second step was the distribution and collection of the pretest via Survey Monkey. The pretest was composed of five demographic questions and 24 questions based off content from APS Gnosis Shoulder Dystocia module content.

The third step was the shoulder dystocia simulation scenarios that took place at the Simulation, Teaching and Academic Research (STAR) Center. Noelle birth simulator was the manikin available at the simulation center to simulate shoulder dystocia. A background of the patient history and current hospital situation were given to the group and then the simulation began. The group was evaluated on competency using the shoulder dystocia simulation evaluation tool created by the project manager with guidance from the Creighton Competency Evaluation Instrument (CCEI). Once the scenario was completed, there was a debriefing session.

The fourth step was the debriefing session. During this time, the participants practiced different skills and roles that allowed for feedback from the project manager unlike during the simulation. After all questions, skills and roles were worked through; participants proceeded to the PowerPoint presentation that contains information from the APS Gnosis Shoulder Dystocia module. The risks factors for, appropriate maneuvers, the role of the nurse, documentation, patient inclusion in debriefing were reviewed. The debriefing session lasted about 30-45 minutes.

The fifth step was the exact same step as the third. A second shoulder dystocia scenario was performed and the groups were evaluated using the shoulder dystocia simulation evaluation tool. The repeat simulation also lasted about 15 minutes. The last step was the distribution and collection of the posttest via Survey Monkey.

Expected Outcomes - There were two outcomes measured in this EBP change project: knowledge and competency. The level of knowledge the nurses possessed in regards to shoulder dystocia was evaluated using the pre and posttest. The outcome of competency was based on the performance of clinical skills performed during a simulation experience using the simulation evaluation tool.

Data Analysis - In order to evaluate the chosen outcomes to see if they were effective, different data analysis techniques were utilized. In order to analyze whether there was an increase in shoulder dystocia knowledge there was a comparison between the pre and posttest scores. That was done by using a dependent t-test for paired samples with a p value < 0.05. The benchmark for test scores were 80% or better, which was, based on facility continuing education standards.

The second outcome of competency of nursing skills were analyzed using the simulation evaluation tool and a pre and post intervention instrument scoring comparison. The benchmark for the tool score was 75% or better on the post intervention instrument scoring as used by the creators of the CCEI instrument. There was also a dependent t-test for paired samples with the p value < 0.05 because the pre intervention score could meet the benchmark and an improvement or lack thereof needed to be demonstrated.

Results: The results, discussion, and summary of findings are pending following completion of the EBP simulation sessions and posttest completion. The data collection phase is still ongoing at this time.

Clinical Implications: The results of the EBP project can be used to better prepare and orient new labor and delivery nurses. The training can also be useful for seasoned nurses as shoulder dystocias are rare and the skills necessary are not utilized on a regular basis. The simulation trainings can become a part of an annual competency testing for the labor and delivery staff to stay sharp on those skills.

Future Projects: In the future, the EBP project can be expanded to include other disciplines. When a shoulder dystocia occurs, there is more than just nurses that are involved in the emergency. There are also attending physicians and midwives, residents from OB/GYN and anesthesia, and the NICU staff. In order to decrease adverse outcomes, increase patient safety, all members of the team need to practice for the unexpected.

Generalizability: The EBP project can be generalized to simulate and practice other obstetrical emergencies. Other emergencies that occur on labor and delivery are eclamptic seizures, cord prolapse, postpartum hemorrhage, and emergency cesarean section. Simulation training can improve the skills needed for all obstetrical emergencies, not just shoulder dystocia.

Conclusion: The obstetrical emergencies that occur are luckily a rare occurrence but that does not help to keep health care providers knowledge and skills up to date for when they do occur. Research has shown that for those incidences that do not occur on a regular basis, simulation training is effective in keeping skills and knowledge up to date and reduces adverse outcomes. The purpose of the EBP change project was to demonstrate that simulation training for shoulder dystocia could improve knowledge and competency in labor and delivery nurses. Those skills will be transitioned back real practice so that the nursing staff can be better equipped and knowledgeable when a shoulder dystocia arises.

EBP PST 2 - Evidence-Based Practice Poster Session 2

Establishing an American Heart Association International Training Center in Port-au-Prince, Haiti

Becky M. Baird, MS, RN-BC, CMSRN, CNE, USA

Ellen L. Palmer, PhD, RN, USA

Marie Jocelyne Arnoux, MS, RN, Haiti

Abstract

For more than fifteen years several nurse educators from the Dallas-Fort Worth, Texas area have participated in educational activities for health care promoters at Grace Children's Hospital (GCH). GCH was founded in 1967 and has been serving the lower Delmas area of Port-au-Prince since that time, providing outpatient care for both pediatric and adult patients as well as inpatient care for pediatrics. GCH is supported by International Child Care USA, which is a Christian health development organization that supports health programs in Haiti and the Dominican Republic. A collaborative effort began when the U.S.A. nurse educators first developed a trusting relationship with their colleagues at GCH upon realizing a shared vision. Collaborative tasks such as defining how the work gets done, mentoring, identifying what could be accomplished at GCH and following through with commitments has been key to the success of the activities. Through the years, the nurse leaders of GCH have become more and more proficient in many aspects of developing educational programs. These include all elements of activity planning, marketing, conducting learning needs assessments, evaluation of activities, and budget development to include expenses for AV equipment, handouts, electricity costs (in some situations), refreshments, lunches and translators.

In 2015, a simulation laboratory was established at GCH. Although the sim lab has started out modestly, it occupies a large dedicated space in the education division of the hospital. At this time, the director of nurses is responsible for the management of the simulation laboratory. Primarily funded by a grant from the United Methodist Women and anonymous donations, the simulation laboratory features several types of manikins. Resuscitation training is now possible with eight sets of infant, child and adult CPR manikins, and eight French language automatic external defibrillator trainers. Other manikins are used for core pediatric and adult in-hospital clinical skills training, insertion of pediatric IV catheters and the simulation of normal or complex birthing deliveries.

The simulation laboratory has been the site of several trainings thus far. In November 2015, the first course of Helping Babies Breathe (HBB) and Essential Care for Every Baby (ECEB) was taught to 12 traditional birth attendants with both mother and newborn responsibilities. Students were selected by senior nursing staff at GCH. Instructors for the course included two HBB/ECEB Master Trainers (volunteer pediatricians from the U.S.A.) and two pediatric residents trained in HBB and ECEB, assisted by several U.S.A. nurse educators. Course work was taught over a two day period. Tools to facilitate learning included a newborn resuscitation algorithm, learner workbooks, facilitator flip-charts, neonatal simulators and equipment. All written material was available in French. Knowledge checks (written exams) were conducted at the end of the course, which are standardized Helping Babies Survive course material. The second course conducted in February 2016 was a half-day review course and included hands-on practice sessions, and re-administration of the knowledge checks. Nine of the 12 students participated in the second course. The knowledge check exams were provided in both English and French and translators assisted with all teaching as well as assisting with hands-on skills.

Resuscitation training held in June 2016 at the simulation laboratory includes five classes focusing on the 2015 guidelines of the American Heart Association (AHA) for basic life support (BLS). The total number of students included 20 health care promoters and 17 lay persons. The classes were conducted by the U.S.A. nurse educators, one of whom is an AHA BLS instructor. The health care promoter students were nursing staff members of GCH and the Kings Organization Hospital and clinical instructors at several local Port-au-Prince nursing schools. The U.S.A. nurse educators returned in November 2016 to conduct BLS classes to 14 more health care promoters from the Port-au-Prince area. Introduction to electrocardiography classes were provided to the same audience during this time period.

The large death rate numbers from cardiovascular disease in low income countries such as Haiti is a concern. This is a global phenomenon, and in 2011, the United Nations addressed the issue by setting a target of reducing the risk of premature noncommunicable disease deaths by 25% by 2025. Known as the 25 by 25 target, this goal will focus on the reduction of risk factors for cardiovascular disease and the Global Cardiovascular Disease Taskforce will be the disseminator of information and approaches to reach the 2025 targets. With the increase in the numbers of persons with cardiovascular disease, the implication for nurse educators is to work with the AHA to provide the opportunity to teach lifesaving CPR training to both laypersons and health care promoters in low-income countries such as Haiti.

Resuscitation training is a highly requested educational activity for the Haitian health care promoters. However, there are no American Heart Association Training Centers in Port-au-Prince through which an AHA Instructor could request support for training. The process by which American Heart Association Instructors can conduct courses and issue AHA cards is in the country of incorporation. Permission to provide training may be obtained through the approval of the AHA's Global Training department. Approval is not automatic, and the application must have a letter of support from the Instructor's Training Center. Unfortunately, the Training Center in which one of the U.S. Instructors is aligned does not support training outside the Instructor's state.

Through a review of the Grace Children's Hospital simulation laboratory, staff and equipment, the decision has been made to participate in the American Heart Association's International Training Center (ITC) Selection Criteria and Accreditation Process. An ITC is an educational, health-related organization outside the United States that signs an agreement with the AHA to provide the AHA's Emergency Cardiovascular Care programs and issue AHA cards. There are many requirements to become an ITC including legal, administrative, general liability insurance, instructors, facilities, equipment, commitment, territory and number of people trained. The process of evaluation and approval of new International Training Centers takes several steps. There is the presentation of a letter of intent and application form, assessment process, information verification and preliminary approval. The application has to gain legal approval through the AHA International Operations department. Upon approval, the ITC will appoint a Training Center Coordinator, and will be responsible for submitting reports to the AHA twice a year. A quality assurance plan will need to be written as well.

EBP PST 2 - Evidence-Based Practice Poster Session 2

Xiangya-UCLA HIV Nursing Research Training Program: A Global Health Collaboration Between the U.S. and China

Deborah Koniak-Griffin, EdD, RNC, FAAN, USA

Honghong Wang, PhD, RN, China

Xianhong Li, PhD, RN, China

Abstract

This paper describes an international collaboration between academic health institutions in the U.S. and China to promote knowledge exchange and research of post-doctoral degree nurses and mental health specialists (psychologists/psychiatrists) to advance research in the area of HIV/AIDS prevention and treatment and related nursing care. The partnership involves the University of California, Los Angeles, School of Nursing and the Xiangya School of Nursing of Central South University (CSU) and affiliating institutions in Hunan Province, China. Hunan is the 11th largest province of China, located in the southeast. The project is supported by a Fogarty Global Health Training (D43) National Institutes of Health grant that provides funding to foster the next generation of global health scientists in low- and middle-income countries and at established biomedical and health research sites in the U.S. The evidence-based success of Fogarty International educational programs is demonstrated by over 1,200 peer-reviewed publications in infectious and non-communicable disease areas by trainees (U.S. Department of Health and Human Services [DHHS], 2016).

The purpose of this collaborative international global health educational project is to 1) develop research expertise in a cadre of Chinese nurses and psychologists/psychiatrists who will conduct HIV/AIDS behavioral research, and 2) enhance the institutional capacity for behavioral HIV/AIDS research at Xiangya School of Nursing and affiliating health care institutions. The educational project responds to and extends ongoing HIV/AIDS collaborations that have demonstrated the need for additional postdoctoral training in order to conduct rigorous studies of emerging questions related to mental health and behavioral aspects of HIV/AIDS in China.

The rationale for the program is that while Xiangya/CSU has strengthened its doctoral studies program for nurses and psychologists, local expertise is limited regarding the behavioral research methods that are essential to rigorous studies of psychosocial and self-management issues of interest to nurse-researchers and mental health professionals. The specialized training provided in this project enhances the ability of trainees to conduct high quality research needed to prevent and treat HIV/AIDS as well as help people living with HIV (PLHIV) to self-manage their infections. The number of cases of HIV/AIDS continues to grow in China despite the remarkable progress made by that country in tackling their epidemic during the past 2 decades. By the end of 2013, it was estimated that the number of people living with AIDS in China was 810,000 (0.0598%), and new HIV infections remained at approximately 50,000 each year between 2007-2011, but increased to 80,000-100,000 each year in 2012-2014 (Huang et al., 2016). The Hunan Provincial Center for Disease Control had recorded 20,556 HIV/AIDS cases at the end of 2015, including 2,247 new cases in 2015 and 4,621 new cases in 2014 (C. Xi, personal communication, December 5, 2016). The longer survival of people living with HIV/AIDS as a result of effective antiretroviral therapy partially contributes to the increasing number of HIV infections, particularly in the aging population (Huang et al., 2016; see also OAR Working Group on HIV and Aging, 2012; Watkins & Treisman, 2015). The expanded epidemic among Chinese men who have sex with men (MSM) is another contributing factor (Zhou et al., 2014). Research shows that in some regions, 26%-31% of MSM have had female partners in the last 6 months (Yun et al., 2011; Zhang et al., 2013).

Major components of the program are designed to prepare trainees to address the AIDS epidemic in China and related factors. Components of the training program include:

1. Mentored long-term (9-month) postdoctoral research training in HIV behavioral studies for four nurses and four psychologists/psychiatrists at the University of California, Los Angeles. Each trainee develops an Individual Development Plan (IDP) that identifies coursework relevant to enhancing their knowledge and

skills in rigorous research design, ethical issues and protection of human subjects, the HIV/AIDS epidemic, and other areas relevant to their proposed research. In addition, trainees meet with their research mentorship team on a regular basis.

2. Part-time training in behavioral research methods, the HIV/AIDS epidemic, and related areas is provided in China for a cohort of 20 Chinese nurses and psychologists. This training, including biannual conferences and workshops, is designed to increase the ability of trainees to conceptualize and think through research problems with increasing independence.

3. Support is provided for mentored research projects conducted by the long-term trainees following their return to China from the U.S.

As part of this training program, a process for recruitment and selection of trainees was designed and implemented. Research support was allocated for trainees with mentored studies approved by the Institutional Review Boards of the partnering institutions. The program evaluation plan tracks the progress of trainees and outcomes related to their career development as well as the research capacity of participating Chinese institutions. Benchmarks used include the number of research projects conducted by trainees, peer-reviewed publications and professional presentations, successful applications for external funding, and courses taught and individuals mentored by trainees. The achievements of six scholars who have completed the training program are highlighted in this paper to illustrate outcomes of the training.

This project is significant because it is designed to substantially increase the number of young and mid-career nurse-scientists, psychologists, and others conducting research related to mental health and behavioral aspects of HIV/AIDS. The international collaboration design to enhance research training may be replicated by similar countries with maturing HIV epidemics.

EBP PST 2 - Evidence-Based Practice Poster Session 2

Evaluation of PFDs by Vietnamese Commercial Fishermen in the Gulf of Mexico

Ann K. Carruth, DNS, RN, USA
Jeffrey Levin, MD, MSPH, USA
Jennifer M. Lincoln, PhD, CSP, USA
Julie Sorensen, PhD, MA, USA
Eileen Creel, DNS, RN, USA

Abstract

Purpose: From 2000-2009, 504 commercial fishing deaths occurred in the United States, 31% of which resulted from a person falling overboard and drowning (Lucas, Lincoln, Somervell, and Teske, 2012). Of the 504 commercial fishing deaths that occurred across the United States between 2000 and 2009, 116, or 23%, occurred in the Gulf of Mexico fishery (NIOSH, 2015). Similar to other countries, there is no requirement for U.S. commercial fishing crews to wear personal flotation devices (PFDs) while fishing (MAIB, 2016). Yet the leading cause of death among fishermen is drowning due to the loss of a vessel or a fall overboard. The majority of people that have died due to falls overboard were alone while on deck, and none of them had on a personal flotation device (PFD) (NIOSH, 2015). Vietnamese fishermen make up one-third of the licensed fishermen population working on the Gulf Coast. This study is part of a 3 phase NIOSH-funded study, with the long-term goal to develop and evaluate a social marketing campaign to increase PFD use. The purpose of this study is to determine which type of commercially available PFD results in the highest satisfaction and preferences among Vietnamese commercial fishing crews in the Gulf of Mexico. Attitudes/beliefs among Vietnamese shrimp fishermen of the Gulf of Mexico may influence behaviors that are risk factors for both fatal and nonfatal injuries.

Method: Project partners, USCG Safety Inspection Examiners, recruited subjects in three Louisiana fishing communities: 9 captains and 24 deckhands participated in this pre-post test repeated measures study. The captains and members of crews provided baseline data and were then asked to wear three different types of PFDs for a minimum of 3 hours while shrimp fishing in the Gulf. Once the crew returned to dockside, a follow-up survey was distributed. For each of the three types of PFDs: ski belt, inflatable belt, inflatable suspender, crew members were asked to evaluate 11 PFD attributes: weight, tightness, constricting motion, chaffing skin, bulkiness, snagging gear, comfort, how the PFD fit their body, interfering with work, donning and cleaning.

Results: Fishermen averaged 22 years of commercial fishing experience, and worked roughly eight months out of the year. At baseline, only 12% indicated wearing a PFDs frequently and none stated always. Yet 48% reported PFDs are effective if fall overboard. The PFD considered least constrictive of movement was the inflatable suspender (43.5%) compared to the inflatable belt (47.5%) and ski belt (28.3%). The inflatable suspender was rated to interfere the least with work compared to the other 2 types of PFDs. 54.2% ranked the suspender type as very comfortable to wear. When assessing the extent they would wear each type, 66.7 % reporting they would wear the inflatable suspender; 50% of the participants would wear the ski belt and 20.8 % would wear the inflatable belt most or all of the time. Respondents indicated they were willing to pay the most for the suspender type. Fishermen were most likely to wear PFDs if the captain told them to, working alone, working during bad weather, and working on or near the edge of the boat. Less than half of the respondents were influenced to wear any of the PFDs because other crew members wore PFDs.

Conclusions: Although the common barriers reported by fishermen to wearing PFDs are bulkiness and discomfort, some of the PFDs evaluated in this study received high scores for comfort and satisfaction. Given the availability of PFDs that are comfortable to wear while working, fishing vessel captains and owners should consider implementing policies mandating the use of PFDs while working on deck. The inflatable suspender PFD received high scores in terms of weight, comfort and fit. Other studies have found comfort to be one of the most important considerations for wearing various types of PFDs. Interventions to increase PFD use in the fishing industry should be tailored to focus on addressing the significant barriers to PFD use. The development of suitable and effective interventions requires

consideration of cultural influences influencing behavioral change. Additionally, captains are considered key to safety culture on the vessels. When deckhands respect the captain, they are more likely to do the work taking cues from the captain on safe work practices.

Facilitation on the Run: Enabling Work-Based Facilitation in the Midst of Practice

Michele Hardiman, MA, RGN, RPN, United Kingdom

Abstract

The vision of person-centred cultures is core to all policy and standards in healthcare in Ireland (Health Information and Quality Authority, 2012) and globally (World Health Organisation, 2016) implementing these strategies and standards require focused development of staff who deliver care in our health services (Department of Health and Children, 2010). In the acute hospital setting in Ireland this staff development has largely been technical in its approach to date. Evidence suggests that for person centred cultures to emerge, purposeful Practice Development (PD) needs to be facilitated within the workplace (McCormack et al, 2010). The role of clinical nursing leaders is pivotal in developing and sustaining of the person-centred cultures and is therefore a key element of all PD activity (McCormack et al, 2010). If PD is to become more meaningful to nursing leaders as part of their daily work, more focus must be placed on making the development and 'doing' of facilitation easier. Although complex facilitation frameworks such as Critical Companionship (Titchen, 2002) remain an exemplar in the development of expert facilitation skills, use of this particular framework has been minimal due largely to its complexity (Gribben and Cochrane, 2006; Dewing and Wright, 2004).

Two sequential facilitation models Critical Allies and Critical Friends emerge as first steps in the development of work based facilitation skills for novice and proficient facilitators. Thereby enabling nurses to work with colleagues' to help them to learn in and from work, grow their expertise and contribute to developing person-centredness in the workplace.

During the process, Facilitation on the Run (FoR) cards were used to focus conversations and quickly create reflective spaces within the work place. The 28 pack of cards, depict the breakdown of the critical allies and Critical Friends Frameworks unpicking the elements into three sections in each framework (1) prerequisite for facilitative relationships to begin (2) strategies (3) Expected Outcomes. The cards subsequently served as an everyday tool to remind novice and proficient facilitators of the steps that they should be working through to facilitate the learning of colleagues. The FoR cards became an invaluable resource as part of the associated doctoral research study which used insider researcher approaches to work with clinical nursing leaders within their own workplace.

It also makes a contribution to the methods for achieving communicative spaces and discourse in busy workplaces and proposes that facilitation is not stationary space.

Muslim Patients and Carers Satisfaction on the Hospital Hygienic Practices in Meeting Their Spiritual Needs

Munikumar Ramasamy Venkatasalu, PhD, RMN, RN, RNT, Brunei Darussalam

Abstract

Introduction Spiritual needs often associated with diverse rituals relevant to religious affiliation of the individuals, for example Muslims are allowed to perform prayers after with strict personal hygiene. Yet, little is known on how well current hygienic practices would support in meeting spiritual and religious needs of patients with limited mobility during hospitalization.

Aim To explore views of patients with limited mobility and their family carers on the current personal hygienic practices in meeting their religious obligations during their hospitalization.

Design A 19 item self-developed questionnaire survey were administered to adult patients who were undergoing an outpatient rehabilitation programme and their carers in one of the hospitals in Brunei Darussalam, a small Muslim monarchical South East Asian country. Quantitative data were analysed descriptively with R software (version 3.3). Participants' opinions were analysed using a descriptive qualitative approach.

Result 69% of patients had used soaked cotton or wet wipes to meet their personal hygiene needs. 78% of the patients were satisfied with their care of personal hygiene when hospitalized. Qualitative data indicated that this satisfaction had resulted from the use of 'high quality' tissue that was able to hold more water when soaked in comparison to normal cotton. 55% of patients did not carry out their religious obligation, while 46% of the patients agree that they faced difficulties in meeting their spiritual needs because of the hygienic care provided did not meet their satisfaction. Patients stated that they preferred the use of sufficient flow water that resembles common cultural practice when meeting their personal hygiene needs.

Conclusion We conclude that current hospital hygienic practices were not effectively meeting patients' personal hygiene is one of the requirement for them to perform Islamic ritual prayers in meeting their psycho-spiritual needs and wellbeing. Innovative medical equipment needs to be developed to achieve patients' satisfaction in hygienic practice.

Developing a Culturally Tailored Social Risk Assessment Tool for Depression Among Hispanic Women

Giovanna De Oliveira, PhD, ARNP, ANP-C, PMHNP-BC, USA

Abstract

Purpose: Depression is the number one cause of disability in the world, affecting over 350 million people. In the United States, Hispanic women experience depression around twice the rate of Hispanic males and are at a higher risk for depression than Caucasian and African American women due to multiple social determinants of health that affect the individual, family, aggregates, and community. The social determinants of health refer to conditions in which people are born, live, grow, work, and age. Mental health in the U.S. is affected by disparities among ethnic/racial groups. Barriers to assessment in the Hispanic populations subsequently lead to poor care for mental health illnesses. This is evident in the vast research on depression in Hispanics, which suggests that in the U.S., depression in this group is underdiagnosed and undertreated. The underdiagnosis is in part due to an inadequate screening or assessment of the social factors that are linked to depression among Hispanics, such as level of education (which leads to poor health literacy), acculturation level (adaptation process to a new culture), immigration-related issues (family separation), etc. Based on an extensive literature reviewed, a culturally tailored risk assessment tool that highlights the social determinants of depression in Hispanic women is nonexistent. This tool could be used in conjunction with other screening tools, such as the Patient Health Questionnaire-9 (PHQ-9) in settings where Hispanic women of reproductive age are seen.

Methods: This study is a secondary analysis study that uses cross-sectional data from SEPA III: The Effectiveness Trial. SEPA stands for Salud, Educacion, Prevencion y Autocuidado, which translates to Health, Education, Prevention, and Self-Care. SEPA III, the parent study, is a randomized controlled experimental study with adult Hispanic women in Miami-Dade County, Florida, U.S.A. The sample of this study was $n = 280$ self-identified Hispanic women who completed baseline assessments from May 2013 to October 31, 2014. Descriptive statistics will be presented to show the characteristics of the study sample. Then, CFA models using Mplus (version 7.0) will be presented.

Results: Multiple models were analyzed. The prevalence of depression among the sample was 37.5% (mild to severe depression). Social determinants were subdivided as (a) intrapersonal factors (income, education, acculturation, health status, health insurance status, and employment status); and (b) interpersonal factors (relationship status, living with partner, and living with children). The final model, containing CFA and path analysis for both intra- and interpersonal level factors of the social determinants of depression, revealed that, even though the variables income, education, and employment status loaded significantly onto the latent intrapersonal factors, the latent variable did not significantly predict depression. A CFA was no longer possible to test the latent variable "interpersonal factors" due to being left with two variables after further analysis.

Conclusion: Findings of this study point out several important aspects about depression and social determinants among Hispanic women living in South Florida. Based on an extensive literature reviewed, a culturally tailored risk assessment tool that highlights the social determinants of depression in Hispanic women is nonexistent. The American Psychiatric Association (APA) clearly highlights the crucial importance of cultural issues for proper clinical practice in its DSM-V. Concepts such as cultural syndromes, cultural idioms of distress, and cultural explanation or perceived causes need to be taken into account during clinical encounters, as they assist in accepting or rejecting a specific diagnosis. Having taken this into consideration, this study will serve as a starting point to the development of such a screening tool, which could serve as a filter to help identify Hispanic women who may be prone to depression. In order to develop a comprehensive tool, many other possible social determinants of depression need to be explored, such as: *familismo*, *marianismo*, *machismo*, discrimination, separation from family, and family and partner conflict. Moreover, this tool would also need to be piloted, and checked for acceptance and feasibility. This study certainly informs and adds to the existent knowledge in

order to effectively intervene and implement health care practices to reduce health disparities related to depression.

EBP PST 2 - Evidence-Based Practice Poster Session 2

Effectiveness of Cultural Competence Educational Intervention on Patient and Health Professional Outcomes: A Systematic Review

Duckhee Chae, PhD, RN, Korea, Republic of (South)
Jin-Hee Kim, PhD, RN, Korea, Republic of (South)
Jin-A Lee, MSN, RN, Korea, Republic of (South)
Seo-Jin Park, MSN, RN, Korea, Republic of (South)

Abstract

Purpose: The primary aim of this systematic review was to assess the effectiveness of cultural competence educational interventions for health professionals working in health settings on patient outcomes and health professional outcomes. Also it was conducted to identify an effective way to educate health professionals.

Methods: We performed electronic searches in three international databases (Ovid-Medline, Ovid-Embase, Cochrane Library) and six Korean databases (KoreaMed, KMBase, KISS, RISS, NDSL, and KisTi) for original articles published in either English or Korean in July 2016. We included randomized controlled trials (RCTs) and quasi-experimental design studies. Studies that had reported cultural competence educational intervention for health professionals and measured impact on patient or health professional outcomes were included. Cochrane Risk of Bias (RoB) was utilized to evaluate the quality of the studies. Two groups (two authors in each group) independently screened all articles and extracted the data. The qualitative analysis was conducted due to the heterogeneity of the study caused by the diversity of participants (doctor, nurse, nursing assistant, social worker, patients, etc.), training programs, and training periods.

Results: Initial search identified 1,792 potentially relevant studies and only nine (health professional = 778, patient = 7,991) met the inclusion criteria. Six out of nine studies were RCTs and three were quasi-experimental design studies. And seven were from USA and two were Korea. All reported health professional outcomes and two reported patient and health professional outcomes. Seven studies reported the effectiveness of education on health professional outcomes. It also proved to have benefits on patient outcomes. However, teaching methods and the duration of training included in these studies were diverse. The risk of bias was high.

Conclusion: Cultural competence training of health professionals has been proven as beneficial to improve both health professional and patient outcomes. However, it is undeniable that there is a considerable lack of research assessing whether increased health professionals' cultural competence improved patient outcomes. Also, since previous studies used differentiating teaching methods, it is seemed as difficult to determine the most effective way of training. Therefore further research in this field is considered necessary.

Growing in Recovery: A Service Learning Case Study

Amanda Eymard, DNS, APRN, PMHNP-BC, CNE, USA

Heidi Rodrigue, BSN, RN, USA

Abstract

This qualitative case study utilized heuristic phenomenology to explore the potential impact of initiating a garden at a halfway house. For the service learning project, a garden was developed by nursing students in collaboration with clients at the facility. A grant from Sigma Theta Tau funded the project. During this project, one client emerged as the primary caretaker of the garden. This male client, undergoing rehabilitation for drug abuse, became the subject of the case study. A senior nursing student mentored by a faculty member conducted the case study. Over a period of five months, the subject was interviewed extensively during several different encounters to gain an understanding of his lived experience regarding drug abuse, rehabilitation, and the garden. The interviews were transcribed, and then line by line analysis was performed by the nursing student and faculty mentor. This opportunity was the student's first exposure to nursing research and allowed the student to participate in an actual research study. Coding was implemented to identify five themes: new beginning, growth, bumps in the road, hard work, and fruits of labor. Over the course of the case study, the student discovered correlations and illustrates these with a five month timeline. While the garden benefitted the halfway house by providing vegetables for the clients to eat, the experience also impacted the nursing student. The nursing student was able to establish a rapport with the client and over time, better understood addiction and the treatment of addiction. Nursing students need to engage in positive experiences with patients struggling with addiction so they can better relate to the clients and reduce the stigma associated with drug addiction. In conclusion, the subject, the nursing student, and the garden grew and flourished as a result of the service learning project involving a few plants, water, and much hard work and dedication.

Cultivating a Culture of Resilience

Joyce J. Fitzpatrick, PhD, RN, FAAN, USA
Deirdre O'Flaherty, DNP, RN, NE-BC, APRN-BC, ONC, USA
Mary Joy Garcia-Dia, DNP, RN, USA

Abstract

Resilience is a concept that has been applied to research and practice in nearly every possible area of life and academia- from science to sociology, psychology, nursing and medicine. Given the high degree of stress in today's society, nursing has become a focus for studies and interventions that foster resilience in the workplace. Investigators such as Jackson, Firthko, and Edenborough (2007) McDermid (2016) and others have taken the approach that resilience can be learned or developed once the characteristics that exemplify resilience are identified. Active participation of nurses through mentorship workshops for critical thinking and building hardiness aids in the development and strengthening of personal resilience (Jackson et al 2007 and Hart et al 2012).

Nursing management can facilitate resilience in the workplace through strategies that create work- life balance, assist in critical reflection to problem solve and build resolutions to help guide in future situations, and use a shared or professional governance as a nursing care model (Garcia-Dia & O'Flaherty, 2016). Nurse leaders that empower and encourage their staff to develop supportive relationships, provide a positive and optimistic work environment and communicate the importance of quality of life for their team members will also see the benefit of work force retention or decreased staff turnover. This is a key factor in maintaining and staying compliant with the increasing demand to strive for quality and decrease associated turnover and recruitment cost.

Now more than ever, with recent traumatic events associated with gun violence, and terrorism nurses are in the frontline taking care of victims and families, and at the same time dealing with their own personal vulnerabilities. This proposed presentation would explore mobile app interventions that promote mindfulness and healthy engagement in conjunction with debriefing and journaling activities in order to cultivate nurses' own resilience in the workplace. Additionally this presentation will facilitate methods for assessing one's own resilience and methods to cope positively, personally and professionally.

By the end of this presentation the participants will be able to identify leadership strategies and initiatives that lead to developing resilience in nursing staff. Additionally participants will be able to identify the significance of the leaders role in sustaining a work environment that fosters staff engagement, satisfaction, quality and retention.

EBP PST 2 - Evidence-Based Practice Poster Session 2

De-Stigmatization of Mental Illness and Addiction Requires Increased Content in Undergraduate Nursing Curricula Globally

Arlene E. Kent-Wilkinson, PhD, RN, CPMHN(C), Canada
Leigh Blaney, PhD, RN, CPMHN(C), Canada
Marlee Groening, MSN, RN, Canada
Elaine E. Santa Mina, PhD, RN, Canada
Carmen Rodrigue, MScN, RN, CPMHN(C), Canada
Carmen Hust, PhD, MScN, RN, Canada

Abstract

Problem: In 2017, stigma towards persons with mental health conditions and addiction still occurs around the world, unconfined by demographics or national boundaries. Societal stigma towards persons with mental health conditions and addiction remains an overwhelming barrier to safe, comprehensive mental health assessment and care. **Issue of project:** Canadian undergraduate nursing curricula contains limited mental health and addiction content in some nursing education programs. Furthermore, nurse educators may perpetuate societal stigma if their programs do not expose students enough to persons and families experiencing mental health conditions and addictions. **Brief description/ Background:** Mental health conditions and addictions persist as serious health concerns that affect the lives of 20% of Canadians. Attempts by patients to access mental health and addiction services continue to be met with widespread stigma in hospitals, workplaces, and schools, and in both rural and urban communities. Tragically, persons who seek help for mental health conditions report that they often experience some of the most deeply felt stigma from front-line health care personnel. For this reason, health care providers remain one of the target groups of anti-stigma initiatives. Negative beliefs and attitudes exist among health care providers (including nurses) towards persons with mental health challenges and mental illnesses. Nursing students, like all members of society, are not immune to societal perceptions and discrimination towards people with mental health and addiction challenges. **Solutions/De-stigmatization through evidence-informed education:** Reducing stigma in society requires education, and a change in behaviour and attitudes so that people living with mental illnesses can be assured of acceptance, respect, and equitable treatment. The most effective response to increase knowledge and decrease stigma is to ensure evidence-informed education of future nurses through a significant increase of psychiatric mental health and addictions theory and practice in undergraduate nursing curricula. **Relevance:** The author(s) will overview the national stigma campaigns and the role and responsibility of nursing and nursing education in the de-stigmatization of mental illness and addiction. The quality and quantity of mental health and addiction education in undergraduate nursing curricula is critical to de-stigmatization, and to the visibility and advancement of the overall mental health of people globally. **Application to other settings:** Because nursing professionals constitute a strong and influential stakeholder group that can change both mental health care and social attitudes, pre-practice mental health educational programs would benefit nurses, and communities in which they practice.

Changing the Delivery Landscape of Native American Health

Jennifer L. Allis Vazquez, MSN, RN, CPTC, USA

Abstract

Native American populations are plagued with health disparities. The Pine Ridge Reservation, situated in the southwest corner of South Dakota, is noted to be one of the poorest counties in the country. Statistics about the health of Pine Ridge residents provided by The American Indian Humanitarian Foundation ("AIHF") indicate that 97% of residents living on the Reservation live below the poverty line with an average household per capita income of less than \$6,000. There is an 85% or higher unemployment rate (AIHF, 2015). The average life expectancy on the reservation is between 45 and 48 years of age. Health statistics reported by AIHF include diabetes rates of 800 times the national average, infant mortality 300%-500% higher than the national average, teen suicide 150% higher than the national average, and tuberculosis at 800% higher than the national average.

The Pine Ridge Reservation is a large Native American Reservation in South Dakota. Geographically, the Reservation covers almost 3,500 square miles, making the Reservation close in size to the State of Connecticut. The population of Pine Ridge Reservation is reported at approximately 40,000 people (Friends of Pine Ridge, 2015). Healthcare on the Reservation is provided primarily by Indian Health Services ("IHS") and facilities include Pine Ridge Hospital, Kyle Health Clinic, Wanblee Health Clinic and smaller sites at Porcupine, Allen and Manderson (IHS, 2015). Fieldwork was completed at Wanblee Health Clinic in Wanblee, South Dakota. This clinic is staffed by a physician, advanced practice nurse, pharmacist, nurse and part time radiology staff and treats both pediatric and adult patients. The Wanblee Clinic offers care of patients, as well as pharmacy, radiology (two days per week) and dental services. The clinic is limited in services that it can offer. Regular physicals, sick visits, and follow up care can easily be provided. Radiology is only available twice per week, so patients are often transferred to another facility for urgent needs. No orthopedic or surgical services are offered. Pine Ridge Hospital is a 90 minute drive from the Wanblee Clinic. Pine Ridge Hospital is a 45 bed hospital. More complex needs will be referred to the hospital in Rapid City, South Dakota, which is off the Reservation, about two hours away. Ambulance service is also limited and may take several hours for an ambulance to arrive.

This DNP fieldwork project was made possible through collaboration with a group of health professionals from a large health system. Achieving buy in from the group to allow an individual that was not part of the health system took years. Initial planning and networking with this group began in early 2010. Travel was originally supposed to take place in 2014, but due to a change in workplace, the travel was not possible at that time and was deferred to August 2015. Personal goals for the fieldwork included travel to South Dakota, observation of life and healthcare on the Reservation and to identify how skills and resources could be devoted to improving the care of the residents of the Reservation. Significant time was spent on planning of the trip, travel to South Dakota, background checks and fingerprinting, and cultural orientation. Once in South Dakota, further cultural orientation was completed and computer training on the electronic medical record ("EMR") was completed with IHS staff at the Pine Ridge Hospital. After these initial requirements were met, work in the clinic could begin.

Fieldwork at the clinic included direct patient care, observation and discussion with clinic staff and Native American patients. Knowledge that was brought to this experience included cardiothoracic patient care, emergency room care, and case management. Patients of the clinic can make appointments to be seen or can show up and request to be seen. There is no triage system in place, making prioritization of patients and protection of staff difficult. Many patients travel long distances to be seen at the clinic. Patients are seen for everything from well visits/physical exams, follow up for chronic conditions, sick visits and diagnosis of new conditions.

This project will focus on creating a training program to train home health aides to care for elders or disabled members of the tribe. This will not only create jobs for many unemployed tribal members, but will

also allow the elders or disabled members to remain in their homes with assistance for self-care, ambulation, and other factors which affect safety and health.

Nursing leadership is vital to changing the landscape of healthcare delivery to the Native American populations in the western United States. Through leadership and collaboration, this DNP project will continue to build relationships and influence change to improve the lives and health of Native Americans.

Nursing Self-Care: Current Evidence and Implementation Strategies for Improving Patient Outcomes and Nurse Well-Being

Kady L. Martini, DNP, RN, NEA-BC, USA

Steffanie Schweitzer, BS, RN, USA

Jessica Wood, RN, RN, USA

Christine Mayer, RN, USA

Shana Straka, RN, USA

Olivia Bonnano, RN, USA

Corryn Christy, RN, USA

Abstract

The American Nurses Association (ANA) defines a healthy nurse as actively focusing on creating and maintaining a balance of physical, intellectual, emotional, social, spiritual, personal, and professional well-being (Healthy Nurse, Healthy Nation, 2016). While this recommendation may appear simple, the complexity and difficulty of implementing self-care behaviors into a nurse's professional and personal environment is challenging. Poor self-care is a prevalent issue in healthcare (Levtak, 2013). The purpose of this project is to explore the current literature on nursing self-care and its' impact on patient safety, satisfaction, and nurse well-being. Strategies for cultivating self-care behaviors throughout ones' nursing career, and integrating self-care at the unit, and more broadly, promoting a culture within hospitals, which foster staff self-care, will have the greatest impact on patient outcomes, as measured by pre and post intervention patient and staff questionnaires.

A lack of self-care contributes to increased stress, which negatively impacts patient care in a multitude of ways. The 2011 ANA Health and Safety Survey found that the top health and safety concern among nurses is the acute and chronic effects of stress and overwork. (ANA Health and Safety Survey, 2016). Nurses who work with pain or depression reported more medication errors, patient falls and provided a lower quality of care (Levtak, Ruhm, & Gupta, 2014), however, frequent self-care behavior can facilitate stress reduction. A literature review by Letvak (2013) showed 18 studies on improving nurse health. On-site wellness programs, offering Tai-Chi, fitness classes, ergonomic training programs, message, CBT programs, and grief debriefing, significantly improved nurse health. Additionally, hospitals and nursing managers who promote self-care behaviors for staff, as a means of personal empowerment, report fewer falls and nurse-assessed risks (Purdy et al., 2010). These findings support the need for evidence-based interventions to foster self-care.

Self-care is a skill which must be introduced early, and cultivated throughout one's' nursing career. Nursing curriculum should include self-care coursework. Once in the workforce, nurses need the continued support of nursing managers and hospital administrators to ensure self-care is incorporated into the working environment. Adequate staffing, support programs, activities providing opportunities for self-care, and a culture which values wellness are presented in detail. This project will aide in increasing self-care behaviors, and ultimately provide the highest level of care and satisfaction for patients.

Working With the Obese Client: Helping Achieve Lifestyle Changes to Meet Their Weight Loss Goals

Anna Marie Hefner, PhD, MSN, BSN, RN, MaEd, CPNP, USA

Renee Pozza, PhD, MSN, RN, CNS, CFNP, FAASLD, USA

Tarek I. Hassanein, MD, FACP, FACG, AGAF, USA

Catherine McCoy Hill, MSN, RN, CCRN, CNS, ANP-C, USA

Abstract

Background and Significance: Obesity is an epidemic in the United States and worldwide. In the United States, 35% of adults are considered obese and 20-30% of the populations is estimated to have non-alcoholic fatty liver disease (NAFLD) as a result of obesity. There is no current cure, but the literature shows lifestyle modifications for weight loss as the accepted standard of care. The assumption in this study was that participants expressed the desire be healthy and make positive changes in their life. Change theory considers the motivation for change during various stages. Motivational interviewing addresses the process of guiding clients through change.

Purpose: The purpose of this analysis was to evaluate the use of change theory principles incorporating motivational interviewing on weight loss in obese clients.

Methods: This was a retrospective analysis of data from self-selected obese clients from May 2015 to June 2016. A total of 34 clients met the inclusion criteria of BMI greater than 30 and less than or equal to 40. Routine lab tests of liver function tests, CBC, lipid panel, and a Fibroscan to evaluate liver stiffness were performed at baseline, 6 months, and 12 months. The Nurse Practitioner saw the client every 3 months or more frequently as the client requested or condition of health warranted. Nutritional counseling was provided individually with a Registered Dietician for 30 minutes monthly. Exercise was also encouraged. Both providers utilized motivational interviewing to assist the client to achieve their weight loss goals. Categorical variables were analyzed with descriptive statistics and paired t-tests to evaluate changes in BMI, weight, ALT AST, and liver stiffness. The participant data was retrieved over a year time period.

Results: Between May 2015 and June 2016, 34 patients were identified with a diagnosis of obesity-32 females with a mean age of 47 years and 2 males with a mean age of 35 years. The etiology of obesity from the client's perspective was overeating, stress, poor dietary habits, lack of exercise, and stress of everyday life. The initial laboratory values indicated a mild increase in liver injury tests. The combined initial average weight was 220.5 pounds (range was 175-250 pounds) and at 12 months decreased to 190.9 pounds. Waist circumference was initially 39.7 inches collectively and decreased to 37.9 inches. BMI was initially 36.2 and decreased to 34.21 collectively over 12 months. There was significance in weight, waist circumference and BMI over 12 months($p=.001$).

All 34 clients were interviewed individually at 6 months and 1 year for program feedback. Collectively the themes that emerged were 1) the importance of a nutritionist guide how to eat better through portion size and healthy food choices; 2) how to say no; and 3) the tools to help continue on this journey. Clients found the once per month visits with the nutritionist and weighing in was too infrequent. Suggestions made by the clients included 1) weekly weights to increase accountability; 2) included a walking exercise program to receive encouragement and support from others; and 3) continue to have availability of the Nurse Practitioner for questions and concerns.

The dietician discussed monthly the food intake and caloric expenditure of the patient. Though most studies have used a balanced diet with caloric restriction, we focused on the food pyramid and healthy choices of complex carbohydrates and a decrease in fats. Each month the patient would bring in their diet and it was reviewed with the dietician. Suggestions were made for improvement, discussion of exercise patterns and again ways to increase exercise throughout the day. We choose to start small and increase as tolerated.

Conclusion: Obesity is identified as a risk factor for the top five causes of death in the United States- cardiovascular, diabetes, cancer, stroke and kidney disease. Lifestyle modification has been repeatedly shown to achieve modest long-term weight loss. It is critical to identify factors contributing to and maintaining obesity status. Obesity can be moderated or controlled by “behavior change”. However, changing a client’s dietary habits is daunting. Motivational interviewing principles have been successfully used within clinical settings, having a profound potential impact on cardiovascular disease, diabetes, and hypertension.

Most people have the desire to lose weight, and we encouraged them with various suggestions. When a client is allowed to talk, providers actively listen, and reflecting back with what they have heard, there is no more than three minutes to the encounter. Partnering with clients to achieve a meaningful weight loss and investigating novel methods of achieving and maintaining weight loss can we hope to change the tide.

