Purpose: This review describes the methodological quality of systematic and integrative reviews in current nursing literature.

Methods: The Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines (Moher et al., 2009) directed the methodological review for this study. A critical review of nursing reviews published between 2013 and 2015 was conducted. The Cumulative Index of Nursing and Allied Health Literature (CINAHL) database was searched with the terms integrative review “OR” systematic review. Inclusion criteria were: 1) systematic or integrative reviews; 2) search strategy described and 3) published between 2013 and 2015. Limiters applied include: 1) abstract available; 2) written in English; 3) research article; and 4) first author is nurse. Articles were excluded from review if the following exclusion criteria were met: consensus reports, quality improvement projects, concept analyses, research briefs, conference proceedings, policies/guidelines, original research, and clinical articles.

Results: Initially 190 abstracts were reviewed electronically for relevance and then full-text articles were obtained and inspected for required study criteria. Three investigators rated inclusion criteria independently (CT, RR, and BQ) and reached consensus. After each article was independently reviewed then a second investigator assessed each article with a reported 97.87% agreement. For the lack of consensus for 2.13% articles, a third party adjudicator was consulted. Following identification of articles for inclusion, data regarding the systematic review process of each article was extracted. Twenty-three categories of data were extracted in order to identify characteristics of published literature reviews in nursing. A review matrix was used to systematically organize, analyze, and synthesize methods utilized by authors in the included studies. Data were extracted by investigators independently, and then compared by a second investigator and third party adjudicator in the event of disagreement. A total of 11.2% of selected reviews required third party review. Additionally, all three researchers independently reviewed a random sample of 10% of the articles. One hundred fifty one reviews met inclusion criteria. The sample revealed inconsistency in methods used in these reviews. Many of the searches performed were not replicable or exhaustive. Reviews often did not include inclusion and exclusion criteria or perform quality appraisals of included studies. Nearly half of the studies used only electronic databases to identify studies to include.

Conclusion: Findings suggest that methodological quality remains a concern. In an international sample of nursing reviews lack of conceptual clarity regarding similarities and differences between systematic reviews and integrative reviews is an issue that needs to be addressed in nursing. This review supports the need for stronger educational preparation of nurses and nursing students in graduate programs on how to conduct an integrative or systematic review (American Association of Colleges of Nursing, 2010). Clear definitions and procedures will help to ensure efficient and rigorous searches that produce strong conclusions that will strengthen the evidence for practice.

Professional Socialization of Nurses and Nursing Students: An Integrative Literature Review

Seongmi Moon, PhD, RN, Korea, Republic of (South)
Sun-Hee Kim, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: Professional socialization is the process by which people who enter a profession internalize or take in new knowledge, skills, attitudes, behaviors, values, and ethical standards and make these a part of their professional identity (Mariet, 2016). An important aspect of nursing education is to prepare nursing students to become well socialized in their workplace. The purpose of this study is to explore current knowledge of professional socialization in nursing and to recommend directions for future education and research on professional socialization.

Methods: Literature search strategy; Studies published from 2000 to July 2016 were searched in three electronic databases (Medline, CINAHL, and Web of Science). The search terms, 'professional socialization' OR 'professional socialisation' and 'organizational socialization' OR 'organizational socialisation' were used to search the title and text. MeSH terminology 'socializaion' was searched as well. The language of the searches was limited to English.

Inclusion and exclusion criteria; Articles addressing the aims of this study, nurse or nursing student socialization, were included in this study. Also, those dealing with inter-professionals, health professionals, midwives, or newcomers were included because they might include nurses or nursing students. The articles were limited to peer-reviewed primary studies. Therefore, review articles were excluded. Articles were excluded when subjects were animals, people with other occupations, patients, nursing faculty, pre-nurses, or licensed practical nurses. Unpublished manuscripts such as dissertations or presentation materials were excluded.

Study selection; The initial search found 5,586 articles; 4,655 articles were reviewed after duplicates were removed. Based on the inclusion and exclusion criteria, another 3,342 were excluded after screening these on title. Next, 1,313 abstracts were reviewed and 65 studies were selected. The full text of these articles will be analyzed.

Data evaluation; The mixed methods appraisal tool (MMAT-2011 Version) (Pace et al., 2011) will be used for quality assessment of the chosen studies.

Data analysis; Studies will be divided into subgroups according to the study design and samples. Data will be extracted and coded from each study. Coded data will be clustered, contrasted, compared, and synthesized considering the relationships among codes.

Results: The results will provide insight into the current status of professional socialization in nursing.

Conclusion: We will discuss future perspectives on the professional socialization of nursing students.

Mental Injury: Exploring the Factors Related to Abusive Behavior Among Health Professionals

Leah Phillips, PhD, MA, BA (Hons), Canada

Abstract

Purpose: In Canada, Licensed Practical Nurses (LPNs) are a self-regulated profession; they are accountable to the public, the profession, to other members of the healthcare team, and to their employers. LPNs work as part of health care teams that include Registered Nurses, Physicians, Allied Health Professionals, and unregulated care providers.

“Mental injury (or mental suffering) is harm to a person(s) for which some other person(s) is held responsible in whole or in part. It can take the form of either mental distress or mental illness. Mental injury results from negligent, reckless or intentional acts, or omissions” (Samra, 2009). First recognized by Roberts in 1983, and subsequently studied by many nursing researchers, mental injury caused by bullying and lateral violence are harmful pervasive practices in healthcare work places (Croft and Cash, 2012). Research demonstrates that the effects of psychological hazards on the mental health of nurses can significantly affect their ability to perform their work in a safe manner. Performing professional practice while mentally injured on the job threatens public safety therefore making this an important and serious issue. This study aims to understand the complex nature of workplace mental injury for Licensed Practical Nurses (LPNs) in Alberta Canada.

Methods: Cross sectional descriptive.

The College of Licensed Practical Nurses of Alberta, the regulatory college responsible for licensing LPNs in Alberta, conducted a cross sectional study to investigate the incidence of mental injury due to bullying, (hierarchical and lateral) perceived by LPNs in Alberta. The study also aimed to understand what factors (organization, personal, or environmental) contributed to these perceptions and how these factors were associated with increased risks of mental injury.

Results: The survey was sent out to approximately, nine-thousand six hundred practicing LPNs. One thousand eighty-six (n=1086) LPN completed the survey (8.4%). The results indicated the following:

- 70% experienced intimidation and other forms of abuse behavior as students (by practicing nurses, instructors, other team members and preceptors).
- 89.7% witnessed abusive behavior among nursing colleagues (24.7% witnessed the behavior within the last shift cycle worked).
- 85.1% experienced abusive behavior from another nurse (LPN, RN and RPN).
- 14.6% experienced abusive behavior within the last shift cycle worked.
- 80% experienced abusive behavior from health professionals outside of their nursing peers including immediate supervisor, physicians, healthcare aides and other professionals.
- 60% did not report the abuse due to feeling nothing would happen/change anyway, fear of retaliation, the abuser was the supervisor
- When asked if they believed their work setting tolerated abusive behavior among colleagues, 62% said “yes”.

Conclusion: Although these results are partially affected by selection bias, (the likelihood of responding is higher if one has experienced the phenomena) the survey clearly demonstrates that perceived abusive behavior is prevalent. When abusive behavior is perceived among co-workers it can create a toxic work environment with significant consequences to the organization. The overall ‘health’ of the organization is affected. An ‘unhealthy’ workplace can have many effects. According to the Canadian Centre for Occupational Health and Safety, these effects include:

- Decreased morale
- Decreased job satisfaction

- Decreased productivity and motivation, which may, in turn, lead to
- Increased absenteeism and presenteeism
- Increased turnover
- Increased retention and recruitment issues
- Increased costs for recruitment, employee assistance programs, disability, etc.
- Increased risk for accidents / incidents and patient adverse events

The nursing workforce in Canada is under threat due to increased demand for care and too little human resources to meet that demand. Changing population dynamics mean that more people will require nursing care in multiple care settings and at multiple levels of care. This issue is integral to health human resource planning as nurses represent the largest profession in healthcare. Previous research demonstrated that one in three nurses plans to leave his or her position because of co-worker abuse (McMillan, 1995). Approximately 60 per cent of newly graduated nurses leave their first position within six months because of horizontal violence (Griffin, 2004) and some decide to leave the profession altogether (McKenna, 2003).

This study and its results reflect a need for concerted efforts to begin a dialogue about abusive behavior in the workplace. Nursing leaders concerned about this issue can strive to work collaboratively in a shared commitment to address the issue of co-worker abuse. Nursing regulators can work towards supporting the ability of regulated members to meet the professional standards of practice within the work setting. Engaging with employers is key. Collaborative efforts are needed to make the necessary changes to prevent the negative consequences of workplace mental injury.