The client’s states motivation is a key factor to success. Contact with providers and a nutritionist provides a structure which the client finds helps with motivation.

EBP PST 2 - Evidence-Based Practice Poster Session 2

Healthcare Literacy and Communication With Health Professionals: Achieving Healthy Outcomes Among Diverse Populations

Mary Lou De Natale, EdD, MSN, RN, CNL, USA

Abstract

The importance of understanding the culture and literacy in working with individual and families in the community is essential for nurses and health care providers. Whether an individual is accessing food or nutrition for their daily nutritional needs or seeking medical services at a community clinic it is the opportunity to listen to the conversations and respond in a caring and compassionate way to clients at their point of care in the community. Effective communication that is client-centered with knowledge of health resources is necessary in directing the health of the community with diversity in culture, language, and access to health care services. The community resources that are available to support health promotion of their community should have the availability of resources for the clients in order to deliver quality care that can support: (1) access to a consistent health provider locally, (2) time with the physician to clarify the causes of misunderstanding related to health care, lack of compliance of medications and (3) follow-up as needed with a teach-back with a translator at the point of care. Medical follow-up with primary physician can influence overall health promotion and wellness (U.S. Department of Health and Human Services, 2016).

Health providers must be knowledgeable and assist in the navigation of health care services and provide help with literacy and communication that is delivered with care and communication that is client-center and based on the identified health care need. The health and wellness of the person in health care can be compromised if the client's perception of health and wellness is different from that of the primary providers and health team. Additionally, nurses and health care providers can support education in health care and primary language preference with effective communication at the client's appointment or in follow-up by telephone or referrals to case management and social services in the community. It takes a community of providers taking time to understand culture and communication.

Being able to communicate and deliver health care to populations at risk and support literacy skills are important. Keeping language, it is important to keep language simple and being able to define technical terms in the plan of care (National Institute of Health, 2016; U.S. Department of Health and Human Services, 2016). The availability of the health care provider to be able to know their patient, review their plan of care, diet to be maintained, or medication to be taken in the total plan of care is essential. This is important with only 12% of adults having proficiency in health literacy (Center of Disease Control, 2015). The lack of knowledge and misinformation that can be due to health care literacy, primary language, or ease of access to services in the community has been important for disease prevention and healthy lifestyle.

This research project was directed at the client accessing food and nutrition at a local Community Center particularly those with lower incomes or homeless families and older adults. A survey was distributed to clients in English, Spanish, and Mandarin speaking denoting their current health, access to medical care and services, consistency of the care provider, and the quality of their time and communication with the physician and health team. The value of communication and a partnership in understanding health care needs, assisting in health care decisions, and supporting personal concerns in critical to managing care and partnerships in practice in the local community.

Overall, this research project has the potential for nurses and health providers to better understand human presence and communication at community centers or other points of care for all individuals and families. Whether assisting with food choices or being available for a health care concern or offer blood pressure screening there are options for health promotion and wellness. For nurses or health providers there is a need to develop new strategies to assist the individual, family, or older adult with chronic health care needs whether heart disease, stroke, diabetes, and / or cancer. Communication is an integral part of the quality of care in the community and it is important to consistently the options available, accessibility to health care, and social services to meet the priorities of care. This project could provide a foundation for

the health care teams learning to communicate and offer opportunities caring for diverse populations in order to manage care and support quality of life.

Community-Based Nurse Led Biomedical HIV Prevention Service: A Tale of Two Sites

Kellie Freeborn, MSN, RN, ANP-BC, FNP, USA

Abstract

Purposes/Aims: To describe the development and implementation of a nurse-led HIV prevention program utilizing Pre-Exposure Prophylaxis for HIV prevention at two urban sites serving high risk populations.

Pre-exposure prophylaxis (PrEP), using oral tenofovir/emtricitabine in the form of Truvada® was approved by the United States of America Federal Drug Administration in 2012. In October, 2014, the Centers for Disease Control and Prevention (CDC) guidelines were utilized to develop practice protocols for a PrEP program in an urban, community based sexual health clinic for individuals aged 18 and over who identify as men who have sex with men (MSM) or transgender (site one). A free program was launched in November, 2014, using 1.6 full time equivalent nurse practitioners (NPs) offering appointments Monday through Saturday, and benefits navigators to assist clients in obtaining coverage for the cost of PrEP.

Initial visits included complete history and physical, review of co-morbidities and contraindications to PrEP, adherence and safer sex practices counseling, and sexually transmitted infection (STI) testing. In order to meet the prescribed safety criteria, point of care testing was utilized for rapid complete metabolic panel (CMP), HIV and hepatitis C antibody testing, enabling the NPs to prescribe medication at the initial visit. Follow-up visits included HIV and STI testing, CMP, review of adherence to PrEP, STI treatment as needed and safe sex counseling.

Demand for PrEP was high, and those accessing the service were predominately white (55%). Other races included, Hispanic (24%), Asian Pacific Islander (12%) and Black (4%). Trans-men accessed services but trans-women and intravenous drug users did not. The age range was 18-72, the median age was 35 and the mean number of sexual partners was 17.

Feedback from community partners revealed that the location of the clinic—in a gay friendly predominately white area—was a barrier to access for HIV prevention services for trans-women, sex workers, and MSM of color. In order to address this disparity, in September, 2015, a satellite PrEP clinic (site 2) was launched in a high poverty urban neighborhood within an existing HIV community services site. This second PrEP program was available two mornings a week. One NP registered the clients, collected their blood work, anal and pharyngeal swabs, and urine samples and then completed the HIV, Hepatitis C and renal function point of care testing. The NP then collected a health history, completed a physical assessment, and provided education regarding PrEP, adherence counseling and safe sex counseling.

The development of the second site expanded services to sex workers, transgender persons, intravenous drug users, persons of color and MSM unaware of the primary site. The age range for clients at the second site was 20-54, and the median age 31. Although this site also predominately attracted white MSM (47%), 20% of clients reported being unaware of site 1 and its services. This site also attracted Blacks (10%), and Other Race (7%). There were proportionately fewer Asian Pacific Islanders (9%) and Hispanics (21%) at site 2 than at site 1.

Community referrals created a need to expand the PrEP services at both sites, and to accomplish this, phlebotomists and benefits navigators from existing HIV testing services were utilized. In addition, nursing protocols were developed, within the scope of practice of California registered nurses (RNs), to allow RNs to complete follow-up visits, allowing the NPs to offer more PrEP enrollment visits at both sites. Further feedback from community partners led to the clinic times being changed to one morning and one afternoon per week, with 2 new visits with 2-3 follow up visits available during each session.

Currently the two sites provide HIV prevention services to over 1,600 individuals and enroll up to 40 new clients a week. There have been zero HIV infections in this program and ways to increase PrEP services throughout the San Francisco community are being explored.

Combining Literature Review, Qualitative Descriptive Analysis, and Computerized Lexical Analysis to Investigate HRQoL in Schizophrenia

Carlos M. Janela, BSN, BA, MA (Econ), RN, United States Minor Outlying Islands

Abstract

Background: People with schizophrenia experience hallucinations, emotional withdrawal, and cognitive impairment as well as a variety of comorbidities that lessen their health-related quality of life (HRQoL) (Barnes et al., 2012; WHO, 2016). HRQoL refers to ways in which health, illness, and medical treatment influence a person's perception of functioning and well-being (Chan et al., 2007). Optimizing HRQoL is a goal set by leading national and international health organizations such as the Centers for Disease Control and the World Health Organization (Healthy People 2020, 2016; WHO, 2016). Recently, the National Institute of Nursing Research (NINR) 2016 draft strategic plan identified the improvement of QoL for individuals with chronic conditions as a current research priority (NINR, 2016). Mental health services focus increasingly on alternative and complementary approaches that take into account people's well-being and functioning (Bouwman et al., 2015). Recent efforts have focused on supporting patients and improving their QoL in the community (Nakamura, Watanabe & Matsushima, 2014). Gaining more information about HRQoL in groups of people with low perceived health could lead to improved treatments/strategies to improve their situations (CDC, 2016). Yet, the current methods used to define and measure QoL in serious mental illness represent a challenge for researchers and clinicians (Barnes et al., 2012). Authors have recently called for a need to assess HRQoL in people with schizophrenia (Montgomery et al., 2015) and to identify its influencing factors (Chou et al., 2014).

To date, most HRQoL studies in people with schizophrenia have identified discrete measurable factors that contribute to or detract from HRQoL in this population. Few studies, however, have explored what concerns persons with schizophrenia identify related to their HRQoL. In order to develop more comprehensive treatment strategies for people with schizophrenia, it is important to understand how they experience HRQoL from their own perspectives.

Although HRQoL concerns reported by people with schizophrenia have great value, low insight and impaired cognition in this population (Zhou et al., 2015) raise concerns about the accuracy of findings resulting from subjective interviews (Lysaker et al., 2005). An approach to address some of the concerns related to accuracy is to use multiple data sources to enhance the validity and reliability of qualitative analyses (Creswell, 2012).

Today researchers can use innovative technologies to advance science and influence clinical nursing practice. In recent years, researchers started to use computerized lexical analysis to count words in text data, to sort them into pre-defined word categories, and to investigate the topics most represented in the data (Firmin et al., 2016). Lexical analysis can further inform our understanding of commonly observed deficits in schizophrenia that are linked to emotions and social processes (Buck et al., 2015). Cognitive deficits are the most likely to impact QoL in people with schizophrenia (WHO, 2015). Since cognitive deficits include language dysfunction, further investigation of language patterns in people with schizophrenia is warranted.

Yet, few studies have used lexical analysis in people with schizophrenia (Buck et al., 2015; Minor et al., 2015). Most of previous studies implementing lexical analysis in this population have focused on comparing word use between people in the schizophrenia spectrum disorder and control groups. For example, people with schizoaffective disorder use more sadness words compared to the general population (Minor et al., 2015). Although computerized lexical analysis can conveniently and reliably analyze text data and relate word use to clinical variables, there is little work on how qualitative studies and computerized lexical analysis can inform each other and draw on their respective strengths (Firmin et al., 2016). To our knowledge, no study investigated the relationship between word use and reported HRQoL concerns in people with schizophrenia.

Research project: The overall purpose of this research project is to better understand HRQoL in people with schizophrenia to provide foundational information that can later be used to develop strategies to improve the HRQoL in this population. This project will occur in three phases:

1- We have conducted an integrative review with the aims to complete a formal assessment of the research of HRQoL in people with schizophrenia by examining its conceptual definitions, identifying its influencing factors, and identifying its methodological limitations. We sought to clarify our understanding of the concept, further support the validity of existing research, and direct future research.

The major findings were (1) that the conceptual ambiguity of HRQoL limits its ability to contribute to practice and research; (2) that there is strong evidence that HRQoL in people with schizophrenia is influenced by the severity of psychiatric symptoms, the presence of medical comorbidities, the impact of treatments, and opportunities for social contacts; (3) that there is moderate evidence that HRQoL in people with schizophrenia is influenced by the engagement in leisure and physical activity, the physical living setting of individuals, and the quality of interactions with health care providers; and (4) that the studies reviewed unequally spanned the population of people with schizophrenia, thus producing a selection bias. The manuscript that presents these findings will be submitted to SAGE Open Nursing journal.

2- We are currently conducting a qualitative descriptive study with the aim of describing common HRQoL concerns in persons with schizophrenia based on narratives in which they describe their life experiences. Qualitative descriptive methods as described by Sandelowski (2000) guide the analysis and are expected to provide a coherent and useful summary of events that could be relevant to practitioners and policy makers. Data for this study were drawn from a larger on-going study exploring language, thinking, and symptoms in people with schizophrenia. Twenty participants completed the Indiana Psychiatric Illness Interview survey (IPII), a semi-structured narrative interview in which they shared in as much details as possible their life stories.

For the current study, narratives are analyzed with conventional content analysis as described by Miles, Huberman, & Saldaña (2014). To begin the organization of the codes into meaningful categories, the research team used Ferrans' (2005) HRQoL domains (biological function, symptoms, functional status, general health perceptions, and overall quality of life). A person-by-topic matrix (Miles, Huberman, & Saldaña, 2014) was developed to provide a structure by which the data could be organized and displayed.

The analysis is currently in progress. Initial results suggest that participants are primarily concerned about their social dysfunction with family and friends, their symptoms, their occupational challenges, their health perception, their financial constraints, their lack of romantic relationships, and their uncertainty about the future. I anticipate that the final product will be a typology that identifies the major concerns of people with schizophrenia related to their HRQoL. The manuscript that describes this typology will be submitted to the Journal of the American Psychiatric Nurses Association.

3. Building on the findings from the qualitative descriptive study, I plan to design a mixed methods study that has the purpose of investigating the potential of computerized lexical analysis to assess HRQoL concerns reported by people with schizophrenia.

Although this study has not yet been designed, I anticipate to use a convergent mixed method design (Creswell, 2015) to integrate the qualitative and the quantitative findings. I anticipate (1) to quantitate the qualitative descriptive data to display the relative importance of HRQoL concerns for each participant; (2) to translate the participants' narratives into percentages of word use through computerized lexical analysis; and (3) to investigate the relationship between agreed-upon pairs (Qualitative HRQoL concern / lexical analysis category). The qualitative HRQoL concerns will be numerically represented and summarized in frequency tables displaying the relative frequencies of HRQoL concerns for each participant.

For the purpose of this study, Linguistic Inquiry and Word Count (LIWC) will be used because it provides more nuanced categories of words compare to other software and because of its prior use in the schizophrenia population (Buck & Penn, 2015). The LIWC2015 (Pennebaker, 2015), examines words in a text file and matches each word to a dictionary of more than 6400 word stems, organized into 90 categories.

A joint display will merge HRQoL concerns and their associated relative frequencies, as well as the agreed upon matching LIWC categories and their associated percentage of word use. (e.g., social functioning 20% / social words 15%). I anticipate that the more overlap there is between the description of HRQoL concerns (e.g., negative symptoms, work related concerns, social functioning) and the description of their matched LIWC categories (e.g., negative words, achievement, social words), the more strongly HRQoL concerns will be related to LIWC categories.

Conclusion: By advancing the understanding of HRQoL in people with schizophrenia, this project advocates for the needs of this marginalized group. Results could help identify additional targets and avenues for intervention and lead to comprehensive strategies for improving the lives of all people with schizophrenia. Today, nurse researchers are well placed to integrate traditional qualitative methods and innovative technologies to advance the science of HRQoL in people with schizophrenia and to influence clinical practice.

Recommendations for future research include (1) developing a theory that connects the biological, psychological, and social determinants of HRQoL in schizophrenia and (2) testing the feasibility of computerized lexical analysis as a supplemental means to assess HRQoL concerns in clinical practice.

Enhancing Nursing Knowledge and Application of Education to Opioid Addicted Pregnant Women: A Literature Review

Jennifer Lynn Davis, BSN, RN, USA
Jeanette Rossetti, EdD, RN, USA

Abstract

Purpose: Nursing care of the opioid addicted pregnant woman, postpartum mother, and her newborn demands a multi-disciplinary, non-stigmatic approach that meets the patient's physical, psychological, and psycho-social needs. Based on a review of existing literature this presentation will identify the demand for an updated evidence-based nursing protocol that encompasses the care, treatment, and educational needs of this complex patient dyad as well as share pertinent nursing considerations.

Methods: In order to develop an educational plan regarding the care, treatment, and education protocols of the opioid addicted pregnant woman, postpartum mother, and her newborn; research of current, evidence-based articles and professional healthcare websites were evaluated. A literature search was conducted during August and September 2016 using CINAHL, PubMed, Medline, and the Cochrane databases. Keywords and phrases used were: 'opioid dependency', 'nursing care of addicted pregnant women', 'patient education needs of addicted pregnant women', 'effects of opioid addiction with pregnancy', 'postpartum care and substance abuse', 'addiction treatment during pregnancy' and 'neonatal abstinence'. Health-based website resources were also evaluated for relevance and quality using the Health on the Net Code of Conduct. No date restrictions were imposed during the initial search. However, upon review of the over one-hundred research articles and tens of health-based websites, the sources utilized were all written within the last five years.

Results: Within the United States the rate of opioid addiction of pregnant women has become a public health issue of epidemic proportions (Meyer & Phillips, 2015). Specific to the pregnant population, there was a 5-fold increase of antenatal substance abuse and a 3-fold increase for neonatal abstinence syndrome (NAS) regarding occurrence and treatment between 2000 to 2009 (Meyer & Phillips, 2015). The Substance Abuse and Mental Health Services Administration (SAMHSA) report an increase in the use of illicit substances to 5.9% of pregnant women (Amatetti & Young, 2016). These staggering statistics reveal the need for change in healthcare practices specifically; the care, treatment, and education of the opioid abusing pregnant woman during the antepartum period as well as the mother-newborn within the postpartum period. The overarching principles of a new plan of care would be inclusive of ensuring this vulnerable population have access to treatment services, receives respectful care with patient autonomy, are provided with comprehensive medical and psychological care and education, and are safeguarded against discrimination and stigmatization (World Health Organization [WHO], 2014). These principles should be employed into patient care and education through the initiation of a standardized substance abuse screening assessment, physical and psychological assessment and support, medication-assistance treatment (MAT), pain control assessment and management, breastfeeding assistance, mother-newborn bonding, neonatal abstinence syndrome assessment and treatment, as well as maternal and newborn discharge needs.

Conclusion: It is apparent based upon the intensive literature review this vulnerable patient dyad requires comprehensive, holistic, and ongoing care and education. The protocols in place currently do not appear to meet the patients' physical and psychological needs. Therefore, nurses working collaboratively with varied healthcare providers (HCPs) need to enable a change in the plan of care promptly as it would affect healthy outcomes for the opioid addicted pregnant woman, postpartum mother, and her newborn. Implementation of an opioid care and education protocol reflective of the physical, psychological, and psycho-social needs would be most effective toward a holistic positive outcome. Providing these comprehensive services in a non-threatening, and non-stigmatic approach throughout the hospitalization would improve treatment success and lead to improved patient addiction recovery and a healthier future for the mother and newborn family (Amatetti & Young, 2016; WHO, 2014). Each article and organizational resource significantly confirmed the mandate for an enhanced care and education protocol, wherein the

opioid abusing pregnant woman, postpartum mother, and newborn would receive collaborative holistic care and education leading to addiction treatment compliance and improved health outcomes.

Deaf and Hard-of-Hearing Youth: Needs for Health Risk Prevention Interventions?

Huey-Shys Chen, PhD, RN, MCHES, FAAN, USA

Ying Xue, BSNc, RN, USA

Yu-ku Chen, BSN, RN, USA

Yu-han Zheng, BSN, RN, USA

Abstract

Introduction: Although the number of sign language users in the United States has not been measured by census efforts, estimates range between 500,000 and 2 million users. 17.1% lost their hearing before age 19 and 6.6% lost their hearing before age 3. Compared with the hearing population, they have poor health knowledge and inequitable access to medical and behavioral care in our health system due to cultural and language barriers. The deaf populations are at high risk for health disparities.

Purpose: The purposes of this literature review are to synthesize current literature on health risk behaviors of deaf and hard-of-hearing youth and to summarize health risk preventive interventions that have been used in deaf and hard-of-hearing youth population.

Search Strategy: The CINAHAL, PubMed, Google Scholar, and Proquest were used to obtain evidences and unpolished students' dissertations and theses. Keywords included deaf, hard of hearing, health needs, risk behaviors, health promotion. The Limits included date of publication no earlier than 2000, English language, peer reviewed journals, and opinions of authorities or expert committees.

Results: The search resulted in 16 articles that met inclusion criteria. The level of evidence ranged from level 3 to 7 with no systematic literature review and no randomized controlled trials. Studies have found that previous studies focused on health risk behaviors of deaf and hard-of-hearing you include mental health (suicide), physical abuse, unintentional injuries, alcohol, tobacco, and other drug use; risky sexual behaviors; HIV prevention, overweight; and physical inactivity.

Conclusions: This population is clearly in need of linguistically and culturally accessible health risk prevention interventions. Synthesis of evidence supported that deaf individuals have higher rates of suicide and mental disorder, higher rates of obesity, higher rates of unintentional injury risk, higher rate of substance abuse (alcohol, tobacco, and other drug use), and increased rates of HIV and sexually transmitted infections than those who are hearing.

Implications: Limited evidence has emerged to support health preventive interventions for deaf and hard-of-hearing youth. It's suggested that further research using a variety of study designs is needed to close gap in our understanding of health risk prevention issues in this population. Understanding needs of health risk prevention interventions is critical to developing interventions for this culturally and linguistically unique population.

Purposeful Proactive Hourly Rounding: A Positive Influence on Outcomes and Experience

Deirdre O'Flaherty, DNP, RN, NE-BC, APRN-BC, ONC, USA

Renee Murray-Bachmann, EdD, CDN, RN, CDE, CPT, USA

Mary J. Deady-Rooney, MSN, RN, CCRN-K, USA

Emily Alter, BSN, ONC, USA

Linda R. DiCarlo, MS, RN, USA

Abstract

Lenox Hill Hospital (a member of the Northwell Health System) is a comprehensive acute care facility located in New York City. It is recognized nationally for its outstanding patient care, as well as its innovative medical/surgical modalities. The market shift from volume to value based care, coupled with Lenox Hill Hospitals' own mission to provide exceptional patient centered health care with compassion and respect, is the foundation on which nursing leadership develops an environment that engenders staff contribution.

Patients' perception of their care significantly impacts their response to both Press Ganey and HCHAPS surveys, which directly correlates to incentive payments. Communication with the nurse is paramount in that it optimizes care, increases satisfaction and facilitates safe discharge thus enhancing survey response ratings.

In order to achieve high performance scores in the communication with nurse dimension and patient satisfaction, several best practices must be adopted. These include consistent and purposeful hourly rounding, bedside shift reporting (hand-off), use of scripts and the recruitment of nursing candidates that exhibit strong interpersonal skills. In addition, leadership rounding has proven to sustain quality outcomes.

The Institute of Medicine (IOM) endorses empowering all members of the healthcare team to engage in creating a culture that promotes patient safety. This recommendation is further validated by nursing research involving the effect of empowerment and the importance of consistent workplace strategies to promote staff and patient satisfaction.

The theory of Structural Empowerment has been widely applied in nursing research and practice. This philosophy is defined as the ability to accomplish goals in an organization by having access to information, resources, opportunity and support. Kanter, the founding theorist, acknowledged that management plays a significant role in the provision of these structural factors and postulates that empowered leaders are more effective in endowing their employees. This results in an increased commitment to ensuring that the organizational goals are achieved (DiNapoli, & O'Flaherty 2015; DiNapoli et al., 2016; Boamah & Laschinger, 2014). In espousing this theory, the leadership team has developed strategies that empower the staff, have positively impacted patient and staff satisfaction and increased engagement scores (Clavelle et al., 2013). The nursing leadership team fosters an environment that promotes competence and confidence in our nurses (Purdy et al, 2010; Neville et al., 2016). This has resulted in the delivery of safe and outstanding care as evidenced by the outcomes in our patient satisfaction scores and quality data.

A Pilot Study Evaluating the Effectiveness of Diabetes Prevention in a Medically Underserved Community

Stefanie A. Schroeter, DNP, APRN, FNP-BC, USA
Kelley Anderson, PhD, RN, FNP, USA
Andrew C. Robie, MD, USA

Abstract

Purpose: This pilot study evaluated the effectiveness of participation in the National Diabetes Prevention Program (NDPP) for weight reduction in a sample of prediabetic individuals in an urban medically underserved community. The study also evaluated the challenges of implementing the NDPP into such a community, where rates of low education, poverty, medical comorbidities and psychosocial comorbidities are high. The NDPP was developed from a large multicenter study by Knowler and co-authors (2002), Diabetes Prevention Program Research Group, demonstrating a reduced risk for diabetes in prediabetic individuals who participated in an intensive lifestyle intervention program aimed at reducing weight and improving lifestyle habits. There is limited literature describing the use of the NDPP in medically underserved communities.

Methods: The NDPP was integrated into existing health services within a federally qualified health center (FQHC) in an urban medically underserved community. Participants were identified prediabetics receiving primary health care services within the FQHC, with hemoglobin-A1c levels between 5.7 and 6.4 percent, over the age of 18 years, with a body mass index (BMI) 24 and higher. Participants were excluded if they had a previous or current diagnosis of type I or II diabetes, or a prior hemoglobin-A1c level of 6.5 percent or higher. The participants received weekly to biweekly group sessions aligning with the 2012 NDPP curriculum. Study data was obtained through the 16-session core program of the NDPP. A pre-test, post-test paired group *t*-test was completed to evaluate the change in mean weight and BMI at the beginning and end of the core program. Correlational analyses were completed to evaluate the association between weight change, age, gender, number of sessions attended, and total minutes of physical activity. Anecdotal evidence regarding successes and challenges of implementation of the program within the FQHC were noted.

Results: Twelve participants initiated the program, and eight completed at least four of the 16 sessions. The mean weight loss for all participants was 5.3 pounds, and 7.4 pounds for those who completed at least four sessions. There was a significant difference in pre-weight, post-weight and BMI ($p < 0.05$) for all participants and those who completed a minimum of four sessions. Weight loss was independent of age or gender. Weight loss was more significant when the lowest weight attained was considered in place of the last recorded weight. A significant positive correlation was found between weight loss and number of sessions attended ($p < 0.05$), and between weight loss and total minutes of physical activity ($p < 0.05$).

Conclusion: Participation in the core portion of the NDPP significantly reduced weight and BMI in a group of prediabetic individuals in an urban medically underserved community, with weight loss unrelated to age and gender. These results are consistent with prior research that demonstrated the effectiveness of an intensive lifestyle intervention on reduction in diabetes risk. A greater level of weight loss was associated with higher levels of program participation through session attendance and physical activity. There was an observable discrepancy between the final program weight and the lowest weight attained, suggesting the importance of considering weight fluctuations in evaluating program effectiveness. Challenges such as low literacy and education, and medical and psychosocial comorbidities were documented and suggested a potential negative impact on weight loss.

I Got the Money! Key Strategies to Secure Grant Funding for Research and Evidence-Based Practice

Rebecca Clark, PhD, MSN, BSN, RN, USA
Kimberly Ferren Carter, PhD, RN, USA

Abstract

With today's tight healthcare budgets, nurses often struggle to secure the resources needed to support research studies and evidence-based practice projects to improve outcomes. Nurses must compete with organizational priorities and find innovative ways to fund their projects. While grants can provide resources for these projects, they can be challenging to identify and secure. The mere mention of the word "grant" can instill angst for nurses, and few nurses have the experience and expertise required for writing the successful grant application. Competition for funding is intense, and only outstanding applications are funded. Therefore, the valuable time that a nurse spends writing grants to support new knowledge and innovation must be used efficiently and effectively. There is limited professional literature to provide guidance for nurses who wish to expand their skillset as grant seekers.

Grant funders view grants as investments in improving the future and furthering their mission and reject projects that do not address these priorities. The successful grant application presents a novel proposal that is feasible, well written and advances the goals of the funding organization. It also requires that grant seekers find appropriate funding sources, ones that closely match the goals of the project, the expertise and experience of the primary investigator and the infrastructure of the organization to support the implementation of the project. While these points may sound obvious, it takes practice, team-work, time and energy to craft the successful application. It is process that has vast rewards, both professionally and personally, when successful and it is a process that can be learned!

In this presentation, two nurses who have secured over \$2 million grants for clinical and academic projects will explore approaches that have led to successful funding from federal, national and local sources. They will share strategies for finding funding sources, with attention to types available, including public, private, and non-traditional grant opportunities. In addition, they will discuss best practices for a systematic approach to writing a successful grant application. These practices include: crafting a feasible workplan, developing an attention-garnering introduction, writing the outstanding narrative and crystalizing the details of the work, processes, outcomes and parameters. In addition to developing writing skills through the writing process, certain professional endeavors contribute to composing that successful application. The presenters will discuss the importance of collaborating with others on writing; reviewing grant application for professional organizations and developing skill in writing for publication and presentations.

Examples of grant applications will be discussed with insights into components that contributed to successful (or not-so-successful) funding.

The importance of obtaining grant funding is clear. While the grant application process is time-consuming, difficult and daunting, it is possible for nurses to secure funding by learning how to identify appropriate funding sources and write compelling applications! These funds can be used to provide the financial support for developing the nursing knowledge and practice to advance health across the globe. Indeed, becoming the recipient of grant funding can help launch future endeavors to impact practice.

Improving Hypertension Management Through Computer-Based Staff Education, Simulation, and Incentivization: One Organization's Quality Improvement Journey

Nancy J. Slizewski, DNP, RN, CDE, USA
Caroline H. Fender, BBA, ADN, RN, USA
Patti E. Reinagle, MS, RN, USA
Krissy L. Flick, MBA, BBA, USA

Abstract

Background: Hypertension is a risk factor for cardiovascular disease which is a leading cause of death in the United States (Centers for Disease Control [CDC], 2014; Coogan, Marra, & Lomonaco, 2015). Although approximately one-third of the adult population has hypertension, almost one-half of those diagnosed are not meeting target blood pressures of less than 140/90 (CDC; Coogan et al.). Proper diagnosis and management of hypertension is based on blood pressure readings. Correct blood pressure measurement technique by staff is critical (American Association of Critical-Care Nurses, 2016; Bland & Ousey, 2011; Coogen et al.; Giorgi, & Ganem, 2016; Rabbia et al., 2013; Vieira da Silva, Mendes da Silva, 2016). Error in blood pressure measurements by staff can result in an incorrect diagnosis of hypertension or over/under treatment of the patient (Coogen et al.; Rabbia et al.; Vieira da Silva et al.). Education and evaluation of staff blood pressure measurement techniques has been shown to improve the accuracy of patient blood pressure readings (Ballard, Piper and Stokes, 2012; Coogan et al.; Garcia, Ahmad & Lim, 2012; Grim & Grim, 2013).

A rural health care organization sought to improve hypertension management of their patients. The organization's target for achieving blood pressure of less than 140/90 in patients with a diagnosis of hypertension was set at 88% or greater. Since 2008 this quality metric had remained relatively unchanged with 71-74% of patients achieving blood pressure control as reported by Wisconsin Collaborative for Healthcare Quality (WCHQ). These percentages did not meet the organization's target. Additionally, the organization's ranking for blood pressure control among other state health care organizations was 13 of 21 and declining (WCHQ). A quality improvement project to address this issue was developed and initiated in 2014.

Methods and Findings: Recognizing the critical piece staff education and training play in management of patients with hypertension, the health care organization began mandatory blood pressure education for all medical assistants, registered nurses and licensed practical nurses performing blood pressure testing in the primary care areas in 2014. Staff were required to complete a yearly computer-based learning module that tested knowledge of correct procedure. In-person manual blood pressure testing using a simulation arm was done. Proper technique and accuracy of the reading were assessed. In addition, staff were required to measure a clinical staff educator's blood pressure using an automatic blood pressure machine. Proper cuff size, placement, technique and positioning of the educator were assessed. If deficiencies were noted, immediate remediation was done. If staff could not accurately hear the manual blood pressure on the simulation arm, recommendations for possible hearing evaluations were sent to the manager.

In addition to educational requirements, the primary care staff began verifying the accuracy and correct technique for use of patient blood pressure home monitors. Patients were encouraged to bring in their home monitors at least yearly for comparison to a blood pressure taken either manually by staff or with the clinic's automatic device. Once the home device accuracy and correct patient technique was verified, patient blood pressure home records could be entered into the electronic health record. Patients were given directions on testing technique, frequency and when to contact the provider with readings.

Utilizing the electronic health care record and the population health dashboard, reports listing patients aged 18-74 with a diagnosis of hypertension who were not meeting blood pressure goals of less than 140/90 were generated. Staff received education and training on how to generate reports and the

management of these patients which included contacting patients for follow-up blood pressures or reporting home blood pressure measurements.

The results of the 2014 quality improvement project showed the percentage of patients aged 18-74 meeting target blood pressures of less than 140/90 had increased. WCHQ's first report for 2015 showed an increase from 73% to 81% of patients in control (Quarter 3/14 to Quarter 2/15). In an effort to improve blood pressure management, an incentive program was initiated in 2015 with a small percentage of the primary care physician's salary tied to achieving a minimum target of 82% of hypertensive patients in control. While primary care physicians were responsible for treating blood pressures greater than 140/90, they were not always aware of a patient's increased blood pressure reading. If a patient had an elevated blood pressure in a specialty area, this blood pressure was recorded in the electronic medical record but the primary care physician was not notified. The organization recognized the need to expand participation in this quality improvement project to the entire organization. As a result, starting in January 2015, all of the organization's staff performing blood pressure testing (excluding providers) received computer-based and in-person training using simulation and live subjects. An emphasis was also placed on the need to perform a second blood pressure measurement on all patients having an initial elevated blood pressure.

The increased number of staff needing training required a coordinated effort with the organization's education department responsible for the training and the departments requiring education. The education department training assistant and educators worked with managers to set up in-person training times and places. Training was ideally done within the learner's department, but was also done in classrooms. Thirty minutes of individual training time was allotted per learner.

The results of the 2015 quality improvement project showed patients meeting target rose from 81-82% (WCHQ). This did not meet the benchmark of 88%; therefore, the quality improvement project was expanded for 2016 to include specialty care areas. Staff testing continued to include all staff (excluding providers) performing blood pressure measurements on patients. In addition, staff in all areas were required to take a second blood pressure on patients having an initial blood pressure of 140/90 or greater. If the second reading was still 140/90 or greater, a referral to their primary care provider was mandated. The specialty care physicians were required to ensure this was done in order to receive their incentive bonus. There was also a potential for staff incentive if the organization's budget allowed and hypertension targets were met. The primary care provider's incentive would continue as per the previous year.

In an effort to meet this new initiative, computerized reports of patients not at target, reports of missing second blood pressure readings and missing referrals for elevated blood pressures were generated. Each provider was able to view these reports and staff were assigned to contact patients via phone call or letter for follow-up. All follow-up visits to recheck elevated blood pressure measurements were done free of charge.

The quality improvement project ended December 2016 with WCHQ reporting 85% of patients meeting blood pressure targets at that time, thus increasing the state's organizational ranking to 6/24. Education of all staff performing blood pressures on patients continues. The organization continues to track patients not meeting hypertension goals.

Conclusions: The management of hypertension is essential in preventing cardiovascular disease and complications. Correct techniques utilized by staff measuring patient blood pressures are essential in correct diagnosis and treatment of hypertension. Through computer-based training, simulation, one-to-one education and staff incentive programs, one health care system improved patient blood pressure management outcomes 12% over a three year period of time. Recommendations for the future are to assess the percentage of patients meeting target blood pressures when incentivization is no longer used and to assess the rate of decay for proper blood pressure measurement by staff.

EBP PST 2 - Evidence-Based Practice Poster Session 2

Nursing Rounds: A Best Practice Implementation

Juli Daniels, PhD, CCRN, CNE, NEA-BC, LHRM, USA

Abstract

Background: Purposeful and timely rounding is a best practice intervention to routinely meet patient care needs, ensure patient safety, decrease the occurrence of patient preventable events, and proactively address problems before they occur. The Institute for Healthcare Improvement (IHI) endorsed hourly rounding as the best way to reduce call lights and fall injuries, and increase both quality of care and patient satisfaction. Nurse knowledge regarding purposeful rounding and infrastructure supporting timeliness are essential components for consistency with this patient centered practice.

Objectives: The project aimed to improve patient satisfaction and safety through implementation of purposeful and timely nursing rounds. Goals for patient satisfaction scores and fall volume were set. Specific objectives were to determine current compliance with evidence-based criteria related to rounding times and protocols, improve best practice knowledge among staff nurses, and increase compliance with these criteria.

Methods: For the objectives of this project the Joanna Briggs Institute's Practical Application of Clinical Evidence System and Getting Research into Practice audit tools were used. Direct observation of staff nurses on a medical surgical unit in the United States was employed to assess timeliness and utilization of a protocol when rounding. Interventions were developed in response to baseline audit results. A follow-up audit was conducted to determine compliance with the same criteria. For the project aims, pre- and post-intervention unit-level data related to nursing-sensitive elements of patient satisfaction and safety were compared.

Results: Rounding frequency at specified intervals during awake and sleeping hours nearly doubled. Use of a rounding protocol increased substantially to 64% compliance from zero. Three elements of patient satisfaction had substantive rate increases but the hospital's goals were not reached. Nurse communication and pain management scores increased modestly (5% and 11%, respectively). Responsiveness of hospital staff increased moderately (15%) with a significant sub-element increase in toileting (41%). Patient falls decreased by 50%.

Conclusions: Nurses have the ability to improve patient satisfaction and patient safety outcomes by utilizing nursing round interventions which serve to improve patient communication and staff responsiveness. Having a supportive infrastructure and an organized approach, encompassing all levels of staff, to meet patient needs during their hospital stay was a key factor for success. Hard-wiring of new practices related to workflow takes time as staff embrace change and understand how best practice interventions significantly improve patient outcomes.

Incorporating a Collaborative Perioperative Training Program in Undergraduate Nursing Education

Linda Wilson, PhD, RN, CPAN, CAPA, BC, CNE, CHSE-A, ANEF, FAAN, USA

Rosalyn McGrath, MSN, RN, CNOR, USA

Marianne Saunders, MSN, RN, CNOR, USA

Colleen Mattioni, DNP, RN, CNOR, USA

Donna Trinkaus, MSN, RN, USA

Deanna Lynn Schaffer, PhD, RN, CNE, ACNS-BC, USA

Abstract

In nursing today we have heard the many concerns of the nursing shortage in many specialty areas including nursing education. According to an article by Dr. Rose O'Sherman (2012) perioperative nursing is ground zero for the coming nursing shortage. The specialty of perioperative nursing workforce has been experiencing a shortage for many years now due to the aging workforce (O'Sherman, 2012). Many perioperative leaders already report they are having problems with recruitment and they expect that difficulty to increase over the next five years (O'Sherman, 2012). An additional problem is the absence of perioperative curricula in most nursing programs (Ball, Doyle, Oocumma, 2015) and lack of perioperative experiences and exposure to any of the perioperative areas (operating room, holding area, post anesthesia care unit, interventional radiology, endoscopy, etc.) has been eliminated from the nursing curriculum in most nursing programs in the United States (O'Sherman, 2012).

This session will present a Collaborative Perioperative Training Program developed between a university-based undergraduate nursing program and a hospital perioperative services department in an urban setting in Philadelphia, United States.

Planning for the Collaborative Perioperative Training Program was initiated in 2014 with several group planning meetings. The collaborative decided to initiate the program with the Accelerated Career Entry (ACE) undergraduate nursing students with a call for applications for the "ACE Perioperative Immersion Experience" in December 2105. The ACE students have a bachelor's degree in another field and are completing the BSN program in 11 months. Once the selection process was completed the participants completed the Association of Perioperative Registered Nurses (AORN) Perioperative 101 Fundamentals Course Modules. The immersion portion of the experience took place during break week between sessions where the participants completed 40 hours of education, simulation and clinical experiences with preceptors in the perioperative environment. The immersion included experiences in Pre-operative Observation, Operating Room, Post Anesthesia Care Unit, Surgical Center, and training on Introduction to Perioperative Nursing, Perianesthesia Nursing, Surgical Environment, Scrubbing Gowning Gloving, Aseptic Technique, Preoperative Assessment, Quality & Safety, Skin Antisepsis, Nursing Leadership, Shared Governance, Patient and Equipment Safety, Professionalism and much more. The feedback following the immersion experience was overwhelmingly positive from both the student participants and the clinical training site and six participants were hired full time out of the first cohort. The "ACE Perioperative Immersion Experience" continues to be offered two times a year in June and December with an additional seven students hired out of the second ACE cohort.

The second phase of the Collaborative Perioperative Training Program included implementing an "Introduction to Perioperative Nursing" minor for the traditional (4 year) undergraduate nursing students. Phase two was initiated in the fall of 2016. This "Introduction to Perioperative Nursing" minor program includes two courses and one week long immersion experience offered in the senior year. This program includes completion of the Perioperative 101 Course Modules along with lecture, simulation and clinical experiences and concludes with a 40 hour intensive immersion experience.

This Collaborative Perioperative Training Program developed between a university-based undergraduate nursing program and a hospital based perioperative services department in an urban setting in Philadelphia, United States has proven to be very effective in introducing nursing students to the specialty

of perioperative nursing and successful for recruitment of new graduates as perioperative nurses into the clinical environment. This collaborative team is looking forward to a continued successful relationship for many years to come.

EBP PST 2 - Evidence-Based Practice Poster Session 2

Starting the Conversation on Hypertension Self-Management in Primary Care to Improve Cardiovascular Outcomes

Jean Ann Davison, DNP, RN, FNP-BC, USA

Abstract

Background: Cardiovascular disease (CVD) – heart disease and strokes - caused one in three deaths in the USA in 2014 and The American Heart Association (AHA) projects that by 2030, 40.5% of the U.S. population will have some form of CVD, with an estimated cost to the national health care system of \$1 trillion per year (Tomaselli, Harty, Horton, & Schoeberl, 2011). In 2012 the U.S. Department of Health and Human Services (HHS) launched the *Million Hearts* initiative, (<http://millionhearts.hhs.gov/>) to prevent 1 million heart attacks and strokes in 5 years (2012-17). Strategies were directed at the leading modifiable risks for CVD to support improved outcomes in the "**ABCS**" - **A**spirin for those at risk, **B**lood pressure control, **C**holesterol control, **S**moking cessation and **S**odium reduction in the diet. The focus of this campaign is to empower Americans to make healthy lifestyle choices to reduce CVD risks and for healthcare providers to support their patients in these healthy lifestyles.

Hypertension (HTN) is the single most independent and modifiable risk factor for cardiovascular disease (CVD), stroke, congestive heart failure, and chronic renal disease (CRD) (Chobanian et al., 2003). The *Million Hearts* campaign set a clinical quality measure for blood pressure control goal at 70% in the clinical population with a diagnosis of hypertension; the measurement was defined as the "percentage of patients 18 to 85 years of age with a diagnosis of hypertension (HTN) and whose blood pressure (BP) was adequately controlled (<140/90) during the measurement year". In the Southeast Region of the United States, it is currently reported by the Department of Health and Human Services (2016) that only 53% of the of the population has achieved the clinical control blood pressure (BP < 140/90) - a large gap from the 70% goal (<http://millionhearts.hhs.gov/data-reports/cqm.html>, 2016).

The Centers for Disease Control and Prevention (CDC, 2013) *Hypertension Control: Action Steps for Clinicians* recommends to:

- Provide patients who have hypertension with a written self-management plan at the end of each office visit.
- Encourage or provide patient support groups.
- Use all staff interactions with patients as opportunities to assist in self-management goal-setting and practices.
- Print visit summaries and follow-up guidance for patients.

Purpose: The aim of this nurse led quality improvement (QI) project was to improve the clinical performance in the management of hypertension (HTN) with a focus on self-management support (SMS) among adult patients (18-75 years) at a rural primary care clinic with an exceptionally high rate of cardiovascular disease. The six-month QI initiative was designed with a goal to have 80% or more of the adult patients with a diagnosis of HTN actively setting goals in collaboration with their providers for CVD risk reduction.

Data Sources and Implementation: The study design was a six month long quality improvement study. Data included a retrospective baseline of meaningful use population data (N = 1210) generated six months prior to the QI study start date and an analysis of the data during the six-month QI study (N = 1409). Interventions included provider and staff quality improvement training along with patient education and lifestyle goal setting for self-management support (SMS) of HTN. All adult patients with a diagnosis of HTN or an elevated BP reading at their office visit were offered the brochures *Starting the Conversation on Blood Pressure* by the NC Prevention Partners(2011) and *Start with Your Heart Prescription for Better Health* from the NC Department of Health and Human Services(2011) in English and Spanish. Questions were answered on hypertension and risk reduction by all health care providers throughout the office visit. **Specific, Measurable, Attainable, Realistic and Time specific (SMART)** goal setting and action plans were encouraged and a written self-management plan was given at the end of each office visit. Electronic

medical record data was used to compile population statistics for blood pressure (BP), LDL cholesterol, tobacco use, body mass index, and self-management goals monthly throughout the QI study. Pre and post results of the QI six month period were compared.