RSC PST 1 - Research Poster Session 1

Identifying the Impact of a DEU Experience on Critical Thinking in Associate Degree Nursing Students

Elizabeth C. Campbell, MSN, RN, USA

Thomas W. Gunning, MSN, RN, USA

Nancy Phoenix Bittner, PhD, RN, CNS, USA

Abstract

Purpose: The purpose of this project is to identify the impact of the DEU experience on AD nursing student's Clinical Reasoning ability. Using Benner's model of Novice to Expert progression, this model supports development through role modeling, acquisition of skills and deliberate practice, as well as more total immersion into the role of the nurse on a chosen unit.

Methods: Design and Methods - The Health Sciences Reasoning Tool will be administered pre-and post DEU experience to measure the development of critical thinking in the experimental group of DEU students (n= 18 per semester) against a control group of students in each course (NU102 Days and Evenings, and NU 201 Evenings at baseline as the course begins, and again following the clinical experience of all groups. The Health Sciences Reasoning Test (HSRT) measures high-stakes reasoning and decision-making processes. The HSRT is specifically calibrated for trainees in health sciences educational programs (undergraduate and graduate) and for professional health science practitioners. Scores on this instrument have been found to predict successful professional licensure and high clinical performance ratings.

Setting and Sample - All adult nursing students 18 years or over in the second semester nursing course of both the day and evening nursing program will be included in the study. We plan to begin the project on two medical-surgical units in acute care hospital settings.

Data analysis - The tool is analyzed per the company formula for univariate and bivariate, correlations.

Results: This study is a new study in progress over the academic year and will be continued sequentially in subsequent semesters.

Conclusion: The study question here is: " Does participation in the clinical experience of a Dedicated Education Unit (DEU) as an AD nursing student have a significantly positive effect on Clinical Reasoning development?" It is the belief of the researchers that the study will support positive results given the one on one teaching and mentoring of a student versus the traditional approach of 1:7 currently seen in our clinical group. This is an ongoing study but results will be available by the end of our academic year, We have significant positive anecdotal feedback from students and clinical faculty about the experience, but as previously stated no studies can be found to support the growth of clinical reasoning in students. We know that the needs for orientation, and subsequent costs for orientation can be reduced by use of this model, but we have no hard evidence to support the professional growth we presume occurs.. In addition, professional growth of Clinical Teachers is an added bonus, and while not part of the study discussion here will be addressed in the poster as the role allows nurses with an interest in teaching to work with students, an added benefit in the known faculty shortage here in the US.

Nursing Leadership Influence on Male Graduate Nurses Retention Experiences Explored in the Professional Practice Environment

Dianne T. Juliff, MSc (Nsg), RN, RM, MCH, CertRAN, GradCertMgmt (Ldsp), BSc (Nsg), Australia

Abstract

Purpose: To investigate the lived experience of the graduate registered nurses who are male with view of understanding how these newly registered nurses transition into the professional-practice environment and ultimately the nursing profession. Thus opening the discussion on schemes that may assist with future recruitment and sustainability of males entering the nursing workforce.

Methods: A qualitative longitudinal phenomenological study, explored the lived experience of nine newly graduated nurses who are male during their first year in their professional-practice environment. Interpretative phenomenological analysis (IPA) was utilized both as the study design and the methodology. The aim of using IPA was to enhance exploration of the lived experiences of newly graduate nurses who are male, by investigating the meaning of such experiences and how these are made sense of. Moreover, the analysis was "committed to understanding how particular experiential phenomena have been understood from the perspective of particular people, in a particular context" (Smith, Larkin, & Flowers, 2009, p. 29). Purposeful sampling, using a snowball technique, ensured expertise was obtained through the voiced experiences of the nine participants who are male and newly graduated registered nurses about to commence the first year in their professional-practice environment.

Results: The findings from the second stage of this study supports Duchscher's 2007 Transition Stages Model in exposing the likelihood of crisis around the four to six month stage of newly graduate nurses commencement in their new profession (Duchscher, 2008). Leadership and collegial support, moreover the lack of, seeded doubts on whether nursing was the right career for them. Unprofessional nurse to nurse communication and workplace marginalisation of nurses who are male added to their doubts. For the newly graduated men in nursing the added issue focused on the co-cultural aspect of working in a female-dominant profession. The study participants need to fit in, to be part of the team, is consistent with Orbe's (1998) co-cultural communication model's 'outsider within perspective' in relation to their professional socialisation.

The study participants, as expected and consistent with previous literature, revealed constant pressure, both from within and from others, to 'hit the ground running' (Chernomas, Care, McKenzie, Guse, & Currie, 2010). This feeling of 'hitting the ground running' led to the participants repeatedly expressing that they were overwhelmed and afraid of their actions more so than the lack of their actions. Moreover, all of the participants experienced the associated fear of making a mistake and feeling unsafe. This fear, described by Judy Duchscher (2007) as 'Transition Shock' impacts on a new graduate's confidence and self-image, which became apparent in various degrees by all the study participants. Again the study participants concurred with Duchscher (2007) 'Transition Stages Model' where their fear heightened around the four to six month stage known as the 'Transition Crisis' (Duchscher, 2008). It was during this crisis stage that the participants reported that nursing leadership is paramount. Without the explicit nursing leadership in the form of collegial support and caring behavior within their professional-practice environment, the majority of them revealed that they would have left the nursing profession. It was this willingness to help from their colleagues, both male and female, and the role modeling of other nurses who are male, of the various communication techniques these nurses utilized to influence the professional-practice environment that persuaded the participants to continue on their nursing journey. They concluded with the essence of helping being at the forefront of nursing, not just in relation to patient care but also towards their nursing fellows and other health care workers, and believed that this can only be achieved through proactive nursing leadership at all levels. Overall, the study participants reinforced that a viable work environment is embedded in role modeling the nursing leadership characteristics of a welcoming, supportive and inclusive culture. Furthermore, this modeling starts with the welcoming of newcomers such as novice nurses including student nurses and graduates into the workplace, through constructive support in their learning and assimilation into a no blame gender-neutral culture. Moreover,

the acknowledgment of the new comers' status and the willingness to support them in their transition into the professional practice setting is important in the retention of a sustainable nursing workforce.

Conclusion: Nursing leadership at all levels is at the forefront of recruitment and retention of nurses. Support for newly graduated nurses in promotion of a proactive and engaging nursing profession and investment in leadership programs, especially of the minority groups such as men, cannot be underestimated

Cognitive Apprenticeship in Hospital Orientation for Newly Graduated Nurses

Betty Key, MSN, RN, CCRN, USA

Abstract

Purpose: Most hospitals utilize the preceptor model for the clinical portion of orientation with newly graduated nurses. The transition from student nurse to practicing, newly graduated nurse can be stressful. Many newly graduated nurses cite the transition period as a time of challenge, uncertainty, and lack of self-assurance, which may also affect patient safety (McDonald & Ward-Smith, 2012). Some researchers believe that this time of stress and uncertainty has contributed to the high rate of turnover for newly graduated nurses (Robitaille, 2013). Nurse retention has become a global issue. Other countries such as Australia, UK, and Canada are also studying transition to practice strategies for newly graduated nurses (Gordon, Aggar, Williams, Walker, Willcock & Bloomfield, 2014). Cognitive apprenticeship (CA) is an instructional strategy that may facilitate ease of transition for NGNs during the clinical portion of hospital orientation. The term cognitive apprenticeship, coined by Collins et al. (1989), describes the cognitive and metacognitive processes shared by a teacher or expert with a student or apprentice. Cognitive apprenticeship seeks to make learning visible by teaching the problem-solving processes used by experts in a way that promotes metacognition in the apprentice or novice as they progress to expert (Collins et al., 1989). Moreover, the methods in CA are often seen in the promotion of the development of expertise (Collins, Brown, & Holum, 1991). The purpose of this mixed methods pretest-posttest design is to explore whether there is a difference in the NGN's sense of confidence, clinical skills, and ease of transition to practice, after completing a CA based orientation.

Methods: A power analysis was performed using G*Power to determine appropriate sample size, $n = 51$. Newly graduated, non-experienced, newly hired RNs who may have already taken or are preparing to take the National Council Licensure Examination (NCLEX) will be solicited for participation. This population was chosen selected because these are the individuals who experience role transition from student nurse to practicing nurse. Nurses, who currently serve as preceptors, will be solicited to attend training on CA. The training will include a preceptor manual, which will illustrate the principles of, and activities of CA, along with weekly clinical guidelines. The primary investigator using the ADDIE model for instructional design, review of literature information, and over twenty years of preceptor experience developed the manual.

The Casey-Fink Graduate Nurse Experience Survey (CFGNES) will be administered at the beginning of the clinical orientation and again at the end of the clinical orientation. This instrument was chosen because it generates data regarding the NGNs transition into practice, confidence, skill set, and aspects of job satisfaction. Additionally, data will be collected from a focus group of both NGNs and preceptors at the end of the orientation process. It is believed that the data collected both quantitatively and qualitatively will answer the research questions.

Data Analysis: Quantitative data analysis will be conducted with the latest version of SPSS, using independent sample t-tests. Qualitative data will be recorded and transcribed during the coding process using NVivo.

Results: It is expected that there will be an increase in confidence, skills and ease of transition to practice at the end of the clinical, preceptorship orientation process. Which could help with new nurse retention, improved patient safety, and improved patient outcomes.

Conclusion: Newly graduated nurses have a high rate of job turnover as they begin the transition from student nurse to practicing nurse. Nursing literature cites lack of confidence, skills, and stress as significant factors for NGNs during the transition to practice progression. Preceptor-based training is frequently utilized during the orientation phase as a means of support for NGNs. However, a gap exists in the literature regarding an exact pedagogical strategy for preceptorships, both during hospital clinical orientation and academic clinical preceptorships. This study will employ CA as an instructional strategy

during the preceptorship phase of orientation to investigate its effectiveness as a transition to practice strategy.

RSC PST 1 - Research Poster Session 1

Using Story-Guided Online Deliberate Practice to Develop BSN Students' Critical Incident Reporting Skill

Jen-Huei (Vicky) Yeh, BSN, RN, USA

Gwen Sherwood, PhD, RN, FAAN, ANEF, USA

Abstract

The use of stories in healthcare education is a teaching-learning strategy used to provide the context of a clinical situation in a way that learners can relate the facts with the concept (Billings & Kowalski, 2016). Listening to stories, as opposed to reading a clinical case presented in a third-person view with objective clinical values, encourages learners to think critically while allowing them to react with emotions (Billings & Kowalski, 2016). The nature of stories brings the context to a person level and links actions with consequences as the stories unfold (Sherwood, Durham, & Zomorodi, 2016). Without visual cues, audio stories decrease the introduction of preconceived assumptions and free the learners to use their imagination. For these reasons, stories present a unique way to introduce and simulate clinical scenarios. Deliberate practice (DP) is an intentional, repetitive practice that is performed with the goal to improve a skill from the current level and has been identified as a critical activity to excel in a given skill (Ericsson, Krampe, & Tesch-Romer, 1993). Its use in simulation-based medical education suggests that DP is more effective when compared to the traditional "see one, do one, teach one" approach (McGaghie, 2011). The key components of DP include 1) practice, 2) feedback, 3) self-reflection, and 4) repeat practice (Ericsson, 2008). This study uses story to guide pre-licensure nursing students as they engage in online DP sessions in reporting a patient critical incident using SBAR (Situation, Background, Assessment, Recommendation), a standardized communication tool, to another healthcare provider (Kaiser Permanente).

Purpose: The purpose of this study is to evaluate pre-licensure nursing students' experience in completing story-guided online DP sessions to practice reporting a patient critical incident using SBAR to another healthcare provider. Main topics evaluated include students' 1) feedback on using story to introduce clinical scenario, 2) perception of the helpfulness of different components of the DP session, and 3) overall satisfaction in completing the story-guided DP sessions. The reported preliminary results are a part of a pilot experimental study measuring the impact of the online DP sessions on students' critical incident SBAR reporting performance.

Methods: Eighty-one pre-licensure nursing students completed a minimum of two (mean=2.6) story-guided online DP sessions as a summer course requirement. To simulate clinical scenarios, audio case stories provided by StoryCare®, Eefform, LLC were used to introduce scenarios with a patient critical incident that required calling another provider for his/her immediate attention. The online DP sessions were accessible to students on an educational platform used by the University. In each session, students listened to an audio story and then constructed and recorded a verbal SBAR report to a provider. Subsequently, students completed a self-assessment checklist (Foronda et al., 2015) and four self-reflective questions before recording a refined SBAR report. At the end of each session students listened to an example of a good SBAR report recorded by an experienced clinician. Each session had a 45-minute time limit. Upon IRB approval and after the summer session ended, an online evaluation survey was sent to all students to evaluate their experience in completing the story-guided online DP sessions.

Results: Forty-six students (56.8%) completed the online evaluation survey. In using story to introduce a clinical scenario, survey results revealed that students rated the audio stories to be realistic (100%). They also indicated that stories help them establish the context of how clinical situations develop (93.3%) and see different perspectives of other healthcare team members (93.3%). Among different components of a DP session, the most highly rated elements were: actually recording a verbal report, completing the self-assessment checklist, and listening to the example SBAR report provided. Overall, students reported the DP sessions were helpful in developing critical incident reporting skills using SBAR. All but one student perceived some level of improvement in their ability to use SBAR in communications and 30.4% stated they have made significant improvements throughout the summer session. Despite the overall

satisfaction of the experience, 40.0% of the students experienced technical difficulties in recording their verbal reports directly on the educational platform and 15.6% wished they had more time to complete each session.

Conclusion: Results of the evaluation study suggest that using story is an effective teaching-learning strategy in providing the context of a clinical situation and further guiding a DP learning experience to report a patient critical incident. These preliminary results supported the use of audio stories to simulate clinical scenarios. Analysis of students' verbal reports and a study of a larger scale are needed to further assess students' actual performance change in relation to completing the DP sessions. Modifications to overcome technical difficulties associated with the educational platform are necessary to provide students an improved learning experience. Online DP for skill development can be an efficient teaching approach to meet both students and faculty time management needs.

The Teaching Implementation of Hospital Experts Effects on the Self-Efficacy of Nursing Students

Fu-Fei Tsai, MHA, RN, Taiwan

Abstract

Purpose: The purpose of research was to investigate the evaluation of the third years nursing students after the critical care program which hospital nursing experts teach. More specifically, the aim of the paper was to examine the changing self-efficacy of nursing students.

Methods: This study was a quantitative, pretest-posttest ,and comparative design.

This quantitative research used the questionnaire, including baseline demographics, and self-efficacy between the experimental groups (N=40) and control groups (N=40). The experimental group performed the critical care program of the intervention, and the control group received the traditional classes. The SPSS software packages 21.0 for Windows was used for analyze data according to results of quantitative research. Descriptive statistics provided frequency, percentage, mean, and standard deviation. Chi-square test and Mann-Whitney U test were used to analyze the baseline demographics of participants between two groups. The independent two-sample t-test was used to analyze self- efficacy. The paired t-test was compared pre with post of self- efficacy. One-way ANOVA was used to compare the increased scores of self-efficacy within and between different groups. Linear regression was applied to examine the associated between post-test score of self-efficacy and baseline data, and pre-test score.

Results: The results on the baseline demographics of 80 participants between two groups showed that four variables of them were significant in sex($X^2=6.05$ or Mann-Whitney U test, $p<.05$), religious affiliation($X^2=18.81$ or Mann-Whitney U test, $p<.05$), number of sisters (Mann-Whitney U test, $p<.05$) and interest in nursing(Mann-Whitney U test, $p<.05$). No significant differences were found the other 11 variables such as age, horoscope, gender, aborigines, blood type, family in nursing, household income, number of brothers, ranking at home, volunteering in nursing, and ideal spouse occupation.

The analysis of the independent two-sample t-test indicated no significant differences in pre-test scores of self-efficacy. After the intervention in the experimental group, the post-test score of self-efficacy ($M=2.63$, $SD=0.47$) is higher than the pre-test score ($M=2.49$, $SD=0.51$), but analysis of paired t test show that no difference is statistically significant between pre-test and post-test ($t=-1.906$, $p=0.064$). In contrast to the control group, the post-test score of self-efficacy ($M=2.54$, $SD=0.53$) is lower than the pre-test score ($M=2.61$, $SD=0.64$), and analysis of paired t test show that no difference is statistically significant between pre-test and post-test ($t=-0.496$, $p=0.622$).

Analysis of a one-way ANOVA revealed that there were group differences in the increased scores of self-efficacy ($F=4.433$, $p= 0.038^*$).

The results of stepwise regression demonstrated that pre-test score of self-efficacy predicted the post-test scores of self-efficacy in the experimental group ($\beta =0.560$, $t =4.165$, $p <.001$) and explained variation 31.3% (coefficient of determination). Also, pre-test score of self-efficacy predicted the post-test scores of self-efficacy in the control group ($\beta =0.753$, $t =7.051$, $p <.001$) and explained variation 56.7% (R^2).