Results: The primary objective, > 80% of adults aged 18 to 75 years would have documented self-management goals, was achieved and significantly improved from baseline. **SMART** goals discussed included following the recommendations for the Dietary Approaches to Stop Hypertension (DASH) diet, aerobic physical activity, weight loss for healthy body mass index, tobacco cessation, moderate alcohol consumption, stress reduction, medication adherence, home BP monitoring, and, as applicable, blood sugar control. A secondary objective was to see significant improvement in controlled HTN (BP < 140/90) for this population, but this did not occur. A limitation of this QI study was the short length (six months) of observation time.

Implications for Practice: The goal of this QI project to help patients in self-management support for modifiable risk reduction of HTN was achieved to help reduce the burden of CVD in this population. Nurses can have a vital role in meeting the current demand for HTN management in primary care, to support patients in their self-management. Working with patients to achieve healthy lifestyle CVD risk reductions and medication management could help reduce the burden of CVD at a population level.

EBP PST 2 - Evidence-Based Practice Poster Session 2

Teaching Strategies for the Promotion of Effective Patient Communication in Vulnerable Women

Ginny Moore, DNP, WHNP-BC, USA

Abstract

Effective communication skills are an essential component in the ability to obtain necessary information regarding medical conditions and treatment plans (Institute of Medicine [IOM], 2004). The inability to obtain this information may result in erratic medication dosing, non-adherence to treatment plans, and missed follow-up appointments. These are factors associated with higher rates of hospital admissions, increased costs, and poorer health outcomes (Fetter, 2009; IOM, 2004).

Patients need to know what questions to ask and possess the confidence to ask those questions during the clinical encounter. At highest risk for lack of essential communication skills, are vulnerable populations. Vulnerable populations include those with low income (poverty-level or below), low education level (high school or less), chronic medical conditions, minorities, and homeless (Glassman, 2011; IOM, 2004). The purpose of this project was to educate vulnerable patients through the use of evidence-based written instruction and skills training about questions they could ask their health care providers to better understand their health.

The relevance of this problem for current society is multifaceted. Effective patient-provider communication is an essential component in patient outcomes. A decrease in the areas of patient recall of information, treatment adherence, and satisfaction has been associated with ineffective patient-provider communication (Cegala, McClure, Marinelli, & Post, 2000; Kaplan, Greenfield, Gandek, Rogers, & Ware, 1996; Rao, Anderson, Inui, and Frankel, 2007; Street et al., 2010). Conversely, effective patient-provider communication has been associated with increased effectiveness of pain management, treatment plan adherence, and patient satisfaction with care (Street et al., 2010; Wright, Sparks, & O'Hair, 2008).

Research evidence for interventions to improve patient-provider communication can be divided into provider focused and patient focused categories. Categories of patient focused interventions can be further divided into the communication skills of information seeking, provision of information, and verification of information. Cegala, McClure, Marinelli, and Post (2000) provided written instruction on these communication skills in the form of a training booklet delivered to participants two to three days prior to their scheduled provider appointments. The booklets afforded participants the opportunity to record relevant details of their medical histories, and to list questions and concerns for health care providers. Study results indicated that participants receiving this intervention provided more detailed information, asked more questions, and verified the information received during the clinical encounter more often than participants who did not receive the intervention.

After a systematic review of the evidence on patient communication interventions, Rao, Anderson, Inui, & Frankel (2007) reported that patients who received interventions containing a skills practice component were better able to begin and direct discussions with healthcare providers. They also obtained more information through the questions they asked than controls who did not receive the interventions. The use of both written information and skills practice was supported by Street et al. (2010) in a study that examined the effects of "tailored education –coaching" (TEC; p. 42) on patients' ability to effectively communicate their cancer related pain concerns. The TEC interventions were delivered in the form of a written information booklet and skills practice. Skills practice consisted of preparation for visits, and role-playing exercises where patients practiced asking questions, and expressing their needs and preferences. Patients who received the TEC intervention demonstrated greater efficacy in communicating their concerns which led to reported improvement in health outcomes.

A community education forum consisting of a 20 page "How to Talk to Your Doctor" guidebook, video clips of effective patient-provider communication, and role-playing of techniques to enhance communication was implemented by Tran et al. (2004). The forum was developed as community

education rather than a clinical intervention in an effort to reach diverse communities of people who might not otherwise have access to communication skills training. Participants were encouraged to employ an ABC (Ask questions, Be prepared, express Concerns) mnemonic during health care encounters. After completing the forum, participants reported increased confidence in the ability to effectively communicate with care providers.

Evidence findings indicate that written instruction and skills training have been equally efficacious in improving patient-provider communication. Patients receiving both interventions obtained more information and expressed a greater degree of confidence in their ability to communicate effectively with care providers after implementation of the interventions. These findings support the use of both written instruction and skills training interventions to promote effective patient communication skills.

This project involved the review of written information followed by the opportunity to practice application of the information through role-play. Written information included a wallet sized card from the Agency for Healthcare Research and Quality (AHRQ) used for listing medications and medical conditions and three basic questions that the National Patient Safety Foundation (NPSF) recommend be asked during every healthcare encounter. After reviewing the written material, application of the information during any scheduled healthcare encounters was discussed.

A pilot of the project was conducted during May and June 2012 with 20 women in a two-year residential recovery program for women who have survived lives of prostitution, addiction and violence. Study findings indicated self-reported increases in knowledge of questions and confidence in asking questions during health care encounters. The project replication was conducted from January 2015 through April 2015 in a six-month residential transition program for women recovering from addiction, trauma and incarceration. All women in the program had co-occurring substance use and mental health disorders. Both pilot and replication project programs were located in the southeastern United States.

The effectiveness of the practice change was evaluated with a pre-and post-intervention, self-report survey rating participants' knowledge of questions to ask healthcare providers and self-perceived confidence in asking those questions. The survey was a self-developed, pen and paper, Likert scale tool. Expert opinion was sought for validation. The outcomes measured were knowledge of questions to ask providers during healthcare encounters and self-perceived confidence in the ability to ask those questions during encounters. The difference in pre-and post-survey scores were calculated to determine project effectiveness in addressing the clinical problem.

A total of 13 active members in the recovery program participated in this EBP change project. The responses of "No", "Not Sure", and "Yes" were naturally ordered and hence ranked as 1,2, and 3, respectively, for the analysis; i.e., the higher the rank, the more positive response to the questions. Wilcoxon signed-rank tests were used to test whether the ranked responses after the intervention would be higher than those before the intervention. The scores (ranks) of responses after the intervention were significantly higher than those before the intervention for both survey items ($p=0.009$ and $p=0.009$, respectively).

On the pre-intervention survey, 2 of the 13 project participants responded "No" to the statement regarding knowledge of questions to ask providers during health care encounters. Two of the participants responded "Not Sure" and 6 responded "Yes". On the post-intervention survey, all 13 participants responded that they knew what questions to ask to get information about their health. Larger increases were reported in confidence. Prior to the intervention, 5 participants responded "No" and 2 responded "Not Sure" regarding confidence about talking with health care providers. Post-intervention, all 13 participants responded that they felt confident about talking with their health care providers.

Project findings indicate self-reported increases in knowledge of questions to ask and confidence in asking those questions. These findings confirm the value of teaching essential communication skills. Application of these interventions may enhance clinical care particularly with vulnerable and marginalized populations. Nurses can use this information to proactively guide patient education in the clinical setting,

empower patients in the community setting and educate students in the academic setting regarding essential patient communication strategies.

A Prospective Evaluation of Health-Related Quality of Life in Lymphedema Treatment

Chia Yu Lin, MS, RN, Taiwan
Hsueh-Erh Liu, PhD, RN, Taiwan

Abstract

Background: The vascularized lymph node flap transfer was the flap of choice for lower extremity lymphedema. Although physical rehabilitation is important for lymphedema treatment, there is no standardized procedure for different stage lymphedema. This study was conducted to investigate the vascularized lymph node transfer (VLNT) and Complete Decongestive Therapy (CDT) long term result in lymphedema.

Methods: An IRB-approved prospective study was performed of patients who underwent vascularized lymph node transfer for symptomatic upper (ULL) or lower limb (LLL) lymphedema. Patients who had either submental or groin VLN transfer for upper or lower limb lymphedema were isolated. Outcomes were assessed using improvement of circumference reduction, decreased number of episodes of cellulitis and health-related quality of life (HRQOL) metric.

Result: A total 138 patients were identified and met inclusion criteria. More identified patients underwent VLN (50.7%) as compared to CDT (49.3%) for lymphedema. Patient age, BMI, tobacco use, diabetes, hypertension, lymphedema grading and lymphedema reason were similar between groups ($p=0.4$; $p=0.2$; $p=0.6$, $p=0.5$, $p=0.5$, $p=0.7$, $p=0.7$, respectively). Circumference reduction was higher in the VLN group (35.3%) as compared to the CDT group (23.4%) and post-operative episodes of cellulitis was higher in the CDT group (4 ± 1.5 times per years) as compared to the VLN group (1.4 ± 1.3 times per years) during the 12-month follow-up evaluation, have statistical significance ($p=0.03$ and $p=0.04$, respectively). In HRQoL part, overall quality of life and function, body appearance, symptom, and mood domains were all significantly improved in the VNL group ($p<0.01$ within each domain).

Conclusion: The vascularized lymph node transfer and complete decongestive therapy VLN and are both valuable treatment options in treating lymphedema especially VLN transferred in severe lymphedema (Grade III to IV) was more effective. These improvements are mirrored by improvements in patient-reported outcomes and quality of life measures. These changes can be seen 12 month post-operatively and continued steady improvement can be expected.

EBP PST 2 - Evidence-Based Practice Poster Session 2

Identifying Exercise Barriers for Nurses Working in Sedentary Work Roles

Carol M. Patton, DrPH, RN, FNP-BC, CNE, USA

Abstract

More and more nurses and nurse educators are working in sedentary work roles that require them to be sedentary for long periods of time. Typically nurses working in sedentary roles know intellectually they need to engage in physical activity to stay healthy; however, there are many barriers and challenges preventing nurses working in sedentary roles to engage in adequate physical activity. Contemporary literature indicates there are numerous physiological impacts on the health status and outcomes for nurses completing fewer than 5000 steps per day. Nurses completing fewer than 5000 steps per day are considered to have a sedentary work role. Nurses completing fewer than 5000 steps per day are at increased risk of developing chronic disease. Nurses working in sedentary work roles are at increased risk of mortality and morbidity from elevated body mass index (BMI). For example, nurses with an elevated BMI are more likely to experience poor health status and chronic disease resulting in higher rates of work absence, earlier exit from the nursing workforce, or retire early from the nursing workforce. Obesity is a compelling health issue for nurses and is linked to inactivity and sedentary occupational roles. Fewer than 50% of American adults currently meet the National Guidelines for Physical Activity when compared to the National Clinical Guidelines for *Physical Activity Guidelines for Americans*. For example, the National Center for Chronic Disease Prevention and Health Promotion indicates all adults should engage in 150 minutes of moderate-intensity aerobic physical activity weekly or have 75 minutes of vigorous-intensive physical activity weekly. Following the recommended guidelines of the Physical Activity Guidelines for Americans decreases risk of chronic diseases including heart disease, diabetes, and many cancers. The Exercise Benefits-Barriers Scale (EBBS) is a valid and reliable measurement tool that helps identify cognitive and perceptual factors and barriers of persons with regard to exercise and physical activity. The EBBS provides participant responses and insight into one's ideas about exercise. The EBBS is a valid and reliable for use in adults age 18 and older. The purpose of this evidence-based intervention is to administer the EBBS to nurses working in sedentary work roles to identify barriers and challenges for these nurses with regard to daily exercise and physical activity. Based on the data and outcomes from the EBBS, an at-work exercise program will be designed for nurses working in sedentary roles to improve their health status and reduce risk of chronic disease.

EBP PST 2 - Evidence-Based Practice Poster Session 2

Polysubstance Use, Decision Making, and Geosocial Networking App Use Among MSM

Michael Sanchez, DNP, CRNP, FNP-BC, USA
Deborah S. Finnell, DNS, RN, FAAN, USA
Jose Bauermeister, PhD, MPH, USA
Jason Farley, PhD, MPH, RN, CRNP, FAAN, USA
Rob Stephenson, PhD, MSc, USA

Abstract

Men who have sex with men (MSM) exhibit the greatest risk for HIV and are disproportionately affected by HIV infection. At current rates, 1 in 6 MSM will be diagnosed with HIV in their lifetime, including 1 in 2 black MSM, 1 in 4 Latino MSM, and 1 in 11 white MSM. MSM account for 55% of people living with HIV in the United States in 2013. While it is estimated that MSM represents 2% of the male population in the US, this group accounts for 66.7% of HIV infections diagnosed in 2014². From 2005 to 2014, HIV diagnoses steadily decreased in the United States by 19%, however, the incidence continues to rise among MSM aged 13 and older. Among males, MSM accounted for 83% (29,418) of the estimated new HIV diagnoses. Within this sexual minority group, diagnoses rates continue to rise among certain racial/ethnic minority populations (e.g., African American and Hispanic/Latino MSM) in contrast to the noted drop among other racial/ethnic groups.

Geosocial networking (GSN) applications (e.g., Grindr, Scruff, and Jack'd) have become a new environment through which young MSM can meet potential sex partners. Smartphones and GSN applications have changed the traditional paradigm for identifying sexual partners and provides new means for MSM to locate partners outside of traditional venues. GSN applications facilitate the identification of sex partners nearby. Sexual encounters between MSM are often expedited by the use of these GSN. These meetings may occur quickly, with little discussion of each partner's HIV status or sexual history. Users of these applications may rely on incorrect perceptions of what types of people are HIV-positive to make decisions regarding their sexual practices with their potential partners. The role that GSN applications play in potential exposure to HIV among young MSM is of particular interest given that MSM in the 13 to 24 year age group accounted for 92% of new HIV diagnoses among this age group overall, and 27% of new diagnoses among all gay and bisexual men.

Little is known about the associations of polysubstance use and decision-making process among MSM in the realm of GSN applications use. Social networks may influence members' sexual behavior via social comparison, social sanctions and rewards, socialization, and information exchange. These processes may be exacerbated/confounded by polysubstance use, but has not been extensively studied. It is known that alcohol and substance use among MSM is a significant predictor of risky sexual behavior. Moreover, alcohol consumption directly affects sexual-decision making and is associated with increased risk behaviors linked to HIV infection. One study found that the effects of alcohol on intentions to engage in unprotected sex were stronger when sexual arousal was heightened. Additionally, alcohol consumption, particularly binge drinking, has been significantly associated with more unplanned sexual encounters and can also affect sexual communication and negotiation.

Many of the studies evaluating polysubstance use and decision making among MSM were conducted before 2009, before new technologies, particularly GSN applications were developed and broadly adopted. Thus, these studies did not consider or evaluate the implications of substance use in association with sex-seeking behaviors among MSM specifically within the context of GSN application utilization. Additionally, some of these GSN applications target varying subcultural identities of MSM, highlighting the heterogeneity of this population that is often overlooked¹⁰. Given that GSN applications are increasing in popularity as a means of meeting sexual partners, further research in this area is warranted to aid the development of novel and effective HIV/STI prevention programs.

Food and Activity: A Competence Enhancement Project for Persons With Developmental Disabilities and Caregivers

Solrun G. Holm, MSN, RN, Norway
Ragnhild Holdal Rasmussen, BSN, RN, Norway

Abstract

Background: In Norway persons with developmental disabilities live in community-based settings. Managers and caregivers are expected both to promote residents' health and to support their autonomy. Ideas that serve as guiding principles in today's care of persons with intellectual disabilities are Individualization and participation. Persons with intellectual disabilities have the right to be included in the community and to make their own choices in everyday life. Persons with developmental disabilities both obesity and malnutrition are problems (Hove, 2004; Ruud, Raanaas, & Bjelland, 2016). In our municipality most persons with developmental disabilities have these problems. Staff shifts make it difficult to keep track of persons with developmental disabilities' nutritional status, diet and activity. Persons with developmental disabilities do not have sufficient knowledge or understanding relating to own diet. The competence of the caregivers in the field of nutrition and activity varies much. They assist with grocery shopping, preparation, and implementation of meals, and follow up the wishes of users. The need for increase in competence in nutrition and physical activity, both persons with developmental disabilities and caregivers, is huge.

Purpose: The main purpose of the project is that persons with developmental disabilities should have a better diet and increased activity level.

Method: Quality improvement intervention involving persons with developmental disabilities and their caregivers.

Results: Based on the cookery courses the caregivers and persons with developmental disabilities developed a spiral booklet with recipes and shopping list tailored to one person. Tuesday Club got a better structure with regular activities like disco, party games and fitness activities. Persons with developmental disabilities participate in planning what to eat and they also participate in cooking.

Persons with developmental disabilities and their caregivers made a walking trail in the neighborhood with 5 checkpoints where the person who walk the trail get a mark in a card with a ticket punch. Five marks give a reward.

Conclusion: Persons with developmental disabilities and their caregivers got better knowledge of how to conduct a healthier diet. Cooking courses gave the persons with developmental disabilities increased expertise on practical cooking, and how to make single servings. Spiral booklet helps persons with developmental disabilities and their caregivers planning purchase of healthier groceries. The caregivers seem the spiral booklet is useful for guidance and motivation. The walking trail leads to increased physical activity outdoors and now the persons with developmental disabilities demand more checkpoints.

Bed Climate for Infants and Their Mothers: From the Viewpoint of Absolute Humidity

Rie Ikeda, PhD, RN, RM, Japan
Sachiko Takahashi, EdD, Japan

Abstract

Objective: The microclimate created between bedding and the body is referred to as the "bed climate", with a bed temperature of 33°C and relative humidity of 50-60% considered optimal. In 2005, the guidelines for the prevention of SIDS (sudden infant death syndrome) referred to the issue of sleep environments, including "the types of bed" and "overheating". Wilson (2005) reported that infants' bed climate of the eastern countries was warmer than them of the western countries. Overheating is one of the chief risk factors for SIDS¹⁾. The objective of the present study was that bed climate of Japanese infants and mothers is examined from the point of relative and absolute humidity for safe and comfortable sleep environment.

Methods: Data were collected from four infants (age range, 2-5 months) and their mothers. Bed climate and sleep-wake status while using the following three different mattress types (a cotton futon, cotton pad and a polyester futon) were monitored for three nights. A data logger was used to record the temperature and relative humidity associated with each mattress under the back and at the feet of each infant and mother for one minute. Absolute humidity was calculated from Relative humidity by computer. Sleep-wake status was assessed using an actigraph. Data associated with each bedding material for each night were then analyzed and compared.

Results: Regarding bed climate, use of the cotton futon and the cotton pad resulted in lower bed temperature and humidity compared with the polyester futon. The bed climate was found to be influenced by the bedding when a water-proof sheet was used. Regarding infants' sleep, total sleep time was longer with use of the cotton futon and pad. Sleep of mothers was influenced by sleep of their infants.

Conclusion: The cotton futon and the cotton pad appeared to provide favorable bed temperature and humidity. Use of them were indicated to positively affect the infants' sleep.

Determining the Level of Engagement in the Ohio State University Wellness Innovator Program

Megan E. Amaya, PhD, CHES, AFAA, USA

Leah Colleen Mitchell, MPH, USA

Bernadette Mazurek Melnyk, PhD, RN, CPNP/PMHNP, FAANP, FNAP, FAAN, USA

Lauren Battista, MPH, USA

Abstract

Background: A wellness champion team is an essential component of a worksite wellness program initiative. The role of the wellness champion team is to communicate, participate in, motivate colleagues, and support the worksite wellness program. Champions are often the “voice of the employee” for wellness offering considerations. However, very little is known about the impact and level of participant engagement of these teams. Developed 4 years ago under the direction of the University Chief Wellness Officer, the wellness team at a large academic institution in the United States includes 500 faculty/staff members who are Wellness Innovators from across the university. **Methods:** A pre-experimental, cross-sectional study design to study multiple variables in a single point in time. An anonymous 9-item survey was developed and administered to all participants in the Wellness Innovator program. Items were created based upon an extensive review of the literature. **Analysis:** Means of continuous variables (e.g., age) will be compared across groups using two-sample t-tests (engaged vs. less engaged Wellness Innovators). Chi-squared tests will be used to compare distributions of categorical variables (e.g., gender) across groups. If differences in demographics across groups are found, then linear and logistic regression models will be used to test for differences in manager support across the groups to control for demographic differences by including them as covariates in the models. **Results:** Survey items include questions about engagement and support of Wellness Innovators in their current role. To provide consistency, definitions of these terms are provided in the survey. Demographic information on participants will be presented, as well as current level of engagement in the program and perceived manager/supervisor support for their role in the program. Data will be presented on the following two research questions: 1) are there demographic differences among Wellness Innovators that are engaged and less engaged within the Wellness Innovator program? and 2) are there perceived differences in direct manager support among Wellness Innovators that are engaged and less engaged within the Wellness Innovator program? **Conclusion:** Measuring level of engagement of a worksite wellness team is vital to the longevity and support of the program. Although many worksite wellness programs employ wellness champion teams, the field as a whole has little understanding of how level of engagement and manager/supervisor support can influence the champion’s decision to remain committed to the wellness program. Implications exist for not only a worksite wellness program but for other environments where wellness champion teams exist, such as community health promotion efforts, medical centers, and patient advocacy populations.

EBP PST 2 - Evidence-Based Practice Poster Session 2

The Association with Social Skills and Self-Monitoring in Japan

Mio Sato, MSN, RN, Japan
Riho Mitsubayashi, BSN, RN, Japan
Chizuru Mori, PhD, RN, Japan

Abstract

Background: Japanese people have difficulty with certain interpersonal interactions such as expressing and explaining their opinions, expressing their feelings, and face to face communication. In order to communicate with others, it is necessary to develop one's social skills. Social skills are cognitive processes that enable an expression of interpersonal action and include both verbal and nonverbal actions that are used to react adequately and effectively in an interactive situation. In Japanese culture, social interactions are very strongly directed by the social context in which they occur. Furthermore, Japanese people tend not to give clear verbalization of their thoughts or feelings. Japanese people are, therefore, required to understand subtleties in one another's words and behavior in order to act appropriately and meet certain group or social expect actions. Thus, social skills are important to expand one's social life by helping individuals to adapt to various social situations such as in school or in the work place.

To meet social expectations, it is necessary to control one's behavior an ability that comes from a personality train known as self-monitoring. Self-monitoring involves being conscious of one's own behavior during interpersonal contexts in order to accommodate to that situation. People with a high self-monitoring tendency can easy modify their behavior, while people who have a low self-monitoring tendency act according to their own beliefs and volition. Self-monitoring, therefore, involves not only the ability to regard one's self objectively, but also to control and adjust one's behavior accordingly. So while social skills are generally competences relates to understanding and associating with others, self-monitoring is an introspective consciousness process that dictates one's behavior. Thus, self-monitoring is an important factor for effective social skills, particularly in a Japanese cultural context.

Concern over interpersonal relationships is a major factor that contributes to emotional suffering in the lives of Japanese people, while, social interaction with in communities is known to raise well-being in daily life. Therefore, it is important to investigate the causes of difficulties that arise in interpersonal relationships in Japan, and find ways to help construct and maintain such relationships.

Objective: The purpose of this study is to show the association between social skills and self-monitoring in a Japanese population.

Methods: Participants - A total of 203 participants were recruited for this study.

Measurement Instrument: Social skills - To gather data for this study, we used the Social Skills Self-Rating Scale for Adults (SSSA), which was developed in Japan by Aikawa et al (2005). The SSSA instrument, which includes 6 subscales and 35 items, is able to comprehensively assess communication and interaction skills. The 6 subscales are: 1) Construction of relationships (the skill to construct relationship with others); 2) Decoding (the skill to decode an expression and feelings of others); 3) Assertion (the skill to express one's opinion by an appropriate way); 4) Control of emotion (the skill to control one's emotional expression); 5) Maintenance of relationships (the skill to behave in consideration for others' emotion); and 6) Symbolization (the skill to express one's mental state with expression and non-verbal gesture). Participants gave each item a profile score, ranging from 1 (hardly suitable) to 4 (very suitable), and the range of score is from 35 to 140. A high profile score indicates high levels of social skills.

Self-monitoring - To measure self-monitoring, we used the Cognitive Behavioral Self-Monitoring Scale (CBSMS) developed by Tsuchida et al (2007) in Japan. This instrument is an appropriate way to objectively measure self-monitoring. The CBSMS is self-rating scale that consists of 3 subscales with a

total of 17 items. Each item is scored, from 1 (hardly suitable) to 5 (very suitable) and the maximum total score is 85. A high total score indicate that self-monitoring function is high. The 3 subscales are: 1) Behavior monitoring (indicate a tendency to control oneself along the situation); 2) Circumstance monitoring (indicate a tendency to monitor others and atmosphere, and catch them analytically); and 3) Monitoring cognition (indicate a tendency to recognize a state of the self, such as feelings, thought, and sense of values).

Analysis - We used Spearman's correlation test to identify the relationship between the SSSA and CBSM scales, and age. The Mann-Whitney U test was used to detect variations between genders. For the analysis we used the Statistical Package for Social Sciences (SPSS) version 21, at a 95% confidence level.

Ethical considerations - This study was approved by the Ethics Committee of the University of Tsukuba, Faculty of Medicine. Written informed consent was obtained from all participants included in this study.

Results: A total of 177 participants (70 men and 107 women) were included in the assessment, (mean age: 34.6 years [SD = 15.6]). Cronbach's alpha score for the SSSA and CBSMS were .90 and .81, respectively.

The mean overall score for SSSA was 94.1 ± 11.9 (range: 52-133). The mean scores for each subscale, when divided by the number of the items, were: 'Construction of relationships' = 2.7; 'Decoding' = 2.8; 'Assertion' = 2.4; 'Control of emotion' = 2.5; 'Maintenance of relationships' = 3.1; and 'Symbolization' = 2.8. The CBSMS mean overall score was 61.9 ± 8.4 (range: 17-85). The mean score for each subscale, when divides by the number of the items, were: 'Behavior monitoring' = 3.5; 'Circumstance monitoring' = 3.7; and 'Monitoring cognition' = 3.8.

The overall score for SSSA was significantly correlated with the overall score for CBSMS ($r_s = .43, P < .01$). The score for 'Behavior monitoring,' which is subscale of CBSMS, was correlated with: overall score for SSSA ($r_s = .55, P < .01$); 'Decoding' ($r_s = .47, P < .01$); and 'Maintenance of relationships' ($r_s = .55, P < .01$). SSSA and CBSMS had no significant correlation with age.

Discussion: The results of the subscale scores pertaining to social skills perhaps indicate a typical characteristics of the Japanese. While Western cultures are said to be individualistic, Japanese culture is typically more group-oriented; Japanese are more likely to express a community-oriented and relationship-centered opinion rather than an individual opinion. The score for 'Assertion' and 'Maintenance of relationships' reflect a tendency of the Japanese to not insist upon their own opinion and the importance they place on cooperation with others.

Our results suggest that a tendency towards self-monitoring in interactive situations is associated with an effective influence on social skills. In the CBSMS subscale 'Behavior monitoring' was correlated with 'Decoding' on the SSSA subscale. Items in the 'Behavior monitoring' subscale, indicate tendencies of the ability to adapt one's behavior according to a particular situation, and items in the 'Decoding' subscale indicate skills to interpret the mental states of others. Where there is a strong tendency to adapt one's behavior to a particular situation, there is an accompanying high level of skill to interpret the mental states of others (intentions, desires, expectations) and understand the social expectations.

The CBSMS subscale 'Behavior monitoring' was significantly correlated with the SSSA subscale 'Maintenance of relationships', for which the items are about adapting ones behavior to suit the social context that one is in. Our results demonstrated that a strong tendency to adapt behavior is associated with social skills that are thoughtful and considerate of others.

Implication: Problems arising from interpersonal interactions are one of the major causes of stress and trouble in daily life. This problem is particularly acute in Japan because of its strongly group-oriented culture. In order to promote mental well-being and it is important to address such problems. Self-monitoring is an important character trait in an interactive situation as it serves to adjust a person's behavior appropriately to the situation. Thus, for people with difficulty in interpersonal relationships it is important that they have support available to help them develop self-monitoring and social skills.

Acknowledgement: This study received Japan Academy of Psychiatric and Mental Health Nursing grant (2016). This abstracts got the English proofreading by Thomas D Mayers, Assistant Professor, University of Tsukuba Faculty of Medicine, Medical English Communications Center.

Unspoken: Decreasing Attitudes of Stigma Towards Obese Women By Healthcare Providers

Mary Ellen A. Burke, MSN, RN, CNM, USA

Abstract

There is evidence of significant implicit and explicit bias towards obese individuals by health care providers (Sabin, Marini, & Nosek, 2012). Goffman's theory of stigma states that when a person is perceived different from others in a negative way, they become discounted as a full person. Stigma is a relationship between an attribute and a stereotype (Goffman, 1963). Adult obese women may delay or avoid gynecological care due to stigma secondary to implicit or explicit bias of health care providers, exacerbated by societal stigma, resulting in decreased empathy caused by lack of knowledge and training about the care of obese women (Mold & Forbes, 2013).

This will be a quality improvement project with a pre and post test of explicit and implicit bias of health care providers in an OB/GYN practice. The post-test will be conducted after an intervention that includes provider education on improving the environment of care for obese women as well as viewing a video of obese women's experience of stigma and bias in the health care setting. Data about explicit and implicit bias will be collected from providers. Demographic data about providers will be collected including professional role, age, gender, years of practice, race, ethnicity, and BMI. The Implicit Association Test for obesity and the Anti-fat Attitudes Test for explicit bias will be administered pre and post intervention. The Implicit Association test has been validated by a multitrait, multimethod validation that has found the instrument to be a credible measure of implicit attitudes (Nosek and Smyth, 2007). The Antifat Attitudes Test of explicit bias has 47 items in 3 major categories found to have r values $>.60$ validating the acceptable quality of this instrument (Lewis, Cash, Jacobi, & Bubb-Lewis, 1995). Data will be collected and the educational intervention will be facilitated over approximately 1 month at a chosen OB/GYN practice.

The goal of this project is to improve the quality of care and empathy towards obese women by health care providers in an OB/GYN practice through provider education about experience of obese women who receive healthcare and provision of resources to improve comfort and quality of care to obese women in an OB/GYN practice.

The Risk Factors Affecting Survival in Colorectal Cancer in Taiwan

Shu-Fen Wu, MSN, RN, Taiwan
Chao-Hsien Lee, PhD, Taiwan
Shu-Chen Cheng, MS, RN, Taiwan
Hong-Yi Tung, MS, MD, Taiwan
Shih-Chang Chang, MD, Taiwan
Ching-Yun Ching, BSN, RN, Taiwan

Abstract

Background: Colorectal cancer (CRC) is the second and third most commonly diagnosed cancer type in females and males, respectively, representing almost 10% of the global cancer incidence. The incidence of colorectal cancer (CRC) in Taiwan is rising. Cancer survival is an indicator of the overall effectiveness of health services in the management of patients. In this study, we sought to determine the five-year survival rate of patients diagnosed with CRC and to determine factors affecting survival. **Methods:** In this study, we conducted a single-center, retrospective cohort study to estimate the survival outcome of patients diagnosed with colorectal carcinoma at medical center hospital in North Taiwan between 2007 and 2013. Data were extracted from medical records and the cancer database by trained data collectors. In all, 869 patients with CRC were included in this study. Survival analysis was performed using Kaplan-Meier curves, and differences between the curves were analyzed using the log-rank test. Cox proportional hazards regression models were used to analyze survival by each variable. **Results:** We retrospectively evaluated 869 CRC patients from 2007 to 2013. Of these, 454 subjects were males (52.24%), and the remaining (47.76%) were females. The mean and median ages at diagnosis were 63.70 years (SD = 0.45) and 64 years (range, 17-97), respectively. The mean survival time was 71.27±1.27 months. CRC-specific survival was 95.3%, 79.4% and 68.7% at 1, 3 and 5 years. The five-year survival rate for patients with stage I, II, III and IV disease was 91.20%, 82.20%, 63.20% and 21.70%. The Cox forward stepwise regression model revealed a significant potentially curable disease and risk of CRC death. The following factors were associated with a relative excess hazard for death: age ≥ 65 years (HR = 2.36, 95% CI: 1.76 - 3.17, $P < 0.001$); high grade of pathological differentiation (HR = 1.84, 95% CI: 1.27 - 2.66, $P = 0.001$); perineural nerve invasion (HR = 2.90, 95% CI: 2.03 - 4.14, $P < 0.001$); metastasis to distant organs (HR = 2.78, 95% CI: 2.00 - 3.87, $P < 0.001$); intestinal obstruction (HR = 1.38, 95% CI: 1.04 - 1.84, $P = 0.026$); and multiple regional lymph node metastases (HR = 1.81, 95% CI: 0.28 - 2.57, $P = 0.001$). **Conclusion:** Long-term survival from colorectal cancer remains good with 68.7% of patients being a live five years after their diagnosis. In this study, we found that perineural nerve invasion, distant metastasis, age, pathological differentiation grade, obstruction and regional lymph node metastasis are independent predictors of the survival and prognosis of patients with CRC. Perineural nerve invasion and distant metastasis appeared to be important prognostic factors affecting the entire patient cohort, and the earlier detection of CRC would improve patient survival. One limitation of this study was the small sample size; in addition, the findings were generated using data from a single medical center hospital in North Taiwan. Thus, the results of some survival comparisons were not significant. These limitations should be considered when applying these results to other districts in Taiwan that may have demographic differences. Furthermore, multicenter studies should be conducted to merge patient datasets for further research in Taiwan.

EBP PST 2 - Evidence-Based Practice Poster Session 2

From Novice to Competent: Developing an Innovative Nurse Residency to Increase Confidence and Job Satisfaction

Karri Davis, DNP, RN, NE-BC, USA

Peg Parniawski, MSN, RN, NE-BC, USA

Meredith Wallace Kazer, PhD, APRN, FAAN, USA

Abstract

The purpose of this presentation is to highlight the innovative components of a nurse residency program including how each of the residency sessions are comprised of all of the following: a specific body system and the associated disease processes, patient experience segments, simulations, tales from the bedside: discussing challenging first year situations, support, mentoring, journaling, case studies, and senior executive leadership segments to promote a global healthcare perspective. The goal of this evidence-based project was to improve nursing confidence and job satisfaction.

New graduate nurses today are entering healthcare at a time when the Affordable Care Act has created the need for rapid changes in care delivery. Patients are admitted to the acute care setting requiring highly skilled, complex medical and nursing care. Hospitals are faced with trying to provide treatment for these patients using evidence based best practices while maintaining economic viability. Registered nurses utilize critical thinking in conjunction with policies, procedures, and care pathways to provide safe and effective patient care in an often-stressful environment. New graduate nurses are expected to care for these complex patients just as their experienced counterparts while still learning how to function as a novice nurse. New graduate registered nurses experience a 6-9 month "honeymoon" phase as they transition into their professional role. At the end of this phase, new nurses lose confidence as they realize the expectations of the role based on educational preparation did not meet the actual required responsibilities of the position. The concept of reality shock was just accepted as an inevitable part of the profession (Stacey & Hardy, 2011). Decreasing new graduate turnover is a priority in order to decrease the direct and indirect costs associated with replacing the nurse.

Initial job satisfaction, retention and workforce engagement are directly linked to the initial employment experience. New graduate nurses transitioning into the professional role of registered nurse have verbalized a variety of concerns that would benefit from the additional support of a nurse residency program. Issues, many of which increase dissatisfaction, include: workplace stress, physician communication (Zinsmeister & Schafer, 2009), high performance expectations, increased accountability relating to quality indicators, inadequate preparation (Reinsvold, 2008), fear of making a mistake, interpersonal conflicts, bullying, or incivility (Danque, Serafica, Lane, & Hodge, 2014), delegating to unlicensed personnel, managing multiple priorities of the patients and families (Anderson, Hair, & Todero, 2012) and a general lack of confidence to organize and manage the workload (Dyess & Sherman, 2009).

Nursing administration and education has the unique opportunity to improve, advance, and promote the profession of nursing (Phillips & Hall, 2014). There is a well-documented body of evidence surrounding the positive results of a year-long new graduate nurse residency program including confidence, decreased turnover resulting in cost savings, increased retention rates, and job satisfaction (Ulrich, Ashlock, Kroek, Africa, Early, & Carman, 2010). There is a gap in the literature that includes all components of the residency program that encompassed the success. This interactive presentation of the Medical Surgical Nurse Residency Program created to meet the needs of the new medical surgical nurse will use lecture, videos, and audience participation in a low fidelity simulation to discuss the development and implementation of a successful, cost effective, nurse residency program. The design and content outline of the residency program will be shared in depth including and how each of the residency sessions are comprised of all of the following components:

- A specific body system and the associated disease processes
 - Gastrointestinal (GI): GI Bleed, Nutrition, Colitis, Liver Failure, Colostomies, etc
- Patient experience segments

- “I woke up with a colostomy” –Residents wear a colostomy filled with chocolate pudding for the day.
- Simulations
 - NG Tube placement during a GI Bleed
- Case studies
 - The patient with Liver Failure
- Tales from the bedside: discussing challenging first year situations
 - Has anyone made a medication error? Let’s talk about it.
- Support
 - You are doing a great job; I heard last week about how well you did with that patient and the family
- Mentoring
 - Senior leaders offer during presentations
- Journaling
 - Write about how you applied what you learned today to improve patient care
- Leadership segments: From Bedside to Boardroom

Examples: Finance, political advocacy, quality, regulatory agencies, and risk management are presented by directors and senior executives to promote the global perspective beyond the bedside into the boardroom and provide a knowledge base for growth to future leadership positions.

The implementation of this evidence based project also fostered the opportunity for further research. A quasi-experimental design was used. The survey tools used are available from the American Academy of Medical Surgical nursing entitled Confidence Scale for New Nurses Scale and Job Satisfaction Scale. The surveys use a Likert Scale to measure confidence and job satisfaction. The surveys were determined to have psychometric validation prior to use. Power analysis revealed that an n of 19 would achieve statistical significance however this project achieved an n of 31 participants. Participants were surveyed prior to the start of the program, at the halfway point of the program, and at program completion. Descriptive statistics were utilized to analyze demographic data. Bonferroni ANOVA analysis was utilized to measure mean differences amongst nursing confidence and job satisfaction over the one year with a P = 0.001 through the first two cohorts. The presenters will share both quantitative and qualitative data from the first two cohorts of this evidenced based; quality improvement project.

Meeting the Needs of Women Veterans in Civilian Primary Care Practices

Alicia Gill Rossiter, DNP, FNP, PCPNP-BC, FAANP, USA
Catherine G. Ling, PhD, FNP-BC, FAANP, USA

Abstract

Problem/Purpose: Women are the fastest growing segment of the veteran population—approximately 1.8M are currently serving in the armed forces and 220,000+ have deployed in support of the wars in Iraq and Afghanistan. Women are now eligible to perform duties in more than 90% of all military career fields. Women in the military have steadily progressed from serving in support roles to serving in combat support roles to ultimately evolving to women currently serving with men, not only in combat zones, but in wars where there is no defined frontline, thus placing them in the direct line of fire. Due to the influx of women serving during this latest conflict and the increase in the number of women veterans seeking care in Veteran Administration (VA) clinics requiring a wide variety of physical and psychological health services, women veteran health issues have become a population of interest for the VA and the Department of Defense (DoD).

The DoD has prioritized programs to address rising rates of veteran homelessness, divorce, and suicide. The Institute of Medicine (IOM) and Congress have indicated a need for increased funding for educating health care providers to care for veterans to minimize enduring military service related physical and psychological co-morbidities. These issues appear to be increasing amongst the women veteran population. According to a study conducted by the VA, women veterans are “2.1 times more likely to be homeless than their nonveteran counterparts” and regardless of age or race, all women veterans are at an increased risk from homelessness⁴. In 2010, the Pentagon acknowledge concern regarding the divorce rate of women in the military—7.8% of women as compared to 3% of men in the military. The rates of divorce among women in the enlisted corps are estimated to be slightly higher at approximately 9%. Finally, according to a 2015 VA report, the risk of suicide for women veterans ages 18-29 is 12 times the rate of non-veteran women. Between 2000 and 2010, suicide claimed the lives of more than 170,000 veterans of which suicides among female veterans rose by 40 percent during the decade. A study conducted by the VA looked at the differences between male and female OEF/OIF/OND veterans and VA healthcare utilization for mental and physical health services and results showed that women had more visits to primary care and mental health clinics as well as higher use of community care outside the VA.

The realization that women veterans' healthcare needs are inherently different than male veterans and an increase in women veterans seeking care in the civilian sector has created a need for increased knowledge and expertise regarding identification of women veterans in civilian healthcare practices as well as a need for continuous improvement and evaluation of women veteran specific services. Studies show that less than 20% of all veterans are actually seen in the VA Health care system by providers who are aware and knowledgeable about their patient's military status and possible service connected risk factors and exposures. This leaves roughly 80% of veterans, many of whom are women, receiving care in the civilian sector where military status and women veteran specific healthcare needs are unknown to providers.

Fredricks et al., 2015 concluded that more than half of the 141 physician respondents they surveyed were not comfortable discussing health-related exposures and associated risks experienced by veterans and more than half expressed unfamiliarity with referral/consultation services available to veterans. There is a lack of knowledge regarding the military, the military culture, and the effect of military service on the overall mental and physical health of veterans, in particular women veterans, which leaves the veteran at a significant disadvantage in regards to their overall healthcare needs. Women veterans have unique physical and psychological healthcare needs that vary from their male counterparts and it is important that civilian healthcare providers are educated on the importance of screening women for military service and are aware of the unique healthcare needs of this population.

Methods: This study will pilot test a 42-item survey amongst a minimum of 100 APRNs who are members of the AANP. The sample will include APRNs who are at least 18 years or older. We will recruit from AANP by posting recruitment e-flyers through the AANP listserv. The survey link will be included on the recruitment materials. Data will be collected from an online survey posted on Qualtrics and all data will be collected anonymously.

Results: The study is currently in progress. To our knowledge this will be the first study looking at the knowledge and comfort level of Advanced Practice Registered Nurses caring for women veterans in civilian clinical practice. Based on data from the Fredricks et al. study, the investigators on this study hypothesizes that knowledge and comfort level of APRNs regarding caring for women veterans will have less knowledge and a decreased comfort level in regards to women veterans specifically than veterans as a whole.

Discussion: The Joining Force campaign developed by First Lady Michelle Obama and Dr. Jill Biden challenged colleges of nursing around the country to work to improve the healthcare of our veterans. To date over 660 nursing programs in all 50 states have joined forces to include veteran centric healthcare issues into nursing and advanced practice nursing curriculum with several colleges including specific needs of military families in their curriculum. In 2012, the American Academy of Nursing launched the "Have You Ever Served in the Military" campaign to meet the needs of veterans receiving care in the civilian health care system. While much work has been done, much work is still needed. APRNs are on the frontlines of healthcare often working in clinics, hospitals, and community agencies, and may be the first to encounter a woman veteran in crisis or experiencing physical and/or psychological co-morbidities secondary to their military service. Due to the potential correlation between military service and physical and psychological comorbidities, it is imperative for all healthcare providers to screen women patients for a history of military service and to be educated provide appropriate care and the knowledge regarding resources and referrals available to women veterans in the community. Prompt identification and treatment is imperative to decrease deleterious health consequences related military service and to improve the care women veterans receive in the civilian sector.

Meeting the Needs of Women Veterans in Civilian Primary Care Practices will help assess the knowledge gaps of Advanced Practice Registered Nurses (APRNs) in regards to women veteran health issues. Data gained will be used to promote early identification of women veterans in civilian clinical practice where upwards of 80% of veterans receive their care. This study will help bridge the knowledge gap of civilian providers regarding military service related risk factors and co-morbidities as well as knowledge regarding referral sources/resources in the community that would improve health outcomes of women veterans and their family members. This study has the potential to decrease the impact of homelessness, post-traumatic stress, military sexual trauma, suicide, and other co-morbidities women veterans' experience.