Conclusion: The clinical nursing teachers of the program play the important role models. The sources of self-efficacy are followed as previous performance or mastery of experiences, observe and learn from models, social persuasion or the feedback. They might help students set goals, encourage the use of challenging and proximal goals, provide honest and explicit feedback to increase students' efficacy beliefs, facilitate accurate calibration of self-efficacy, and use peer modeling to build self-efficacy. When students experience success or get positive feedback, their self-efficacy become better. If nursing experts share their successful life, students can motivate to learn and increase their self-efficacy. Little by little, their higher self-efficacy might promote the persistence in performing tasks or learning challenges.

Likewise, the lower self-efficacy might be resulted from suffering difficulty and uncertain socialization during college learning period.

The results have a contribution to explain the evaluation of the critical care program in increase the self-efficacy of nursing students. The department of nursing will improve the instructional program design inadequately. When new nurses are assigned to critical unit, they have the ability to adapt the task. The new nurse turnover rate remains lower than past, especially during the entry several months. Some of new nurses do not leave hospital due to reality shock.

Matched Preceptor-Preceptee Learning Styles on Student Self-Efficacy in Midwifery Students

Zofia Rapaport, MA, RN, Israel

Cheryl Zlotnick, DrPH, MPH, MS, RN, Israel

Abstract

Purpose: Students with high self-efficacy become more confident and competent midwives. Contributing to the development of self-efficacy in midwifery education is the clinical learning environment, particularly the preceptor-student relationship. Matching student and preceptor learning styles might contribute to the preceptor-student relationship and self-efficacy; however, this hypothesis has not yet been tested. This study aims to examine the impact of matched preceptor-student learning styles on the link between the quality of the preceptor-student relationship and student self-efficacy in midwifery students.

Methods: This study will use a quantitative approach and a cross-sectional design to enroll a convenience sample of all midwifery program preceptees in Israel (n=75). The procedure will be to ask all three schools' program directors to encourage their preceptees and preceptors to participate in the study. There will be two questionnaires. The first questionnaire will be for the midwifery students and includes: Prenatal Nursing Self-Efficacy scale, the Clinical Teacher Characteristics Instrument (CTCI), and the VARK (learning styles) questionnaire. The second questionnaire will be for the preceptor and will only include the VARK.

Results: Expected Contributions: If nursing schools learn that matching preceptor-preceptee learning styles increases preceptees' self-efficacy and better prepares them to be autonomous practitioners, programs may want to institute this practice (preceptor-preceptee learning styles) into their educational system.

Conclusion: This study will contribute to midwifery nursing education, training and research. Specifically, this study builds on the knowledge that midwifery nursing preceptors have a great influence on their preceptees, and the advancement and future of midwifery practice in Israel. Preceptees' perspective of their preceptor is internalized and influences their learning, practice and self-efficacy. Self-efficacy is linked with better performance; consequently, understanding methods to improve self-efficacy is paramount as it is translated into their patient care.

Besides selecting the best preceptors, nursing schools want to pair their students with preceptors who will be the most successful at helping them learn. If nursing schools learn that by matching preceptor-preceptee learning styles, preceptees' self-efficacy will increase, they may want to institute this practice into their educational system. There is far less literature about the impact of nursing preceptors on midwifery nursing student's perceptions on self-efficacy.

Innovative Leadership in Nursing Education for Maryland Healthcare Systems: Supporting Professional Advancement in Nursing

Tener Goodwin Veenema, PhD, MSN, MPH, RN, CPNP, FAAN, USA

Abstract

Purpose: The US Health Resources and Services Administration (HRSA), recently reported that Maryland is one of 16 U.S. states projected to experience a serious shortfall of registered nurses (RNs) by 2025 (HRSA, 2014). This problem is not unique to the US as globally, the nursing shortage is limiting access to health care services and impacting health outcomes across many countries. Innovative education and workplace partnership programs are needed to retain new nursing graduates in times of shortage and funnel them into open 'high-need' positions at area health care systems while simultaneously providing support and encouragement for the nurse to return to graduate advanced nursing studies. An opportunity exists to establish strong coordinated and collaborative academic-workplace partnerships to improve the way 1) advise and assist our pre-licensure nursing students with identifying and obtaining appropriate job placements, 2) onboard and support the transition of the new nurse into the clinical setting, 3) use technology and social media to establish an innovative communication and information sharing system to support their first three years in practice, 4) meet the nurses' need for professional growth and career development, and 5) facilitate the new nurses' enrollment into graduate nursing programs of study. The purpose of this research was to design and evaluate an innovative workforce development program that would be generalizable and reproducible in other countries and world regions.

Methods: In 2015, the Johns Hopkins University School of Nursing (JHSON), in partnership with five area hospitals and health care systems received grant funding from the Maryland Higher Education Commission to develop, implement and evaluate an innovative phased program of research called.

Results: The first two years of this innovative academic workplace partnership program is now complete. Thirty students applied and completed their senior practicum experience at a partner health care system. Twenty out of the 24 students were offered full-time nursing positions and all students accepted. Students remain gainfully employed, have transitioned successfully into the workplace and are applying to graduate advanced nursing programs of study.

Conclusions: The data suggest that 1) students are very receptive to this new opportunity early in their career, 2) academic-workplace partnerships improve communications between organizations and nurses who work in them, 3) an Innovative Smart phone based text-messaging system to disseminate a series of timed messages of support and information can enhance and sustain the nurses' engagement in the academic-practice partnership.

RSC PST 1 - Research Poster Session 1

The Effects of Task Characteristics and Cognitive Loading on Clinical Examination Performance in Nursing Students

Hsiang-Chu Pai, PhD, RN, Taiwan

Abstract

Purpose: The integration and education and practice has received wide attention in the nursing profession. In this regard, the objective structured clinical examination (OSCE) is being increasingly used with students in nursing programs in Taiwan before they enter clinical practice in hospitals. Most studies, however, examine OSCE's advantage, while few focus on the impact of task characteristics and the relationship between task characteristics, task cognitive loading, and skill performance for the OSCE. The purpose of this study was to examine the task characteristics of and cognitive loading that occurs during OSCE administration among third-year nursing students who are seeking a baccalaureate in nursing and to explore the association between the task characteristics, cognitive loading, and clinical examination performance.

Methods: A correlation study design was employed. A total of 118 nursing students who sat for the clinical examination were recruited. The data were collected in January 2015. Students' ages ranged from 21 to 31, and the mean age was 21.68 (SD =1.23). The majority of students were female (78.05 %). The measures included task characteristic, task cognitive loading, and skill performance scores. The structural equation modeling (SEM) approach with partial least squares (PLS) was used in the data analysis.

Results: The results of this study indicated that students perceived the top dimensions of the task characteristics of the OSCE was "task significance". Further, "task identity and feedback from job" and "task autonomy" had a significant negative effect on task cognitive loading ($\beta = -0.14$; $\beta = -0.18$, $p < .05$), respectively. In contrast, "task variety and significance" had a significant positive effect on cognitive loading ($\beta = 0.20$, $p < .01$), and cognitive loading had a significant negative effect on student's OSCE performance score ($\beta = -0.25$, $p < .001$).

Conclusion: We found that increased task variety and significance and reduced task autonomy, task identity, and feedback during OSCE were associated with increased task cognitive load, which, in turn, reduces OSCE performance. This study demonstrated that task cognitive loading plays an important role between students' perceived task characteristics and performance during the OSCE. We suggest that skill examination begin with the presentation of a simple strategy (low element interactivity) and gradually work up to more complex tasks

RSC PST 1 - Research Poster Session 1

Measuring Changes in Cultural Awareness, Sensitivity, and Behaviors Among Online Graduate Nursing Students

Janet A. Levey, PhD, MSN, BSN, RN-BC, CNE, USA

Abstract

Purpose: Cultural competency is embedded at the graduate level to prepare nurses for advanced roles in nursing education and practice (Clark et al., 2011). Nurse educators employ several learning opportunities for graduate students to develop a higher level of cultural awareness, sensitivity, and behaviors. Some graduate online cultural diversity courses use blogging, recorded lectures, synchronous classrooms, social media, video conferencing, and short-term immersion experiences (Arbour, Kaspar, & Teall, 2015). However, short-term immersion experiences may be a burden on students related to cost, family commitments, and use of vacation work benefits (Sagar, 2014). The purpose of this presentation is to describe the effect of an online graduate cultural diversity course on transforming nursing students' perceptions towards cultural awareness, sensitivity, behaviors, and course learning objectives over a 16-week time period. The primary investigator (PI) created a graduate online course using innovative teaching strategies as an alternative to the university's hybrid course requiring short-term travel. Leininger's Transcultural Nursing Theory served as the theoretical framework for the study.