Conclusion: The number of women veterans in this country has increased significantly since the onset of OEF/OIF/OND. They have answered our nation's call to defend our country. Sadly, by doing so, many are at risk for service connected physical and psychological health issues that go undetected in civilian healthcare facilities due to the lack of knowledge and comfort level of civilian healthcare providers. There is a lack of knowledge regarding the military, the military culture, and the effect of military service on the overall mental and physical health of veterans, in particular women veterans, which leaves the veteran at a significant disadvantage in regards to their overall healthcare needs. Women veterans have unique physical and psychological healthcare needs that vary from their male counterparts and it is important that civilian healthcare providers are educated on the importance of screening women for military service and are aware of the unique healthcare needs of this population. It is imperative that APRNs understand the need to screen every patient, especially female patients, for a history of military service as well as receive education and training regarding the unique healthcare needs of women veterans; their risk of trauma, subsequent PTSD and other psychological co-morbidities; identification of physical co-morbidities secondary to military service; and have access to evidence-based clinical practice in the civilian sector where most women veterans receive care. This study will close the gap surrounding knowledge deficits by providing colleges of nursing, state licensure boards, veteran healthcare related stakeholders, and national agencies and provide data and guidance for inclusion of evidence based veteran centric

healthcare, to include women veteran specific healthcare, into education, training and certification programs for APRNs.

Impact of Cultural and Linguistic Diversity on Success of the First Attempt of the NCLEX-RN®

Ernestine Cuellar, PhD, RN, PMHCNS-BC, USA

Abstract

Schools of nursing and nursing faculty are struggling with high attrition rates and low NCLEX-RN first time pass rates. Many of the students identified among those with high attrition rates and low NCLEX-RN pass rates are culturally and linguistically diverse (CLD). Census data has identified a significant change in the cultural and linguistically diverse composition of the United States. Languages currently spoken in homes among CLD students in the United States include Spanish (73%), Vietnamese (2.7%), Chinese (2%), French/Haitian (2%), Hindu (2%), Korean (1.5%), Arabic (1.2%), and Russian (1%). The proportion of births among those who are from non-English speaking backgrounds is increasing; therefore our student population is representative of this growing demographic. Currently in some classrooms there are as many as 5 to 10 culturally and linguistically diverse students, representing different cultures, in one class. Students often find themselves in situations where they have difficulty understanding the accents of their peers (Rogan, Miguel, Brown & Kilstoff, 2006). There is also an increase in male nursing students that may also impact cultural diversity in the classroom. Many culturally and linguistically diverse students as well as those who are not challenged by culture and language (males, Native Americans, blacks) describe the need for emotional and moral support.

Most often CLD is used to define students whose linguistic interactions are different in comparison to other individuals in a given environment (Barrera & Cosco, 2003). Even though some blacks, Asian Americans, Pacific Islanders, Hispanic Americans, and Native Americans, may fall into this category, faculty must thoroughly investigate before automatically assuming by skin color or family history that a student is CLD. Even though there are studies that support the idea that black students speak English as a second language (Goff, Martin & Thomas, 2007); that assumption is not representative of all black students. In 1996, the Reverend Jesse Jackson stated, "Black youths around the nation need to be challenged to speak proper English," so they may be accepted into colleges and universities (Lewis, 1996). Each student must be assessed individually to determine that student's proficiency with English. Many students from diverse backgrounds are culturally acclimated; therefore we need to ensure that we address the needs of those individual students who are experiencing difficulty in the realm of CLD.

The most significant factor that impacts student success is the personal and academic relationship developed between faculty and students (Burnette, 1999). It is strongly recommended that faculty focus on how students learn so that didactic activities are focused on the skills that best address the student's needs (1999). Unfortunately incivility among students and faculty hinders the learning process. Often students are marginalized because they are identified as CLD (Altmiller, 2012; Clark, 2009; Jenkins, Kerber & Woith, 2013). There is a strong need to increase awareness of incivility among nursing students and faculty in order to adapt appropriate skills that accommodate teamwork within both clinical nursing and academic settings. Since the 1960's studies have been conducted that focused primarily on identifying and defining bad behaviors, but these studies fell short of providing meaningful evidenced-based intervention solutions. A new educational modality grounded on evidence-based research is vital to intentionally increase awareness of incivility, change negative behaviors, and influence teamwork within the clinical setting and the nursing curriculum.

Students identified as CLD may speak English but have difficulty with reading and remediation. Those students may not understand idioms or jargon in books or audiovisual aids, in addition to test questions. Some students from other cultures were educated in systems that taught students to memorize and regurgitate information rather than to think critically. Therefore it is the responsibility of faculty to assist students in developing critical thinking skills as well as to learn the new language. In nursing the most important component of learning is the need to learn to use information in the real world rather than to memorize" (Cohen & Rotem, 1983). NCLEX-RN is an assessment of the graduate nurse's ability to think critically so that patients receive safe care.

Nurse scholars have addressed multiple strategies to address retention that are focused on one or two elements. However, retention, graduation, and NCLEX-RN success encompass multiple entities. Faculty-student relationships, family support, student population (diverse CLD population) civility in the classroom and clinical setting, remediation, and student self-confidence are all components of student success. Very little literature addresses the intersection of these dynamics and the role of the intersection of these entities.

Stress, Burden, and Health Status in Caregivers of Heart Failure Patients

Ya-Ching Liu, MBA, RN, Taiwan

Abstract

Background: Exploring the relationships between stress, burden, health status and disease prognosis in patients with heart failure will help to improve the care cognition in caregivers of heart failure patients. In this study, we tried to investigate the stressors, load, and health-related factors of major caregivers in patients with heart failure

Methods: During a period of one year, a total of 116 participants was recruited. A descriptive method, structured questionnaires and physiologic variables were conducted in this cross-sectional study. Received the location for the Cardiology Department of Cardiology and Cardiology Internal Medicine ward. The participants were the caregivers of patients with heart failure with grade II-IV according to the New York Heart association classification of heart failure. Patients with heart failure at least 1 year of illness, and their caregivers meet the above conditions. The assessment items included the stressors, load, health status and life quality. The blood cortisol level was also done. Using multiple regression analysis to analyze the relationships between the three main independent variables and the quality of life and Pearson's correlation was used to examine the correlation between the three principal independent variables from SF-36.

Results: The results showed that when the caregiver's stress level and load level are higher and the quality of life will be worse, especially in the psychological and physical aspects of quality of life. In addition, the blood cortisol levels of caregivers had negative correlations with the scores of physical functioning, role-physical, mental health, vitality, general health, Physical and Mental dimensions from SF-36. On the other hand, the higher the time load of the caregiver, the more likely the patient's health including the items of physical functioning, bodily pain, mental health, general health and Physical and Mental.

Conclusions: The results of this study may provide the nursing staff to assess the care and health aspects of caregivers, handle the stress of caregivers in caring and improve the quality of care of patients with heart failure.

Everything is Alright: Teaching an Online Nursing Course Using Technology

Cynthia A. Bautista, PhD, RN, CNRN, SCRN, CCNS, ACNS-BC, FNCS, USA

Abstract

This evidence-based educational project was to facilitate nursing students' learning and mastery of course outcomes by using a variety of technological applications for online nursing courses. Nursing faculty were challenged by the Academic Computing Department to improve student's engagement and satisfaction for their online courses. The Center of Academic Excellence at the university provided a 3-day course to learn about the variety of technology tools available to engage students in an online course. Online course nursing faculty used the technology tools to re-design their online courses using reverse course design. A variety of technology tools addressed the learning styles of nursing students as well as motivated them to participate online. These technological tools made the online course more meaningful to the students by encouraging collaborative-based learning peer interactions. Nursing faculty found the use of interactive technology in an online nursing course, fostered nursing students learning, engagement, and satisfaction.

Online course nursing faculty were very satisfied integrating a variety of technology tools to engage their online nursing students in meaningful learning. Collaborating with the Academic Computing Department provided a positive experience for online course nurse faculty to revise their online course to engage their students. Nursing students were satisfied and became more engaged in the online course activities to achieve successful completion of their course. Using the technology tools, online nursing students were able to learn together and from each other. Both nursing faculty and students developed strong connections with the use of technology tools in an online course.

Online course nursing faculty should assess technology tools that are available to engage the 21st century learner. Nursing faculty should select the technology tool based on the course outcome they are trying to achieve. A variety of technology tools should be integrated into online nursing courses for nursing faculty and students to achieve successful course objective outcomes as well as active participation.

Using Focus Groups to Explore the Facilitators and Barriers of Evidence-Based Nursing Among Clinical Nurses

Ling-Yu Wu, MSN, RN, Taiwan
Ching-Tai Hsu, MSN, RN, Taiwan

Abstract

Background: The research on the facilitators and barriers of implementing evidence-based nursing (EBN) by nursing staff has been discussed overseas currently. However that application is limited for the clinical situations in Taiwan due to cultural context differences. Even though there have been a few domestic studies exploring the facilitators and barriers when implementing EBN by nursing staff, the results were not consistent. The use of focus groups approach of the qualitative research is supposed to be helpful to comprehensively understand the facilitators and barriers of EBN by nursing staff and then to effectively promote the practice of EBN.

Aims : This study will explore the barriers and facilitators affecting the evidence-based practices in order to find out the integrated models and strategies on evidence-based practices by using a qualitative research approach -focus groups among the seeded nurses of a teaching hospital.

Methods: Data will be collected by using focus groups with purposive sampling of recruiting evidence-based seeded nurses of our hospital. They are in high homogeneity and grouped into 4 to 5 focus groups by medicine divisions. Each group consists of 4 to 6 people in turn to be interviewed for 60 to 90 minutes per time section. In each focus group, an independent moderator will instruct the guidelines with 7 semi-structural issues that were examined by 2 qualitative experts beforehand. The reliability (trustworthiness) proposed by Lincoln and Guba is expected to adopt as the stringency control. Also, a content analysis will be conducted on the data obtained.

Anticipated outcomes: The focus groups will be organized between December 2016 and May 2017. The expected results is to find out the integrated models and strategies on promoting the evidence-based practices and present it as the reference for the study hospital as well as other domestic hospitals to further promote the implementation of EBN practices and enhance the effectiveness of patient care domestically.

The Relationship Between Activities of Daily Living and Depression Among Community-Dwelling Older Adults

Myoungjin Kwon, PhD, RN, Korea, Republic of (South)

Youngshin Song, PhD, RN, Korea, Republic of (South)

Kawoun Seo, MSN, RN, Korea, Republic of (South)

Abstract

Background and purpose: Depression has recently become a major public health concern, not only to personal suffering but national economic burden that related morbidity and increased mortality. Physical function such as daily activity have emphasized to reduce the depressive symptoms for older adults who cognitively intact in community-dwelling. Studies have proved physiological mechanism of physical activity that not only associate with depressive symptom, but also mediate the relationship between depression and cognitive decline. Despite accumulative evidence showing the interrelatedness between depressive symptoms and ADLs among older adults, the strength of the association may differ depending on sample characteristics and methodology across the studies. For instance, the strength of the relationship between depressive symptoms and ADLs in aged living at home showed the weak correlation than in institutionalized older adults despite of similar cognitive status. Thus, this study examined this relationship among community-dwelling older adults, via a systematic review and meta-analysis. We synthesized the information obtained to calculate the strength of the relationship.

Methods: Systematic review and meta-analysis were conducted to search the existing published observational literature using 5 electronic databases. Published and unpublished studies measuring the direction and strength of the relationship between depressive symptoms and ADLs were independently extracted by the researchers. Several electronic databases, such as PubMed, EMBASE, PsycINFO, the Cochrane library, CINAHL, and Medline, were used. MeSH terms such as "Aged"[Mesh] OR "Aging"[Mesh] OR "Housing for the Older adults"[Mesh], "Depressive symptoms"[Mesh] OR "Depressive Disorder"[Mesh] AND "Activities of Daily Living"[Mesh] were used to retrieve relevant articles from June 2005 to June 2015. Studies reporting *r*-values between depressive symptoms and the ADLs of older adults were included in the meta-analysis. relationship is affected by various factors of interest, such as sample and study characteristics.

Results: Of total 11840 studies, 16 studies that reported the association *r*-values were included in the meta-analysis. A total of 7184 older adults participated in 16 studies, with sample sizes ranging from 44 to 1308. Among the 16 studies, three were designed as longitudinal surveys and the design of remaining studies was cross-sectional. The mean ages of the participants included in these studies ranged from 63 to 84 years. No significant bias was observed for the included studies. The quality of the 16 included studies was assured using the appraisal tool for descriptive/cross-sectional studies. The overall effect size suggested a moderate association between ADLs and depressive symptoms among older adults. The strength of the relationship between ADLs and depressive symptoms tended to be larger in studies in which the majority of the participants were female, under 75 years, and not Asians population. The effect size of residing in a senior residence was significantly greater compared to those studies in which the participants were living at home.

Conclusion: Based on these findings, we provisionally conclude that there is a significant negative association between ADLs and depressive symptoms, and this relationship is of moderate strength. Further meta-analysis should be conducted to confirm this relationship by using data accumulated from individual studies.

The Doctor of Nursing Practice: Promoting Partnerships and Reducing Health Disparities Among Vulnerable Populations

Charlene D. Whitaker-Brown, DNP, MSN, FNP-C, USA
Judith B. Cornelius, PhD, MS, RN, USA

Abstract

The purpose of this presentation is to describe how a collaborative environment was created between two universities to support Doctor of Nursing Practice (DNP) students as they build their programs of scholarly activity to meet the needs of our vulnerable populations.

The University of North Carolina at Charlotte (UNC Charlotte) and Western Carolina University (WCU) established a partnership called the UNC Charlotte/WCU Dual DNP program, awarding the terminal degree of the DNP. Together these two institutions connected to provide the context for the Dual DNP program development, implementation and evaluation.

UNC Charlotte is North Carolina's urban research university. Located in the state's largest metropolitan area, UNC Charlotte is among the fastest growing universities in the UNC System (UNCC, 2016). In contrast as the westernmost institution in the University of North Carolina system, WCU provides comprehensive educational opportunities to residents in the state's western region and attracts students from around the globe to explore the region's natural diversity. Founded in 1889 Western Carolina now provides an education to more than 10,000 students in undergraduate and graduate programs (WCU, 2016).

This is a case history describing the innovative approach of the collaborative process two universities shared to build a growing and successful accredited DNP Program. The first step in developing a successful collaborative environment was planning the partnership. Next, effective approaches in assisting students with their scholarship were identified. DNP students were encouraged to engage in interdisciplinary, scholarly work as they expand and improve innovative methods to deliver care to our most vulnerable populations. Finally, program evaluation was significant in the identification of critical elements of an effective partnership.

Universities must provide the needed opportunities, resources, and mentoring to support both faculty and their students. Successful inter-institutional collaboration and university investment in the development of the Dual DNP Program has helped to increase the knowledge and skills of DNP students as they build their programs of scholarly activity to effect change in vulnerable populations served.

Introducing Simulation to BSN Students and Faculty Situated in a Rural Setting in North India

Jill B. Derstine, EdD, MSN, BSN, RN, FAAN, USA
Marylou K. McHugh, EdD, MSN, BSN, RN, CNE, USA
Leland J. Rockstraw, PhD, MSN, BSN, RN, USA

Abstract

This presentation will describe a cross-cultural experience in which nursing educators from Drexel University conducted a nursing simulation workshop at Akal College of Nursing in Baru Sahib, India. As part of an on-going collaboration between Drexel and Akal, an experiential simulation workshop was conducted for Akal nursing students and faculty and visiting students and faculty from northern India. Morning lectures were followed by two simulation exercises: (1) nursing students participating in a birthing simulation using a birthing simulator, and (2) using students from Akal Department of Education as patient actors who portrayed a patient whose health history was taken by an Akal nursing student. Using two birth simulators, simulation exercises were presented that were congruent with the nurse's work with pregnant moms in rural villages. Groups of students were able to safely practice birthing a baby, educate the parents, and negotiate with the demanding father in the simulation setting. The simulators were donated to the college with the expectation that they would be not only be used to teach nursing students but also used to allow students/faculty to teach expectant mothers in the surrounding rural community. In the patient actor simulation experience, nursing students interviewed the "patients" in individual cubicles. Debriefing sessions to promote learning and critical thinking were led by the three facilitators. Students shared their thoughts and feelings about the exercises. Interestingly enough, the Department of Education Students who were the actors were just as enthusiastic about the learning and felt that they were able to apply the learning methodologies to their education practice. Nursing students at Akal have an extended community experience which includes following families throughout their four years. All students learn midwifery and can be involved in births in the community setting. Follow up activities to this workshop included a return visit within six months by two nurse midwife faculty members who assessed use of the simulators by students in the community. In another recent follow-up visit, the concept of setting up scenarios for student learning was taught to all faculty including newly hired faculty. Four young faculty began the process in October. This workshop is just one example of the successful collaboration between a private university in the United States and a faith-based university in an isolated area of northern India.

EBP PST 2 - Evidence-Based Practice Poster Session 2

A Phenomenological Exploration of the Experience of Antepartum Bed Rest in Mothers: Beyond Postpartum

Gwendelyn S. Orozco, MSN, RNC-OB, USA

Abstract

Background APBR in high- risk pregnancies such as premature rupture of membranes, pre-eclampsia, preterm labor, and advanced cervical dilation/effacement is the current prescription for the prevention of preterm birth. This prescription of bed rest is practiced by 71-81 percent of United States Obstetricians (Maloni, 2012). The current preterm birth rate remains high at 11.4 percent (World Health Organization, 2014 [WHO]).

The March of Dimes Prematurity Campaign aims to reduce preterm birth rates across the United States. Premature Birth Report Card grades are assigned by comparing 2014 preterm birth rate in a state or locality to the March of Dimes goal of 8.1 percent by 2020. This will inevitably increase the number of women who are prescribed APBR. Pregnant women who are at risk of delivering a preterm infant are hospitalized and placed on bed rest. Current evidence demonstrates that prolonged time on bed rest can have physical as well as psychosocial effects (Maloni, 2012). APBR as a treatment is based on the assumption that it is both safe and effective (Maloni, 2011). However current evidence based research indicates that bed rest treatment is ineffective in preventing preterm birth (Maloni, 2011). Psychologically, AP patients hospitalized on bed rest report higher feelings of anxiety and depression (Dunn, Handley, & Shelton, 2007). Physiological side effects include muscle atrophy, bone loss, and maternal weight loss (Maloni, 2011). Despite the questions regarding the effectiveness of APBR, as well as the negative psychological and physiological consequences, it is still widely practiced in the United States and Canada. Although there is no other therapeutic alternative, APBR is offered by physicians as a natural inclination that doing something is better than doing nothing (Biggio, 2013).

Few Qualitative as well as Quantitative studies are done on the experience of APBR as it relates to the patient when they are in the hospital. However, a limited number of studies are done on how it affects the mother in the postpartum period. In fact, no studies exist on the effects of APBR on the mother who has surpassed the postpartum six week period. This gap in the literature warrants investigating, as the negative long term effects of APBR may surpass the postpartum period for some mothers. These mothers may be feeling isolated as routine postpartum checkups have ceased. There is no research into this untreated time period to inform us of how these mothers feel about the experience.

Purpose The purpose of this study is to explore the long-term effects of APBR from the perspective of the mother who has delivered and transitioned into the home environment. The current state of the science of ante partum bed rest (APBR) provides inadequate articulation of it's long term effects. This research, using a qualitative interpretive phenomenological approach, seeks to discover meaning and extrapolate themes from semi-structured interviews with mothers who have had the experience of APBR.

Philosophical Underpinnings The qualitative phenomenological framework used for this study is Heidegger's Interpretive Phenomenology, which will study the first person's point of view. This research project will explore this from the perspective of the mother, as she interprets the meaning of her experience of APBR. This approach seeks to understand the person's reality, opinions, beliefs, knowledge, and questions pertaining to an experience (Schultz & Cobb-Stevens, 2004).

Methods Van Manen's Thematic Analysis will be used to interpret this research as Van Manen states a person cannot reflect on the lived experience until afterwards and this reflection is always retrospective (Van Manen, 1990). This qualitative framework of interpretive phenomenology provides a lens that allows discovery of essence and personal meaning from the participants' individual experiences (Holloway & Wheeler, 2002). A purposeful sample of 10-20 mothers who have had the experience of hospitalized APBR and surpassed the six week postpartum period will be studied. One on one semi structured interviews using open ended questions are used, tape recorded, and professionally transcribed verbatim.

Recruitment will be used via flyers in doctors' offices, churches, community clinics, and perinatal clinics. Inclusion criteria include women who are 18 years or older, can speak read, and write English, were diagnosed with a high-risk pregnancy and prescribed APBR weeks and maintained hospitalized bed rest at a minimum of 14 days just prior to giving birth and have surpassed the postpartum period of 6 weeks.

Nursing Implications Ways of Knowing Evidence based practice efforts today are what currently drive changes in nursing. The support of research materials that are narrative and subjective are qualitative studies of human experiences. The results of this research study can be used to improve patient outcomes by providing insights into patient needs in treatment and interaction with health professionals; evaluate programs and treatments, gain understanding of health professionals roles and identities; examine the perception and efficacy of professional education; and obtain perspectives on community and public health issues. The nursing implications for nursing science are that this study has the potential to be further researched using different inclusion criteria and populations. This informs nursing practice and provides education of nurses via changes made in nursing administration and leadership through policy changes

Results Pending

Rapid Curricular Innovation Using Lean Methodology

Jennifer L. Embree, DNP, MSN, BSN, RN, NE-BC, CCNS, USA

Abstract

Today's rapidly evolving healthcare environments converging with faculty shortages has the potential to compromise faculty's ability to stay abreast with needed curricular enhancements. The proliferation of doctor of nursing practice (DNP) programs has driven faculty to re-examine the focus for the school of nursing DNP Program. Established with previous grant funding, the DNP program was focused on providing a doctorate level program for nurse practitioners. As the program struggled with enrollment, we looked to clinical partners for assistance. Interviewing chief nursing officers helped identify gaps in the (DNP) curriculum and the transformational leadership skills needed in the current healthcare environment. Since curriculum revision in academia typically involves lengthy discourse, faculty with business acumen sought a faster mechanism to rapid curriculum change. The LEAN methodology was chosen for curriculum improvement. Lean is defined as maximizing customer value while minimizing waste and using fewer resources (Catt, 2014). Creating processes that need less human effort, space, capital and time with less defects and variability is also a benefit of LEAN. The categorized responses from the chief nursing officers were compared to the American Organization of Nurse Executives (AONE, 2011) and the American College of Healthcare Executives (ACHE, 2015) competency categories, and were identified as primary and sub-categories. The sub-categories were rank ordered by how many times they came up in the interviews. A stakeholder assessment was completed to identify necessary participants. Inviting selected stakeholders and led by a chief nursing officer, LEAN methodology guided curriculum transformation. Goals were established for the LEAN project. Curriculum revision was required to meet the community needs. The agreed upon goal was to redesign the DNP Program to proactively meet the current and anticipated future demands for transformational nursing leaders. A new project model and needed curricular enhancements were identified. Course sequence was established. Course modifications were identified. Items for faculty retreat discussion were established. The curriculum was revised using LEAN methodology.

Using the MDS-HC to Assess Health Status and Care Needs of the Elderly Living Alone

Chia-Chi Chang, PhD, RN, Taiwan

Yi-Jung Wu, MS, RN, Taiwan

Li-Min Kuo, PhD, RN, Taiwan

Abstract

The aim of the study was to understand the health status, care needs, and the predicative factors that influence their care needs among elderly living alone. The cross-sectional study was conducted and a total of 151 participants were enrolled. The interviewers assessed their health status and care needs by using MDS-HC instruments. The results indicated that who are predominantly male, widowed, and illiterate or with only an elementary school education; their average age is 82.18 years old. In terms of health, the ADL and IADL function are generally good. The 70.9% of participants was having visual impairment. On average, each person have two chronic disease which are most commonly high blood pressure and cataract. The 13.9% of the participants took at least nine medicines. The 87% of the participants were having poor living environment. Each of them has six to seven care needs. The most important care needs were pain control, social interaction needs, and visual function. There were no significant difference between gender and health status. However, significant differences were founded between age, marital status, education, living conditions and the health status. Regarding the result of the regression, the overall health status can predict the care needs. The main related factors of the predictive care needs, in decreasing order, are teeth ($\beta=2.265, p=0.000$), environmental condition ($\beta=0.563, p=0.000$), social function ($\beta=0.355, p=0.02$), health and preventive care ($\beta=0.128, p=0.05$), medical treatment ($\beta=0.128, p=0.012$), and physical function ($\beta=0.112, p=0.001$). The overall explanatory power is 71.4%.

Based on the study results, we should pay more attention to the condition of their teeth, living environment, social function, and health, as well as preventive care, medical treatment, and physical function. It were suggested about the community health care: (1) provide home care regarding the oral hygiene; (2) assess and improve the safety of living environments; (3) encourage seniors to participate in activities designed for them in order to reduce their social isolation and loneliness; (4) offer elderly people related health examinations and counseling, especially visual and audio and oral checks; and (5) integrate seniors' polypharmacy problem and long-term life care assistance to improve elderly people's quality of life.

EBP PST 3 - Evidence-Based Practice Poster Session 3

Redesign of a Post-Licensure Population Health Course Using an Online Virtual Community Environment

Wendy M. Crary, PhD, RN, CNE, USA

Abstract

For purposes of curriculum assessment, the perceptions of both students and faculty were collected regarding their experience with a virtual community in a population health course.

The research question of the study was: Is the efficacy for the use of a virtual community supported; as the source for gathering information necessary for completion of assignments, and thus achieving student learning outcomes?

History of the problem: The motivation for the curricular change was the need to provide a more standardized learning experience and role specific patient interaction for the students. The necessity for change was identified based on student feedback regarding the challenges faced in arranging a practicum experience, lack of opportunity to apply new learning, and faculty report of inconsistent quality of student work related to those observation-only clinical hours. The faculty felt compelled to explore less traditional approaches for providing the students with: the opportunity for patient assessment, exploration of the community based nursing role and development of a plan of care. The choice to move in the direction of using a virtual experience was based on current literature and in-depth discussion with product providers (Fogg, L., Carlson – Sabelli, L., Carlson, K., & Giddens, J., (2013), Schuster, G., Foret Giddens, J., & Roehring, N. (2011), Cant, R., & Cooper, S., (2014).

A review of the Essentials for Baccalaureate Nursing (AACN, 2008) related to population health and clinical prevention in a community setting informed the review of current student learning objectives and writing of new ones to align with using a virtual community. Once this was accomplished, the next steps in developing the learning plan were to design the learning modules, identify from the chosen web-based program the activities to build assignments, and writing of assignment directions and rubrics. The goal was to achieve a high degree of interaction for the students with the virtual community. A scaffolding approach was followed to place the learning tools and assessments in the course design framework (Salyers, V., Carter, L., Cairns, S., & Durrer, L. (2014). A full course redesign was necessary in order to fully incorporate the scaffolding approach.

The course design moved students through activities beginning at an 'explore new concepts' level of learning, to navigating through the four nurses stories, to linking the nurses work in the virtual program stories to community based nursing role responsibilities and finally patient outcomes. Once these steps in the development were accomplished the course was subjected to faculty peer review. Slight modifications were made, then the course moved to the pilot stage and student review. In the final week of the course a free text narrative question was added seeking student feedback on the virtual community. These entries were compiled into a report for faculty review. A discussion group of teaching faculty yielded suggestions for changes to assignments, placement of assignments within the course and enhancement of rubrics. The responses provided by the students resulted in clarification of instructions for how to access the virtual community, assignment direction and more detail added in the assignment worksheets/tables.

The study results reveal that students encountered initial stress with first time access to the virtual community, but once entering the site they found it easy to navigate, the variety of information and presentation methods was appealing, as was the depth of detail on the nurses and patients. The students also report developing an emotional connection with the characters; even going beyond assigned episodes to find out what 'happened next' to the character. They also recognized that there were aspects of patients' lives outside of their acute care practice setting that have an impact on how an effective plan of care is developed; which they had not considered. Another point of new learning was the breadth of the community based nurses role and the variety of ways they interact with and care for their patients.

Use of Integrative Medicine Approaches for Treating Adults With Sleep Disorders

Chiung-Yu Huang, PhD, RN, Taiwan
Hui-Ling Lai, PhD, MS, MSN, RN, Taiwan

Abstract

Objectives: This study determined the prevalence, perceived efficacy, and influencing factors and evaluated the sources of information as well as the barriers and facilitators for the use of integrative medicine approaches to treat adults with sleep disorders.

Design: A cross-sectional postal survey was conducted.

Setting: The sleep center of a 1100-bed hospital in Taiwan.

Participants: Adults with sleep disorders were purposively selected.

Methods: A questionnaire designed by the researchers was used to collect data regarding the use of integrative medicine approaches within the previous 12 months and regarding the influencing factors. Descriptive statistics and binary logistic regression were used to analyze the data.

Results: The response rate was 94.5% ($n = 515$) among 545 adults. The prevalence for the use of integrative medicine approaches was 53.4% ($n = 275$). The three most perceivably efficacious integrative medicine approaches were qigong, meditation, and acupuncture. Educational attainment, the number of chronic diseases/symptoms, and healthy lifestyles (all $p < .001$) were independent predictors for the use of integrative medicine approaches. The three most common sources of information were television/radio (44%), family/friends (38.9%), and the internet (35.3%). The top three facilitators for the use of integrative medicine approaches were side effects of sleeping pills (51.3%), the perceived efficacy of integrative medicine approaches (36%), and the recommendation of health care providers (19.3%). The top three barriers to the use of integrative medicine approaches were limited accessibility (48.7%), time-consuming procedures (42.9%), and a lack of scientific evidence (41.1%).

Conclusion: Integrative medicine approaches are used by a considerable proportion of adults for treating sleep disorders worldwide. This study provides fundamental information regarding the use of integrative medicine approaches in adults with sleep disorders. Our findings suggest that additional comprehensive studies on the decision-making involved in the use of integrative medicine approaches by adults with sleep disorders are needed.

Traveling Well: Leading Students on the Path to Human Flourishing

Llewelyn Prater, PhD, RN, CNE, USA
Shelby L. Garner, PhD, RN, CNE, USA
Lori A. Spies, PhD, RN, NP-C, USA
Cheryl Riley, DNP, RN, NNP-BC, USA

Abstract

Students enter university today for many reasons. Because many begin this experience as 18 or 19 year old young adults, they are developmentally open to new ideas. Their thought processes are being refined, and they come to university with many questions about who they are and what they actually believe. As a result of these converging factors, faculty are in a unique position to influence, encourage and mentor students not only in their academic courses but in extracurricular pursuits as well. This paper aims to present the philosophical connection between international travel and spirituality and to propose how faculty members can cultivate a richer conception and practice of teaching and learning, particularly in the discipline of nursing. Through understanding the spiritual attributes of international travel, faculty can foster students' ability to develop spiritual intelligence, build transcultural skills and learn cultural humility. The philosophical connection between elements of travel and elements of spirituality is especially important as we help our students learn to attend to themselves as a whole person.

There is a long-standing tradition of global pilgrimage; from treks to Lourdes or Machu Pichu for soul enriching experiences to other sites such as famous museums or ruins (Scriven, 2014; Warfield, Baker, & Fox, 2014; Cousineau, 2012). Many of these journeys are motivated by faith and it is not always the destination but also the journey that is of significance. Spiritual attributes of travel are linked to the desire for personal transformation that can happen when one steps outside the routine of daily life, becomes ensconced in another place and is able to view life from a different perspective.

As faculty, we desire to bring our students alongside us as we live out our passion and profess the tenets of our disciplines. By traveling with our students, either on study abroad, service learning projects, mission trips or field trips, we can help them sort out their experiences and work through the disparities that may exist between students' self-perceptions and actual cultural humility. In this way, travel with our students can be a time of spiritual transformation for both student and faculty member alike.

EBP PST 3 - Evidence-Based Practice Poster Session 3

Professional Development of Nurse Leaders

Jennifer L. Embree, DNP, MSN, BSN, RN, NE-BC, CCNS, USA

Abstract

The purpose of this presentation is to describe curriculum innovation using a strengths-based perspective to develop graduate nurse leader talents and emotional intelligence. Health care reform and the resultant complexity require Registered Nurse (RN) leaders to demonstrate transformational skills (Institute of Medicine [IOM], 2011; Trossman, 2010). Challenges in the health care environment include current and future technologic requirements, escalated pay for performance prerequisites, and retention and recruitment of the nursing workforce (Doody & Doody, 2012). Operating in principal leadership roles, leadership students need professional leadership skills and flexibility in order to facilitate nursing care delivery change in morphing health care organizations. Competencies and expectations that leadership students need to meet future health care challenges include being able to identify personal talents, developing emotional intelligence (EI), and expanding transformational leadership skills. Identifying personal talents and EI is foundational to developing transformational leaders (O'Neill, 2013). Supported in the literature, EI and transformational leadership are essential to enhancing organizational productivity (Weberg, 2010). Preparing graduate leadership students (hereafter referred to as leadership students) to guide nursing transformation is critical to the future of health care and to the 3.6 million nurses in the United States delivering care (ANA, 2016). To provide a foundation for nursing leadership transformational skill development, the Nurse Manager Leadership Partnership's Learning Domain Framework's (NMLP) was adopted. The three spheres of the NMLP are: the science: managing the business; the art: leading the people; and the internal leader: creating the internal leader (Lee, Peck, Rutherford, & Shannon, 2008). Specifically related to the nursing leadership course content were: relationship management, influencing behaviors (the internal leader), personal and professional accountability, career planning, and personal journey disciplines (the art sphere) (Lee, Peck, Rutherford, & Shannon, 2008). Faculty developed learning activities allowed students to customize and integrate their abilities into nurse leaders' personal work roles. Since StrengthsFinder and EI assessments provide participants with their baseline strengths and EI, the results of both assessments provide additional information and opportunities for leadership students' developmental changes (Rath, 2007; Bradberry & Greaves, 2009). Threading self-assessment content into leadership assignments can assist leadership students' integration of learning into their clinical leadership practice. All leadership students described learning in relation to their strengths and EI and the importance of these talents to the nursing leadership role.

Cinemeducation: An Innovative Way to Enhance Nursing Students' Communication Skills

Maureen Hillier, DNP, RN, CCRN, USA

Abstract

Purpose: To evaluate the use of cinemeducation with the integration of a TED Talk and a reflective assignment to augment the standard undergraduate class to teach enhanced communication skills in healthcare.

According to Adult Learning Theory, millennials are most interested in learning subjects that have immediate relevance and impact to their job or personal life (Knowles, 1984). As the standard educational lecture becomes obsolete, the combination of media mixture and practices allows knowledge to be brought to life in the 'flipped classroom' (Friesen, 2011). TED Talks which stands for technology, entertainment and design, allow speakers to present their most compelling innovative ideas, in 20 minutes or less, in a manner that most people can understand (TED.com, 2016).

Methods: Undergraduate nursing students were asked to independently view a TED Talk prior to class and write a brief narrative reflection as part of their assignment for an undergraduate lecture on communication in healthcare. Their reflective responses were assessed by two open-ended questions and were analyzed for qualitative themes. The Facilitator's Guide was used as a springboard in a subsequent session to further encourage a free exchange of ideas about effective communication skills in a healthcare setting.

Results: The TED Talk and reflective assignment was completed by 23/25 (92%) of students of which 100% provided consent to participate in the study. Qualitative analysis of the reflective writing identified three primary themes: Value of Communication, Importance of Empathy, and Professional Role Development. The TED Talk was described by the students as a unique learning experience that modeled inspiration, commitment and empowerment.

Conclusion: When incorporated into an introductory communication class session, TED Talks offer educators a way to provide interactive learning for millennial students. The Facilitator's Guide coupled with reflective writing enhances course content and promotes maximal efficiency of class time.

Practice Implications: As educational programs compete with online and open course-ware, TED Talks provide meaningful no-cost content that can easily be integrated into class discussion, on-line activities and hospital orientation programs. When accompanied by the Facilitator's Guide, this TED Talk provides a compelling form of cinemeducation to encourage nursing students to critically reflect and incorporate effective communication skills, prior to entry into practice.

Transforming DNP Practice Partnerships Through Meaningful Student Initiatives and Structured Collaborations

Mary A. Hooshmand, PhD, MS, BS, RN, USA
Jessica R. Williams, PhD, MPH, RN, APHN-BC, USA
Kenya Snowden, DNP, ACNP-BC, ANP-BC, FNP-C, USA
Cynthia Foronda, PhD, CNE, ANEF, USA

Abstract

The University of Miami School of Nursing and Health Studies (UMSONHS) Doctorate of Nursing Practice (DNP) program has developed a unique approach to practice immersion. During this time, students have been exposed to an increasingly diverse array of educational experiences with a broad range of healthcare partners across local, national, and international communities. The objective is to expand students' leadership skills for serving at the forefront of the 21st century health care system by providing transformational experiences. Ensuring such opportunities remain available for each successive class requires maintaining strong bonds with an infrastructure of health providers throughout the community and continuing to build new networks on an ongoing basis, both through and with our recent graduates. The result is a veritable menu of practice immersion options tailored to each student's needs and program of study. The purpose of this presentation is to discuss the impact of collaborative partnerships involving the DNP prepared nurse with intra and interprofessional colleagues to transform healthcare, identify methods to maximize partnerships, and to further explore the cultivation of partnerships between academia and practice as we develop nursing leaders for the future.

Established in 2009, the UMSONHS DNP prepares students for the highest level of nursing practice and includes an intensive practice immersion experience affording students the opportunity to apply, integrate and synthesize the American Association of Colleges of Nursing (AACN) DNP essentials while participating in practice experiences in a variety of health care settings. Prior to 2013, students identified local projects and preceptors across the community in coordination with faculty. The projects varied in respect to scope, depth and quality of experiences, preceptor qualifications, integrations of the identified DNP essentials, outcomes, and continuity. Challenges included limited access to 'live/ real time' practice improvement projects, lack of visibility regarding the DNP, contrasting/ lack of congruent goals and priorities between academic and practice partners, and a lack of continuity and project development in projects from cohort to cohort contributing to a feel of 'lack of ownership' impacting perceived and real sense of commitment.

In 2012 – 2013, SONHS leadership initiated collaborative meetings across the community and health care organizations to develop a formalized 'DNP Practice Immersion Program' involving multiple sites, formalized collaborative agreements, a menu of ongoing live practice improvement projects, established project criteria with deliverables, business planning components, integrated DNP essential requirements with project elements, and overall developed practice initiatives as a fusion of course objectives, individual student objectives, and agency/ organizational priorities. The program transitioned in 2013 beginning with five practice partnerships and has expanded to 12 practice partners in 2016 with a menu of over 45 'live' practice projects each semester. These projects are predetermined with the practice partners and are subsequently 'matched' with students based on student requests, learning needs and goals, faculty recommendation, agency needs/ requirements, and finally mutual agreement between faculty, student, and agency representatives. Meetings are held regularly between academic and practice partners to review projects, revise current projects integrating updated deliverables, evaluate progress, assure continuity for long term projects, and develop new practice initiatives based on mutual needs, goals, and objectives. This presentation will highlight practice improvement case examples and will provide an update on overall aggregate outcomes of the UMSONHS DNP practice immersion program.

Creating a Successful Online Learning Environment for Introverted Nursing Students

Kathleen Ann Muglia, DNP, RN, APRN-BC, DNP, USA
Melissa A. Murphey, DNP, FNP-C, USA

Abstract

In order to educate more nurses, many nursing instructors are beginning to teach online, often with little instruction on how to teach online or how to teach students with different learning styles. Introverted students may be more drawn to online learning due to the attractiveness of a low-stimulation environment, yet introverts have unique learning needs that instructors are often unaware of. Instructors who understand online pedagogy and create online learning environments with the unique needs of introverted learners in mind, may notice greater student satisfaction and success. How instructors engage with students is an important factor in whether or not a student will be successful. Instructor interaction is a major component in success of online learning (Kim, Hong, Bonk & Lim, 2011). In the traditional face-to-face classroom, nursing instructors can usually identify the introverted students sitting in the back rows of the class. In an online environment however, nursing instructors may have a hard time identifying introverts. Why is it helpful to identify introverted students? Introverts are thinkers and like to take their time when answering in class. Nursing faculty may falsely conclude that the introverted online student is less engaged or less interested if the student is lagging behind others, such as being last to post to a discussion bulletin. Introverts may want to think about their response for a few days before they post their thoughts for others to see. Studies have demonstrated a relationship between learning style and the use of e-learning systems (Clark & Mayer, 2011). Nursing faculty may label the introvert as a “lurker” and assume they are not as engaged as they should be. Student personality has been shown to affect involvement in discussions as introverts prefer written assignments and extroverts may prefer a more “revealing communication medium” (Blau & Barak, 2012). When creating online exercises, introverts may appreciate asynchronous activities more than synchronous live sessions where they would be expected to spontaneously answer in class. Al-Dujaily (2013) found extroverted/introverted personal traits significantly influenced learning activity on adaptive e-learning system for computer science students. Online nursing instructors may want to consider allowing students options of assignments to complete so they may demonstrate competency in a variety of ways. An introvert may choose a written assignment and an extrovert may choose an oral report. There are multiple ways for students to demonstrate competency. Because introverted students are less vocal in class, many instructors may view them as uninterested or not as smart as their extroverted classmates (Cain, 2012). Introverted students may not be appreciated for their thoughtful nature and ability to critically think through problems. Many times the extroverted student is viewed as the ideal student because they will eagerly answer in class and participate in live discussions. Instructors who learn the positive qualities of introverted students, and learn to design exercises in which all students have an equal chance for success, may enjoy greater satisfaction and improved student outcomes. The introverted student may also benefit from the instructor gently encouraging them out of their comfort zone. Appreciating that introverted learners have unique needs and best practices in online education need to be implemented, instructors at a small, urban college of nursing received education on the unique needs of introverted online learners. After review of this information, several online master’s nursing courses were designed, considering the needs of the introverted learners. Student feedback was positive after implementing best practices for introverted learners. Faculty response was also positive after receiving education on introverts and how to implement best practices for introverted online learners. This work has implications for nursing education practice. Although there are millions of online learners, there appears to be dearth amount of work done on instruction of online introverted nursing students. As the technology and innovation revolution continues, and more nursing courses are being taught online, nursing instructors have yet another area in which they need to receive additional education and training. First, nursing faculty should not assume that introverted students are not as smart or not as engaged as their extroverted classmates, and instructors should not discriminate against students based on personality traits. Second, when nursing instructors are using innovations and technologies and teaching online, they should learn how to design and implement best practices for online education and learn how to engage students with different

personalities including the introverted learner. Finally, if more online nursing instructors understand introverted students and implement best practices, we could see more nursing students graduate, the nursing shortage may be minimized and students and faculty may have greater satisfaction with online teaching and learning.

The Development and Incorporation of Combined Maternal-Child and Pediatric Global Learning Experiences Undergraduate Nursing Students

Amy McKeever, PhD, RN, CRNP, WHNP-BC, USA

Abstract

Preparing entry-level clinicians in today's complex healthcare markets requires an improved awareness of the globalizations of today's society. Healthcare providers are being challenged with providing care to an even more diverse population, and with the challenges worldwide, migration by choice, or force means that the nurses caring for patients are from vast geographic communities. As a result, cultural competence has emerged as a critical element of professional nursing practice and nursing education is challenged with meeting the need of preparing culturally competent nurses.

Nursing leaders, and educators recognize that the incoming work force has to be prepared to care for that global community and preparing this workforce has to begin with entry-level clinicians. Commonplace in traditional undergraduate baccalaureate education students receive some training, and experiences in providing cultural competent care, but international healthcare experiences vary among higher BSN education programs. Cultural competence requires both formal knowledge and clinical experiences with culturally diverse individuals and communities. The purpose of this presentation is to highlight one of the unique global service learning experiences that Villanova University developed and implemented during a curriculum revision in 2014 to continue in which threaded an international experience among several clinical courses for students to learn with and among different clinical courses. Goals of the curricular change include: marrying theory and clinical content among the maternal-child health and pediatric courses with building concepts for junior to senior nursing students, having traditional undergraduate nursing students work with second degree nursing students, allowing graduate nurse practitioner students participate in mentoring undergraduate nursing students prior to and in country, and incorporating health promotion and prevention concepts into core clinical courses. The authors will highlight how teaching across the curriculum was incorporated into this global service learning experience at home and in country and demonstrate how clinical courses can work together to achieve similar theory and clinical course and student outcomes.