Methods: A longitudinal design was used to measure the impact of an online graduate course on students' perceptions towards the attributes of cultural competency and course learning objectives at baseline and upon course completion. An additional aim was to identify effective teaching strategies used to teach cultural competency and skills during a 16-week educational experience. The research questions included: (1) What is the effect of a 16-week online cultural diversity course on nursing students' perceptions of cultural awareness, sensitivity, and behaviors?; (2) What is the effect of a 16-week online cultural diversity course on nursing student behaviors and course learning objectives?; (3) Which online teaching strategy was the most effective for teaching cultural diversity content and skills?; and (4) What is the relationship between teaching strategies and students' perceptions of achieving course learning objectives?

Participants in the study were students in the graduate nurse educator or nurse practitioner programs at a Midwestern University who registered for the online cultural diversity course. The study was approved by the university's instructional review board and launched in August 2015 and data collection for this phase of the study will end in December 2016. Participants received a survey invitation and reminder emails two weeks prior to the official course start date. The emails explained data would be collected over two points in time and was not related to a grade. No incentive was provided for participating and consent was implied when participants linked to the survey. Qualtrics Survey Software provided the portal in which to collect and store password secured data for the PI. Participants provided their unique student identification number to link survey responses. After grades were submitted, the class received the same survey invitations and reminder emails, minus demographic survey. G*Power determined a sample size of 34 achieved adequate power (effect size = 0.5; alpha = .05).

The Cultural Competence Assessment (CCA) instrument was used to measure perceptions of cultural awareness, sensitivity, and behaviors. Permission was received to use the CCA and demographic survey for research purposes. The CCA instrument has a test-retest reliability index of .89. The CCA has two subscales: Cultural Awareness and Sensitivity [CAS] (11-items; reliability index .75) and Cultural Competence Behaviors [CCB] (14-items, reliability index .91). Participants rated their level of agreement on the CAS and CCB using a 7-point Likert scale (strongly agree to strongly disagree). The CAS and CCB is scored using a range of 1 to 7 per item. A higher score indicates a greater level of cultural awareness, cultural sensitivity, and cultural competence behaviors. The second part of the survey contained items specific to course learning objectives (CLO) in which the stem was formatted in first-person (7-items), similar to the CCA. Face and content validity were established before the start of the study. A higher score indicates a greater level of culturally competent behaviors as related to the course objectives.

Results: The study is currently in progress and findings will be presented during the poster presentation. Descriptive statistics will describe the sample characteristics and identify the pedagogical approach most effective when teaching cultural diversity online. Cultural awareness, sensitivity, and behaviors mean scores will be compared using a paired t test statistic at baseline and course completion. Pearson correlation will examine the relationships between teaching strategies and students' perceptions of achieving course learning objectives. Anecdotal student feedback and comments will be shared with the audience.

Conclusions: Findings from this study might provide nurse educators with insight on engaging teaching strategies to connect online graduate students to cultural awareness, sensitivity, and behaviors. Examining the relationships between course learning objectives and student behaviors can offer an opportunity for educators to evaluate if course outcomes are congruent with student behaviors and make appropriate course revisions. Measuring the desired online course outcomes for the cultural attributes of awareness, sensitivity, and behaviors of future nurse educators and nurse practitioners is important to ensure we are preparing our graduates for complex settings. Phase II of the study will compare perceptions over three points in time for participants and will be disseminated at a later date.

Attempting Shared Governance Within a School of Nursing

Laura L. Opton, DHSc, RN, CNE, USA
Carol Boswell, EdD, RN, CNE, ANEF, FAAN, USA
Donna C. Owen, PhD, RN, USA

Abstract

Purpose: The governance structure of schools of nursing has the capability to augment the work environment for both faculty and staff. The pressure and intricacy of the multifaceted academic milieu have been postulated as contributing issues in the significant number of open academic nurse educator positions (Baker, Fitzpatrick, & Griffin, 2010). While staff members are usually involved as a supportive role in the hierarchical academic structure, they are frequently separate from faculty. Although faculty and staff both work to meet the strategic aims identified by the school of nursing, this structured separation by role has the potential to create a faculty-staff divide that impacts the work environment. Few studies have scrutinized shared governance as it relates to educational organizations. Shared governance holds the ability to influence the direct work of both faculty and staff by affecting job satisfaction and the level of work engagement. Job satisfaction has been connected to engagement and empowerment within other workplace settings.

Methods: The aim of this research study was to compare the School of Nursing's faculty and staff perceptions of job satisfaction and engagement in the workplace prior to and following the implementation of an integrated shared governance system. A longitudinal quasi-experimental, pre-post design is being used. Data was collected at the beginning of shared governance implementation and after the first full year of implementation. The project will continue to survey annually for an additional two years. Approximately 115 full time educators along with 150 full time staff are employed at a Texas public health sciences center school of nursing. Each of these individuals was asked to participate in the study. A power analysis was done that indicated a minimum sample of 120 (60 faculty/60 staff) was needed to obtain an eighty percent power with medium effect using regression analysis (Faul, Erdfelder, Buchner, & Lang, 2009). Six instruments were selected: An investigator developed qualitative online Engagement in the Work Environment Survey; Meyers' (1993) Affective Commitment Scale; Spreitzer's (1995), Psychological Empowerment Scale; Laschinger et al's, (2001) Conditions of Work Effectiveness II (CWEQ-II); Hackman and Oldham's (1975) Job Diagnostic Survey (JDS) and an investigator-developed demographic questionnaire.

Results: This presentation will report the findings from the initial survey along with the data collected after the first year of shared governance. Sixty-nine total individuals completed the initial survey out of the 269 employees within the school of nursing. Three questions results from the analysis: What values guide your work as a faculty or staff at the School of Nursing?; What are the positive "things" you get out of SON's committee work/meetings?, and What are the barriers to participation and/or being productive in SON's committees/meetings?

Conclusion: The idea of shared governance is a process which is needed within each and every governmental setting whether locally or globally. The comments provided by the School of Nursing team members using the survey in this study opened the avenue for dialogue between faculty and staff. The process of implementing an effective shared governance structure which embraces staff roles, faculty roles, and administrative issues continues to be a challenge. The lessons learned through this process can be employed in a wide variety of settings and situations.

E-Learning in Tertiary-Level Nursing Education in Germany and the Role of the Nurse Educator

Lee F. Koch, MSc, RN, Germany

Uwe Fasshauer, PhD, DGfE, Germany

Karin Reiber, PhD, DGHD, DGP, Germany

Abstract

Purpose: Experts in Germany's healthcare sector predict a rising need for at least 10% of the nursing workforce to be academically trained. In light of increasing occupational demands, some even anticipate a much higher quota of 50%. New legislation set to reform nurse education in Germany includes provisions for a partial transition of basic nurse education from vocational training to the tertiary level (equivalent to a BSN). In order to provide opportunities for nurses to gain academic degrees, the number of academic nursing programs must increase. This presupposes an increased need of qualified faculty with the professional and scientific training necessary for tertiary level nursing education. At the same time, e-learning is becoming more commonplace in tertiary level nursing education. Research has shown that e-learning can be just as effective at helping students achieve learning objectives as traditional face-to-face courses, provided that certain quality criteria are met. The decentralized, asynchronous nature of e-learning enables individualized and varied learning as well as the possibility of reaching many more learners than with conventional methods. However, it also precludes spontaneous, personal interaction between the instructor and the learner, which affects teaching and learning processes. In addition to this, learning objectives in nursing are not only within the cognitive, affective and psycho-motor domains, but also include clinical skills, a domain in which e-learning has its limitations. These circumstances lead to the assumption that e-learning has changed the nurse educator's role.

Research Questions & Objectives: How will e-learning affect and change tertiary-level nursing education in Germany? How will these changes affect the developing role of tertiary-level nursing educators? The results of this study will show experts' expectations of future developments in tertiary-level nurse education and the nurse educator's role in light of the increasing prevalence and importance of e-learning in the form of virtual teaching and learning arrangements.

Methods: One of the premises of symbolic interactionism is that patterns of interpersonal interaction contribute to the sense of identity of the subjects. The interaction between instructor and student is a central element of the teaching and learning process. The subjective views of the participants in these interactions must therefore be considered, in order for us to gain insights into how e-learning affects nurse education and the nurse educator's role, thus placing both student and instructor in the role of an expert. According to role theory, however, social roles (such as that of the nurse educator) are collectively defined, making it necessary to consider both normative input as well as the views of other stakeholders. Thus the decision was made to include members of scientific and professional nursing organizations as well as media designers involved in the production of e-learning modules on the expert panel. A total of 20 panel members was agreed upon, drawing five members from each subgroup of experts. Assuming an average panel mortality of 40%, this leaves us with input from at least three experts from each subgroup.