Transformative Learning and Development of Public Health Nursing Practice From a Philosophical Perspective of Personhood

Kristina Mountain, MSc, RN, RSCPHN, United Kingdom

Abstract

Paper: Fostering transformative learning and development of practice within Specialist Community Public Health Nursing curriculum from a philosophical perspective of Personhood.

Purpose: The presentation will consider the articulation of key person-centred concepts in a post registration Masters level Specialist Community Public Health Nursing (SCPHN) curriculum based within the Division of Nursing at Queen Margaret University, Scotland, and the potential for transformative learning.

Methods: The programme was implemented in 2015-2016. A person-centred approach to facilitating learning was adopted and the critical and creative engagement of students in concept clarification and reflexivity encouraged exploring the limits of approaches that focus exclusively either on the person or on the population within the changing context of public health nursing practice. This brings to the fore the complexity of holistic assessment, judgement of risk and safeguarding, centred on the child and young person within the context of public health and wellbeing (Cowley et al 2013; Malone et al 2016). By providing a safe and authentic environment for students to critically evaluate their existing beliefs and values, build on their knowledge, and construct a new frame of reference as part of their professional and personal development is key to this process. Students, as adult learners, experience not just new practice and university settings but a different professional cultural context (Cowley et al 2013; McCormack & McCance 2010; Mezirow 2012).

Throughout the learning journey of the programme students and facilitators are encouraged to explore personhood across the lifespan (from childhood to adulthood) and the connections and relationships between persons (children, young people, families, communities). Through situated and collaborative learning, research evidence is applied to devise person-centred interventions with a view to advancing and developing practice. An ongoing dynamic process of evaluation draws on formal student feedback, presentation of group work through creative methods such as poster presentations, poetry, artwork, reflective narratives, debates, and online discussions. There is a particular focus on the core module on child and family centred practice. In our evaluation framework we will maintain an evaluative relationship with graduates to analyse their pre-graduation reflective narratives and continue to 'reflect on their reflections' in the context of impact on their practice.

Results: The evaluation is ongoing. The group work and discussions were considered thought provoking; students on the programme seem to be gaining a deeper and broader understanding of child and family centred practice from a person-centred perspective. The link of theory to practice has been identified as one of the strengths, together with the emphasis on thinking critically on the exploration of personal values and beliefs, of personhood, and of child and family centred practice.

Conclusion: Part of the process of undertaking a programme of study as an adult learner, and engaging with the transition to a new professional identity, involves challenge to the assumptions, values and beliefs that each person brings with them. It brings into play the philosophical perspective of Personhood, and what it feels and means to be a person (McCormack & McCance 2010). There are parallels between the person's (as a child and young person) journey and the person's (as a student) journey – emphasising the relationship between praxis and reflexivity and the potential for transformative learning and development of practice to take place.

Using Team STEPPS® to Improve Teamwork and Collaboration in the Emergency Department

Melissa A. Pollard, DNP, CCRN, CEN, RN-BC, ARNP-BC, WCC, USA
Elizabeth Cummings, RN, CEN, USA

Abstract

This session will address an education initiative to promote the adoption of Team STEPPS tools in our emergency department. The goal of this project was to create a healthy work environment that embraces Team STEPPS tools in day to day work flow. Our Emergency Department underwent an unprecedented turn-over in staff, including a new contracted team of Emergency providers, resulting in many changes in work flow, throughput and communication. The retirement of the longtime nurse manager also prompted changes in management structure, with additional senior nurse turnover. With the many changes, it was noted that collaboration and communication among staff was inconsistent, and some interventions to improve this were pursued. Our emergency department had training in Team STEPPS six years ago, with moderate degree of buy in at the time. Our clinical professional development team continued to embrace Team STEPPS concepts and weave these tools and verbiage into our simulations facility wide, including during our American Heart Association classes such as PALS, ACLS, and Neonatal resuscitation, which the ED team attend.

It was noted that a majority of the Emergency Department team had not been present during the initial Team STEPPS training, and that revitalizing this program might show improvement in teamwork skills. A plan was drafted, and presented to senior leadership, and then to the unit based council for input. We first surveyed the department using the Team STEPPS Teamwork Perception Questionnaire (T-TPQ) prior to Team STEPPS classes or introducing interventions and then again four months after the trainings. Using the results of the survey as a guide, we are implementing tools to improve identified areas of perceived inconsistencies. The Team was surveyed again approximately one year after initiation of this initiative.

The coordinating team worked to identify issues, why the tenants of Team STEPPS was felt to be a good fit to address some identified needs of this department, and the results of this intervention. We will address how the partnership between the Unit Based Council chair, the ED physician lead, and the professional development specialist were integral to the success of this project. This initiative did not immediately demonstrate objective improvements in teamwork. However, after building on the initial program, significant improvements were found both objectively and subjectively.

The Effectiveness of Online Case Studies Among Medical-Surgical Nursing Students

Shu-Yi Wang, PhD, RN, CNS, USA
Theresa G. Buxton, PhD, CNE, USA

Abstract

Vendor provided online case studies were integrated throughout a medical-surgical nursing course. Case studies are a form of active learning that support student's development of problem solving, critical reasoning, and analytical skills, which are valuable tools needed by professional nurses. Providing simulated hands-on experience in the form of realistic patient problems allows students to identify and apply principles to new or changing situations. The purpose of this study was to examine the effectiveness of case studies integrated throughout medical-surgical nursing course and to evaluate the learning experiences among medical-surgical nursing students. A cross-sectional design was to assess 110 BSN students. 12 online case studies provided by a nursing education vendor were used in medical-surgical courses. Measurements were used to assess student perceptions of case studies regarding overall satisfaction with this type of learning activity and their effectiveness to enhance learning. Measurements included a 10-item of overall rate of case study, 11-item of satisfying found the each session of case study, 1-item of rate of the case study overall, and 1-item of descriptive question. The first category contained 10-items reviewing the overall experience of case study using a rating of 1= strongly disagree to 5= strongly agree numerical scale (strongly disagree, disagree, neutral, agree, & strongly agree), the 2nd category contained 11-items rating the satisfaction for each of the 11 online case studies ranging from 1=Very Poor- 5=Excellent (very poor, poor, average, good, & excellent), and the 3rd category had a 1-item rating from 1=Very Poor- 5=Excellent – of the overall satisfaction using case study. General comments and suggestions were also collected at end of survey to obtain additional information. Descriptive statistics were applied. The results showed there have a greater overall satisfaction using case studies among BSN students, as well as the overall rating for using case studies ranged between very good and excellent for BSN students. The online case studies emphasize practical thinking and assist students in identifying situations. Educators may choose this instructional strategy for accomplishing particular educational objectives. The results of this study can be applied as a reference for effective instructional, to extend independent online learning activities, or used as a flipped classroom teaching-learning strategy for a face-to-face classroom.

EBP PST 3 - Evidence-Based Practice Poster Session 3

Quality Enhancement Plan: Interprofessional Educational Program to Improve Nursing Students' Self-Efficacy in Scholarly Written Communication

Jeanette Lee Plodek, PhD, MSN, RN, USA
Lela Hobby-Burns, DNP, MSN, APHN-BC, USA
Linda C. Tibbits, MA, BSN, RN, USA
Rustian C. Phelps, MA, BA, USA

Abstract

Introduction: Effective communication is essential in business and academia for professional success. RN-BSN students struggle with scholarly composition as a result of limited formal writing opportunities during their prior studies. A collaborative interprofessional education effort is described to improve students' professional writing skills.

Methods: After assessing observational qualitative data from Nursing, English and Writing Lab faculty, two (2) online, 7-week, asynchronous, 1-credit hour courses were developed and implemented. Both courses are instructed by English or Writing Lab faculty. To promote content alignment Nursing faculty are 'guest instructors' in the course.

The first course is co-requisite with the introductory course in an online RN to BSN program. The second writing course is co-requisite with the EBP Research Essentials course. Using nursing content, writing activities provide nursing students with learning opportunities for practicing grammar mechanics, writing skills, and organizing scholarly summaries.

Specifically, students receive an overview of professional and technical writing principles that focus on identified skills necessary for success in the academic and professional environments. The students develop their skills through multiple writing assignments, and constructing a professional portfolio of documents deemed essential. These documents include emails, letters, literature reviews, annotated bibliographies, and scholarly papers. Other assignments such as the annotated bibliography, curriculum vita, and portfolio creation and management are specifically designed toward the nursing educational and professional expectations.

The Interprofessional education (IPE) effort was piloted in Spring & Summer 2016. By design, the writing courses supported success in the two (2) associated nursing courses. Seventy (70) students participated in this quasi-experimental study. The validated 20-item *Post-Secondary Writing Self-Efficacy Instrument* assessed students' pre- and post- intervention belief in their ability to meet writing objectives. Scores were compared for both individual student questions, and total means of all questions. Successful course completion is another outcome measured. Upon program completion, graduates will also complete the *Professional Role Confidence* survey provided by the University Quality Enhancement Plan office.

Results: Pre- and post-intervention scores on *Post-Secondary Writing Self-Efficacy Instrument* were compared. Statistically significant improvements were found both individually, and on combined mean scores. Scores significantly improved on 15 of the 20 instrument items, and, overall pre-post mean scores ($p < 0.0001$), indicating higher confidence in students' writing ability. Student qualitative comments are overwhelmingly positive, with participants reporting that they learned valuable skills, information, and increased confidence in completing scholarly writing assignments. Faculty report a decreased need to spend time on correcting grammar, APA format, and style and an opportunity to spend more time on content evaluation and feedback.

Discussion: The interprofessional instruction in these two writing courses is key. English composition faculty provides purely grammatical feedback on students' writing practice. This division of faculty instruction focuses on word usage, paragraph organization and APA writing mechanics, all within the background of nursing context. The co-requisite practice prepares students for the concurrent Nursing

course activities. The two co-requisite courses are the initial *Transition to Nursing* course, and later, in the *Research Essentials in Evidence-based Practice* course.

Pilot course offerings were initiated during the 2016 Spring and Summer terms. The English and Writing Lab faculty continue to work closely with Nursing Department faculty to update the new courses based on student and faculty feedback.

Conclusion: These foundational writing activities help students' express scholarly language, and promote critical thinking abilities. Linking the writing workshop course assignments to selected existing nursing course assignments allows for the utilization of profession-specific academic assignments while providing a theoretical foundation of communication skills and specific feedback to enhance development and proficiency of the students' critical writing, learning, and thinking skills.

Supporting and promoting self-efficacy and competence in professional writing creates nursing students who can be successful communicators (Miller, et.al, 2014).

Lessons Learned: Incorporating Global Health Patient Experiences Into a BSN Curriculum

Kathryn Sridaromont, PhD, RN, USA

Wendy Renee Thal, DNP, APRN, FNP-C, APHN-BC, USA

Belinda Gallegos, MSN, RN, CNE, USA

Abstract

The development and implementation of global health experiences in our concept-infused BSN curriculum is valued at an institutional, administrative, and curriculum level to foster interconnectedness, compassion, clinical judgement and future advancement of nursing research. The institutional mission supports providing high quality culturally diverse educational opportunities for students and faculty to improve the health of people (TTUHSC Strategic Plan, 2016). Due to administrative value and support of global health experiences, our school of nursing has global health faculty representatives who collaborate with course faculty throughout the curriculum to compare the objectives of the global health experience to semester course objectives to determine synchrony and mastery and the number of clinical hours the student receives in each course after completing the global health experience. According to Glazer, Clark, and Bankston (2015), meeting the demands of the diverse 21st century population is dependent upon providing “high quality culturally competent care (p.1).” Providing students an opportunity to participate in global health experiences at an undergraduate level enhances the development of cultural competence and the likelihood of career involvement and future nursing research at the global level (Glazer, Clark & Bankston, 2015). Through the transformation of globalization the world is challenged to meet individual and collective needs of all cultures represented. Reflection, application and theory are guiding the transformation of praxis with a focus on global health and wellness. Recognizing Healthy People 2020 wellness goals for selected aggregates and populations includes health promotion across the life span and compares to the World Health Organization goals to improve health worldwide. The leading health indicators include: access to health services, clinical preventive services, environmental quality, injury and violence, maternal, infant and child health, mental health, nutrition, physical activity, and obesity, oral health, reproductive and sexual health, social determinants, substance abuse and tobacco (About Healthy People, 2016) . These indicators were used in the development of the global health experience to assist in promoting global health and wellness (Cock et. al., 2013).

Implementation of Faculty Clinical Research Mentorship to Improve Academic Clinical Partnerships and Nurse Led Projects

Mary G. Heitschmidt, PhD, APN, CCRN, USA
Beth A. Staffileno, PhD, RN, USA
Ruth M. Kleinpell, PhD, RN, FAAN, FAANP, USA

Abstract

The American Association of Colleges of Nursing supports partnership opportunities between academic nursing and academic health centers yet information to operationalize a systematic approach connecting bedside clinical nurses interested in conducting evidence based practice projects and research, to nursing faculty, is sparsely found in the literature. Health care systems are expected to have clinical nurses participate and lead research and evidence-based practice (EBP) projects in order to achieve and maintain Magnet® status, the highest recognition for nursing excellence.

The purpose of this presentation is to describe a unique academic nursing faculty mentoring project which provides faculty with the resource tools needed to work with clinical nursing staff and multidisciplinary project teams who want to engage in clinical evidence based practice and research projects. The Center for Clinical Research and Scholarship (CCRS) was established in 2007 as a joint venture between a medical health care system that includes a college of nursing (CON), located in the Midwestern region of the United States. One of the objectives of the CCRS is to promote clinical nursing research that improves clinical practice and patient outcomes. The CCRS also supports clinical research and scholarship activities within the health care system to promote best practices in patient care and improvements in health care delivery.

Guidelines established by the members of the CCRS are provided to nursing faculty who are interested scholarship opportunities that include working with clinical nurses on EBP and research work. Projects that connect faculty to clinical nurses address a variety of patient and clinical care topics. Faculty can identify their areas of interest to be matched to a clinical project.

Referrals from health care system clinical nurses or nursing leaders requesting faculty project involvement are matched with CON faculty who have expertise and are interest in the work. The CON faculty mentor may also provide consultation and assistance to the project team with project development, IRB submission, oversight of project implementation and with dissemination (abstract development; poster presentation; manuscript preparation) of the project. Participating as a faculty mentor enables the CON faculty member to have active involvement in scholarship as well as authorship on projects related presentations and publications.

This distinctive partnership between CON faculty and clinical nurses is an example of how to systematically elevate clinical scholarship in an academic medical center with the intent of providing improved patient care outcomes from the results of EBP or research projects, opportunities for faculty to participate in scholarship as clinical mentors, and positive leadership experiences for both clinical nurses and CON faculty.

EBP PST 3 - Evidence-Based Practice Poster Session 3

Dietary and Supplemental Therapy in Crohn's Disease: Promoting Self-Care Through Knowledge

Jennifer Mary Senior, DNP, ARNP, NP-C, USA

Abstract

Background and Purpose: Crohn's disease affects millions of people worldwide. It is a complex inflammatory condition of the gastrointestinal tract and requires a high knowledge level in both the patient and provider for successful management. Many research studies are done on pharmaceutical options to treat Crohn's disease, but few studies detail the impact of nutritional deficiencies. The purpose of the project was to increase knowledge levels in patients with Crohn's disease regarding the latest dietary and supplemental therapies showing promise to support their disease state while promoting self-care and improving well-being. Additionally, the project demonstrates to other healthcare professionals the importance of evaluating and educating patients in a meaningful, effective way.

Methods: The clinical improvement project began with an extensive review of the literature related to dietary and supplemental therapies for Crohn's disease. The results were compiled into an educational session. The project utilized a quantitative pre-test, post-test survey method. Participants' knowledge levels on 5 key topics of fiber, probiotics, vitamin D, other vitamins and minerals, and specific diets were tested before and after the evidence-based educational session. A small qualitative component highlighting the impact of the gain in knowledge on participants' lives after the educational session was captured on a follow-up survey.

Conclusions: A statistically significant raise in knowledge level was found following the educational session ($p < 0.0001$). Pre- to post-test scores rose by 21%. Data analysis revealed participants' age, gender, level of education, and disease duration did not impact learning. Qualitative reports cited improved knowledge of diet, vitamins, and better disease management.

Implications for Practice: Creating an evidence-based educational session from a comprehensive literature review is effective at raising patients' knowledge levels. This knowledge improves patients' abilities to engage in self-care and improves their quality of life. The methods utilized in this clinical improvement project can be applied to any chronic disease state.

Is This the Profession for Me? Pre-Nursing Students Simulated Hospital Day Observations

Sarah Yvonne Jimenez, MSN, RN, USA
Melissa Wholeben, PhD, RN, USA

Abstract

How does one know if a chosen course of study in college will lead to a satisfying career upon graduation? At the University of Texas at El Paso, pre-nursing students in the Foundations of Nursing course have the opportunity to observe a simulated hospital day activity carried out by upper division nursing students. Pre-nursing students complete one-hour observations of hospital day activities and then answer a questionnaire about what they have observed. Students report that the simulated hospital day observation is an eye-opening experience that provides them with valuable insight as they prepare to apply for UTEP's nursing program and set career goals.

Simulated hospital day is a clinical simulation activity. Clinical simulation is an active learning method that promotes the development of critical thinking and clinical reasoning through experiential learning in a safe environment. Nursing students involved in clinical simulation activities benefit greatly from the experience. The use of clinical simulated experiences has been established as a best practice that maximizes retention of important concepts and solidifies the translation of theoretical knowledge into clinical practice. During a simulated hospital day, upper division nursing students engage in simulated clinical scenarios that are designed to simulate an actual hospital day. Elaborate case scenarios are acted out through role-play. Some upper division nursing students take on the role of the nurse, while other upper division nursing students take on the role of the patient. Simulated patient records are reviewed, patients are assessed, medications are administered, procedures are done, and communication with other health care professionals is facilitated per various scripts.

This observation activity is often the first exposure many pre-nursing students have to a clinical setting. Students have reported that simulated hospital day has given them an idea of what is expected of upper division nursing students as well as what is expected of nurses in professional practice. Students have stated that this observation has helped them see what nurses really do. They have reported that they found this to be an extremely beneficial activity and have expressed that they think this experience will help them as they make decisions about pursuing a career in nursing.

Students of all disciplines may realize similar benefits with early exposure to the activities of the profession they are pursuing. Students given the opportunity to observe professional practice early in their academic career may be able to make more informed decisions about their future course of study.

EBP PST 3 - Evidence-Based Practice Poster Session 3

Implementing a Dedicated Education Unit for Senior Year Baccalaureate Nursing Students in Primary Care

Sarahi Y. Almonte, MS, RN, USA
Sharon Liann Taylor, MPH, USA
Ranbir Bains, PhD, MSN, APRN, CPNP, USA
Mary L. Blankson, DNP, APRN, FNP-C, USA

Abstract

The Dedicated Education Unit (DEU) is a clinical-education experience that allows nursing students to receive hands-on learning with frontline nurses to ensure they are reinforcing their academic teaching while also gaining the clinical pearls and practical knowledge from those who regularly perform the job. The DEU concept came out of Flinders University of South Australia School of Nursing in the 1990's due to the growing need for quality clinical placements for nursing students. This allowed for an improved strategic partnership between academia and clinical sites, to ensure an excellent student experience while also factoring in the clinical challenges of placement sites.

In the United States, clinical placements can be challenging to identify, particularly because rotations generally focus on acute settings, and because partnerships with primary care settings are typically not well established. The minimal focus on this nursing role in academic curriculum previously highlights why primary care clinical competencies are not well defined. With the growing workforce demand for primary care nurses, particularly roles in complex care management, nursing students need to have additional education and experience with frontline nurses in these settings to truly understand the care continuum and the full array of job opportunities available to them upon graduation.

A DEU was developed at the Community Health Center, Inc. (CHCI) to provide senior year baccalaureate nursing students experience in an interprofessional collaborative practice environment with frontline primary care nurses that support complex care management work for the provider panels they support. This was one facet of the implementation of a complex care management program across 12 clinical sites of CHCI. CHCI is a statewide agency providing care to individuals with low socioeconomic status, including many that are uninsured and underinsured. It has 14 integrated patient-centered primary care sites, delivering medical, behavioral health and dental services along with other ancillary care services such as those delivered by registered dietitians, podiatrists or chiropractors to name a few. CHCI delivers care in over 200 total service delivery sites, when school based clinics and health care for the homeless sites are included in the total count.

Through the DEU, nursing students learn how to deliver care to patients in the primary care setting. At the CHCI, students receive support and mentorship from clinical instructors and clinical faculty coordinators who prepare them for the rigor of caring for patients in the primary care setting. The clinical instructors are nurse care managers who have experience delivering care to patients in the primary care setting. In pre-clinical conference, students receive brief didactic to support their understanding of the role of the primary care nurse and to ensure they truly understand the shift in critical thinking needed for this setting. As the students learn about primary care competencies in their academic programming in the classroom, they are reinforced with real examples in pre-clinical conference and then concurrently practice them during their rotation time at the primary care site.

Students also experience innovative healthcare practices such as team huddles, integrated care meetings, and population management. They are trained on how to use dashboards, scorecards and other data sources to inform their practice throughout the day. They also participate in innovative training delivered to CHCI's nurses such as Project ECHO®: Complex Care Management, which is a telehealth model that creates a knowledge network for nurses. It includes both didactic and case-based learning, where frontline nurses and student nurses can present complex cases and get feedback and support from a multi-disciplinary team of experts on next steps in their care planning.

Students were part of focus groups during the first two years of DEU implementation to provide direct feedback that informed performance improvement between year one and year two. They contributed changes to the length and content of the DEU, as well as to further confirm the potential benefit. This ongoing quality improvement will ensure an optimized student experience, and hopefully will improve nursing preparation, and possibly increase the number of new nurses that choose primary care as their chosen career. One student shared during the focus group: I like how they kind of changed my view about where nursing can go...it's not just, you see a patient and that's it and you move on. You can stay with that patient and follow-up with them and make sure that everything in their life is not affecting their health.

The DEU is vital in training the next generation of nurses to understand the critical role of the primary care nurse. As students build this understanding, they also learn what it means to work on an interprofessional collaborative practice team. Simultaneously, they have the opportunity to build their leadership and collaboration skills to better care for complex patients once they enter the nursing workforce, no matter which part of the care continuum.

Evidence-Based Tool Dissemination to Assess Bruising as a Forensic Bio-Marker of Abuse in Nursing Homes

Brenda Sheingold, PhD, MBA, RN, FNAP, USA

Abstract

Purpose: To improve the assessment of bruising as a forensic biomarker of abuse in older adults receiving healthcare in long-term care facilities.

Problem Statement: Older Americans experience between 2-5 million episodes of abuse annually in multiple forms which is under-reported.

Background: Long term care facilities are required to report allegations of abuse per the Center for Medicare and Medicaid Services. All alleged violations involving resident abuse as well as injuries of unknown origin are required to be reported no later than 24 hours following discovery (CMS, 2016). A bruise is a recognized sign of physical abuse, (DHHS, 2015), however some bruises are accidental and no effective assessment of whether bruising is indicative of abuse currently exists.

The Elder Justice Roadmap (DHHS, 2014) identifies that a strategic investment of resources toward research can expand the knowledge needed to better understand abuse and “make a difference.” A valid and reliable assessment tool would not identify all cases of physical abuse; however, the tool should assist in identifying causes that are not abuse related and wide-reaching education is needed.

Aim: To improve patient safety and support the delivery of efficient, effective, timely, and equitable patient centered care by improving the ability of all stakeholders to assess bruising as a possible sign of abuse by disseminating web-based education.

Methodology (Tool development) - Literature Search: An extensive literature review utilizing PubMed, Medline Ovid, and Cinahl databases was conducted with key words, yielding 399 articles for review. The application of inclusion and exclusion criteria narrowed the yield to 78.

Expert Identification: From the literature review, characteristics of bruises associated with intentional bruising (vs. accidental) were identified; potential experts with respect to bruise assessment and analysis also were identified within the clinical, legal, and social science disciplines.

Delphi Consensus: A list of 100 potential experts identified through the literature was narrowed to 74 based on self and/or investigator elimination. The pool was further narrowed to 68 due to poor contact information; The survey sent in one round resulting in 23 responses.

Focus Groups: Ten groups were scheduled to review the draft bruise assessment tool.

Field Testing: Testing of the resultant tool occurred in two long term care facilities.

This phase has been completed and was funded by the Center for Medicare and Medicaid through the State of Maryland Office of Healthcare Quality.

Methodology (Tool dissemination) - The dissemination phase is to provide wide-spread education on the instrument for assessing bruises experienced by nursing home residents to determine if they may or may not have been caused by abuse.

A 20-minute documentary style educative video has been scripted and designed in partnership with WETA television studios. The aim of the video will be to raise awareness of bruising as a forensic bio-marker of abuse in nursing homes and to introduce the newly developed Bruising Assessment Rubric (BAR) to variety of stakeholders. An overview of how to utilize the tool will be included. The roll-out of this

evidence based deliverable will include in-studio and field shoots, still shots of bruises, and the acquisition of all permissions/releases for production in preparation of video distribution for educational purposes.

Hosting of Video Online Training via Website will be sponsored by the Beacon Institute, 10280 Old Columbia Road, #220, Columbia, Maryland 21046. The Beacon Institute is the largest provider of education for elder care on the East Coast of the United States and trains thousands of providers annually.

Online provision of an expert educational video program to professionals, caregivers, providers and other relevant stakeholder groups with supportive competency-based testing is also planned. This phase is a work-in-progress and is currently funded by the Center for Medicare and Medicaid through the State of Maryland Office of Healthcare Quality.

Implementing Care Coordination and Transition Management in a Critical Care Telemetry Unit

Helen S. Kane, MSN, MBA, RN, CCRN, USA

Linda Wilson, PhD, RN, CPAN, CAPA, BC, CNE, CHSE-A, ANEF, FAAN, USA

Abstract

This session will present the process for the implementation of care coordination and transition management in a critical care telemetry unit in one urban community hospital. Care Coordination and Transition Management is a new focus and role for the bedside nurse to be competent in care coordination and transition management of patients in the clinical setting. The primary organizations involved in this initiative are the American Academy of Ambulatory Care Nursing (AAACN) and the Medical Surgical Nursing Certification Board which is the organization that offers the certification for this specialty. The preparation and education for both staff nurses and the clinical nurse specialists include extensive education, reading and lecture sessions to become knowledgeable on the concepts and competencies for this role. The key content areas include "advocacy; education and engagement of patients and families; coaching and counseling of patients and families; patient centered care planning; support for self-management; nursing process: proxy for monitoring and evaluation; teamwork and collaboration; cross setting communications and care transitions; population health management; CCTM between acute care and ambulatory care; informatics nursing practice and telehealth nursing practice" (AAACN, 2016). The primary goals of care coordination and transition management are to "improve patient outcomes, enhance quality of care, decrease hospital admissions, decrease health care costs, help patients to navigate the health care system, ensure continuity and seamless transitions between levels of care, and improve the patient's individual experience" (AAACN, 2016). The final step is completion of the certification exam to become certified in care coordination and transition management (CCCTM). Challenges of implementing this program in one critical care telemetry unit in an urban community hospital will be presented as well as strategies for success. Ongoing implementation and management of the program will continue until all nurses are certified including all staff nurses and all advance practice nurses. Evaluation of the implementation process and program will be ongoing.

The Clinical Clusters Education Model Supporting Nursing Student Learning: An Implementation Case Study

Lyn T. Armit, MHSc, BA (BehavSc), RN, MACN, Australia

Julie M. Shaw, MPH, BAppSc (Nsg), RN, Australia

Susanne Pearce, PhD, RN, Australia

Thea F. van de Mortel, PhD, MHLthSc, BSc (Hons), DipNsg, RN, Australia

Laurie A. Grealish, PhD, RN, FCNA, Australia

Abstract

Clinical education in nursing has undergone significant transformation since the turn of the century. In particular, evidence to support high levels of student engagement and learning in the Dedicated Education Unit (DEU) model indicates that this approach has value for students, hospitals and universities (Mulready-Shick et al., 2013). The process of implementation of clinical education programs based on the successful DEU model has not been well addressed to date. Further, implementation of evidence-based programs, such as the DEU, often requires adaptation to meet local sociocultural contexts. The risk with adaptation is loss of program fidelity (Chambers et al., 2013), in this case student engagement and learning.

The aim of this presentation is to describe the implementation of an adaptation of the DEU model, known as the Clinical Clusters Education Model (CCEM), at one hospital in southeast Queensland. The Dynamic Adaptation Process (DAP) of implementation (Aarons et al., 2012) provides the theoretical framework for the case study of implementation. The DAP has been used for large-scale program implementation in family services. Like family services, clinical education is grounded in multiple networks of relationships and interests, therefore the selection of DAP is considered to be appropriate.

Using the DAP framework, the stages of development and evaluation are described. In the Explore phase, the aim was to shift the focus from facilitator-centred learning to student-centred learning, consistent with the DEU model. This was undertaken in a pilot study of one area of the health service, whereby the primary learning relationship was between the students and the ward staff rather than the clinical facilitator and the student group (1:8 model). In the Preparation phase, the structure of the CCEM took shape, with clinical facilitators working in teams to support student learning in a group of wards. The focus of learning shifted from a direct facilitator-student relationship to a student-ward staff focus, where students had greater locus of control over their learning experience, within established boundaries (scope of practice). The preparation phase focused on comprehension and translation of the model to the hospital context, and renegotiation of facilitator-student relationships. The Implementation phase began in early 2015 and continues today. During the implementation phase, evaluation data was collected to ascertain model feasibility and effectiveness, and implementation success. The process of implementation has been challenging as ward staff learn to engage the students into their work, providing experiences that are appropriate to their learning journey. Early data suggests that the model is feasible and effective, in terms of student learning. Initial student dissatisfaction with the model has since been replaced with student feedback indicating increased levels of confidence and satisfaction. We are entering the final phase, Sustainment. In this phase, we will focus on (1) program fidelity, mapping the elements of the DEU model that have been employed in the CCEM; (2) program adaptation, mapping deviation from the original DEU model; (3) program effectiveness, how students are engaged and learning; and (4) implementation fidelity, focused on clinician and facilitator confidence to support student learning in the CCEM and alignment of this strategic change with the multiple education partner expectations for student learning and the health service's Magnet® Recognition journey.

The DAP provides a useful framework for implementation of evidence-based clinical education models. Process evaluation is an important consideration in program implementation, focusing on the effects of adaptation on overall program effectiveness.

The Integration of Mental Health Competencies Into a Primary Care Nurse Practitioner Curriculum

Pamela Aselton, PhD, FNP-BC, USA

Gabrielle P. Abelard, DNP, MS, BS, RN, PMHNP, PMHCNS- BC, USA

Linda A. Lewandowski, PhD, RN, FAAN, USA

Raeann Genevieve LeBlanc, DNP, AGPCNP-BC, CHPN, USA

Clare Lamontagne, PhD, RN, USA

Lori Anne Lyne, MS, ACNP-BC, USA

Abstract

Purpose: Primary care clinicians must be prepared to assess, treat, and refer patients for appropriate services for mental health care. Studies have shown that the majority of prescriptions for antidepressant and anxiety medication are written in primary care offices. More than 50% of adult patients with depression are diagnosed and managed by primary care providers (Scandis and Watt, 2013). Less than 60 percent of adults with significant mental illness receive treatment in the United States (NSDUH, 2013).

Mental health services need to be better integrated into primary care given the shortage of mental health providers in many areas.

There is a great need to address these problems and try and get patients connected to therapeutic services in primary care. One study found that the average wait time for a first time visit with a psychiatrist in the United States is 25 days, although many communities report much longer rates (Mozes, 2014). Providing mental health care in primary care settings improves access to care, improves clinical outcomes and saves money (Insel, 2008). With these facts in mind we undertook a curriculum revision to add content on the treatment and management of common mental health and behavioral issues to our primary care Nurse Practitioner (NP) tracks in our online DNP program.

Methods: Many primary care NP programs have not traditionally included a strong focus on behavioral health issues. However, recognizing the need we undertook a comprehensive revision of our content and clinical courses. After soliciting input from community practitioners on important content we revised the curriculum to address the importance of mental health awareness and treatment throughout the primary care tracks: Family NPs (FNPs) and Adult Gerontology Primary Care NPs (AGPCNPs). A required three-credit course entitled *Assessment and Diagnosis of Psychiatric and Mental Health Disorders* course was created and added to the curriculum to address this need. This course reviews mental health disorders using DSM5, reviews diagnostic and screening tools, familial patterns, community, and socio-cultural contributions to the diagnostic process. In addition mental health topics were integrated into core DNP courses in Family Systems, Pharmacology, Pathophysiology, Health Policy and Ethics as well as case studies in all the clinical courses. We have also incorporated content regarding evidence based complimentary and integrative treatment into the curriculum via webinars and workshops.

Results: Our Primary Care NP students rated this course highly and were surveyed to see how much of this mental content they felt they learned in their program of study. Multiple student reflections in clinical logs and surveys support the integration of behavioral health into the student clinical education and experiences. Faculty and preceptors concur on the need to better educate students on the assessment and treatment of mental health issues in primary care settings.

Conclusion: Given the realities that much of mental health care is being provided in primary care settings, it is clear that primary care NPs must be competent to address these types of issues. We have seamlessly integrated mental health content and competencies throughout our curriculum. The required course has emphasized the importance of this content for primary care clinicians who will be encountering patients with mental health problems such as substance abuse, depression, anxiety, and dementia in primary care. Integrating mental health concepts throughout the curriculum has also

emphasized the skills needed to treat patients and families in crisis, mental health assessment and diagnosis.

EBP PST 3 - Evidence-Based Practice Poster Session 3

The Dauntless Nurse: Communication Confidence Builder

Arna K. Robins, MSN, CEN, CFRN, NREMT, USA

Abstract

PURPOSE: The American Association of Critical Care Nurses (AACN) standards state that nurses must be as competent in their communication skills as they are in their clinical skills because effective communication fosters the psychologically safe work environment where collegial teamwork can thrive. Additionally, the American Nurses Association (ANA) standard of professional behavior states any form of horizontal violence is unethical practice and passive-aggressive communication falls under this umbrella.

Currently, a passive-aggressive style predominates. Nurses are lacking a critical skill: the ability to handle conflict and speak assertively with confidence and professionalism. Without this skill, nurses doubt themselves and are prone to making mistakes, thereby putting themselves, their colleagues, and their patients in danger. In a psychologically unsafe and emotionally unsupportive environment, humans cannot think straight, let alone access the critical thinking skills that are essential to providing quality nursing care.

This presentation reviews the process by which nurses gained the confidence and skill to confidently address experiences and behaviors that had previously left them feeling undermined or uncertain. Understanding why these behaviors occurred diminished their effect. Knowing how to respond built confidence and hardwired muscle memory. And analyzing scenarios of how other nurses effectively handled similar situations inspired nurses to be dauntless in their communication.

DESCRIPTION: Fifty-three trauma nurses self-assessed their communication skills in three categories: novice, moderate and expert. Only 25% were expert communicators and more than 50% were still at the novice level.

By guaranteeing their psychological safety through anonymity, these nurses were able to identify an important conversation that they had been avoiding. They then identified the reasons they had been avoiding the conversation. Through coaching, these reasons were addressed and overcome using specific communication models to create a script for the conversation. The primary communication model used was the Describe, Explain, State, and Consequence (D-E-S-C). They then rehearsed these conversations with their coaches and selected partners.

EVALUATION: After hearing all the reasons that their peers self-silenced, nurses realized that their professional role as a nurse and patient advocate required them to be dauntless and take the risk of speaking up. Further discussion of how self-silencing supports passive-aggressive communication and the development of horizontal violence in their culture followed. Realizing that the reasons for avoiding conversations are largely universal helped the nurses overcome previous biases and fears, as did the desire to become accomplished patient advocates.

DISCUSSION: The crux of communication at the professional level is that nurses value their own social safety in peer relationships over patient safety. The desire to be accepted by their colleagues frequently voided the need to ask questions, address a perceived error, or create a situation that could have been perceived as uncomfortable or painful. The confidence gained through developing communication skills by exploration of the models and rehearsing skills in coaching sessions motivated a shift in conscious values. When the environment is perceived as safe and accepting, nurses are far more likely to speak up in a way that contributes to excellent teamwork and protects their patients.

Human Resource for Health Development in Rwanda: Challenges and Opportunities in Nursing Education and Training

Sheila Shaibu, PhD, MSN, BEd, RN, Rwanda
Oluyinka Adejumo, DlittePhil, RN, RPN, RNE, Rwanda
Olivia Bahemuka, DNP, MSN, RN-BC, CTN-B, Rwanda
Gilbert Banamwana, MSc, RN, Rwanda

Abstract

Background: - Rwanda has several Schools of Nursing that offer a baccalaureate in Nursing Science and an equivalent of a diploma in Nursing Science. The Enrolled Nursing equivalent of nursing has since been phased out. The University of Rwanda (UR) now has 4 campuses of nursing who all offer a Baccalaureate in Nursing and Midwifery program (Mukamana, Uwiyeze & Sliney, 2015). In 2015, the UR Human Resources for Health program admitted 117 students into the Master's degree in Nursing which offers 8 tracks, among them an Education and Leadership and Management track with an enrollment of 14 students. The purpose of this presentation is to discuss the trends, challenges and opportunities that are observed in Nursing Education in Rwanda.

Trends: Nursing Education in Rwanda is evolving, with more nurses being enrolled into the baccalaureate Nursing program. More male nurses are being admitted into the Nursing program, including the faith based Schools of Nurses which previously did not admit male students. Although most schools of Nursing are short staffed, the schools also have a few faculty who are prepared at Master's degree level in various specialties, including Nursing Education. Most Schools of Nursing have a Simulation Laboratory that are used for clinical teaching for both Midwifery and Nursing. All the campuses of the University of Rwanda are equipped with teleconferencing equipment and are therefore, also offering distance E-learning Nursing program to upgrade diploma nurses to baccalaureate nursing.

Challenges: Due to shortage of faculty, nurses are still teaching non-nursing subjects such as microbiology and anatomy and physiology among others. Nursing education is moving towards learner centered environments (Valiga, 2012), yet classes are large and teaching strategies used are not always student centered. Teaching generation Y students using traditional teaching strategies may pose a challenge to this cohort of learners (Eckleberry-Hunt & Tucciarone, 2011). Clinical supervision of undergraduate students is limited given the student numbers and the distances from the Schools of Nursing where students are attached, as there are not always resources available for faculty travel for follow up of students. The curriculum is congested and not harmonized across the different Schools of nursing. Many nursing programs still struggle with letting go of content and decongesting the curriculum (Benner, 2012; Dalley, Candela & Benzel-Lindley, 2008). Issues of overloading courses with content and using student centered teaching strategies are addressed in the curriculum review workshops and curriculum assignments. Resources such as teaching equipment for simulation laboratories, books, video conferencing, and journals also pose limitations.

Opportunities: Evolving regulation requirements have been used to both adopt new requirements of the Higher Education Council and address curriculum changes as well as harmonizing the curriculum. Nursing education workshops have also been offered to faculty to address gaps in teaching. The Smart Rwanda Master Plan (Ministry of Youth and ICT, 2015) can transform nursing education in Rwanda through e-learning courses. There is a global shortage of nursing faculty (Nardi & Guryko, 2013) however, Rwanda's nursing faculty is young and vibrant, and can transform nursing education and practice given the opportunity. The consortium of the United States Institutes (USI) have donated teaching resources and the twinning of local faculty with USI faculty have transformed nursing education and practice in Rwanda.

Significance to Nursing: Nursing is the backbone of the health workforce in many countries including Rwanda and any health goals and targets set by the international community and the government require a well-educated nursing workforce to transform the targets through practice. Nurses are pivotal to

achieving the Sustainable Development Goals and addressing the social determinants of health. Therefore, an increase in the nursing workforce will go a long way towards improving practice and the health of the Rwandans.

Intentional Nurse Leader Rounding on Patients Daily

Jeffery Hudson, DNP, RN, USA

Abstract

The patient's voice is never as important as it is now. The patient care experience is directly correlated with nurse leadership at all levels. The patient care environment where cost cutting can interrupt the patient-centered focus, is at the core of nurse leader (charge nurse, manager, director, executive) competence to meet the financial challenges of providing outcome-based nursing care in our global nursing community.

This evidence-based project focused on implementing intentional nurse leader rounding daily on all patients in a 34-bed medical/surgical unit. The daily rounding was based on a hybrid program based on the scholarly literature and patient care experience models from the global community. There was a heavy influence used by the researcher using the Studer principles and guidelines of purposeful nurse leader rounding. Pre-education and training was conducted with the nurse manager and charge nurses who were charged with intentional rounding daily. This framework provided a consistent launch of the project with consistency using checklists and iTool used for collecting responses to prescribed questions asked by nurse leaders daily with patient and family members. Autonomy for nurse leaders during rounding to act on service recovery is a strong consideration to be made by nurse executives for service recovery guidelines. The data collected with rounding is an essential element of the nurse leader rounds. This collected data on an iTool with rounding software provides support for interventions and real-time scoring, tracking and trending of narrative documentation by the nurse leader. The aggregate data of rounding can be analyzed to change culture and drive behaviors and performance of patient care team. Additionally, data will support recognizing the patient care team through feedback from the patients and family members which support improved staff engagement, which in turn is demonstrable back to the patient care experience.

The unit where the project was completed will provide the source of discussion of anticipated and learned outcomes with the use of nurse leader rounding. There was a notable 10% increase in patient experience scores on this unit within the 60-days of the project. This elevated the patient experience scores beyond the 50th percentile with some scores in the 75th percentile. The unit was performing below the 50th percentile in the United States prior to this intervention. The project is being sustained and replicated in other inpatient and outpatient units in the organization as best practice.

Grit: The Power of Passion and Perseverance in Nursing

Indra Hershorin, PhD, RN, CNE, USA

Abstract

Attrition of nursing students has been described as the “Achilles heel of the nursing world” (Buchan, 2016). The Affordable Care Act and as the increasing number of aging and diverse individuals in society increases, access to the health care will expand and the need for more competent and diverse nurse graduates will increase. An adequate number of nursing graduates will be imperative to meet societal demands, however this is complicated by high nursing student attrition rates (Harris, Rosenberg, & O’Rourke, 2014). Newton and More (2009) reported attrition rates of 50% for students enrolled in baccalaureate nursing programs and 47% for students enrolled in associate degree nursing programs. High attrition rates not only have negative impacts on students and nursing programs but are also a potential loss to the nursing workforce and community.

A literature review was conducted to determine extant information related to attrition rates, retention and strategies to increase student success. The review of the literature found that measurement and analysis of progression and graduation rates to be a well-established activity in nursing programs. Horkey (2015) reported that there was a lack of consistency in admission requirements between institutions. Most nursing schools used a combination of quantitative academic factors such as grade point averages (GPA), pre-requisite course grades, and standardized admission examination scores. Limited inclusion and evaluation of qualitative factors for admission into nursing schools has been conducted. Qualitative factors included the use of admission essays, admission interviews, academic self-confidence, and personality indicators rates. The literature review indicates that in a culture of standardized testing with an exclusive focus on ability and potential nursing educators can easily become distracted from the importance of other variables that contributes to success. One such variable is grit.

Duckworth (2016) describes grit as a combination of passion and perseverance. Grit entails working strenuously toward challenges, maintaining effort and interest over years despite failure, adversity, and plateaus in progress. The gritty individual approaches achievement as a marathon; his or her advantage is stamina. Whereas disappointment or boredom signals to others that it is time to change trajectory and cut losses, the gritty individual stays the course. The importance of intellectual talent to achievement in all professional domains is well established, but less is known about other individual differences that predict success (Duckworth, Peterson, Matthews, and Kelley, 2007).

Horkey (2015) suggested that if nursing programs admit students that embrace, embody, and live the art of nursing, attrition may decrease benefiting the profession of nursing and the patients’ nurses serve. One potential solution is to identify and address factors that impact student success. Nursing programs should determine if students have what it takes to succeed in nursing. Do nursing students have grit and is grit a predictor of success in nursing? To answer these questions a descriptive, cross-sectional, study will be conducted with undergraduate nursing students from one university in South Florida. The 8-item grit scale developed by Duckworth (2016) will be used to measure the concept of grit. The grit scale measures trait-level perseverance and passion for long-term goal.