A three wave Delphi survey combining both qualitative and quantitative methods is being conducted, as this allows us to determine not only the experts' subjective views on the effects of e-learning on nurse education and the nurse educator's role, but also to compare their expectations of future developments in nursing education and the nursing educator's role in light of the increasing prevalence and importance of virtual teaching and learning arrangements. The first wave questionnaire was comprised of open-ended questions and was administered to a select group of experts ($n = 8$) from each of the four subgroups. Seven questionnaires were returned and the data was evaluated utilizing Mayring's method of qualitative content analysis. The second and third wave questionnaires were comprised of statements extrapolated from the results of the first wave and an earlier literature review. These were administered to the expert panel ($n \geq 12$) who were asked to indicate the degree to which they agreed with each statement. The second wave data is currently being analyzed using quantitative methods to determine percentages of

agreement. In the third wave, those items having reached a consensus in the first wave will be excluded. The experts, having been provided feedback on the 2nd-wave results, will then be asked to indicate the degree to which they agree to each statement. The variance between answer tendencies in the 2nd and 3rd waves will then be analyzed.

Results: The first wave resulted in statements which could be grouped under four main codes pertaining to e-learning in tertiary level education in general, to e-learning in tertiary level nurse education, to the influence of e-learning on role of tertiary level educators in general, and to the influence of e-learning on role of tertiary level nurse educators. The statements pertaining to the effects and influence of e-learning on tertiary level education in general and the tertiary level educator's role in general were informative and could be useful for further research on this general topic. Of primary interest, however, were the results pertaining to nurse education and the nurse educator's role. The experts state that, while e-learning is conducive to many learning outcomes in nurse education, there are certain outcomes, such as clinical skills, clinical decision making, or caring, for which e-learning is not suited. Furthermore, electronically mediated communication and interpersonal interaction, which are considered vital elements of nurse education, lead to a depersonalization of the relationship between instructor and student. The experts also conclude that a vital aspect of the nurse educator's role is their function as a professional and academic role model, which e-learning hampers. The data from the second wave is being collected and analyzed at the time of abstract submission. Results from the second wave will be available by the time of presentation in July 2017, while results from the third wave may be available by that time. This knowledge could prove useful in re-designing curricula for the training of tertiary level nursing educators.

Conclusion: This study contributes to field of tertiary level nurse education by providing insight into how e-learning is changing nurse education and, at the same time, affecting the role of the nurse educator. The results are important for re-designing curricula for the training of tertiary level nursing educators in order to adequately prepare them for the challenges posed by e-learning. The results can also inform the practice of current nurse educators involved in e-learning by helping them to critically reflect their own teaching practice and to gain a deeper understanding of their role in the virtual setting. Limitations: Due to limited resources, this study is being conducted on a small scale, with panel members drawn from stakeholders involved in e-learning in nurse education in Germany. The results may not necessarily apply to other disciplines or to tertiary level nurse education in other countries.

Relationships Between Personality Traits and Teaching Self-Efficacy in Clinical Nursing Preceptors

Su-Ya Huang, MS, RN, Taiwan

Abstract

Purpose: Clinical nursing preceptor is an important key of professional development in new nurses. Clinical nursing preceptor can provide effective teaching for new nurses to reduce Reality shock, decrease early burnout, and enhance retention rate. Few studies have examined the factors relationships between personality traits and teaching self-efficacy in Clinical nursing preceptors.

The objective of this study were to examine the statuses and relationships of personality traits and the teaching self-efficacy in clinical nursing preceptors.

Methods: The study methods applied a cross-sectional design using structured questionnaires, including (a) demographic characteristics, (b) personality traits questionnaire, and (c) the teaching self-efficacy evaluation. A total of 200 participants were recruited from two hospitals in south Taiwan through a convenient sampling procedure. Data were analyzed using descriptive statistics, independent t-tests, one-way ANOVA, and Pearson's correlations.

Results: The results of the study showed that clinical nursing preceptors had an average score of 3.86 in the teaching self-efficacy. In terms of the five dimensions of the teaching self-efficacy, the score from the highest to lowest was harmonious interpersonal relationship, objectivity of teaching evaluation, maturity of personal characteristics, proficiency of professional knowledge and effective teaching strategies. Personal characteristics including age, marital status, years of teaching experience, job titles, and the job ranking had significant relationships with the teaching self-efficacy. In consider with personality traits, except to the "Openness", the teaching self-efficacy had significant positive relationships with the "Conscientiousness", "Extraversion", and "Agreeableness" ($r = .632$, $r = .316$, $r = .374$); and the significant negative relationships with the "Neuroticism" ($r = -.339$).

Conclusion: The subjects of the study targeted at the clinical nursing preceptors to understand the personality traits and the current situation of the teaching self-efficacy of the clinical nursing preceptors. The aspects of the clinical preceptors' teaching self-efficacy in a descending order based on the mean scores include harmonious interpersonal relationship, objective teaching assessment, mature personal quality, professional competence and effective teaching. The overall teaching self-efficacy was significantly correlated with age, marital status, teaching seniority, rank of position and job title in the individual attributes. In terms of the correlation with the personality traits, the overall teaching self-efficacy had significant positive correlation with conscientiousness, extraversion and agreeableness except for the openness, and had significant negative correlation with the neuroticism in the personality traits.

Exploratory Study on Evaluating the Effectiveness of Implementing the Culture of Huddling in Ambulatory Care

Carol Bloch, PhD, MAEd, BA, RN, CTN-A, CNS, USA

Carolyn Bloch, PhD, MAEd, BA, RN, CTN-A, CNS, USA

Abstract

Purpose: This follow-up study measured if *huddles* were occurring in ambulatory clinics post-didactic education to nursing staff. Interrelating Dr. Madeleine Leininger's cultural care theory with the definition of culture of safety from the Centers for Disease Control and Prevention National Institute for Occupational Safety and Health Education and Information Division in the healthcare setting, the two concepts were explored for commonality and clarification. Although the concept of sharing and reviewing patients prior to clinic staff beginning care is not new, *huddle* was new terminology for clinic staff. Instruction for entire ambulatory nursing staff in both primary and specialty clinics was provided to clarify and demystify what a huddle is and what team members' responsibilities would be regarding this new concept.

Methods: A follow-up survey of 173 staff was conducted over 3 days to evaluate the effectiveness of huddles in ambulatory care clinics. The survey included direct questions about implementation of huddles in clinics and open-ended questions regarding feelings, problems solved, likes, and dislikes of huddles.

Results: Findings revealed the following: (a) Most clinics have daily huddles; (b) most are convened at the nurses' station; (c) huddles contribute to interprofessional communication between attendings, residents, interns, and clerical staff; (d) there are designated leaders for the huddles; and (e) the majority of huddles are led by registered nurses. The top three topics for huddles were (a) team staff present or absent, (b) number of patients for the day, and (c) who is working with whom in the clinic. Huddles occurred verbally, written, or electronically, and there was no one way huddles are documented to have occurred for review or verification. A specific method for documenting a huddle occurred was called a Huddlegram. It is interesting that survey results indicated access to Huddlegrams on the intranet is limited to specialty clinics only, not primary clinics. Analysis of open-ended survey questions revealed that if one misses a huddle, there are (a) feelings of missing connectedness to clinic activities, (b) emotional milieu of being lost or empty, (c) other ways to get the information, and (d) indifference. Regarding problems solved by huddles, three themes were (a) daily planning of staff and workflow, (b) improved communication, and (c) daily topics involving teamwork, support, and awareness. Two themes emerged on how participants liked huddles: enhances clinic communication and group cohesiveness and team spirit. Likewise, two themes emerged about not liking huddles: interrupts clinic schedule and timeliness of topics and updates. The final survey question was, "How can huddles be useful for you and your patients?" (AMA, 2015). The two themes were (a) improves team communication and (b) better patient care.

Conclusion: There is evidence of team culture-building through communication in the huddle, and huddles have become routine in clinics. Huddles had a clear checklist for staff daily planning and workflow. Further evaluation is needed of huddles' effectiveness in improving interprofessional connectedness. In combining Dr. Leininger's definition and the CDC definition of culture, nurses learned, shared, transmitted, and influenced the communication culture by focusing on patient safety to ensure and improve effective communication among team members. Congruence was achieved by combining the two frameworks, in that communication among the team was improved based on elements of the concept of culture. Study limitations included (a) only nursing staff completed the survey even though it queried about interprofessional communication, and (b) not all interprofessional staff were surveyed. As noted in survey results, very few medical staff attend huddles, possibly because huddles focus on attendance issues vs. patient problems or issues. Implications include that further research is needed to identify how to encourage interprofessional staff to participate in huddles that have clinical relevance for all.

Effectiveness of an Evidence-Based Practice Training Program on School Nurses' Knowledge, Attitudes, and Skills

Pei-Lin Hsieh, PhD, RN, Taiwan

Sue-Hsien Chen, PhD, RN, Taiwan

Abstract

Purpose: When school nurses embrace evidence-based practice (EBP), higher-quality care is provided to students, their families, and the larger community. However, there is little or no research on the adoption and implementation of EBP among school nurses in Taiwan, many of whom have limited experience using and lack the necessary skills to confidently implement EBP. The purpose of this study, therefore, was to evaluate the effectiveness of a multifaceted EBP training program on the knowledge, attitudes, and skills.

Methods: Four hundred and fifty-six school nurses recruited. The program comprised 9 hours of face-to-face lectures, 10 hours of online teaching, and outreach support for 3 months. Support involved email, online interaction and telephone contact. Knowledge, attitudes, and skills were assessed using a questionnaire, administered at baseline, post-training program, and 3 months follow-up, with the effectiveness of the training program being analyzed using a repeated-measures ANOVA.

Results: The age of the participants ranged from 31 to 66-years-old, with a mean age of 41.95 years, and the mean length of time employed as a school nurse was 8.4 years; the majority had a bachelor's degree (73.3%), with 41.3% coming from medium-sized schools. The results revealed significant gains in knowledge at the post-training program stage ($p < .001$), which was maintained at follow-up. Although there was no statistically significant difference between pre-test and post-test attitudes, the scores at follow-up were significantly higher than at post-test ($p < .001$). The improvement in skills between post-test and follow-up was small and non-significant.

Conclusion: In summary, targeted education and outreach support led to a marked improvement in evidence-based practice knowledge and attitudes, but only minor changes in skills. Therefore, health educators should focus on skill development and helping school nurses to establish new routines around evidence-based practice. Finally, this study can be used as a basis to developing a comprehensive strategy for building evidence-based practice competencies through proper training for school nurses.

Examining Nurse Attitudes and Knowledge Gaps Related to Substance Use Disorder

Pamela Quinn, MSN, RN, USA

Joanne Parhiala, BSN, RN, CARN, USA

Abstract

Purpose: The Substance Abuse and Mental Health Services Administration (SAMHSA) (2015) reports that in 2014, more than 21 million people over the age of 11 had a substance use disorder (SUD). Substance use and abuse contributes to more deaths (which have more than doubled since the early 1980s), illnesses, and disabilities than any other preventable health condition (NIDA, 2012). Dilonardo (2011) concluded that SUD treatment in the medical setting is imperative, reduces costs, and is an essential component of quality care delivery; however, the majority of healthcare workers including nurses are unlikely to have adequate training in addiction.

Patients with SUDs are admitted hospital-wide with complex conditions that require intense nursing care. A review of the literature related to the nursing care for the patient with SUD consistently revealed two major themes. First, negative attitudes are held by nurses toward this patient population. Foster and Onyeukwu (2003) report that nurses tend to have negative attitudes toward patients with SUD and that these attitudes directly impact not only the nurse-patient relationship, but the quality of care delivered. The World Health Organization (WHO) study that found positive attitudes are essential when caring for patients with SUD. Second, there is a lack of knowledge related to providing competent care. Nurses feel ill prepared for the multifaceted sequelae of SUD due to a paucity of nursing education on SUD related care (Raistrick, Russell, Tober, & Tindale, 2008). Although this patient population is growing, nursing education on SUD and related care has not been emphasized in the curricula of undergraduate nursing programs (Pillon, Villar Luis and Laranjeira, 2003).

Pens and Couture (2002) state that the more information a person has, the less stigmatizing they tend to be. Nurses need education about the how and whys of addiction in order to appropriately, competently, and compassionately provide quality and safe care to patients who suffer with SUDs. The evidence tells us that patient outcomes should improve, costs should be reduced, and the patient experience should improve.

Cramer, et. al., (2014) tell us that certification in a clinical specialty is one way of measuring nursing excellence and expertise. Among nurses caring for patients with addictions, certification has been shown to reduce failure to rescue and associated mortality of patients with SUD as well as achieve or promote statically significant improvements in delivery of clinically competent care.

The purpose of this pilot study was two-fold: 1) to examine whether nurse attitudes and knowledge of SUD and related care were influenced by a 5-month educational intervention, and 2) whether nurses in the cohort passed the Certified Addictions Registered Nurse (CARN) exam. The cohort members understood this to be an expectation at the completion of the 5 months educational intervention.

Methods: This pilot study employed a pre/post design to examine whether educating a heterogeneous sample of 31 volunteer nurses, recruited from non-procedural in-patient hospital units, improved attitudes and increased the nurses' knowledge about care of the patient with SUD. This pilot study used the Drug Problems Perception Questionnaire (DPPQ), which includes 20 questions and a 7- point Likert scale, with established reliability and validity that measures attitudes of professionals working with patients with SUD. The questionnaire was administered before and after the educational intervention to determine improvement and sustainability of nurses' attitudes. The educational intervention was conducted from May, 2016 through September, 2016, preparing the participants to sit for the Certified Addictions Registered Nurse (CARN) exam in October, 2016. The CARN exam pass rate will provide the measure of improved knowledge.

Results: Based on the primary outcome of passing the CARN exam, 17 nurses took the CARN exam in October 2016 and 14 reported passing the exam. Our pass rate was 82% compared to the average pass rate in the United States of 74%. Two nurses state they are planning on retaking the exam and 8 other nurses that indicated they will be taking the exam for the first time after January 2017. Our first bimonthly post course assessment of nurse attitudes toward patients with SUD demonstrated consistent improvement in nurse attitudes as measured by the DPPQ.

Conclusion: Early results reveal that this intervention achieved the primary expected outcome of improving nurses' attitudes and knowledge of SUD.

Pediatric Behavioral Health in the ED: A New Normal?

Jamie Beth Rivera, MSN, RN, CPN, USA

Abstract

Purpose: The purpose of this study was to gain knowledge about the experiences, perceptions, and feelings of pediatric emergency department nurses caring for behavioral health patients. It presents an overview of nurses who care for pediatric psychiatric patients in the emergency department.

Methods: Colaizzi's (1978) descriptive phenomenological method was used to discover the essence of the phenomenon of the nurses' experience in caring for behavioral health patients in pediatric emergency department setting. The philosophical underpinnings of this phenomenological research will have the potential to promote the understanding of rich, detailed description surrounding the experiences of nurses who care for behavioral health patients. By learning the meaning of the experience, this researcher was able to expand the very limited body of knowledge of this topic. Data were collected through semi-structured interviews of three pediatric emergency room nurses. Interviews were audiotaped and transcribed by the researcher for analysis and description of themes using Colaizzi's seven steps.

Results: One hundred and four significant statements regarding the nurses' experiences caring for behavioral health patients in a pediatric emergency room were extracted from the transcripts. From the significant statements, formulated meanings were created. After these formulated meanings were identified, they were organized into seven clusters of themes. The themes that emerged were: being on roller coaster of emotions, tis the season, working in a ticking time bomb, abuse of the system, a place for error, a sit and wait game, and threats and assaults.

Conclusion: This study of the nurses' experiences of caring for behavioral health patients in a pediatric emergency department setting adds valuable insight to the literature. The study begins to address the deficit in the literature regarding the nurses' perceptions and experiences of caring for these patients. These findings also provide nurses with a better understanding of how to care for pediatric behavioral health patients and their families. This can ultimately lead to increase in staff satisfaction, which would then increase patient and family outcomes in the ED.

Reinvigorating a Shared Governance (SG) Model in a Community Hospital

Kathleen M. Kane, PhD, RN, USA
Catherine M. Hennessy, MSN, RN, USA

Abstract

Purpose: In acute care hospitals, shared governance (SG) is widely recognized as best practice for a professional nursing environment. In addition to being associated with nurse empowerment, SG has been linked to increased job satisfaction, decreased turnover, and improved patient safety. However, while there are important benefits associated with SG, its implementation requires a huge paradigm shift and its sustainability demands a large investment of time and resources.

A 350-bed community hospital located in the Greater New York Metropolitan area had implemented a professional practice model using SG several years ago. Staff turnover, changes in leadership, and financial considerations contributed to a “drift” in adherence to the model. Prior to completely suspending the model, there were only three functioning councils. Using nurses’ perceptions of SG as measured by the Index of Professional Governance [IPNG] tool developed by Hess (1998), a new administrative team made a commitment to utilize a data-driven approach to reinvigorate a sustainable SG model to improve patient care and nurse empowerment, satisfaction, and retention.

Accordingly, the purpose of this study was to examine nurses’ overall perceptions of a community hospital’s governance structure after a SG model lapsed and prior to reinvigorating it with a new model.