Creating a Culture of Evidence-Based Practice: A Journey From Vision to Outcomes

Jacalyn S. Buck, PhD, RN, NEA-BC, USA
Ruth M. Labardee, DNP, RNC, CNL, USA

Abstract

In this turbulent era of healthcare reform, organizational success will be defined in terms of collaborative teams delivering evidence-based, patient-centered care which results in safe, high quality patient outcomes (IOM, 2010). The development of evidence-based practice (EBP) knowledge and skills, design of EBP infrastructures, and promotion of a widespread EBP culture is a strategy that can effectively thrust organizations toward achieving these goals (Melnyk & Fineout-Overholt, 2015). In light of the importance placed on promoting EBP in nursing, there is a gap in the literature identifying effective organizational EBP models that provide a foundation for which evidence-based clinical care is developed and supported (Flodgren, Rojas-Reyes, Cole, & Foxcraft, 2012).

This presentation describes the ongoing journey within a large academic health system to create a culture in which EBP flourishes. The design of an infrastructure where nursing quality and EBP have a natural synergy was a key strategy in creating the new EBP paradigm. An important tactic in our journey was the sound integration of EBP into the role of the Clinical Nurse Specialist (CNS). The CNS has a strong link to clinical practice and is linked to the daily challenges faced by the direct care nurse. They have the skill set to evaluate the current body of literature and determine if there is sufficient evidence to support practice change. In addition, the CNS is able to lead EBP change through their work with interdisciplinary teams, formulating policies and procedures, and measuring process and outcomes (Campbell & Profetto-McGrath, 2013; Melnyk, Gallagher-Ford, & Fineout-Overholt, 2016). The CNS's were realigned to report to Health System Nursing Quality, Research, EBP Department. This realignment created a structure that promoted the translation of evidence into bedside practice while aligning with specific quality initiatives at the unit level to improve outcomes. The CNS job descriptions were redesigned to incorporate the EBP competencies assigned to the Advanced Practice Nurse and these competencies are incorporated into their annual performance evaluations.

Specific EBP implementation strategies as well as key steps for successful development and support of EBP experts and leaders will be discussed: (1) creation of an EBP strategic plan; (2) a key leadership role dedicated to EBP; the Associate Director of EBP Standards and Practice; (3) the development of a cadre of EBP mentors who are immersed in EBP across the health system; (4) re-design of our shared governance councils to include a Research, EBP & Innovation Council where EBP mentors are selected to serve as mentors on all shared governance councils to promote EBP and ensure decisions are based on evidence and best practices (5) creation of a collaboration site to house our fluid EBP database; (6) quarterly EBP mentor meetings to sustain engagement and update mentors on initiatives across the medical center; (7) CNS membership on the policy and procedure committees.

Outcomes from this innovative infrastructure redesign include: (1) nurse driven CAUTI protocol; (2) CLABSI protocol; (3) skin to skin in the labor and delivery operating room; (4) nasal CPAP suctioning protocol in the NICU; (5) implementation of the ABCDE Bundle in the ICU setting; (6) implementation of the Yale Swallow Protocol; (7) creation and implementation of care coordinator role.

Creating an infrastructure that supports and nurtures the EBP process and structure is essential in achieving safe, high quality patient outcomes (Melnyk & Fineout-Overholt, 2015). Nurse leaders are key individuals to redesign systems within their health care organizations to promote EBP and attain positive outcomes.

EBP PST 3 - Evidence-Based Practice Poster Session 3

The Opportunity for the Clinical Nurse Leader Role in Transitional Care Leadership

Pamela Kohlbry, PhD, RN, CNL, USA
JoAnn Daugherty, PhD, RN, CNL, USA
Joy Gorzeman, MBA, RN, NEA-BC, USA
Joseph A. Parker, MSN, BSN, RN, CNL, USA

Abstract

The purpose of this presentation is to describe the opportunity for leadership of the Clinical Nurse Leader (CNL) in transitional care. Leadership in transitional care is often missing resulting in any number of healthcare challenges related to errors and quality. For example, fragmentation and specialization result in problems in patient safety, medication administration, patient education, patient follow up, and gaps in communication. Typically, it is the chronically ill with the highest potential for frequent hospital visits due to the complexity of their healthcare illnesses. These hospital visits increase when there is miscommunication, breakdown in follow up, and/or lack of patient understanding. Transitions occur among patients, families, care providers, nurses, clinicians, physicians, hospitals, care settings and all along the care continuum. When problems around transitions occur it is costly for patients, families, healthcare providers, and healthcare payors which often results in unnecessary errors and poor outcomes.

The CNL would potentially bridge gaps 1) by participation of the CNL as navigators or coaches at the point of care and across the transitional care continuum and 2) as a leader in interprofessional transitional teams. This presentation will discuss the CNL skill set and its applicability in transitional care. In the United States (US) a variety of models of transitional care have been implemented in healthcare.

Research has demonstrated a positive impact of transitional care on health outcomes while reducing costs. In a recent transitions of care model, a southern California hospital utilized a CNL in the leadership role on a transitional healthcare team. Team members were identified as Health Care Coaches (HCC). Based on research of the characteristics needed, expectations, barriers and benefits of health care coaches, qualities and characteristics were identified. Interestingly, these characteristics aligned with the skill set of the CNL. Further, in this model the transitional healthcare team leader was a CNL. Savings documented using this model in the southern California hospital were as follows: Medicare Fee For Service 30 Day Readmission Rate from June-November, 2013 at 12.77% however, with the patients enrolled in the transitional care model, the 30 Day Readmission Rate June-November, 2013 was 7.15%. The cost for a 30 day readmission event is \$14,225, with the 12.77% versus the 7.15% yielding an annualized savings of over 2.3 million dollars in one hospital alone.

The CNL brings a skill set and competencies that support organizational processes in both the microsystem and macrosystem. These abilities are essential for coordinated and successful transitional care. The presentation will compare and contrast the CNL skills with the HCC and transitional care team leader.

This presentation will discuss several current models of care and the relationship to CNL competencies and education. Characteristics for HCC in transitions of care and the alignment of CNL competencies will be identified. The topic of models of transitional care is relevant to this conference because the CNL role in nursing is particularly suited to facilitate transitions of care for the chronically ill. The model of having the CNL role in transitional care leadership and the qualification of a skill set that fosters positive patient outcomes and decreases cost is a significant opportunity for nursing to contribute to improving healthcare and evidenced based practice. There is growing research on the role of the CNL as well as the need for smooth and uncomplicated transitions between care events and systems. Further, nursing has an opportunity for leadership with the CNL in transitional care.

EBP PST 3 - Evidence-Based Practice Poster Session 3

Incorporating Flipped Classroom Strategies Into a Nursing Research Course

Patricia Keresztes, PhD, RN, CCRN, USA

Abstract

The nursing research course, which also focuses on evidenced-based practice, is taught in the junior year in the undergraduate nursing program. The research course has been typically taught in a lecture format measuring student outcomes through quizzes and lectures. The content has been presented in a lecture format using slides while students take notes during the lecture. This format may help students learn terminology and basic principles but does not provide for application and synthesis of the content. It is imperative that students entering into the nursing profession be able to appraise and incorporate evidenced-based practices. After graduation, these new nurses will be expected to read and critique research articles and make decisions about practice changes based upon the evidence in the literature. Over the past two semesters, I have incorporated strategies associated with the flipped classroom pedagogical approach of teaching into the research course. The flipped classroom approach involves delivering instructional content prior to the class time such as watching online videos of content. The class session is then devoted to engaging the students in group or individual activities that help the students apply and synthesize the content. This pedagogical approach shifts students from being a passive learner listening to a professor deliver a lecture to being an active learner applying and developing a deeper understanding of the course content. The time that is spent in lecture is done to answer questions to help students develop a deeper understanding of the content. There are various strategies that can be employed in a flipped classroom. The strategies I have incorporated into the nursing research course include: use of videos students watch prior to class, completion of worksheets that cover the content to be covered that week and assigned articles to critique. During the class period, students work in groups to review the assigned article and respond to the critique questions about the research article. I spend time individually with each group answering questions they may have about the critique of the article. The last twenty minutes of the class is spent with the class as a whole discussing and reviewing each of the questions from the assigned article. This change in classroom format can be challenging for students as it is a shift in what they have typically experienced in college. Therefore, I have not completely incorporated this pedagogy into the entire semester but have revised at least half of the semester into a flipped classroom format. The students have given positive feedback about the assignments prior to class and the in class group discussions and activities. I will continue to present the nursing course using a flipped classroom strategy.

Improving the Confidence of Health Professionals Searching for Best Evidence Using PICO

Denise L. Blanchard, PhD, RN, Australia

Kim A. Van Wissen, PhD, RN, New Zealand

Abstract

The purpose of this poster is to foster awareness and build the confidence of health professionals as they work to find a solution for clinical problems using best evidence. We identify that clinical problems are complex and within these, there are often multiple discrete problems that can be managed by searching effectively in the databases using the PICO tool to support the patient outcome.

Locating evidence to support clinical reasoning and decision-making needs a considered approach to finding the best possible information by the health professional. This means health professionals need to develop more efficient habits to search and locate evidence. Additionally, a positive patient experience relies on attention to detail by the health professional exercising a reasoned approach to gathering and utilising information.

At times, clinicians are unclear about finding and accessing the best evidence. Added to this, health professionals do not always know how to interpret and apply the information clinically or use it in their learning. To overcome this, we review how to ask questions about patient care and subsequently how to work within the databases. We suggest that asking questions in a logical manner helps the health professional to gain confidence in their ability to access evidence and assess the worth of evidence when applying it to solve clinical problems.

In practice, clinicians are commonly time-poor, hence searching for and applying the best evidence does not always take precedence in daily work. An existing tool, PICO, allows health professionals to pose clear clinical questions that allow more successful interrogation of databases for evidence. PICO can be used on ward rounds in the clinical setting to direct the clinicians thinking toward clear concepts or wording that has more success in finding meaningful evidence for clinical queries.

PICO is an acronym for Patient or Population problem, Intervention, Comparison and Outcome(s) and remains one of the best tools to help formulate questions to locate research from which to develop critical thinking that contributes directly to clinical interventions, which enhance clinical knowledge. In our experience, clinicians often find themselves asking clinical questions that are complex and need teasing out into several PICO formulated questions. PICO is a tool to help navigate and clarify how to interrogate and ask questions of the databases once questions have been narrowed down so databases can provide specific answers.

PICO remains one of the best tools to help locate research from which to develop knowledge about clinical interventions. PICO encourages the use of words inherent in databases as, for example, Major Headings to identify specific search terms and how they are mapped and linked throughout a database. PICO encourages health professionals to practise consistent search strategies in relevant databases and clarifies that there may be multiple PICO questions that they need to be aware of for any one patient. Ultimately, it is the patient outcome driving the use of the PICO tool so as to achieve patient-centred care as better outcomes for people with ill-health, for example, prevention of stroke.

While databases allow searches using natural language (everyday language), this may limit the success of finding information online, therefore, understanding a patient problem or the desired outcomes for the patient is key. It is essential that health professionals be able to translate the 'natural language' PICO into language orientated to that of the database they are searching within. This means a natural language search may not transfer to the database easily with the health professional experiencing, possibly, no results at all or so many results; they may just pick the first ten results and are unable to ascertain whether results are worthwhile following up. Therefore, it becomes essential for health professionals to be

familiar with the database language, headings and concepts, to optimise their success in finding the best evidence.

Starting with the primary outcome agreed on for and with the patient is the health professional needs to plan the PICO from the desired outcome which ought to reflect a solution to the primary problem. As the health professional works to identify the primary outcome, they are most likely to encounter multiple outcomes that need to be addressed and these need to be decluttered and patient-centric. Additionally, in evidence-based health care, the professional needs to question what is the desired outcome is for this person. It may not relate to the primary problem, however, is as important as this is the patient perspective that needs to be included.

In this poster, we will provide a scenario example, identify the key clinical problem. From this, we will identify multiple problems that need to be addressed that feed into the solution to achieve the desired outcome. Asking questions of a clinical scenario we will demonstrate that for one patient, there are likely to be multiple PICOs that need to be built, answered and prioritised; that the way evidence is located will contribute to the prioritisation of clinical care and interventions.

Using Context-Inquiry Teaching Model to Enhance Advanced Clinical Medical Writing

Yi-Ru Chen, BSN, RN, Taiwan

Abstract

Abstract Introduction: The practice of clinical ladder enhances professional capacity in nursing. With senior nursing staff's guidance and through mutual learning, professional values of nursing and specialized medical writing ability could be enhanced. Such influence on motivating nursing staff to actively participate in advanced clinical ladder has been a vital issue.

AIMS: To probe into barricades affecting advanced specialized medical writing among the nursing staff. With breakthrough in related problems and diverse teaching strategies, inquiry-based learning model was employed to enable nursing staff to actively participate in advanced clinical ladder and to overcome the challenges of specialized medical writing, thus enhancing nursing achievement and confidence.

METHODS: This study focused on one Respiratory ICU in a medical center in southern Taiwan. The participants were 11 nurses, having promoted to N4 from N3. The research ranged from November 2014 to November 2015. Teaching strategies included (1) establishing the instructor database of specialized medical writing, (2) setting up online learning guidance, (3) forming specialized medical writing workshop (teacher-pupil ratio at 1:2, monthly progress check and report), and (4) peer care as well as reward system. Evaluation was based on the qualified project reports announced by the Taiwan Nurses Association.

RESULTS: The results revealed that the bimonthly presence in 2015 was 69.2%, satisfaction of teacher-pupil counseling was 100%, and that 5 specialized medical reports were completed by May 2015 (100%). A total of 3 project reports were deemed qualified in the October 2015 Announcement by the Taiwan Nurses Association. The passing rate improved by 60%, indicating the positive effects of inquiry-based teaching model.

CONCLUSIONS: The nurse clinical ladder is vital to enhancing professional nursing capacity, thus highlighting the top priority of cultivating and establishing a quality instructor database of specialized medical counselling. The inquiry-based diverse learning model effectively strengthened the analytical and handling capacity concerning clinical problems, and enhanced nursing staff's confidence and superiority. Thus, a parallel promotion is highly recommended.

EBP PST 3 - Evidence-Based Practice Poster Session 3

NICU Nurses and Families Partnering to Provide Family-Centered Developmental Care

Candy Bruton, MSN, RNC-NIC, USA
Jennifer Meckley, BSN, RNC-NIC, USA
Lori A. Nelson, BSN, RNC-NIC, USA

Abstract

The aim of this evidence based practice (EBP) project was to determine how implementing the seven neuroprotective core measures of family-centered developmental care will impact the satisfaction of the NICU nurses through new knowledge, skills and families through partnering with care compared to traditional care. According to the American Academy of Pediatrics (AAP) Committee on Hospital Care and Institute for Family Centered Care policy statement made in 2003 family-centered care is a method in which medical care is grounded in the principle that optimal health outcomes are accomplished when patients' family members participate in an active role in contributing emotional, social and developmental support (American Academy of Pediatrics, 2003). There is urgency for nursing education and guidance in neuroprotective family-centered developmental care using the seven core measures due to the increase rate of premature birth acquired disability due to being born premature globally (Butler & Als, 2008). Growth continues outside the shielding environment of the uterus and neuroprotective family-centered developmental care creates a healing environment that requires the entire family to partner in the care and growth of their infant (Altimier & Phillips, 2013; Altimer, Kenner & Damus, 2015). Benefits of family-centered care are that families feel more valuable when partnering with nurses in the care of their infant (McGrath, Samra & Kenner, 2011) and feel more empowered when they provide care for their infant. In addition being active participants in developing and maintaining the program increases a sense of fulfillment and nurse satisfaction (Phillips, 2015).

In order to accomplish this, nurses needed a firm understanding of the developmental problems with the high risk and the premature infant. It was critical that this group of caregivers understands the fundamentals of neurosensory growth of these infant. It is also vital that they understand how the intrauterine environment protects the infant from being exposed to the fluctuation of an unstable extrauterine environment.

The Neonatal Integrative Developmental Care Model (NIDCM) was the model we utilized for implementing the seven neuroprotective core measure of family-centered developmental care and are identified as: the healing environment, partnering with families, positioning and handling, minimizing stress and pain, safeguarding sleep, protecting skin and optimizing nutrition. This model is represented by the lotus flower. In the center the first core measure is the healing environments. Each of the remaining six core measures are depicted as overlapping petals to display the integrative nature of developmental care (Altimier, & Phillips, 2013).

The goal of the unit was to empower families by partnering with them to develop proper skills in caring for their infant (Westrup, 2007) positively impacting their stress level, comfort level, and confidence as well as increasing family satisfaction (Cooper, Gooding, Gallagher, Sternesky, Ledsky & Berns, 2007). The goals of the NICU nurses was to gain new knowledge, skills and increase nurse satisfaction by providing developmental care using the seven neuroprotective core measures of family centered-care for every infant every time (Cardin, Rens, Stewart, Danner-Bowman, McCarley & Kopsas, 2015).

The NICU staff was educated on the "Seven Core Measures of Neuroprotective Family-Centered Developmental Care" by lecture, printed education and hands on training with a developmental care specialist. After completion of the training the neuroprotective interventions were implemented on every NICU infant. Parents were give verbal and printed information and educated on the meaning of family centered care.

Conclusion from pre and post surveys that were collected from our NICU nurses showed an increase in knowledge of the appropriate care and potential benefits of these interventions. Pre and post Press-Ganey reports were collected from parents and results showed an increase in satisfaction over most categories. Also the results from parents during discharge phone call surveys showed NICU families had a strong satisfaction with the partnering of care and the level of family centered care their infant received.

EBP PST 3 - Evidence-Based Practice Poster Session 3

The "Cost of Caring" for Cancer Patients: Mixed Methods Research With Victories and Hazards Exposed

Laurie Freeman-Gibb, PhD, RN, ANP, Canada

Kathryn A. Pfaff, PhD, RN, Canada

Linda J. Patrick, PhD, MSc, MA, BScN, RN, Canada

Abstract

Compassion fatigue (CF) is a form of secondary traumatic stress and burnout (Figley, 1995). CF is experienced as emotional and physical erosion on a personal level, and occurs when helping professionals are unable to refuel or regenerate (Joinson, 1992; Figley, 1995). As CF most commonly occurs during and/or following prolonged interactions with individuals who are in distress, it is also thought to be the result of stress coupled with ongoing self-sacrifice (Potter et al., 2013). The prevalence is particularly high in oncology settings (Potter et al., 2013; Vachon, 2012; Yu, Jiang, & Shen, 2016). The 'cost of caring' intensely impacts on patient and organizational outcomes in that caregivers become unable to nurture or empathize with persons in their care (Figley, 1995). The results can impact on patient satisfaction, patient safety due to increased sick days and reduced productivity of staff, along with higher turnover rates (Hooper, Craig, Janvrin, Wetsel, & Reimels, 2010). Initially thought to only be a nursing related phenomenon (Joinson, 1992) it is now known that all healthcare providers are at risk for CF (Hooper et al., 2010).

A six-week pilot CF resiliency (CFR) program was developed and offered to interprofessional healthcare providers and staff at a regional cancer centre in Ontario, Canada. The intervention was offered as a two-hour program after the workday in the hospital setting and based on the *CF – Accelerated Recovery Program (ARP)* (Gentry, Baranowsky, & Dunning, 2002; Traumatology Institute, 2012). It was evaluated using an experimental embedded mixed methods research study design (Creswell & Plano Clark, 2010) to evaluate the impact of the pilot CFR Program. The purpose of this presentation is to examine the use of an experimental embedded mixed methods research study design and discuss the best ways to achieve victories and avoid research hazards when doing workplace interventional studies.

In keeping with a mixed methods design a combination of qualitative and quantitative methods was used to evaluate the CFR program. The use of a mixed methods design provided a better understanding of the complex phenomena of compassion fatigue than either approach alone (Molina-Azorin, 2016). Standardized instruments to measure CF and related concepts were administered before and after the educational program intervention. Focus groups and individual interviews were conducted at mid-intervention and at completion of the CFR program. The qualitative and quantitative data were analyzed separately and merged to produce the overall findings. Researcher triangulation was used throughout all phases and processes of the study enhancing the inferences made.

After ethical approval was granted from both the university and the healthcare system Faculty of Nursing members drove the research component separately from the educational intervention undertaking that was totally supported by the cancer care facility. Initial support from the cancer care facility extended to assistance with study packet photocopying, communication with participants interested in the educational intervention and other administrative oversight.

The mixed methods design used a phase one quantitative data collection through voluntary recruitment prior to the initiation of the CFR program. Complete study packets from clerks, managers, registered nurses, physician's, radiation therapists and other care workers for analysis were received. The research team was available during this portion to assist with question on how to fill in the questioners. At the end of the quantitative data collection a separate form asked participants if they would consent to being contacted at the mid point of the educational intervention to participate in 3 scheduled focus groups or an individual interview to discuss their experiences as the qualitative section of the method used. Final data collection was done at the end of the last session of the educational intervention and again participants

were asked if they would like to be contacted to participate in focus groups or have an individual interview.

Our Victories: The working relationship between the cancer center staff and the faculty members was excellent. Recruitment into the educational program and initial enrolment into the study portion exceeded our expectations. It was also thrilling to have participation from so many segments of the healthcare team. Initial assistance with study packets and having a room in the hospital dedicated to the study and then to the educational intervention made it convenient for staff and for the research team. Financial support from the management team supported the endeavour and encouraged participation in the educational intervention.

Encountered Hazards: Support from the cancer center management team was withdrawn halfway through the educational program when the main program champion changed jobs. This significantly impacted the educational sessions and planned activities. Hospital printing of the study packets for final data collection had errors that were not correctable therefore valuable data was lost. Expecting multidisciplinary groups to learn together has its own set of concerns that must be addressed prior to doing this type of education. Many participants did not complete the program nor stay for final data collection again significantly impacting the results. Focus groups were poorly attended with many participants' preferring individual interviews, which can be costly and time consuming.

Conclusion: Mixed methods design can acquire rich data on areas that are not well researched. Use of this methodology can be complicated but truly does allow for a more complete analysis of the situation. Describing how to successfully embed qualitative and quantitative methods will assist other nursing researchers in the future use this methodology. Multiple victories and hazards were encountered when doing the research component of this program. Bringing awareness of them and the impact they had on doing this type of research is necessary to assist other nurse researchers in avoiding the same issues in future research endeavours.

Getting Back to the Basics: Handwashing 101

Abigail Mitchell, DHEd, MSN, RN, CNE, FHERDSA, USA

Heather Nugent, MS(c), RN, USA

Theresa MCNamara-Beatty, MS-ANP, RN, TNCC, NPA/ACCN, USA

Abstract

In nursing school handwashing was first skill we learned and a skill that we demonstrated throughout the program, especially in clinical settings. As nurses' handwashing is an essential task that must be completed many times a day to safe guard ourselves and to protect our patients. Handwashing is one of the most important way of reducing the spread of infection. However, despite the many studies and literature hand washing compliance rates remain low. Lack of hand washing compliance is a global issue. The World Health Organization has declared nosocomial infections a serious global problem. Hand washing with soap is recognized as one of the most important means of reducing spread of infectious organisms' world- wide (Green, Kalaycioglu, Barch, et al, 2014). Each year, Healthcare Associated Infections (HAIs) affect over 722,000 patients and approximately killing 75,000 of them, in the United States alone (Musuuza et al, 2016). HAIs are among the most common preventable medical complications that result from errors and unsafe practices. Hand hygiene is known as a primary and crucial tool for reducing infections caused by health care personnel. The use of alcohol-based hand rub solutions are popular and often are used instead of washing the hands with soap and water, or sometimes HCP will use both methods for hand washing compliance. HAIs increase morbidity and mortality and length of stay, placing a great financial burden on health care services. To assist hospitals with reducing the risk of HAIs evidence-based guidelines have been introduced by multiple national and international agencies, often with a focus on the role of hand hygiene for lowering infection rates (Boyce & Pitte, 2002). Florence Nightingale's environmental theory guided this study. Her theory changed the face of nursing to create sanitary conditions for patients to receive care and improved sanitation in the hospital setting. The goal of nursing is to facilitate a healing process by placing the patient in the best possible environment for nature to influence health (Nightingale, 1860). The purpose of this study is a twofold. First the researchers performed a systematic literature review and secondly an observational study of hand hygiene compliance was conducted using an audit tool on all health care personnel (HCP) working on units in a community hospital. HCP were observed by two auditors during rounds and unaware that hand hygiene was under observation.

Building Integrity into Nursing Curriculum and Culture

Patricia Severt, MSN, RN, USA
Amanda Page, MFA, USA

Abstract

Academic dishonesty is on the rise nationwide due to advances in technology. This creates a dilemma in nursing education. In the nursing profession, integrity is not an option; it can determine the outcome in a life or death situation (Bavier, 2009). Studies reveal that there is a connection between poor integrity in nursing school and poor integrity in the professional nursing role. The purpose of this project is to reveal the issue of cheating among nursing students and determine ways to diminish its existence, maintain the integrity of the nursing profession and, ultimately, improve patient outcomes.

A review of articles published between 2004-2015 was conducted using Ebsco databases and the keywords academic dishonesty, academic misconduct, nursing students, plagiarism, and cheating. The focus was on the definition of academic dishonesty, students' views, faculty views, and methods to decrease cheating. The definition varies among students and faculty and suggests that societal norms have shifted so that cheating in some forms is not seen as unethical. For example, students have plagiarized, looked at other students' papers during an exam, used another student's paper as their own, used technology to photograph an exam and pass it on, falsified patient information in the clinical setting, and falsely stated illness to be absent from clinical (Laduke, 2013). And yet few of these instances were defined as "cheating."

In reviewing the literature, it was noted that the mentality which promotes dishonesty in the academic arena continues into the professional arena (Laduke, 2013). Arhin and Jones (2009) found that evolving technology has aided in academic demise. Students find it easier to cut and paste parts of documents from electronic sources. Additionally, internet services are offered that, for a fee, an essay can be written for the student. Johanson (2010) states academic rigor, competitive environments, larger class sizes, inadequate faculty, and lack of faculty support as reasons given by students for dishonesty.

The rationale for becoming a nursing student has changed over the years. Students joining the nursing profession are doing so for solid career paths, financial security, and prestige (Laduke, 2013). This suggests that not all students are students with high standards of morals and integrity. Nursing is among the top most trusted profession and action must be taken to ensure it remains as such (Laduke, 2013).

Changes are needed in nursing education to ensure the integrity of the students that are successful in the nursing programs. The use of screening tools during the admission process can focus on the ethical and moral standards of the incoming student. Institution policy definitions and revisions with clearly stated consequences for academic dishonesty are needed. Administrator support of faculty at the front lines of the fraudulent behavior is imperative. Developing and utilizing student leaders as mentors can help model and develop integrity in other students. Further recommendations may be provided.

In conclusion, the literature clearly demonstrates the parallel of dishonesty in nursing programs and declining integrity of nurses at the bedside. If we want nurses to remain the most trusted profession because of intact ethical and moral principles, then we as educators must ensure that those qualities are present in the student throughout the program. It is our ethical duty as educators to make moral and ethical decision making opportunities fundamental in every aspect of our nursing programs (Bavier, 2009). Building integrity into all nursing programs will safeguard the highest quality of nurse that society receives and that can be trusted with patient lives.

A Nurse-Led Heart Failure Education Program to Improve Knowledge and Self-Care and Reduce 30-Day Readmission

Martha Sissay Awoke, MSN, RN, USA
Diana Lyn Baptiste, DNP, MSN, RN, USA

Abstract

Purpose/Objectives: Heart failure is a burdensome condition that affects more than 6 million Americans and an estimated 23 million people worldwide. Individuals living with heart often experience breathless, edema, and fatigue leading to frequent hospital admission. The purpose of this quality improvement program was to standardize a nurse-led heart failure patient education and evaluate its impact on knowledge, self-care behaviors, and all cause 30-day hospital readmission at a large urban academic medical center.

Methods: We implemented an evidence-based standardized heart failure patient education program with telephone follow-up at 7, 30 and 90 days post-discharge. A convenience sample of (N=19) Individuals who were hospitalized with diagnosis of heart failure completed two questionnaires: 1) the Dutch Heart Failure Knowledge Scale (DHFKS) and, 2) the Self-care Heart Failure Index (SCHFI).

Results: Descriptive statistics were analyzed using SPSS® version 23 to provide demographic characteristics for the sample. The mean age for the sample is 68, with ranging from 54-90, almost evenly distributed gender, and most of the sample size reported they were unemployed, retired, or disabled. Nine participants (47%) had an ejection fraction less 40% and 47% had an NYHA IV classification. Among (n=19) participants, baseline knowledge scores ranged from 9-15. The mean score was 12.21 SD=1.548, which is comparable to scores reported in previous studies which were mean 11.4 and 12.6, respectively.

Self-care maintenance shows (n=4) participants scoring between 40-50% and another 4 patients scoring between 70-80%. Six participants scored between 50-70%, 1 participant scored 100% and 2 patients each scored between 20-40% and 80-90%. Self-care management score describes a normal distribution curve in which the majority of the responders were under the bell curve. Answers ranged from "I did not recognize symptoms" to "I recognize the symptom of heart failure quickly." Of the (n=19) participants, 11 stated that they "did not recognize HF symptoms". However, when asked about how likely they were to try some of the remedies (reduce fluid intake, reduce salt intake, call your doctor or nurse) if they experienced trouble breathing or ankle swelling, 13 patients stated they are "very likely" to try one of the remedies.

Conclusion: Implications from this study suggest the importance of developing education programs that are focused on improving knowledge, self-care maintenance, self-care management and self-care confidence for heart failure patients. Those who score lower self-care behavior scores after the intervention may benefit from additional education, resources, and support. Nurses are uniquely qualified to implement such programs that can improve health outcomes and need to accommodate evidence-based recommendations to global practice settings.

Nursing Clinical Practicum: Integrated Application Process

Nancy S. Goldstein, DNP, MS, RNC-OB, ANP-BC, USA

Diana Lyn Baptiste, DNP, MSN, RN, USA

Sibyl Snow, MA, BA, USA

Abstract

Pre-licensure nursing students have a final capstone practicum or clinical course as they transition to the professional nurse role. Generally, the student role requires increased independent practice, which can be a challenge. Nursing students' final clinical course is typically expected to facilitate their transition to professional practice. The senior practicum or transitions practicum is designed for the student to partner with a practicing nurse preceptor to learn both nursing role and skills. Learning during the senior practicum is important as the student will recognize the development of their own intellectual knowledge, psychomotor skills, and affective attitudes as they transition from nursing student to nurse graduate.

Supporting nursing students in learning is an important role for educators. The student's decision of where they should complete their nursing school practicum can be a difficult decision, especially when there are many options in the specialty, local, and distant areas, and internationally. Developing a process to improve selection quality for an integrated application became a challenging goal. By analyzing and reorganizing the process, a strategy was developed, one with the functionality and technical capabilities to support the wide-ranging needs of all clinical practicum options.

We developed a web-based application using Qualtrics® survey software. Students were provided a link to complete the application within a two-week time frame. We divided options into the categories based on specialty areas. Students were provided a text box to provide a 250-word narrative about why they are interested in the practicum specialty areas. Practicum requests were received from all 106 student applicants. Results were uploaded to an Excel spreadsheet and reviewed by educators to assign all student placements.

Using technology to support the application has enabled educators to successfully assign students to the practicum site of their choice. Further investigation is necessary to explore students' satisfaction with the system used for the application.

An Orientation Program to Improve Teaching Competency in Clinical Nurse Faculty

Bonnie M. Shaffer, MS, RN, CNS, USA

Abstract

A critical component of undergraduate nursing education is learning the hands-on skills of a nurse in the clinical setting. The problem with providing that clinical instruction is the lack of experienced and qualified clinical faculty (AACN, 2015). Due to the urgent need for clinical faculty to teach students in the clinical environment, hiring nurses with strong clinical skills addresses the immediate need although these nurses have little or no experience teaching. Sending inexperienced educators into the clinical environment without adequate preparation presents a number of problems for the new faculty as well as the students. The purpose of the pilot project was to determine the impact of a formal orientation program on improving clinical teaching competency for Clinical Nurse Faculty (CNF).

Using a pretest-posttest quasi-experimental design, faculty recently hired to teach clinicals were asked to participate. The project consisted of the subjects completing a self-assessment utilizing the Clinical Teaching Competency Inventory (CTCI), which is a reliable and valid instrument for clinical nursing preceptors to self-evaluate competence in providing clinical instruction (Hsu, Hsieh, Chiu & Chen, 2014). The subjects then attended a structured orientation program, after which the CNF taught one clinical rotation. Upon completion of teaching a clinical rotation, the CNF were asked to complete the CTCI again.

The post-intervention data is currently being collected and will be entered into a Microsoft Excel Spreadsheet and imported into IBM SPSS Statistics version 23 program. Descriptive statistics will be used to analyze and report sample characteristics and to perform preliminary analyses for the assumption of normality. If the assumption is met, a parametric Paired Samples *t*-test will be used to determine if there is a significant difference in scores from pre to posttest. If the assumption is not met, the non-parametric alternative, Wilcoxon Signed Test will be used.

The findings from the project will be shared as analysis will be completed at time of presentation. Regardless of the findings, schools of nursing find themselves in need of CNF. In order to meet the needs of the students in the clinical environment, experienced nurses are hired from the bedside and placed in a teaching role without adequate preparation, lacking the competence needed to be an effective educator. An orientation program is clearly needed, as evidenced in the literature review, to improve the competence of the bedside nurse who is transitioning to the role of CNF. The “nuts and bolts” needed to develop a clinical faculty orientation will be provided.

Enhancing Academic Writing Atmosphere Among Nurses in the Emergency Department

Hui-Ching Hsu, RN, Taiwan
Hui-Ju Chung, RN, Taiwan

Abstract

Purpose: Academic writing is regarded as an important professional skill in the clinical ladder. Despite rich nursing experiences most nursing staff possess, their unskilled written expression often results in difficulty in writing relevant reports. The underlying reasons for their unwillingness to participate in academic writing were difficulty in passing, inability to comprehend the literature, lack of motivation, the state of being unable to search for related data, and lack of professional guidance. Since academic writing combines higher-level abilities (such as synthesis, analysis, and evaluation), logical thinking, and organizational skills, such capacity helps learners to enhance professional abilities and nursing quality involved in the caring process. Therefore, it is hoped that a good learning environment could be created via improvement projects drafted by a special committee, with the aim to increasing motivation of academic writing among nursing staff and further enhancing nursing quality.

Method: A special committee workshop was formed to locate the nursing staff that needed to hand in academic reports. The following procedures included making plans for handing in reports, holding writing workshops (case study workshop: twice a year; special committee workshop: once a year), using teaching resources for guidance (with clinical instructors helping nursing staff find cases and topics appropriate for academic writing), and forming a LINE group. Workshop instructors provided timely solutions based on the learners' questions and monitored their writing progress, to increase the motivation of academic writing and the completion rate of report submission among nursing staff in the emergency department.

Results: With special committee workshops used to increase the motivation of academic writing among nursing staff in the emergency department, the results revealed that during January 2015 and June 2016, 13 out of 15 case report submissions passed, yielding a high passing rate of 87%. Significant enhancement in writing academic reports and searching for literature was also found among those nursing staff.

Conclusion: A serious lack of nursing workforce in recent years and the unique need for taking shifts have affected nursing staff's motivation to participate in academic writing. However, the clinical ladder program requires nursing staff to move upward based on their completion of academic case reports. The intervention from a special committee to enhance the writing ability among colleagues in the emergency department enabled nursing staff to utilize their professional knowledge for discussion over the caring issues related to patients, thus enhancing nursing quality and job satisfaction as they built professional confidence.

Nursing Programs and Supportive Housing Sites: Mutual Benefits of Multigenerational Engagement Through Innovative Academic-Practice Partnerships

Maureen F. O'Shea, DNP, AGPCNP-BC, USA
Mary McCarthy, MEd, USA
Barbara J. Pinchera, DNP, ANP-BC, USA
Margaret Sullivan, MSN, ANP-BC, USA

Abstract

Through a collaborative partnership, traditional baccalaureate undergraduate nursing students, together with residents of an older adult community with supportive services, engage in purposeful, semi-structured activities while considering factors that influence individual, community and population health throughout the lifespan. Participants utilize evidence-based assessment tools and explore aspects of individualized aging, complexity of care, and personal vulnerability during life transitions. The focus on the five domains of wellness: physical, social, cognitive, spiritual, and emotional. A range of topics include: medication management, health assessment, disease prevention and management, home safety, falls assessment, psycho-social well being, delirium, dementia and sensory impairments, depression and anxiety management, and end of life issues.

Activities are designed to foster an increased appreciation and enhanced awareness of the impact of evolving demographic trends locally, regionally, nationally, and internationally in relation to healthcare policies and systems, as well as to promote consideration of careers in gerontology.

Specific goals of this partnership include:

- Increasing nursing students' awareness of shifting population demographics as a key factor in the evolving need for highly skilled geriatric specialized nurses
- Dispelling stereotypes of aging
- Enhancing understanding of the aging process from a whole-person perspective, including physical, cognitive, social, emotional and spiritual health
- Promoting meaningful engagement through intergenerational experiences
- Identifying evidence-based best practices in geriatric care
- Increasing nursing students' consideration of careers in gerontology
- Providing opportunities for seniors to share their experiences and impact the lives of young adults as well as assist in educating the next generation of nurses.

Nursing students and older adults gain further appreciation for viewing health through a wider lens. Vitality is possible at any age, and so is living a healthy, active life with chronic conditions. When students interact with residents who are in their eighties, nineties and one hundreds, who are living independently in a supportive environment, they are able to dispel the negative connotations often associated with aging stereotypes.

Discussion regarding shared commonalities, as well as comparing and contrasting similarities and differences, enriches the learning experience for nursing students and older adults in this innovative, non-traditional practice partnership.

EBP PST 3 - Evidence-Based Practice Poster Session 3

Connection of Partner Violence and Women's Loss of Fertility Control and Impact on Health

Fuqin Liu, PhD, RN, USA

Judith M. McFarlane, DrPH, RN, FAAN, USA

Sandra Cesario, PhD, MS, BSN, RNC, FAAN, USA

Abstract

Intimate partner violence (IPV) against women is a serious global health issue. Abused women experience a wide range of adverse health consequences, including physical health concerns, mental health dysfunctions, and adverse reproductive health outcomes. Fertility control is documented in the literature as an important concept connected to partner abuse. However, the assessment of women's fertility control has focused mainly on the controlling behaviors of men.

Informed by a review of the literature, the researchers developed a questionnaire to collect information on fertility control dynamics in an abusive relationship. More specifically, the researchers wanted the questionnaire to assess fertility-controlling behaviors of the abusers, women's responses to the controlling behaviors, and pregnancy outcomes when the fertility control of the women was compromised. The questionnaire was administered in a multi-year prospective study designed to investigate mother and child outcomes when abused mothers seek assistance in the forms of safe shelter or justice services for the first time. The goal of the parent study is to expand the body of evidence regarding the long-term consequences of IPV on women and their children. Data collection began in 2011, and participants have been interviewed at 4-month intervals since the onset of the study. During the 32-month interview, participants responded to a one-time, investigator-developed fertility control questionnaire in addition to the ongoing repeated measures. The parent study is ongoing in a large urban metropolis in the United States with a population exceeding 4 million people.

The researchers examined the interactions among IPV, fertility control, pregnancy outcomes, and mental health. The findings confirm a strong relationship between severity of abuse, mental health functioning, and fertility control in the context of partner violence. The researchers also found that compromised fertility control was associated with the likelihood of miscarriage, premature birth, and abused-induced premature birth. The fertility control questionnaire expands on recent work on reproductive coercion by other scholars. The findings also indicate that it is important for clinicians to assess abused women about their fertility control.

EBP PST 3 - Evidence-Based Practice Poster Session 3

A Nursing Educational Intervention for Patient-Initiated Verbal Aggression

Mary C. Poquette, MSN, RN, USA
Carolyn Rutledge, PhD, CFNP, USA
Tarry Wolfe, DNP, FNP-C, PMHNP-BC, USA

Abstract

PROBLEM: The incidence of patient-initiated verbal aggression (PIVA) has increased significantly in acute care hospitals. Many nurses, working in medical-surgical environments, lack both the knowledge and skills to safely care for these patients.

PURPOSE: This study aims to increase nurses' willingness to confront patients exhibiting PIVA. The long term goal is to improve quality of care by creating a culture of safety, protective of both nurses and patients.

EBP QUESTIONS: (1) Is there a relationship between knowledge, perceived barriers, de-escalation behaviors, comfort level to confront PIVA, willingness to confront PIVA, personal characteristics, and professional characteristics for nurses working in medical-surgical environments? (2) Is there a difference in knowledge, perceived barriers, de-escalation behaviors, comfort level to confront PIVA, and willingness to confront PIVA following participation in an advanced practice nurse (APN) led PIVA education program, for nurses working in medical-surgical environments?

METHODS: This study will be conducted using a pre-experimental pre-test/ post-test design with a single group of medical-surgical nurses. Only one group will receive the intervention, an APN-led PIVA education program.

OUTCOMES: The medical-surgical nurses who participate in this APN educational intervention will experience an increased awareness of self-efficacy learning concepts, de-escalation techniques, perceived barriers to confronting PIVA as well as discovering one's comfort level to confront PIVA with the ultimate goal of enhancing the quality of nursing care while creating a safer environment for patients and staff.

SIGNIFICANCE: PIVA education must incorporate the notion that patient behavior may change abruptly. Often verbal aggression, a leading indicator of pending conflict events, is not confronted by nurses. PIVA education may enhance the quality of nursing care delivered while keeping all involved in patient care delivery safer.

Problem: Patient-initiated verbal aggression (PIVA) has become an all too common occurrence (Park, Cho, & Hong, 2015) in hospitals, requiring skills other than therapeutic communication techniques taught in traditional nursing curricula. Many nurses, working in medical-surgical environments, indicate they lack both the knowledge and skills to safely care for patients displaying PIVA. The primary means of communication between patients and staff remains verbal interaction, unlike the surrounding global environment that relies on smartphones and other communication technologies. Patient demographics are changing, co-morbidities are more frequently identified and with evolving healthcare economics and technologies, the acute care environment has become an atmosphere of shorter lengths of stay (LOS), more complex care-delivery issues, and growing patient expectations. In turn, many patients demonstrate the behavioral health challenges associated with PIVA towards the healthcare staff providing care services (Gunenc, O'Shea, & Dickens, 2015); often in the absence of a formal, mental health diagnosis. This current-state description has become far more the standard within the confines of today's acute care hospitals. Nurses form interpersonal relationships with patients through the use of therapeutic communication techniques that are taught in every undergraduate nursing school curriculum. However, these academia-taught communication skills are insufficient when patients exhibit PIVA behaviors that may cause harm to themselves or staff.

Purpose: This study will explore differences knowledge, perceived barriers, and de-escalation behaviors following participation in an advanced practice nurse (APN) led patient-initiated verbal aggression education program, for nurses working in medical-surgical environments. Nurse comfort level and willingness to confront PIVA, along with personal and professional characteristics will also be explored.

Specific Aims: This study aims to increase nurses' willingness to confront patients exhibiting PIVA. The long term goal is to improve quality of care by creating a culture of safety, protective of both nurses and patients. Research questions will include:

Research Question 1. Is there a relationship between knowledge, perceived barriers, de-escalation behaviors, comfort level to confront PIVA, willingness to confront PIVA, personal characteristics and professional characteristics for nurses working in medical-surgical environments?

Research Question 2. Is there a difference in knowledge, perceived barriers, de-escalation behaviors, comfort level to confront PIVA, and willingness to confront PIVA following participation in an advanced practice nurse (APN) led PIVA education program, for nurses working in medical-surgical environments?

Scope and Importance: Aberrant patient behavior can create safety concerns for nurses assigned to patients exhibiting PIVA behaviors within the geographical footprint of an adult, medical-surgical, acute-care unit. Knowledge and communication skills obtained from a PIVA education program may enhance the quality of nursing care delivered while keeping all involved in patient care delivery safer.

Variables: The independent variable for this study is the APN-led patient-initiated verbal aggression (PIVA) education program. Dependent variables include knowledge, barriers, de-escalation behaviors, comfort level to confront PIVA, and willingness to confront PIVA. Nurse personal and professional characteristics will also be explored.

Incidence/Statistics: Workplace violence in healthcare settings is exploding while known to be significantly under-reported (US-OSHA, 2015). Incidents of serious workplace violence defined as incidents requiring time away from employment are occurring at a rate four times more often or 7.8 cases per 10,000 full-time employees which is more than any other industry inclusive of construction and manufacturing as reported by the United States Occupational Safety and Health Administration (US-OSHA, 2015). Further data analysis indicates that "patients are the largest source of violence [or 80%] in healthcare settings" (US-OSHA, 2015, p.2).

Additional review indicates that "verbal aggression [has become] a common form of communication [between patients and the nurses caring for them accounting] for a significant proportion of the violence and aggression that occurs in the nursing workplace" (McLaughlin, Gorley, & Moseley, 2009, p. 735). Within a 12 month period, 413 of 762 nurses or 54% participating in a research survey located in a mid-Atlantic, urban community hospital reported verbal abuse by a patient (Speroni, Fitch, Dawson & Dugan, 2014). A more alarming research study found that 39.6 % of the participating nurses or 981 of 2,478 nurses reported emotional abuse which then rose to 77.6% when reporting verbal threats of violence during the last five shifts worked (Roche, Diers, Duffield & Catling-Paull, 2010). Similar results have been found by Veterans Administration officials when researching this topic in 2011 (VA-OIG, 2013). Upon review of 889 patient records, 56.6% of the time, healthcare staff encountered verbal aggression or verbal attacks (VA-OIG, 2013).

Verbal aggression can occur in the forms of abusive language, shouting, threats, racism, being argumentative or verbally challenging (Stewart & Bowers, 2012). Yet one's ability to confront conflict inclusive of reporting may be enhanced or inhibited by individual self-efficacy beliefs (Bandura, 1977). Knowing that each identified form of verbal aggression is a negative stressor for the nurse experiencing such events, these incidents negatively impede self-esteem, can create negative work performance behaviors and/ or eventual 'burn-out' (McLaughlin, Bonner, Mboche & Fairlie, 2010) which are counter-productive circumstances within any profession especially nursing.

There remains wide variation (17% to 94%) in the reporting of verbal aggression encounters by nurses in the general, acute-care setting both nationally and internationally (Edward, Ousey, Warelow, & Lui, 2014). The phenomenon of “widespread under-reporting” (Stone, McMillan, Hazelton, & Clayton, 2011, p. 194) is perceived to exist related to external barrier factors such as behavioral scenarios will not change if reported and/ or reporting of the incident may create perceived, additional retribution for the reporting nurse (Stone, McMillan, Hazelton, & Clayton, 2011). Whether reported or not, this is an experience that should be treated with zero-tolerance and with appropriate training prevented.

Addressing the Gaps: PIVA is increasing at a disquieting rate (US-OSHA, 2015, Speroni, Fitch, Dawson & Dugan, 2014; VA-OIG, 2013; Roche, Diers, Duffield & Catling-Paull, 2010). For direct-care, medical-surgical nurses to be able to effectively manage PIVA situations, additional knowledge must be acquired regarding verbal cues that may lead to PIVA, self-efficacy learning principles, potential barriers to confronting PIVA, one’s comfort level as well as willingness to confront PIVA along with de-escalation techniques. There is presently a literature gap of how these constructs collectively can assist the acute-care nurse in more effectively being able and willing to confront PIVA when it occurs. This study seeks to add to the body of nursing literature on how an advanced practice nurse (APN) led patient-initiated verbal aggression education program can increase nurses’ willingness to confront patients exhibiting PIVA with the stretch goal of improving the quality of care by creating a culture of safety, protective of both nurses and patients.

Need for Mental Health and Addiction Curriculum in Undergraduate Nursing Education in Canada and Globally

Arlene E. Kent-Wilkinson, PhD, RN, CPMHN(C), Canada

Leigh Blaney, PhD, RN, CPMHN(C), Canada

Marlee Groening, MSN, RN, Canada

Elaine E. Santa Mina, PhD, RN, Canada

Carmen Rodrigue, MScN, RN, CPMHN(C), Canada

Carmen Hust, PhD, MScN, RN, Canada

Abstract

Purpose: Mental health and addiction conditions persist in 2017 as serious health concerns that affect the lives of one in every five Canadians and their families. Nurses, as the largest group of health care providers are significant stakeholders in meeting the mental health and addiction care needs of citizens globally. The purpose of this paper is to emphasize the importance of inclusion of mental health and addiction content in the curricula of all undergraduate nursing programs, addressing the need for entry-to-practice competencies; and, discussing the responsibility of nursing education and professional associations.

Need/Issue: The complexity of concurrent disorders supports the need for entry-level undergraduate nursing education in Canada to prepare all new RNs to identify, care for, and manage mental health and addiction disorders. Results of an environmental scan in 2015 revealed that 22 percent of Canada's 46 undergraduate nursing programs lacked a designated mental health theory course in their curriculum, and 28 percent of the nursing programs did not offer a clinical placement in mental health. How will new graduate nurses be able to advocate for persons with mental health conditions and addictions if they have not had theoretical and clinical nursing exposure in their undergraduate nursing program? Education (both theoretical knowledge and psychomotor/psychosocial clinical skills) in mental health and addiction for all undergraduate nursing students is essential. Although it is common for undergraduate nursing students to feel apprehensive about transitioning into the graduate nursing role in any area of nursing, entry-to-practice core competencies in mental health and addictions are needed in undergraduate nursing programs. When approximately 50 percent of people with a mental health disorder also have an addiction problem, and at least 20 percent of people with an addiction problem also have a mental health disorder, education is needed. The undergraduate education of all registered nurses (RNs) must provide student nurses with the ability to also recognize co-existing physical and mental health conditions and the interconnections between them. Future graduates entering nursing, the largest component of the health care workforce, need education in mental health and addiction to provide many workplace settings with health promotion education, access to preventive health services, and links to primary, secondary, and tertiary health care.

Responsibility of Nursing Education and Professional Associations: In 2015, the Canadian Association of Schools of Nursing (CASN) partnered with members of the Canadian Federation of Mental Health Nurses (CFMHN) to develop the *Entry-to-Practice Mental Health and Addiction Competencies for Undergraduate Nursing Curriculum*. Members of the CFMHN Education Committee focused their CFMHN (2016) 3rd position statement and paper on this crucial need in nursing education: *Mental health and Addiction Curriculum in Undergraduate Nursing Education in Canada*. The scope and complexity of mental health conditions and addiction issues provides a clear justification for including mental health and addiction competencies within all nursing undergraduate programs in Canada and globally. In this presentation, the author(s) will argue that it is reprehensible for schools of nursing to graduate nursing students who have limited knowledge of caring for at least 20 percent of the population in Canada, and similar rates globally, who live with mental health and addiction conditions.

Enhancing Interventions to Impact Healthcare Transition Readiness and Preparation of HIV-Infected Young Adults

Sandra C. Jones, MSN, RN, APN, CPNP, USA

Yeow Chye Ng, PhD, MSN, BSN, BSE, RN, FNP-BC, NP-C, NRCME, AAHIVE, USA

Shelley R. Ost, MD, FAAP, AAHIVS, USA

Abstract

Introduction: Human immunodeficiency virus also known as HIV, is now considered a chronic disease and many people are living longer as a result of the use of antiretroviral therapy (ART) (Centers of Disease Control, 2016a). Due to this improved life expectancy, preparation for transition of HIV positive adolescents and young adults (AYA) from pediatric/adolescent health care to adult health care becomes a significant priority as there are more than 25,000 young people ages 13 to 24 years living with HIV who will most likely need to be transitioned to adult HIV or Infectious Disease health care providers within the next 10 years (Dowshen & D'Angelo, 2011). However, adolescents and young adults are not prepared to transition nor manage their own health care and need assistance in developing critical skills necessary for independence, transition and their success in treatment management (McManus et al., 2015). The American Academy of Pediatrics (AAP) recommends setting transition goals with the patient, using a continual assessment of transition readiness with validated measures of transition related skills and adapting/guiding interventions to assist adolescents in preparing for transition (Wood et al., 2014). Despite these recommendations, many practices do not comprehensively assess health care transition readiness skills on a continual basis nor incorporate measured assessments of transition readiness into routine care (Wood et al., 2014; Sharma, O'Hare, Antonelli, & Sawicki, 2014).

Due to the lack of a formal transition readiness assessment with validated tools, there is not a defined process of tracking and evaluating transition readiness and often not enough time to ensure retention of acquired skills or knowledge which ultimately may impact the health and future of young adults with HIV who transition their healthcare from a HIV clinic into another clinical setting. The practice question is: In HIV positive adolescents and young adults, does the use of a Transition Readiness Assessment Questionnaire (TRAQ), a validated transition readiness assessment tool, enhance health care provider interventions and follow up to improve acquisition of skills and knowledge necessary for transition compared to not using TRAQ?

Review of Evidence: In general, principles for transitioning include creating a formal policy of transition to define the goals and timeline of transition for AYA, developing an individualized approach including creating a portable medical summary or EHR ensuring understanding of the chronic illness, providing AYA with critical skills such as maintaining health insurance, independently refilling prescriptions, and adhering to medications and appointments, monitoring the development of skills, tracking their progress, addressing barriers and modifying interventions as indicated (New York State Department of Health AIDS Institute, 2016; Committee on Pediatric AIDS, 2013). However, there is limited information about how to determine when adolescents are ready and competent enough to successfully transition their healthcare (Moynihan et al., 2015; Schwartz et al., 2014; Ferris et al., 2015). There is considerable variability among institutions regarding transition practices especially in regards to addressing comprehensive care needs related to transition such as medical, psychosocial and financial needs in addition to limited descriptions of tools and processes used for transition (Committee on Pediatric AIDS, 2013). Health care transition is a purposeful, planned strategy of various interventions to assist adolescents and young adults (AYA) with chronic conditions transfer their health care from pediatric to adult care settings (American Academy of Pediatrics, American Academy of Family Physicians, and American College of Physicians, Transitions Clinical Report Authoring Group, 2011; Zhang, Ho & Kennedy, 2014; Maturo et al., 2011). Transition includes assessing and monitoring skill development and modifying interventions as needed (New York State Department of Health AIDS Institute, 2016; Committee on Pediatric AIDS, 2013). The use of validated tools to measure transition readiness can assist the patient and provider to develop and evaluate skills, set goals and guide interventions to better prepare adolescents for transition and can also

be a catalyst for development of evidence based interventions to support a successful health care transition (Wood et al., 2014; McManus et al., 2015).

The middle range transition nursing theory provides a conceptual framework which emphasizes the complexity of transition and each patient's need for assessment, identification of barriers/facilitators to transition and development of specific interventions to promote mastery of skills and knowledge related to transition (Meleis et al., 2000). Nurses have an opportunity to identify types, patterns and properties of transition their patients are experiencing, assess anything that may inhibit or facilitate that transition such as stigma related to their disease, acceptance of their illness, substance use or mental health problems and develop interventions to promote mastery of the skills and knowledge reflective of each unique patient experience to prepare and promote healthy responses to the transition (Meleis et al., 2000).

Objectives: The objectives of this project are to review pre-existing data over a 12 month period of HIV infected patients, ages 22-24, preparing for healthcare transition to HIV providers who completed TRAQ, describe provider interventions for transition prior to use of TRAQ, analyze TRAQ scores, characterize knowledge or skill deficits elicited from TRAQ, and describe > 1 provider intervention related to transition delivered and subsequent follow up after use of TRAQ. The objectives are to assess if using the TRAQ tool further enhances the quality of care regarding transition measured by documentation of each patient's individual transition needs and documentation of provider intervention targeted to address those specific needs on a consistent basis.

Evaluation: Analysis of data will include use of descriptive statistics to show the range, mean and median score of initial TRAQ scores as well as types of knowledge or skill deficits identified by patients. Further analysis will include descriptive statistics to display patient demographics such as gender and years aware of diagnosis, types of education provided (medication, HIV), types of skill training provided (calling for refills, scheduling appointments) and anticipatory guidance provided (fundamentals of health insurance and access to community resources). Run or control charts will be used to determine if improvement in our transition process has been enhanced by describing patterns of use of TRAQ and if interventions are increased after use of the TRAQ tool. In addition, through the use of correlation analysis, relationships will be described among selected indicators included but not limited to relationships between TRAQ scores, specific knowledge or skill deficits and years in care, years aware of HIV diagnosis, adherence to HAART and medical appointments and social support.

Summary/Implications for Practice: Tertiary prevention is unmistakably the solution to reducing the prevalence of new HIV cases. After many years of research, preparation for transition of HIV positive adolescents and young adults from pediatric/adolescent health care to adult health care has become one of the top priorities in HIV /AIDS care. Therefore, it is the responsibility of advanced practice nurses to embrace the challenge and explore any feasible and research based methods to assist the transitioning phase for this vulnerable population. This study will present the impact of implementing use of Transition Readiness Assessment Questionnaire (TRAQ) among young adults with HIV who transition their healthcare from a HIV clinic.

Advancing Population Health in the BSN Program through Interprofessional Simulation: Creating Curriculum to Create Change

Katie Hooven, PhD, MBA, RN, CNE, USA

Abstract

In 2015 The Department of Nursing secured grant funding from the Robert Wood Johnson Foundation to enhance student learning about population-based health care in our BSN curriculum. Population health requires that nurses (a) understand the broader issues involved in determining health, (b) be able to approach solutions or interventions from that broader perspective as well as existing research evidence or best practices and (c) be able to mobilize existing community resources in the service of better health outcomes. To support these initiatives, the grant funded the purchase of the Community Action Poverty Simulation program from the Community Action Network. This interactive program allows students to “experience” a month in the life of someone living in poverty in a 3-hour simulation activity. Through implementation of the Community Action Poverty Simulation (CAPS) program, students in Nursing and other majors across campus are engaged in experiential role playing and guided reflection with local community members, thereby deepening their understanding of realities and myths of poverty in America. The simulation experience challenges students to examine some of our nation’s most pressing social justice problems, including socioeconomic, racial, ethnic, environmental, educational, and health disparities, among others. The first simulation was run as a pilot in the Spring of 2016 with 75 nursing students. Approximately 250-275 students will participate in this project during the academic year 2016-2017. The participants include: 90 sophomore-level nursing students and 60 freshman/sophomore-level public health students, 26 mixed majors, 40 health and exercise science students, 20-30 pre-medical students, 20 graduate nursing students, and 21 RN-BSN off site students.

Information will be collected to evaluate the simulation as an interprofessional activity. Matched pre and post test data will be collected without the use of student names, along with qualitative information about the simulation experience. The 16 question survey include questions regarding knowledge, attitudes, and opinions regarding people living in poverty. Information will also be collected about the experience overall and in regards to working with other professionals.

Effect of Simulation Training on Nursing Students in Adult Nursing

Takashi Ohue, PhD, RN, Japan
Chise Wada, MSN, RN, Japan
Mari Hirota, MSN, RN, Japan
Sachiko Shiragami, MSN, RN, Japan
Chiaki Otsuka, MSN, RN, CPCN, Japan
Takako Sagino, MSN, RN, Japan
Mutsue Shio, MSN, RN, Japan
Yoshiko Ishida, MSN, RN, Japan
Taku Kodama, PhD, MD, Japan

Abstract

Purpose: This study aimed at verifying a student nurse's simulation education effect in adult nursing.

Method: The subject was targeted at the third-year nursing student (120 persons) who is taking a lecture on the Adult Nursing Methodology I simulation education in 2016. Evaluation of intervention were asked to complete a questionnaire that measured the image about an operation (the SD method), normative attitude toward helping scale, Scale of Oriented Problem Solving Behavior in Nursing Practice(OPSN). Measurement was performed 2 times of a baseline, after the end of session. Analysis of t-test was performed. The scenario set up the 1st day (atelectasis, postoperative bleeding) after the operation of the patient of stomach cancer. After performing assessment, a related figure, and nursing care plan planning by a paper patient to a case, the simulation was carried out for 60 minutes and it carried out for debriefing 30 minutes into the group.

Results: The subjects included the nurses students (n=91; 14 male 77females) who were able to participate in all sessions. According to the results, about the image of an operation, "flexible - stereotyped," (p< 0.01), "serene- tense," (p< 0.01), "instability - stability," (p< 0.01), "lively - settled," (p< 0.01) , "Cool - Hot," (p< 0.01) , "The image sum total of the operation" (p< 0.01) was significant. Moreover, With regard to subscales of normative consciousness, "normative attitude toward helping" (p< 0.05) improved intentionally. With regard to subscales of Oriented Problem Solving Behavior in Nursing Practice (OPSN), "Giving assistance in patients' activities in daily living and treatment, alleviating symptoms, and maintaining and promoting life function for solving and avoiding problems, and their individualization" (p< 0.05), "Making smooth interaction with patients in order to solve problems" (p< 0.05), "Changes in values brought about by self-evaluation of the extent of problem-solving " (p< 0.05) was significant.

Conclusion: It was suggested that the simulation to the student nurse in adult nursing science was considered that the validity as nursing education was confirmed.

Impact of Standardized Surgical Checklist on Communication and Teamwork Among Interdisciplinary Surgical Team

Regalado A. Valerio, MS, CRNA, USA

Abstract

A surgical timeout or surgical pause (Tang, Ranmuthugala, & Cunningham, 2014) is a hospital policy in the operating rooms (ORs) which is usually performed immediately prior to a surgical incision or entrance into a body orifice. This is a final verbal confirmation of patient's identification, planned surgery, and other critical elements to safety that involves multi-disciplinary team such as physicians, nurses, anesthesia providers, and technicians. Poor compliance in the effective performance of surgical timeout results in OR time delays, inadequate preparation of needed intraoperative apparatus, improper administration of required antibiotics, late blood product requests, etc. To improve surgical time out compliance at Los Angeles county hospital (LAC), a quality improvement project standardizing the performance of surgical pause by means of a Standardized Surgical Checklist (SSC) was implemented. This clinical concern is important to be addressed because based on current evidence, performing effective surgical time out using SSC can impact patient safety by reducing complication and mortality rates following surgery (Tang et al., 2014), and can promote good communication and teamwork among medical care team (Fudickar, Horle, Wiltfang, & Bein, 2012; Lyons & Popejoy, 2014). The innovation aims to develop, implement and evaluate the impact of SSC on communication and teamwork among interdisciplinary surgical care team at LAC. The design of this quality improvement project was a pre- and post- innovation survey. The participants were the members of the interdisciplinary care team who participated in surgical time outs before surgical incision at LAC. Descriptive statistics of the sampled surgical team members was expressed in proportion (percentage). This determined the share of each group of professionals (surgeons, anesthesia providers, RNs, technicians) who participated in the pre- and post- intervention survey. The difference in 2 means of the pre- and post-groups was obtained via independent t test, p value<0.05 (two tailed) and was used to analyze any significant improvement in communication and team work among interdisciplinary care team. The survey consisted of 105 participants in the pre-innovation phase and 114 participants in the post-innovation phase (N=219). The mean improvement in communication score in the pre-innovation group was 3.57 (SD=1.252) compared 4.15 (SD=0.989) in post-innovation group. In terms of improvement in team work score, the pre-innovation group had a mean score of 3.63 (SD=1.325) as compared to a mean score of 4.12 (SD=0.997) in the post-innovation group. The results from an independent t-test demonstrated that the mean improvement score for both communication ($t=-3.704$, $df =190$, $p<.001$) and team work ($t=-3.028$, $df =184$, $p=.003$) were significantly higher in the post-innovation group than in the pre-innovation group. The results support the current evidence that the SSC, if effectively implemented, can potentially improve communication and teamwork among interdisciplinary care team. Improvement in these two domains is known to positively impact the safety culture inside the OR.

EBP PST 3 - Evidence-Based Practice Poster Session 3

The Use of Case Studies and Smart Device Apps to Increase Student Engagement

Deanna A. Janz, DNP, MSN/Ed, RN, USA

Nicole M. Giancaterino, DNP, MSN, RNC-OB, CNS/APN, CNE, USA

Abstract

In an accelerated Bachelor's of Science in Nursing (BSN) course, e-books are available to all nursing students. In addition, an on-line progressive case study approach was used. The nursing educator also implemented a free pregnancy application (app) (among many to choose from) to engage the digital world nursing student learner with the implementation of an interactive virtual pregnancy experience. Both the free pregnancy app and the course's online progressive case studies provided a better understanding of pregnancy within a "safe" simulated client experience. The goal was to bring the obstetrical content to life and assist with critical thinking while maintaining an engaging and fun learning environment. The app engaged learning with a daily calendar on timely information on their "virtual" pregnancy, changes in fetal growth and development, and bodily changes. The app provides an interactive checklist and expert advice on everything from nutrition to relaxation, safety, common concerns, and what to expect at each visit both within the office, and once admitted to the hospital. Fetal kick counters, nutritional dos and don'ts, contraction timers, and automated text messaging brought the virtual pregnancy to life. Students visualize their baby's growth with a widget using real-world examples of fruits and veggies. Students learn the importance of monitoring their baby's movements. Nursing related safety topics in which all pregnant clients should be taught are repeatedly emphasized within each trimester of their virtual pregnancy. The learner also had unlimited accessibility to award-winning videos of their virtual baby's development in the womb to the experience of birth, virtual baby kick-counters, contraction timers and interactive case studies. Weekly text messages alerted the learner to the changes in their virtual baby as a feature of the free app. During the students immersion within the specialty area 8 week course, the course objectives and outcomes were supported with the progressive case studies and utilization of the free app to support learning both inside the boundaries of the classroom and outside of the traditional learning environment. Having the availability of the progressive case studies and virtual pregnancy experience on the home screen of their smart phone or laptop enhanced and supported the engagement of course content for the nursing student.

Purpose: The purpose of this project is to demonstrate to educators how to incorporate technology based instruction methodologies with the utilization of smart device apps and case studies throughout a nursing course.

Introduction: In a Bachelor's of Science in Nursing (BSN) course, e-books are available to all students. In addition, an on-line case study approach was used. The goal was to bring the obstetrical content to life and assist with critical thinking and retention of information. "Zeondra" and "Arial" were introduced during the first lesson within the course case studies, who were both just weeks into their pregnancies, progressed throughout the course to complete their journey as new postpartum family unit. The instructor also implemented a free app (among many to choose from) engaged the digital world learner with the implementation of an interactive virtual pregnancy (Yu, Lin, Ho, & Wang, 2015). The free pregnancy app, provided a better understanding of pregnancy. The app engaged learning with a daily calendar on timely information on their virtual baby and body changes. The app provides an interactive checklists and expert advice on everything from nutrition to relaxation, safety, common concerns, and what to expect at each visit both within the office, and once admitted to the hospital. During their 8 week BSN course, students visualize their baby's growth with a widget using real-world examples of fruits and veggies. Students learn the importance of monitoring their baby's movements and safety topics. Weekly text message reminders alerted the learner to the changes in their virtual baby as a feature of the app. The learned had unlimited accessibility to award-winning videos of their virtual baby's development in the womb to the experience of birth, virtual baby kick-counters and contraction timers; all available on their home screen of their phone or laptop. The educator can utilize progressive virtual case-studies and a free app as supplemental methods for the digital learners of today both within and outside the classroom environment (Flood & Commendador, 2015).

Implementation: During each lesson, their online multi-cultural lives were explored. From one who was a single parent to the other who was interested in drinking extra fruit punch to make sure her fruit intake was adequate, students learned how their patients' choices would impact their pregnancies. Normal and abnormal scenarios take the students further into their patient's lives. The online interactives were developed and included in the lessons to assist the students with practicing and applying the information (Flood & Commendador, 2015). Learning how to calculate a due date, learn lab values and decide which risk factors existed for each patient provide critical thinking, active learning opportunities (Popil, 2011). "Zeondra" and "Ariel" progressed and delivered healthy babies, one vaginally and one via caesarean section. Students prepared for the birth and practiced newborn assessments.

To further peak the interest of the millennial student nurse population, the implementation of a free pregnancy app was utilized (Montenery, et. al, 2013). Each student entered a "virtual pregnancy" during the course. By providing simple registration instructions, the students entered their birth month and day as their pregnancy due date. Staggered and various gestational stages were then explored among the class population as an opportunity for student dialogue and engagement to teach the class about what was occurring during their virtual gestation. Weekly class discussions centered on the student's virtual pregnancy and its progression. Students shared what they learned from diagnostics, nutrition, exercise, safety and myths on what to expect and how to best care for their future (real) pregnant clients in the clinical setting.

The fetal-kick count became an interactive learning moment when students were asked to apply a "kick" to the app's tracker each time over the next twenty-four hours in which they personally experienced flatulence. As part of the app, if ten (10) kicks are not elicited over a two hour time period, an educational moment occurred. The app would alert the user to evidence-based obstetrical teaching to the virtual pregnancy student on what to do next. For example, walking, drinking a large glass of water and eating a small snack. If after another hour, less than ten (10) movement (aka flatulence) had not been experienced, the virtual pregnant participant was to now notify their healthcare provider. With active involvement by using the smart device (laptop/smart phone), an increase in responsiveness and engagement was observed. Open dialogue on their virtual pregnancy challenged the nursing students to come to class prepared and ready to share their virtual pregnancy experiences and new knowledge obtained within the classroom.

Evaluation: Despite limitations that included technology glitches for some of the interactive activities, the case study approach offered a positive, creative interactive and exciting opportunity for students to practice what they learned from their textbooks and apply it to their virtual patients and their virtual pregnancy. Students were engaged in a progression within the course via the case studies. The use of the tools on the pregnancy app fostered real-life experiences for a virtual pregnancy through safe experimentation and participation. Text messages provided for continued learning outside the classroom environment.

Conclusion/Recommendation: The inclusion of a pregnancy app and progressive course case studies provided students with an interactive and fun way to learn their maternal child concepts. To continuously improve teaching strategies, student learning outcomes, and professional growth; faculty should consider using contemporary tools that utilize technological applications to actively engage the "digital" learner of today.

Envisioning Magnet Designation: Raising the Bar for a Nursing Culture of EBP Awareness and Practice

Cindy Ford, PhD, MSN, BSN, RN, CNE, USA
Lisa Marguerite Fallon, DNP, MSN, BSN, RN, USA

Abstract

Introduction: Magnet designation requires an organization integrate evidence based practices (EBP) and research into clinical and operational activities (*Magnet*®). Removing barriers for nursing staff at the frontline to become engaged in EBP and creating a culture of inquiry can be a daunting task for nurse executives. A large health care system recently set a goal of increased bedside nurse EBP utilization and nurse confidence with creating a cultural of inquiry. A formal collaboration with university scientists has led to a tremendous increase in the number, quality, and rigor of nurse-led projects in the facility.

Background and Significance: The landmark work of the Institute of Medicine (2001) and requirements from regulatory entities urged healthcare organizations to focus on improving the quality of patient care. The literature currently, and over the last years has increased with evidence supporting nurse led research, implementation of evidence based practice and quality improvement processes. Beginning in 2012, nurse executives embarked on a plan of nursing support to shift the culture of the organization to one of improved understanding and utilization of research, encourage an attitude of inquiry for best practices at the bedside resulting in a shift in culture, and to ultimately become one of the 7% of Magnet organizations in the country.

Literature Review: The evidence from current literature reveals the variety of challenges nurse executives face as they work to promote nursing cultures of inquiry, and shift to cultural norms of care evaluation with implementation of nurse led best practices system wide. The facilitators of research include significant leadership commitment at the organizational level (Scala, Price, & Day, 2016) although competing priorities pull nurse executives in many directions. Stimulating EBP and research required a multi-faceted approach from leadership and our research mentors. One of the highest facilitators to nurse-led research is the presence of research mentors (Kelly, Turner, Speroni, McLaughlin, & Guzzetta, 2013). Often the time, understanding, and expertise needed to implement successful research in hospitals is underestimated by nurse executives (Wilson, Kelly, Reifsnider, Pipe, & Brumfield, 2013) and the presence of a PhD-prepared nurse researcher can minimize these barriers. Understanding the differences between research and quality improvement projects requires processes and clarity (Ryan & Rosario, 2012) our fledgling program couldn't distinguish between without expertise provided by university scientists. Partnerships such as ours increase nurses' ability to identify literature, critically appraise it, and synthesize findings to subsequently increase the research environment (Latimer & Kimbell, 2013).

Conclusion: The nurse executive team has observed multiple measureable outcomes in the few short years of promoting and supporting a nurse led shift in the culture of care provision. Prior to collaborative efforts with university mentors, the standing committee for research, the Research Council, experienced an attendance average of only eight participants per month composed of predominantly nurse educators. Only 30% of nurse educators and 0% of staff nurses attended the monthly meetings. Currently, an average of 20 nurse educators and 18-20 engaged bedside nurses and attend monthly.

Other measurable outcomes include increased participation, from a 10% to 65% participation rate for nurses' system wide with creation of scholarly activities such as poster, abstract and article creation. A poster rubric was created to guide creation and measure improved scholarship of posters submitted for Nurse Week Poster Symposiums annually. Positive attributes of posters include improved content organization, appropriate literature review with clearer methodologies reported, and clearly stated outcomes. The total number of posters submitted for Nurse Week has increased 150% (34) while abstracts submitted for presentation nationally and internationally has increased 300% and manuscript creation/publication has increased 150%.

Today, the Research Council monthly meetings are filled with bedside nurse presentations of nurse identified patient issues resulting in research, evidence based and quality improvement projects, and policy changes. Mentoring of new members of the research council continues while experienced members move on to their second or third projects in recent years. Need assessment surveys are conducted annually to identify learning needs of the novice and experienced research council members. The nurse executives recognized a nursing need that would ultimately impact quality of care and worked to support the nurses of the facility. They provided the support and leadership to help instill and sustain a culture of inquiry and continue to do so.

Utilizing Simulation to Improve Communication and Collaboration in Intraprofessional Nursing Teams

Angelarosa G. DiDonato, MSN, RN, CRNA, USA
Aleaha Peoples, MSN, RN, USA

Abstract

Experts agree that effective inter-disciplinary collaboration is a complex issue that, when achieved, positively impacts patient outcomes. During an acute patient emergency, inter-disciplinary teams commonly struggle to reach a consensus regarding the patient's plan of care. While a successful patient outcome is, without a doubt, the overarching goal of the team, each individual member has a different vision of what success looks like and varied strategies for achieving that success. A focus on collaboration and teamwork translates to an approach in which each team member is cognizant of and integrates the needs and often-competing goals of the other disciplines into his or her roadmap of success (Weller et al., 2014).

Research has shown that groups are more open to information sharing when: the team is made up of similar roles, necessary information is not unique among the group, and members can make decisions independently. Conversely, teams are least likely to share information when the group is heterogeneous and the information that needs to be shared is specific to certain members (Mesmer-Magnus & DeChurch, 2009). This effect "reflects a divergence in what teams actually do and what they should do in order to be maximally effective, and it has particularly meaningful implications for expert decision-making teams, like those employed for emergency response and medical decision-making" (Mesmer-Magnus & DeChurch, 2009, p. 543). Nurses are not immune to this flaw. In US hospitals, it is not uncommon for a team to be comprised entirely of nurses with varying levels of training and perspective.

Although most nurses would agree that effective communication is necessary for successful outcomes, it is often considered a soft skill, of lesser importance than technical skill or education. Communication and interpersonal skills are rarely, if ever, formally taught and practiced, yet, it has been well documented that failures in communication are a common factor in sentinel events (The Joint Commission, 2016).

Simulation exercises have been noted to be an effective means of teaching and practicing communication skills (Saaranen et al., 2015). Many published observations of simulation have focused on inter-disciplinary teams, comprised of nurses, physicians, and allied health staff. As previously mentioned, teams acutely assembled for an emergency can be comprised entirely of nurses: bedside nurses, managers or coordinators, and various advanced practice nurses. These inter-disciplinary nursing teams often struggle with the ability to effectively communicate with each other. A simulation exercise was designed in an effort to strengthen the relationship between nursing students of varying levels with the goal of bridging the gap that may facilitate miscommunication. The simulation centers around four distinct groups of nursing students.

Junior level undergraduate nursing students, senior level undergraduate nursing students, nurse practitioner students, and student registered nurse anesthetists must collaborate to work through an acute patient emergency. The pilot has been shown to be highly effective with an overwhelmingly positive response from the students.

RSC PST 1 - Research Poster Session 1

Using Staffing Analytics to Support Optimal Clinical Resource Scheduling Across a Safety Net Hospital System

Noreen Bridget Brennan, PhD, RN-BC, USA
Eileen Raftery O'Donnell, MBA/MIS, RN, USA
Kerry Small Abbott, MSN, RN, USA
Shawn Jennie-Elin Semedallas, BSN, RN, USA

Abstract

During the past couple of years, many hospitals have closed or decreased their inpatient footprint. Additionally, many hospitals have become part of or formed networks or systems to ensure viability through consolidation of resources (Faller & Gogek, 2016). Scheduling and staffing of nurses is a dynamic process that can have significant financial implications for healthcare organizations. A numeric value of nursing care has always been difficult to quantify. However, researchers have demonstrated findings that show increases in nursing and skill mix are associated with improved quality through a decrease in adverse effects (Martsolf, Auerbach, Benevent, Stocks, Jiang, Pearson, et al., 2014); patient experience and satisfaction are better with increased nurse staffing and positive work environments (Kutney-Lee et al., 2009); and greater numbers of core rather than contingent (i.e. agency) nurses per bed increased patient satisfaction (Hockenberry et al., 2016). Nursing leaders are challenged, as never before, with maintaining and improving quality outcomes with an ever changing and at times shrinking labor force. They are rarely schooled in how to receive and interpret data to support the increasingly regulated and fluctuating staffing needs on the unit and at divisional level. Safe nurse staffing is not just a numbers game, it is a commitment and part of the organizations mission to serve our patients. Data is critical but just one tool in the arsenal needed by nursing leadership. The purpose of this presentation is to describe the development and utilization of analytical tools in supporting nursing leaders in forecasting and planning distribution of nursing resources in a large safety net healthcare system. A safety network describes healthcare providers in hospitals and outpatient clinics who provide care to patients with minimal financial and insurance resources (Moore, Fischer, & Havranek, 2016). New York City Health and Hospitals is made up of 11 Acute Care Facilities; 5 Long Term Care Facilities; and 6 Diagnostic and Treatment Centers that provide health care services to the residents of New York City. The mission of New York City Health and Hospitals is to provide competent, culturally sensitive quality care to our patients with dignity and compassion, regardless of ethnicity, nationality, religion or ability to pay, in a safe environment. The overall program objectives were: determining workloads and building staff plans; allocating activity and determining labor resources; creating schedules that meet operations and clinical needs; correcting staff counts to reduce premium pay and lessen staff deficits; stabilizing and projecting labor costs; forecasting needs; and maintaining a patient and clinician safe environment. Overall, creation of the staffing analytics tool have aided in standardizing language across the system; has provided numerical justification for replacing resources; establishing benchmarks; projecting overtime, agency, and sitter costs; and model scheduling based on historical data. In conclusion, the purpose is to describe the development and utilization of analytical tools in supporting nursing leaders in forecasting, and planning distribution of nursing resources and lessons learned along the way in a safety net health care organization.

Purpose: The purpose is to describe the development and utilization of analytical tools in supporting Nursing leaders in forecasting and planning distribution of nursing resources and lessons learned along the way in a safety net health care organization.

Methods: Development of staffing analytical tools that are utilized across a safety net healthcare system in New York City. New York Health and Hospitals is made up of 11 Acute Care Facilities; 5 Long Term Care Facilities; and 6 Diagnostic and Treatment Centers that provide health care services to the residents of New York City.

Results: Standardization of data collection resulted in determining workloads and building staffing plans; allocating activity and determining labor resources; creating schedules that meet operations and clinical

needs; correcting staff counts to reduce premium pay and lessen staff deficits; stabilizing and projecting labor costs; forecasting needs; and maintaining a patient and clinician safe environment.

Conclusion: Overall, the creation of the staffing analytics tool have aided in standardizing language across the system; has provided numerical justification for replacing resources; establishing benchmarks; projecting overtime, agency, and sitter costs; and predictive model scheduling based on historical data.

RSC PST 1 - Research Poster Session 1

Impact of Handfeeding Assistance on Nutritional Intake for Nursing Home Residents

Melissa K. Batchelor-Murphy, PhD, RN-BC, FNP-BC, USA

Susan M. Kennerly, PhD, RN, WCC, CNE, USA

Susan D. Horn, PhD, MS, USA

Ryan Barrett, MS, BS, USA

Nancy Bergstrom, PhD, RN, FAAN, USA

Lisa Boss, PhD, MSN, BSN, RN, CEN, USA

Tracey L. Yap, PhD, RN, WCC, CNE, FAAN, USA

Abstract

Purpose: Poor nutrition with weight loss remains the largest reversible health problem in nursing home (NH) settings. Cognition and functional ability play a large role in whether or not a resident can engage independently in self-feeding, will require set-up assistance, or be completely dependent on NH staff to provide support.¹ The purpose of this secondary analysis was to examine the impact of cognition (residents with or without dementia) on nutritional outcomes of meal intake based on (1) level of feeding assistance provided, and (2) overall caloric intake for residents who were offered snacks and supplements between meals.

Methods: As part of a large, multisite clinical trial conducted in the United States and Canada (N = 786)², residents with and without dementia (n = 592; n = 194) were examined according to the level of feeding assistance required during mealtimes (independent, setup only, needs help eating) over a 21-day period. Outcomes analyzed were percent of meal intake by meal (Breakfast (B), Lunch (L), Dinner (D)), and overall daily intake (meals + snacks/ supplements).

Results: Residents with dementia who required meal setup assistance had significantly lower meal intake for all three meals (B, p = 0.0046); L, p = <.0001; D, p = <.0001). Residents without dementia experienced significantly lower intake for Breakfast (p = 0.036) and Dinner (p = 0.006), but not for Lunch (p = 0.14). When snacks and supplements were offered between meals, residents with dementia consumed approximately 163 additional calories/ day, and residents without dementia consumed approximately 156 additional calories/ day.

Conclusion: All NH residents are vulnerable to low intake during mealtimes. This study adds new evidence showing that completely dependent residents may not be the most vulnerable group for lower overall daily intake. Instead, two other groups of residents are at highest risk, those that only require setup assistance for meals, and those with cognitive impairment.

Implications for Practice: Nursing home staff should closely monitor meal intake for residents who require setup assistance for meals, and those with cognitive impairment. These two groups should be considered particularly at risk for lower daily intake, and allow for early detection of low meal intake. Early detection can lead to earlier intervention, allowing staff to provide more handfeeding support for these vulnerable groups of residents.

RSC PST 1 - Research Poster Session 1

Effects of Provider Communication Behaviors and Shared Decision Making on QOL Among Advanced Cancer Patients

Aisha M. Alhofaian, MSN, BSN, RN, USA

Abstract

Purpose: Saudi patients are often not well informed about diagnoses, prognoses, and treatment options. Poor communication can lead to health care decisions that insufficiently meet patients' preferences, concerns, and needs and that subsequently affect patient's quality of life. Effective provider communication behaviors are needed to ensure that patients make informed and shared decisions about treatment, enable them to adhere to advice about managing their diseases, and help them adjust and adapt to the fact that they have a life-threatening disease. Moreover, shared decision-making remains an important element in improving patient's wellbeing and satisfaction. The extensive body of literature supported that the relationship among provider communication behaviors, shared decision-making, and patient's quality of life has yet to be fully established. However, most studies were conducted in Western contexts; no such study has been done in Saudi Arabia. The primary purpose of this study to examine the relationships among provider communication behaviors, shared decision-making, and quality of life for patients with advanced cancer in Saudi Arabia

Methods: Street's ecological theory of patient-centered communication (2009) will guide this study. A convenience sample of 134 patients with advanced gastrointestinal, genitourinary, breast, lung or gynecological cancer will be recruited from KAAU hospitals in Jeddah. The design is cross sectional descriptive correlational study. The researcher will orally administer all three questionnaires, one on each of the following concepts: provider communication behaviors, shared decision-making and patient's quality of life, along with the demographic data using Survey Monkey at the hospital where the patients are being treated. The demographic data and the data from all three questionnaires will be analyzed using simple linear regression and descriptive statistics.

Results: in progress

Conclusion: By focusing on cancer patients in Saudi Arabia, this study seeks to add to the empirical knowledge base about provider communication behaviors and shared decision-making, and it will help to advance the body of nursing knowledge related to health care communication in Saudi Arabia. The knowledge will also assist in further research to develop decision aids programs to enhance informed shared decision making in cancer care.

RSC PST 1 - Research Poster Session 1

Nursing Students Attitudes' Toward the Homeless

Patricia MacWilliams Bowe, DNP, MS, RN, USA
Andrew B. Phillips, PhD, RN, USA

Abstract

Purpose: A person who is homeless is someone without fixed housing. The individual may move from couch to couch, motel to temporary shelter, a car to a tent, with no place to call home, minimal belongings, and no sense of permanency. This writer's career has long been one of working with homeless populations. During a twenty year period at Boston Health Care for the Homeless Program (BHCHP) many nursing students from a number of schools in the Boston area had a clinical rotation at this site. Clinical placements began with a tour of the shelter and a discussion around preconceived notions and perceptions about homelessness. Many students acknowledged that they expected to see the stereotypical alcoholic older man, and were surprised to see a younger population. For the majority of students who were initially unsure of the shelter environment and unfamiliar with the context and difficulties faced by homeless people, it was always a positive experience to watch them grow, expand their view of the population, and truly see them for who they are: humans who have a right to health care. A few students actually asked to be placed back at the clinic for a second semester as they truly appreciated the population, including the unique quirks and the inherent humanness involved despite the hardships the patients experienced. Those students who embraced the experience wholeheartedly expressed appreciation for the opportunity of the experience, how it changed their view of the population as a whole, and how they had a better understand the challenges faced by the patients. As a result, they strongly predicted that their practice as a registered nurse or nurse practitioner would be improved accordingly.

Challenges in caring for the homeless include that, as a group, they lack financial resources, difficulty adhering to a healthy diet, hygiene issues, and lack of storage for personal items. When diagnosed with serious health conditions such as cardiac disease, cancer, and psychoactive substance abuse disorders, members of the homeless population are at a higher risk of mortality compared with the general population as abstracted from the Massachusetts Department of Public Health death occurrence files for 2003-2008 and analyzed by Baggett, Hwang, O'Connell, Porneala, Stringfellow et. al (2013). The three major causes of death for the homeless in this analysis were drug overdose, cancer, and heart disease. Younger homeless adults (25-44 year old) had a 9 times greater risk of dying than the general population of Massachusetts, and midlife homeless adults (45-64 year old) died at a rate 4.5 times higher than the general population of Massachusetts.

As a population the homeless are highly vulnerable. More than one million homeless patients in the United States are treated yearly. Chances are high that nurses will interact with a homeless patient at some point in their career. Homeless patients are admitted at a higher rate and have longer lengths of hospital stays than the rest of the population. They often suffer from serious health conditions and many have psychoactive substance abuse disorders leaving them at higher risk of mortality compared with the general population. Homelessness does not discriminate as people of every age, race, color, gender, religion and education are affected. However, clinical rotations with the homeless are not part of the standard nursing curriculum. Providing a clinical experience in a homeless setting may provide a more accepting attitude of working with this growing population.

Methods: The specific aims of this project were:

- To examine nursing students' attitudes towards the homeless
- To determine whether previous exposure to the homeless influences the attitudes of nursing students towards the homeless.

Two methods were adopted to address these specific aims – a literature review and a survey of nursing students using a validated tool measuring attitudes towards the homeless.

Results: The literature review identified thirty-seven potential resources of which eight were identified as relevant to the specific aims of this study. Six studies presented survey data results. Five of the six reported both pre and post survey results after the respondents had direct contact with the homeless in a clinical setting. A common theme noted throughout the literature was the more exposure to the homeless population and its adverse effects on health, the more positive the attitude of the student regarding the patients' health care needs with the recognition that homelessness was perceived to be a result of societal causes and not personal failings. While experiences reported in the literature varied from one day to two weeks, a brief one day interaction, resulted in positive feedback (Boylston and O'Rourke, 2013) which supports the emphasis on exposure and curriculum in achieving more positive attitudes towards the homeless.

Using a validated instrument - Attitudes Towards Homelessness Inventory (ATHI, Kingree and Daves, 1997), an email was sent to 125 second degree direct entry pre licensure Masters- level nursing students soliciting voluntary anonymous participation in completing the survey. Over a period of 30 days 13 respondents participated in the 11 item survey.

The ATHI is divided into 4 sub categories, 1) personal causation, 2) societal causation, 3) affiliation and, 4) solutions (Table 2). Total overall scores ranged from 39-46 with a mean of 42.8, out of a possible 11-66 indicating an overall positive attitude as the higher the number the more positive the attitude. Responders indicated that perception of homelessness was based more on societal causes (mean 2.51) than personal causes (mean 4.12) with a positive relation towards solutions of homelessness with a mean of 5.38. Eleven of the twelve respondents had previous experience with the homeless which correlated to a positive attitude about this population (mean 3.38) and a positive perspective towards solutions for homelessness (mean 5.38). These responses indicated disagreement with such statements as "little can be done.", "rehab is too expensive", "cannot adopt a normal lifestyle."

Table 2 – Survey results by Attitudes Towards Homelessness Inventory Sub-Category. Individual scores for each survey statement can range from 1-6. PC = personal causation, SC = societal causation, AFF = affiliation and, SOL = solutions.

Survey Statement	Sub-category	Mean Score
Homeless people had parents who took little interest in them as children.	PC	4.53
Most circumstances of homelessness in adults can be traced to their emotional experiences in childhood.	PC	3.38
Most homeless persons are substance abusers.	PC	4.46
Recent government cutbacks in housing assistance for the poor may have made the homeless problem in this country worse.	SC	2.07
The low minimum wage in this country virtually guarantees a large homeless population.	SC	2.76
Recent government cutbacks in welfare have contributed substantially to the homeless problem in this country.	SC	2.69
I feel uneasy when I meet homeless people.	AFF	4.76
I would feel comfortable eating a meal with a homeless person.	AFF	2
Rehabilitation programs for homeless people are too expensive to operate.	SOL	5.30
There is little that can be done for people in homeless shelters except to see they are comfortable and well fed.	SOL	5.61
A homeless person cannot really be expected to adopt a normal lifestyle.	SOL	5.23
Attitude toward homeless index (11-66)		42.8

Conclusion: It is evident that little research exist that support the theory that exposure to the homeless population improves attitudes of students toward homeless patients beyond the qualitative results noted in some of the studies. Further research would be beneficial to help guide curriculum development.

Undergraduate nursing students are exposed to many facets of health care. Understanding a vulnerable population such as the homeless and acknowledging the effects of negative attitudes towards the delivery of care would provide insight to both educators and students. As a result, the vulnerable population, specifically the homeless, would be better served.

Continued research to build the evidence to support the hypothesis that experience with the homeless population correlates with a positive attitude on a broader scale would help drive nursing program curricula to incorporate a homeless experience. Compassionate care and a positive attitude should be fostered as part of the nursing education.

While this survey was conducted with a specific focus on the homeless population, the overarching philosophy could be translated to other vulnerable populations worldwide.

Teaching to Develop a View of Life and Death in Nursing Students

Chiaki Otsuka, MSN, RN, CPCN, Japan

Mari Hirota, MSN, BSN, Japan

Sachiko Teraoka, PhD, MN, RN, Japan

Misae Ito, PhD, MSN, RN, RMW, Japan

Abstract

Purpose: As Japanese society increasingly ages, in 2025 it is estimated that deaths will reach a yearly figure of 1,600,000. Against this background, the Japanese Ministry of Science and Education, Culture, Sports, Science and Technology has established as goals for students graduating from college nursing programs that they should have the ability to relieve and reduce suffering at the end of life, respect, support and be able to offer advice to the dying on an individual basis. This paper clarifies an educational project seeking to develop a view of life and death and foster the ability to support and care for people at the end of their lives amongst nursing students, many of whom have been brought up in nuclear families with little chance to see death or end-of-life nursing at close hand.

Methods: Subjects: 3rd year nursing majors who had completed basic nursing practicum and who were taking their first classes in palliative care. Research period: 2015.6.17 – 2015.8.31. Methodology: Questionnaire about changes in view of life and death after a course of lessons in palliative care (one 90-minute class a week for six weeks). The content of lessons was Introductory Cancer Nursing, Holistic Pain Relief, Radiation Treatment, Chemotherapy, Team-Approach Medicine, Family Care, Nursing Care. Teaching materials took the form of a DVD about image of cancer patients, spiritual care, and life review of patients as seen by family members. There was a 10-minute discussion with fourth-year students concerning involvement with end-of-life patients. The questionnaire had 27 items and 7 factors. These were [view of what happens after death], [fear and anxiety concerning death], [death as release], [escaping death], [awareness of purpose in life], [concern with death], [feeling about life span]. The 27 questionnaire items were answered using a seven-point Likert scale (1. Applies - 7. Does not apply). Analysis: A parametric statistical test for mean deviance was conducted and the significance level was set at 0.05.

Results: The number of subjects was 89 students before the classes and 95 after, and 89.7% of the participants were female. The average age was 20.9 (19-45). Changes in view of life and death are stated starting with the maximum degree of change. The following showed a positive change. [Death as release], [I think of death as release from the heavy burden of this life] plus three other items showed a value of 0.51; [feeling about life span], [I think life span is already decided from the beginning] plus two other items showed a value of 0.42; [awareness of purpose in life], [I see a clear mission and purpose in life] plus three other items showed a value of 0.33; [escape from death], [I avoid thinking about death] plus three other items showed a value of 0.09. The following showed a negative change. [Concern with death], [I often think "What is death?"] plus three other items showed a value of -0.01. [View of what happens after death], [I think there are such things as "spirits" and "being cursed"] plus three other items showed a value of -0.03. [Fear and anxiety about death], [dying is frightening] plus three other items showed a value of -0.26. Statistical testing of difference before and after the classes had a t-value of 0.505. The mean score before the classes in the measure of view of life and death was 3.6 and after it was 3.8. Amongst the items, the lowest mean score was for [escaping death].

Conclusion: The variety of teaching methods had an effect in developing students' views of life and death, but the results for [escaping death] show the need for continued efforts.

Comparative Analysis of the Similarities and Differences in Approach to Integrative Scholarly Reviews

JoAnn D. Long, PhD, MSN, MA, BSN, RN, NEA-BC, USA

Paula Gannaway, MEd, MLS, USA

Cindy Ford, PhD, MSN, BSN, RN, CNE, USA

Abstract

Purpose: Primary research provides the scientific foundation for evidence-based practice (EBP)--vital in the attainment of health for all people (World Health Organization, 2012). A comprehensive literature review is essential for determining what is known and not yet known regarding the clinical question (Coughlan, Cronin, & Ryan, 2013; Kearney, 2016). Conceptually, the Stevens Star Model of Knowledge Transformation offers a framework for moving the discovery of knowledge gleaned from research to implementation of evidence-based practice (Stevens, 2012). Yet, meaningful engagement in the synthesis of high-level health care research requires the use of a sophisticated set of technical skills including knowledge of research methods and metrics from which an unbiased assessment, evaluation, and categorization of the level of existing evidence can be made. Explicit methods for evaluating Systematic Reviews (SR's) and meta-analyses [generated from multiple randomized control trials] are well established facilitating the translation of research findings into practice (Cochrane Handbook, 2011; Joanna Briggs Institute Reviewers' Manual, 2014). The research foundation for many clinical questions, however, does not yet have the evidential basis from which SR's are generated. Methodological strategies for capturing lower levels of evidence, emerging questions, and early concepts of clinical importance have historically been approached through more generalized research review processes. The terms integrative research review, evidence review, and scoping review are among the most commonly used to describe knowledge synthesis of a mixture of quantitative and qualitative topics in which lower levels of evidence are available. However, no single methodology has emerged as the gold standard for synthesis of research in this category. The purpose of this study therefore is to present a comparison of the similarities and differences in approaches to integrative scholarly reviews.

Methods: The research team comprised of the university library director and academic nursing faculty systematically searched the Cochrane Library, Joanna Briggs Institute, PubMed, CINAHL, and Medline Complete using "research reviews" AND "method*" as search terms for all articles published to date.

Results: The search yielded 275 articles in the initial results. Studies with a primary purpose of reporting the methodology used for conducting the scholarly review were included. The reference lists were evaluated to generate additional applicable studies. Articles focused on a specific clinical question were excluded. Sixteen articles comprised the final sample. The purpose, key features, use of protocols for data collection and synthesis of data were compared for similarities and differences between integrative and scoping review methods.

Conclusion: Significant conceptual overlap and core commonalities exist between integrative and scoping approaches to knowledge synthesis. Primary differences also exist between the two methods. Scoping reviews generally do not assess evidence quality as compared to integrative reviews which tend to report the appraised strength of the evidence related to the clinical question. As nursing continues to advance knowledge synthesis, movement toward a standardized method for integrative scholarly reviews is needed.

Innovative Nursing Education Pathways and Racial/Ethnic Diversity

Kupiri Ackerman-Barger, PhD, MSN, RN, TNAC, USA

Patricia Farmer, DNP, RN, FNP, USA

Bryan M. Hoffman, MA, USA

Abstract

Purpose: The purpose of this study is to determine whether innovative nursing education pathways reflect the racial/ethnic diversity of traditional pathways. In 2008 the Robert Wood Johnson Foundation partnered with the Institute of Medicine to produce an action-oriented report that would serve as a blueprint for the future of nursing. The report (*The Future of Nursing; Leading Change, Advancing Health*) sought to address issues like the nursing shortage, developing technologies in healthcare, and meeting current and future healthcare demands (IOM, 2011). The results of the report were four key messages. This study focuses on Key Message #2 which states, "Nurses should achieve higher levels of education and training through an improved education system that promotes seamless academic progression" (IOM, 2011). They concluded that an improved educational system was necessary to deliver safe, quality care across care settings.

According to the *Future of Nursing* report a complicating issue in nursing education is there are 2 key ways that students enter into the nursing profession; a bachelor's degree in nursing (BSN) (typically a 4 year university based program), or an associate degree in nursing (ADN) (typically a 2 - 3 year community college based program). In the last few decades the most common education pathway was through an associate degree in nursing. Two salient, but competing issues with these pathways are 1) having multiple options for entry into nursing provides more options for access, which is needed during frequent nursing shortages; and 2) although the evidence is not conclusive, several studies have indicated a significant correlation between levels of nursing education and patient outcomes including mortality rates. Rather, than recommending that nursing discontinue the ADN pathway, the *Future of Nursing* report suggested a goal of increasing the percentage of nurses with a bachelor's degree to 80% by 2020. This entails two components. One is that more students are recruited into BSN programs. The second is that registered nurses with associate degrees have options for obtaining a BSN.

To this end, the Robert Wood Johnson Foundation (RWJF) funded grant initiatives to explore and support enhanced academic progression pathways in nursing. The Academic Progression in Nursing (APIN) program was coordinated through the Tri-Council for Nursing, with oversight provided by the American Organization of Nurse Executives. This project funded nine states in developing and evaluating innovative models of streamlining nursing education pathways. The State Implementation Program (SIP) was based at the Center to Champion Nursing in America, a joint initiative of RWJF and AARP. SIP grants allowed states to select any area of the IOM Future of Nursing report for development, and more than 20 states focused on nursing education. In addition to APIN and relevant SIP projects, a number of programs nationally have also designed creative options and piloted innovative pathways that would lead to seamless opportunities for nurses to obtain higher levels of education. The most promising of these models is to link community colleges with university partners to allow students to concurrently enroll in a community college for pre-licensure nursing courses and a four year university to complete the requirements of a BSN.

As APIN and SIP states have rolled out pilot projects supporting academic progression an area identified by RWJF for grant funding was attention to the recruitment and retention of underrepresented and underserved students in schools of nursing. Anecdotal reports from leaders of programs have indicated a variety of perspectives on this including a possible loss of racial / ethnic diversity in cohorts of students entering new educational pathways. The need to diversify the nursing workforce has been acknowledged across organizations (AACN, 2014; HRSA, 2015; HRSA, 2006; IOM, 2003; IOM, 2011; NLN, 2009).

Methods: An initial written survey tool (questionnaire) was developed and will be distributed to all consenting programs. Only one questionnaire will be completed for each

program/consortium. Questionnaire completion would require detailed understanding of program structure and access to student demographics including race / ethnicity of students. The questionnaire will be designed for completion in less than 15-30 minutes if data is at hand.

We hope to recruit at least 7-10 programs or consortia. Programs that have received APIN or SIP grant funds for education, and who have been identified through other mechanisms as having innovative educational pathways and who meet criteria will be invited to participate in this study. In addition, informational flyers, personalized emails, will be sent to program or consortia leaders. There is also a conference occurring Nov.14-16th in Miami Beach, Florida where many representatives of the APIN and SIP efforts as well as other national nursing education leaders will be in attendance. Potential participants would be approached, given flyers, and questions answered.

Data from questionnaires will be analyzed using basic data analysis features on Survey Monkey to allow compare or find correlations between enrollments and graduations within traditional and non-traditional educational pathways, including evaluation of race / ethnicity of participants. Following analysis of the survey data, individual interviews with respondents may be conducted to clarify data. The latter will be an important step because the design of each consortium is somewhat different such that terms like "traditional" programs may be interpreted differently. Data from this study enrollments and graduations f may be compared to state and national averages.

Results: Pending

Conclusions: The degree to which innovative and/or accelerated programs impact diversity rates, whether positively, negatively or not at all, is important to understand as nursing education simultaneously seeks to offer a variety of options for attaining higher levels of nursing education and diversify the nursing workforce. By understanding what impact, if any, innovative nursing programs are having on the compositional diversity of the student body we can identify consortia who have addressed this issue well and disseminate best practices; and/or identify a potential problems and determine strategies for mitigating them.

The Perceived Leadership Characteristics, Behaviors, and Self-Esteem: Conducting Your Leadership Orchestra as a Hispanic Nurse

Giselle Melendez, EdD, MS, RN, USA

Abstract

Purpose: The purposes of this study were to investigate the perceptions of the leadership characteristics, and behaviors of Hispanic nurses, as well as to evaluate Hispanic nurses' self-esteem. Using the Leadership Practices Inventory (LPI), the Multifactor Leadership Questionnaire (MLQ), the Rosenberg Self-Esteem Scale, and a demographic questionnaire, the investigator intended to describe Hispanic nurses baseline characteristics, behaviors, and self-esteem so that further research studies may enhance how Hispanic nurses can be further developed, educated, trained, and mentored to become nursing leaders.

There is a great shortage of Hispanic nurses and nurse leaders in the United States. Hispanic nurses currently make up only 4.8% of RNs in the United States. As the population in the United States shifts from where Hispanics are the minorities and become the majorities, more Hispanic nurses will be needed to care for the patients. Not only is there a shortage of Hispanic nurses in relation to the size of the Hispanic population, there is an even greater shortage of Hispanic nurse leaders in relation to the size of the Hispanic population and the Hispanic nursing pool. Little research has been done on Hispanic nurses with a focus on leadership development. As more Hispanics are entering the nursing profession, more will be needed as leaders in the profession.

Methods: For the purpose of this study a descriptive quantitative methodology was chosen in order to better understand the perceived leadership characteristics, behaviors, and self-esteem of Hispanic nurses. An online survey was used to collect data from Hispanic nurses throughout the United States. The online survey consisted of the following instruments, the Leadership Practices Inventory, the Multifactor Leadership Questionnaire, the Rosenberg Self-Esteem Scale, and a demographic questionnaire. An advertisement on Facebook, which was created by the online marketing firm Total Market Exposure, was used to recruit participants for the study. In addition, a flyer was created that targeted individuals based on the specifications of this study's focus. Participants in the study needed to be of a Hispanic origin, a licensed registered nurse in the continental United States, able to read and comprehend English, and had passed the nursing licensing exam.

The Leadership Practices Inventory consists of 30 questions which is broken down into five scales. Each of the five scales contains six questions. The Multifactor Leadership Questionnaire consists of 45 questions. The Multifactor Questionnaire measures four different leadership styles: specifically, transformational leadership, transactional leadership, passive-avoidant behavior, and outcomes of leadership. The Rosenberg Self-Esteem Scale consists of ten questions. The demographic questionnaire was created by the investigator and consisted of fifteen questions. In total, participants were required to answer all 100 questions.

Results: Data analysis was completed using various statistical analyses. The investigator reviewed each survey for completeness and eligibility. In all, 208 surveys were completed online through the Checkbox® survey link. After data cleansing a total of 193 surveys were considered for data analysis. Measures of central tendency, mean, mode, median, standard deviation, minimum score, and maximum score were used to describe the perceived leadership characteristics, behaviors, and self-esteem. Upon completion of the data analysis, reliability data from the sample research study was compared to the existing reliability of the Leadership Practices Inventory, the Multifactor Leadership Questionnaire, and the Rosenberg Self-Esteem Scale.

The participants of this study comprised of 167 female and 26 male subjects. The largest age group was 30 to 40 ($n = 71$, 36.8%). The predominant Hispanic origins among participants were Puerto Rican ($n = 59$, 30.6%) and Mexican ($n = 52$, 26.9%). Participants held degrees ranging from an Associate Degree to

a Doctoral Degree. The majority of Hispanic nurses worked as a staff nurse ($n = 82$, 42.5%). Many of the participants in this study have not held a leadership position with a professional nursing association ($n= 131$, 67.9%). The survey was conducted throughout the United States of America.

Conclusion: The demographic findings of this study are similar to those found in the 2013 National Nursing Workforce Survey of Registered Nurses. Based on the demographic findings of this study, it is imperative that more Hispanic nurses are recruited into the profession. There are only 4.8% of Hispanic nurses in the total RN population. As more Hispanic are recruited to become nurses, more needs to be done to increase the number of Hispanic nurse leaders.

Three instruments were used to answer the research question. The investigator did not find any research study that used these instruments with a specific target population of Hispanic nurses. For the Leadership Practices Inventory the highest perceived leadership characteristic among Hispanic nurses is Enabling Others to Act. This characteristic allows the leader to foster collaboration while building trust and strength. For the Multifactor Leadership Questionnaire, Hispanic nurses perceive that leaders need to be transformational leaders. The Rosenberg Self-Esteem Scale showed that Hispanic nurses have a normal to high level of self-esteem. Hispanic nurses who participated in this study have the self-esteem and confidence necessary to be leaders.

The findings of this study offer a promising future for Hispanic nurses in the United States. Based on these findings, greater consideration should be placed on developing Hispanic nurses to become leaders in the healthcare profession. By developing Hispanic nurses into leaders, they will continue to build upon their skills but they will be a mentor to others and one day provide the opportunity to conduct their nursing leadership orchestra.

Resuscitating our Nursing Team by Increasing Resilience in Labor and Delivery Nurses

Susan Faron, MN, CNS, RNC-OB, USA
Julie Albers, BSN, RN, RNC-OB, USA

Abstract

Nurses confront many types of stressors on the job, including the demands from various healthcare environments, providers, patients, families, as well as the physiological demands to which they are frequently exposed. Research indicates that good personal resilience facilitates nurses' ability to endure the numerous difficulties they face in their daily work and contribute to providing effective, safe patient care (Wei et al., 2014, Hart, Brannan, & DeChesnay, 2014). Rushton, Batcheller, Schroeder and Donohue (2015) indicated that a greater resilience protected nurses from emotional exhaustion and contributed to optimal patient care outcomes. When nurses cultivated strategies and practices for resilience, patients were less likely to experience harm. Gaining a better understanding of nurses' resilience and its causes and effects can be very beneficial for nurses in helping them develop greater personal resilience that can contribute to overall quality patient care (Aiken et al., 2012).

There have been some theories that examine the concept of resilience as having several domains that can be empirically studied (Wei, 2014). It has been suggested that resilience should be studied as a multi-dimensional construct focusing on improving stress relief, mindfulness, and work/life balance. Based on the construct from the literature, interventions addressing the three domains of resilience were implemented for bedside nurses working on a busy, high acuity labor and delivery inpatient hospital unit.

Purpose: Resilience has been defined as the ability of individuals to cope successfully despite adverse circumstances and stressful environments (Wei & Taormina, 2014). Nurses' ability to manage day-to-day operations may be influenced by stress which ultimately can affect patient outcomes (Aiken, Clark & Sloane, 2012). There are many strategies that have been shown to be successful at decreasing stress, increasing mindfulness, and increasing work/life balance. Providing nurses with the tools and coping strategies they need to improve their coping skills and increase resilience can impact nurses' professional performance and improve quality and safe patient outcomes.

Methods: The evidence based conceptual framework guiding this project includes an assessment of nurse by conducting a pre-intervention assessment of nurse resilience using the Refined Connor-Davidson Resilience Scale (CD-RISC). Interventions addressing the construct of resilience will be presented to the staff nurses working on a busy, high acuity labor and delivery inpatient hospital unit. Post-intervention assessment of nurse resilience one month following completion of all interventions will be conducted using the same scale. The data from the CD-RISC was analyzed and practice changes that improve stress, mindfulness, and work/life balance will be advanced and adopted in a way that can simply be done on the unit in the future.

Interventions were focused into three dimensions: stress relief, mindfulness and work/life balance. Stress relief was addressed by providing healthy snacks for the staff for both day and night shifts for an entire week. Short hand massages were provided during work hours and nursing staff were encouraged to attend complimentary yoga classes away from the hospital. Mindfulness was addressed with weekly email "Mindful Monday" inspirational messages, providing relaxation tea and starting each shift with a short guided meditation. Essential oil relaxation sprays were available for voluntary use. Work/life balance interventions such as nature hikes and a beachside bonfire were not well attended, but the staff anecdotally reported appreciating the availability of these interventions.

Voluntary pre- and post- intervention assessments were performed using the 10-item CD-RISC. Validity and reliability measures have been established for the Refined CD-RISC in the literature (Campbell-Sills et al. 2007). A prior power analysis was completed and it was determined that a sample size of 100 registered nurses was estimated for a two-tailed test $\alpha=0.05$ to achieve a power of at least 80% at a

medium effect size (Polit & Beck, 2012). A paired t-test was used to evaluate the mean difference for each question included in the pre- and post- data from 106 respondents. Post-intervention data was collected at 1 month post intervention completion to ascertain impact. Long-term impact will be assessed at the 12 month interval.

Results: Among the 10 questions included in the Revised Connor-Davidson Resilience Scale, the post-intervention analysis indicated statistical significance was achieved on question 10: "I can handle unpleasant feelings."

	p Value
Able to adapt to change	.971
Can deal with whatever comes	.728
Tries to see humorous side of problems	.315
Coping with stress can strengthen me	.446
Tend to bounce back after illness or hardship	.135
Can achieve goals despite obstacles	.900
Can stay focused under pressure	.952
Not easily discouraged by a failure	.305
Thinks of self as a strong person	.692
Can handle unpleasant feelings	.039

Conclusion: Stress relief, mindfulness and work/life balance strategies can be used to assist inpatient nursing staff to increase their personal resilience and contribute to providing effective, safe patient care.

Predictors of Readiness for Disaster Management Skills Among Hospital Nurses

Chia-Huei Lin, PhD, RN, Taiwan

Abstract

Purpose: Continuous disasters have been threatening people's lives in recent years. However, studies regarding the readiness for disaster management competency among nurses remain limited. Therefore, this study investigated the predictors of readiness for disaster management competency among nurses.

Methods: A cross-sectional study was conducted. Stratified random sampling was used to recruit eligible cases from 1,197 nurses, who had been registered nurses for at least 3 months in a military medical centre from northern Taiwan. In addition, all male nurses and military nurses were recruited. Data were collected on readiness for disaster management competency using a 40-item, reliable, well-validated, and self-administered questionnaire with four domains (preparedness competence, self-protection, emergency response, and clinical nursing skill). Linear regression models were applied to explore the predictors of readiness for disaster management skills among nurses.

Results: Among the recruited 365 registered nurses who were 32.6 years of age (SD = 8.04), there was an average 12.6 years of work in nursing. The majority (75.9%) had a Bachelor's degree or higher in nursing. Eighty percent ($n = 292$) were civilian nurses without military ranks. Thirty-four percent worked in critical care units or an emergency room. Some participants ($n = 14$, 19.5%) had previously received disaster-related training; 3.8% had previous disaster nursing experience and 13.4% had been deployed for disaster assistance. When adjusting for potential confounding factors the length of nursing work and previously received disaster training are significantly associated with preparedness competency and self-protection competency, respectively. Length of nursing work ($p < .001$), educational level ($p = .02$), working unit ($p < .001$), and previously received disaster-related training ($p = .01$) were associated with emergency response competency and clinical nursing skill competency, respectively. Regarding overall disaster management competency, participants with longer length of nursing work ($p < .001$), with a higher educational level (Bachelor's degree and above) ($p = .03$), working at critical care units or an emergency room ($p = .02$), and having previously received disaster training ($p < .001$), were associated with better disaster nursing competency.

Conclusion: Our study indicates that disaster-related training is recommended to be included in continuous nursing education, and preparing nurses to become critical care nurses helps to improve their own readiness for disaster management competency.

Hoping to Pass: A Multi-Site Study Examines How a One-Time Intervention Affects High-Stakes Test Scores

Alice L. March, PhD, RN, FNP, CNE, USA

Joshua C. Eyer, PhD, USA

Monika G. Wedgeworth, EdD, RN, CNE, USA

Nancy Haugen, PhD, RN, USA

Corrie Harris, PhD, USA

David Feldman, PhD, USA

Abstract

Purpose: The purpose of this subsection of a multisite trial is to test the effect of a one-time hope intervention on high-stakes program-exit test scores among final semester baccalaureate nursing students, compared to a relaxation intervention. There are two research questions posed for this preliminary report. The first question utilized all participants' responses to examine changes in hope scores, and how they differed by group. The second question related only to the final semester students; what are the between group differences in scores on the standardized exam (SE)?

Student success on testing is a clear concern. Nursing education programs throughout the world are tasked with providing didactic content and clinical experiences which produce nurses who practice in a safe and effective manner while advancing global health. To accomplish those goals competencies are established by regulatory bodies, and an expected level of knowledge is required to meet licensure requirements (Hudspeth, 2012). In the United States (US), the National Council Licensure Exam for Registered Nurses (NCLEX-RN®) "... measures the competencies needed to perform safely and effectively as a newly licensed, entry-level registered nurse" (National Council of State Boards of Nursing®, 2012, p. 1). Nursing programs in the US have adopted the use of specialty and exit examinations to predict success within a nursing program, as well as the likelihood of a student passing the NCLEX-RN®.

High-stakes testing is defined as a test or series of tests with outcomes that have important consequences for examinees (National Council on Measurement in Education, 2012). These exams are thought to represent having attained adequate knowledge of the subject at hand. Up to 30% of schools in the US require students to pass high-stakes exams as a condition of graduation (National League for Nursing, 2012; Santo, Frander, & Hawkins, 2013).

Nursing students understand the importance of, and the potential for, grave consequences if required scores are not obtained. Fear of failure may create unfavorable learning conditions as students are driven by this pressure to succeed. For some, this may lead them to study only to achieve the required passing score on the exam. This approach is unlikely to produce the firmly embedded knowledge needed to connect the dots (Dunn, 2014), and even if they succeed in passing, without a deep understanding of core didactic material, the new graduate may function poorly when clinical judgment and decision-making are required in nuanced healthcare situations.

The significance of the situation is demonstrated when nursing programs base progress and completion on SE scores; thus, exams are perceived as stressful to the point of being high-stakes in nature which may create these unfavorable learning conditions. There may be ways to decrease test anxiety and enhance learning by supporting selected psychological aspects related to learning. Hope (the belief in one's ability to achieve desired goals), and achievement goal orientation (why one desires to succeed) are associated with decreased stress, as well as increased academic achievement and higher graduation rates (Feldman & Dreher, 2012). However, this has not been examined as a way to increase high-stakes SE scores or predict nursing student success.

A review of the literature provides an interesting base for consideration. Academic progress and completion of a BSN program requires students to demonstrate competency in clinical skills and didactic

knowledge. Didactic competencies are often tested via end-of-course and end-of-program SEs (Lauer & Yoho, 2013; NLN, 2012). These tests are normed on national samples. Exams are perceived as high-stakes in nature and students may develop positive and negative ways of studying and coping to achieve success. Regrettably, poor coping mechanisms and ineffective learning pathways result in inadequate mastery of material, increased anxiety, maladaptive learning behaviors, and decreased overall performance (Dunn, 2014).

Recent research links hope to success of nursing students (Bressler, Bressler, & Bressler, 2010; Chang, 1998; Dunn, 2014). In a recent study of BSN students a positive association between academic and non-academic factors (mastery and performance, exam scores, and specific types of goal orientation) was found (March & Robinson, 2015). Fortunately, recent research in psychosocial education interventions suggests that a one-time hope intervention may influence how students approach learning (Feldman & Dreher, 2012).

With over two decades of research, hope theory is a well-established model to explain outcomes among students in education, sociology, and psychology (Ames, 1992; Cavazos Vela et al., 2014; Snyder et al., 1991). Hope is composed of two inter-related types of goal-directed cognition: agency thinking and pathways thinking (Snyder, et al., 1991). Agency thinking consists of “the thoughts that people have regarding their ability to begin and continue movement on selected pathways” toward their goals (Snyder, Michael, & Cheavens, 1999). Pathway thinking consists of planning-related cognitions. In short, a pathway is a plan, route, or strategy for accomplishing a goal. Because some pathways may not succeed, high-hope people are theorized to have high agency and to act, in part, to produce multiple pathways in order to circumvent possible obstacles (Snyder, 2002). Higher levels of hope are linked to academic success, such as retention, progression, and graduation (Cavazos Vela et al., 2014; Feldman & Dreher, 2012). Thus, hope theory may predict a variety of academic, social, and emotional outcomes.

Methods: This randomized control trial recruited participants from a traditional baccalaureate nursing program in the southern US. A power analysis for the entire study is available upon request, but does not relate to this subsection of the study. Human subject’s approval was obtained. Once randomized to group the students experienced a one-time 90-minute intervention; either hopeful thinking or guided relaxation. Pre- and immediate post-intervention measures were obtained at that time. Additional post-intervention measures prior to the final HESI exam were obtained and will be reported separately. Instruments for this subset of inquiry included the Goal-Specific Hope Scale (GSHS) and the SE score; end of program Health Education System, Inc. (HESI) exam. Hope was measured utilizing four items from the GSHS that assessed agency and four items that assessed pathways. Each item was scored using an 8-point Likert-type scale ranging from 1 (definitely false) to 8 (definitely true). The HESI exam assessed student competency related to the achievement of course and curricular outcomes.

Results: To answer the first question; what are the changes in hope, and how do they differ by group we used a 2 time x 2 group ANOVA to examine scores on the GSHS (n=134). Scores improved significantly from baseline to post-intervention for those in the Hope group [$F(1, 70) = 36.7, p < .001$], as well as for the Relaxation Group [$F(1, 62) = 25.3, p < .001$]. The 2 time x 2 group interaction was not significant [$F(1, 132) = 2.7, p = .10$].

To answer the second question; what are the between group differences in scores on the SE, a one-way ANOVA compared group scores (n=45). For students in the final semester the scores on the exit SE did not differ. However, there was a slight score benefit for Hope Intervention students (Difference = 25.8), yet this did not achieved statistical significance over the scores for the Relaxation Intervention [$F(1, 43) = 0.61, p = .44$]. Next, we examined the difference in mean scores as “benefit to pass rates” (achieved cut score of 850). This produced a meaningful trend for the Hope group (see Table 1); however, given the small sample the pattern was not significant [$c^2(45) = .73, p = .39$].

Table 1: Benefit to Pass: Cut Score above 850

Score	Hope	Relaxation
Above 850	66.7% (14)	54.2% (13)

Below 850 33.3% (7) 45.8% (11)

Conclusion: The preliminary results that goal specific hope increased are promising. Although the greater increase was seen in the Hope group, it was not statistically different from the Relaxation group. We believe that once data collection is complete this may reach statistical significance. In addition, we did not find a statistical difference between groups on the SE scores. The fact that a distinct trend towards a difference is promising, and additional data will be needed to determine if this occurs. The study is ongoing and this poster only presents preliminary findings from one of the two sites involved in the overall study.

We are encourage by the results to date and if the findings indicate that a one-time intervention could change hope and therefore impact progression through a nursing program it may be possible to deploy this strategy to many nursing students. A future area of inquiry is to examine whether or not re-dosing may be needed, and if it would be effective.

This research is supported by the 2016 NLN Research in Nursing Education Grant and by the University of Alabama Research Grants Committee.

RSC PST 1 - Research Poster Session 1

Adherence a Review: T2DM in Haitian-Americans

Balkys L. Bivins, MSN, ARNP, FNP-BC, USA

Abstract

Purpose: The incidence and prevalence of diabetes mellitus (DM) has soared globally due to socioeconomic, demographic, and lifestyle changes, and lack of social justice. In the United States, DM has become a costly epidemic that resulted in an annual healthcare cost of \$245 billion in 2012. The total prevalence of diabetes in the U.S. is significant at 29.1 million, of which 97.3 % is attributed to Type II diabetes (T2DM). Among the populations affected by the disease and the challenges to effective diabetes treatment and management are Haitian Americans in the U.S. The aim of this review from 1979 to the present on the concept of adherence in diabetes research is to summarize and synthesize recent studies, relevant theories, and models that examine the components of adherence in diabetes management within various populations of individuals diagnosed with T2DM. In addition, this presentation will examine the cultural components of adherence with T2DM in various immigrants in the U.S. This review will address the limited research findings specific to Haitian Americans.

Methods: On the issue of adherence research addressing T2DM in Haitian Americans, the review used the framework of Rodgers' evolutionary process (2000). Its distinct components include: *determining the concept to be studied, drafting a clear research question, defining the research process and gathering the pertinent information, synthesizing the research data and detailing specific conclusions, and research implications*. Multiple searches were conducted using the terms "Haiti", and "Haitians with diabetes", yielding 18 articles on theories of cultural awareness in nursing. An in-depth review of the literature on adherence was generated from the year 1979 to the present with the following search engines: SocINDEX, PsycINFO, Medline, EBSCOhost, Eric, Cochrane, and CINAHL. Searching the term "adherence" resulted in 371,859 articles. Further restriction of the search scope to adherence and medication articles written in English resulted in 105,218 articles. Additionally, subcategorizing adherence and diabetes produced 4,578 articles. Search terms relating to adherence and diabetes management were added, revealing 846 articles. The investigation was further restricted by limiting the publication years to the period between 2010 and 2015 revealing 367 articles. Eventually, using keywords relevant to adherence to the treatment of diabetes uncovered 44 articles on adherence with diabetes. The studies reviewed by the researcher were chosen because they addressed adherence and its definitions, the components of Rodgers' evolutionary process, culture, theoretical perspectives, and implications for nursing practice.

Results: The analysis of research findings using Rodgers' process (2000) identified the various factors for effective behavioral changes that impact adherence, diabetes management, and education in distinct and varied demographic groups. In addition, adherence to treatment of T2DM involves administration of medication, glucose monitoring, nutrition, and exercise. The researcher's findings identified predominantly that adherence to treatment is a difficult process in managing T2DM. Although the review identified some factors as to why individuals do not adhere to treatment protocols, this difficult process remains elusive. Due to scarce literature on Haitian Americans, these studies, however, did not incorporate relevant theories that may explicate the dynamic, holistic, and culturally sensitive component necessary in the care of immigrant individuals, namely the Haitian Americans. Purnell's model addresses this key cultural component directly but does not speak to the component of self-efficacy, a key factor in behavior modification. Therefore, nurses need to explore the complexity of T2DM management specific to the components of adherence, and how and why Haitian Americans face more challenges in managing T2DM.

Conclusion: Globalization, demographic influences, lifestyle changes, the complexities of life, and increased prevalence of chronic illnesses, specifically T2DM, pose a challenge in nursing. Even though adherence is a significant component with effective management of a variety of health conditions, the utilization of theories, behavioral modification, and cultural influences on behavior are often not considered an integral part of the treatment plans of individuals with T2DM. It is imperative that future

nursing studies be directed to effectively develop holistic nursing interventions, nursing education, the use of eclectic theories, and the utilization of multidisciplinary resources. The previously stated interventions may aid in the improvement of health outcomes, social justice, and quality of life in these marginalized and vulnerable Haitian Americans.

International Perspective, International Collaborations: Logistic Considerations for Survey Research in Nursing Study Abroad and Exchange

Helen Aveyard, PhD, MA, BSc (Hons), PDCE, RGN, United Kingdom

Kathleen Greenway, MS, MA, (Ed), BSc, (Hons), RN, United Kingdom

Sarah Hope Kagan, PhD, RN, USA

Elissa A. Acevedo, BSN, BA, USA

Abstract

Purpose: To describe and suggest plausible solutions to address logistical challenges involved in designing and conducting multinational survey research examining study abroad options within degree programs, and participation in these programs at the university level from the perspectives of registered nurse alumni.

Methods: Nursing exists in a global context where essential principles of the discipline are shared, but education and practice vary widely. With the globalization of knowledge and increasingly diverse cultural makeup of communities, nurses contend with challenges in health promotion and maintenance on a trans-national level. Opportunities to experience nursing education and practice in societies other than one's own foster personal and professional growth, valuable comparisons, critical analyses, and possibilities to derive internationally-informed local innovations. Furthermore, trans-cultural study abroad experiences and potential innovations allow for advances in the nursing discipline and attainment of new goals in public health. Despite the potential of study abroad in nursing to address and pose solutions to global health challenges, research broadly constrained by convenience sampling and local foci limits the quality of evidence available and the confidence with which development of study abroad initiatives may be undertaken. Hence, scant evidence exists for use in guiding exchange program development, defining objectives, and evaluating outcomes for the visiting students and host communities. Overcoming logistical challenges of study abroad research in a multinational context is imperative to advancing educational research in this phenomenon. Our methods are to use expert consensus and colleague crowd sourcing to project viable solutions to these challenges.

Results: The logistical challenges encountered in planning survey research in nursing study abroad include four main concerns. These are: 1. identification of nursing programs around the world offering study abroad options within degree programs; 2. identification of registered nurses across multinational context who have participated in study abroad as part of their degree programs; 3. verification of study abroad participation on the part of registered nurses by nursing programs to allow for paired analysis of programs and participants within each program; and 4. optimal survey design to achieve robust assessment of study abroad experiences, perceptions, and consequences. We pose several potential solutions to overcome these challenges including networking strategies to accrue a complete list of study abroad program; development of a survey platform restricting access to confirmed program staff and their alumni study-abroad participants with data collection to facilitate analysis by program and other characteristics including global regions transited; pre-survey invitations to key international and national nursing organizations to promote partnership; and development of a resource website for institutions offering study abroad programs.

Conclusion: Philosophically, study abroad is understood as a broadening enhancement to degree programs in nursing. Current sociopolitical contexts for nursing, health, and well-being suggest such programs may in fact be far more essential to nursing education in the 21st century. These programs are valuable to innovations in nursing education and practice as a means to address and advance trans-national and trans-cultural public health maintenance, promotion, and outcomes. We anticipate important dialogue with potential partners in presenting our work through this poster.

Perceptions/Recollections of Acquisition of the Nurse Advocate Role by Practicing Direct Care Nurses

Marianne Curia, PhD, MSN, RN, USA

Abstract

Purpose: The claim that nurses should be patient advocates has been a hotly debated topic in the nursing profession since the 1970's. The literature reflects this debate in its wide variance of not only the concept but the very definition of advocacy in nursing. Provision 3 of the American Nurses Association *Code of Ethics for Nurses* specifically states advocacy as an expectation of the nurse. It is significant to note that previous editions of the *Code of Ethics* implied advocacy but did not specifically name advocacy until this latest edition. This is a relevant occurrence since it strongly legitimizes the role. Further, a review of the literature makes a case for the contention that if nurses are to assume the advocacy role as their professional association has mandated them to do, then they must be educated for the role and strongly encouraged to incorporate it into their everyday practice. Nurses have adopted the role in varying degrees, in varying manners and with varying results. Whether this variance is based on the characteristics of the nurse, the environment in which nursing is practiced or a myriad of other factors has not been investigated thoroughly. Further, the educational preparation of the nurse for this role has not been analyzed to assess the common elements that promote advocacy in nursing.

Methods: This qualitative study utilized the case study methodology to investigate the concept of advocacy as it relates to the role of the practicing direct care nurse. Participants in a Midwestern state in the United States were sought for journal submissions, focus group meetings and subsequent one on one interviews to investigate their definition of nursing advocacy as well as their perception of their educational/ experiential preparation for the role.

Results: Data analysis assessed the verbatim notes from the focus groups, interviews as well as participant journal submissions for themes. These themes are presented in summary format.

Conclusion: Results of this study will assist nursing educators in both academic and clinical settings to assess and reexamine the components of advocacy education in their curriculum/educational offerings in order to assure that current and future nurses have the knowledge base to fully enact the role.

Ambulatory Playbook: Externs and Delay to Practice New Registered Nurses

Ruth Obregon, EdD, MSN, MBA, RN, USA
Marlene Sarah Ruiz, MA, BSN, RN, USA

Abstract

Purpose: The purpose for this project is to discuss the rationale behind recruiting and utilizing more registered nurses in the ambulatory care setting through a student externship and transitioning delay to practice registered nurses (RN).

Because of the influx of chronically ill patients with complex co-morbidities into the ambulatory care setting, the need for RNs increased. Many treatments and procedures that were formally in the hospital are now performed in ambulatory care. The background to these changes began with the 1986 passage of a law that created Designated Related Groups (DRG). Payment for procedures and conditions began to be paid prospectively. Each diagnosis and procedure was paid prospectively so that, based on evidence there was a limited amount of time an individual in the inpatient setting could receive a treatment. To keep pace the reimbursement changes, new strategies were required and patient care treatments were moved from the hospital to the outpatient setting requiring RNs. Moreover, the 2010 passage of the Affordable Care Act (ACA) brought many patients into the outpatient setting who without previous health care had complex conditions and therefore needed more multifaceted care.

Methods: The method used to meet the need for additional RNs was two-pronged. Begin with schools of nursing and encourage an interest in beginning a career in ambulatory care through student externships and recommending to the organization that hiring new graduates directly into ambulatory care by providing them a new graduate residency transition program (NGRTP). In addition, by recruiting student nurses to experience their externship in ambulatory care a growing interest in beginning a career in ambulatory care evolved.

To encourage the neophyte student RN, a model designed by the director of education engaged the schools to include ambulatory care in their curriculum and provide an optional externship in ambulatory care to interested students. The director of education created a partnership between the school and ambulatory care managers and the birth of the extern model occurred. Each year, the school and healthcare organization, use the model to inform the RN student and assist their consideration of the ambulatory care setting as a viable site for RN practice.

The second option was to recruit the new graduate RN population who were either working underemployed or were not employed at all. The local health care organization standardized the application criteria and to meet the criteria, the applicant must have graduated 1 month to 36 months ago. The first option (encourage the RN student) was easier to implement than the second (hiring the delay to practice RN). First, the delay to practice RN transition was considered more complex than their colleague who immediately transitioned into RN practice. Secondly transitioning any new RN into the ambulatory care setting did not resonate with all managers or educators in the local or other health care settings. Beginning practice in the medical surgical arena was far more acceptable to many RNs than hiring a new RN into an ambulatory care NGRTP.

Results: Against common opinion the local ambulatory care education department conducted 4 DTP-RN transition programs. Of the 4 transition programs, all have remained in ambulatory care, two have been hired into a more acute setting, and one has been promoted to a clinical supervisor position in Primary Care.

The extern program has proven extremely successful, by increasing the number of interested new graduates to enter the specialized field of ambulatory care. Of the 30 externs interviewed, selected to volunteer, and completed the program, as many as 10% chose ambulatory care to practice. Of those who

sought inpatient positions, another 10% stated they wanted to transfer into ambulatory care at some point of their career.

The outcome of the externships was an increased interest in ambulatory care as a site for future practice and it as a choice after graduation. Of the 30 externs that were hired from 4 schools 20% found jobs in an outpatient setting. Others stated that they would work in the ambulatory care setting after they worked one year in the inpatient setting.

Conclusion: Over the last 50 years patients and procedures in the ambulatory patient care setting have changed. Patients with complex needs and higher acuity have replaced patients considered the worried well. In addition massive RN retirements are imminent in the ambulatory care setting and the need for registered nurses has increased. Recruiting new graduates through including ambulatory care in nursing curriculum and by providing nursing students with experiences in the outpatient setting has been one organization's remedy for recruiting nurses into a newly recognized specialty of ambulatory care.