Methods: Institutional review board (IRB) approval was obtained for this study. Participation was voluntary and identification was anonymous. A total of 146 IPNG (Hess, 1998) surveys were distributed to nurses in all areas of practice at a community hospital. Overall, the IPNG assesses three categories of governance: traditional (total score of 86 – 172); shared (total score of 173 – 344); self (total score of 345 – 430). This instrument is also designed to measure nurses’ perceptions of hospital governance on six dimensions: professional control, organizational influence, organizational authority, participation, access to information, and organizational goal setting.

Results: A total of 90 IPNG surveys were returned for 61% response rate. The majority of the participants in the study were females, whose ages’ ranged from 23 to 75 years. Years in practice as a registered nurse ranged from one to 57 years. A bachelor’s degree in nursing was the most common entry level into practice.

Baseline IPNG data indicated that overall, nurses’ perceptions of their governance fall into the “traditional” category with scores ranging between 86 and 172 ($M = 156$. $SD = 30.2$).

Conclusion: Professional governance is a multi-dimensional construct that includes the structure and processes through which individuals control their professional practice and influence the organizational context in which that practice occurs (Hess, 1998). The IPNG (Hess, 1998) measures nurses’ perceptions of this governance along a continuum from traditional to shared to self. Higher scores on the measure are indicative of the belief that nurses have more influence over their practice and governance decisions.

Not surprisingly, the results of this study demonstrated that nurses’ perceptions of their governance were indeed, categorized as “traditional”. In a “traditional” organization managers and administrators dominate control and influence over governance related decisions. High turnover among nursing staff and leaders and the eventual suspension of the model may have contributed to this perception.

This is an ongoing study. The SG model was re-instated in November, 2016. Further data analysis related to baseline subscales needs to be done in order to explore specific areas of strength and weakness in nurses’ perceptions of SG. . The IPNG will be re-administered in April, 2017.

Explore the Clinical Nurses' Viewpoint and Expectations Toward Nursing Assistantship in Taiwan: A Triangulation Method

Su-Hua Tsai, MSN, RN, Taiwan

Abstract

The target audience of this presentation is clinical nurses, nursing assistants, nursing supervisor, hospital managers, human resources director, care association group, patients, important media people and people pay attention to the medical environment. Nursing manpower shortage is deteriorating, due to the rapid growth of aging population and increasing workload of clinical care. Nursing staff have anticipated other personnel such as nursing assistants to join the current nursing care model.

Purpose: The purpose of this study was to, through the frontline nurses' perspectives, in-depth understand their viewpoints of and expectations from nursing assistants. Contacted was a convenience sample of 14 staff nurses, who worked at a medical center or at a regional teaching hospital in southern Taiwan.

Methods: Using data triangulation method, this study applied focus group conferences, questionnaires survey, and individual interviews to collect both qualitative and quantitative data. This study was conducted three times focus groups interviews at two hospitals in Taiwan. 14 nurses from a medical center and a regional teaching hospital in southern Taiwan.

Results: The result deduced three themes as (a) nurses' demands and needs for assistants, (b) the expected work content of nursing assistants, (c) promote skill-mixed collaborative interaction. The results revealed that staff nurses positively support the role of nursing assistants. Many of their working experiences and expectations should be valuable references on developing the scope of practice and establishing the qualification and training of nursing assistants.

Conclusion: The results suggest that the type of hospitals (such as acute or subacute care), the unit characteristics (such as workload and length of stay), and the nursing care model (such as primary or team nursing) should be considered while establishing nursing assistantship. Clear scope of practice of both staff nurses and nursing assistants is conducive to release more nursing hours for staff nurses in playing their professional roles and, in turn, leads to construct a quality nursing work environment.

Improvement Project for Dental Medical Instrument Management in Oral Surgical Ward

Sheng-Lan Hsieh, MSN, RN, Taiwan

Yueh-Li Yu, MSN, RN, Taiwan

Abstract

Purpose: Reduce the damage rate and re-sterilization rate for the medical instruments in oral surgical ward from Taiwan.

Methods: According to the assessment data of ward units for dental medical instruments and sterile sets, dated from June to September in 2015, it's found that damage rate was up to 15%, and the re-sterilization rate of expired set was 6.3%. While the major inductions include, no specialized unit, no exclusive management personnel, device cleaning via in-correct process, no internal check system, and lack of in-service education, etc. Therefore, a project team was set up, implementation period have three stages from September 1, 2015 to March 31, 2016. In the planning period (September 1, 2015 to October 31, 2015), including the platter cleaning equipment planning and sterilization operations, the development of the daily use of equipment benchmarks, arrangements for the management and check, the planning unit responsible for processing equipment Of the job, arranged education and training. During the implementation period (November 01, 2015 to February 14, 2016), the improvement strategies were made, including specialized unit establishment, exclusive management personnel allocation, amendment for standard operation procedure on instrument management, routine in-service education, etc. Evaluation period (February 15, 2016 to March 31, 2016) for the statistical rate of equipment failure and expired sterilization rate.

Results: The damage rate of instrument was down to 3.3% from 15%, and the re-sterilization rate was down to 1.8% from 6.3%.

Conclusion: The correction management of medical instruments could not only prevent the loss of instrument sets from damage or expiration of disinfection validity, reduce the risk of nosocomial infection. Ever since the implement successfully, the project could not only promote the effectiveness of medical instrument management, but also cut down the time in instrument treatment, in addition to improve the environment hygienic, so as to achieve working satisfaction and safe-keeping of patients.

Male-Factor Infertility: The Process to Seeking Treatment

Michele Mayes Lawson, PhD, RN, USA

Abstract

Purpose: The purpose of this study was to gain an understanding of the process that adult males go through from deciding to conceive to seeking treatment for male-factor infertility.

Methods: Approval to conduct the research was obtained from the Institutional Review Board of Texas Woman's University and the Greenville Health System University Medical Center Office of Research Compliance and Administration Institutional Review Board. Appropriate measures were taken to protect human participants. Participants signed a written consent form. A qualitative design utilizing grounded theory was used. Participants were identified and recruited from the fertility center. Participants were in the process of seeking treatment with assisted reproductive technology (ART). A physician contacted some men and invited them to participate in the study and others volunteered after their wives saw a recruitment flyer. Semi-structured, audio-taped interviews were conducted with 10 participants in a private setting.

Results: The participants ranged in age from 27 to 39 years old, with a mean age of 32.7 years old. Their partners' reported ages ranged from 26 to 38 years old, with a mean age of 32.4 years old at the time of the interview. The participants reported their race as: Caucasian, 70% ($n=7$); African American, 20% ($n=2$); and Asian, 10% ($n=1$). Interview transcripts were analyzed using Constant Comparative Analysis techniques.

Findings include categories such as *Just Having Fun*, *Realization that Something Could be Wrong*, *Influenced to Go*, *Testing for the Female*, *Testing for the Male*, *Finding Out, Who was there for you?*, *Seeking Information*, *What's the Next Step*, *Taking a Break*, *Financial Impacts*, *Cultural Impacts*, and *Hindsight*. The process of male-factor infertility: seeking treatment follows a varying timeline. For some participants the timeline was short and for others the timeline was stretched out. A greater understanding of the process and the factors which speed up or slow down the time to the next step is important for helping men with male-factor infertility and their partners navigate through the jungle of infertility and seeking treatment. Time, financial/cost, and culture all have an input into the process from beginning to end. Decision-making for each step is impacted by these categories.

Conclusion: By understanding the process to Seeking Treatment for Male-Factor Infertility, nurses will be able to make a positive impact to decrease the time it takes for men to seek treatment or even assist with navigation of the process by providing valuable information about finances, the big picture and next steps in the plan, resources for information gathering that is specific to each man's circumstances.

RSC PST 1 - Research Poster Session 1

"Analogy" as Methodology in Solving Modern Day Problems By Learning from F. Nightingale's Work

Yoshiko Wazumi, PhD, RN, Japan

Toshie Yamamoto, PhD, RN, PHN, Japan

Shu Chun Chien, PhD, RN, Japan

Abstract

Purpose: In these modern times when considerable environmental changes are taking place on a global scale and a variety of social security systems are showing signs of deadlock, how to live a healthy life is once again a common issue for all mankind. In the midst of radical social changes in Britain in her time, F. Nightingale (1820 – 1910), known as a founder of modern nursing, penned a huge volume of writings containing a number of noteworthy proposals which saw through mankind's future and established the basis for a broad scope of institutional reforms. The challenge for modern day nurses in finding solutions to modern day complex problems could be minimized by learning from F. Nightingale. The purpose of this study was to identify analogies in order to solve modern day complex problems by analyzing from the works of F. Nightingale.

Methods: In an attempt to establish the way of analogies, 12 of her most important accomplishments, related to social reform, such as 'Reform of the Lady's Hospital on Harley Street (1853-1855)' 'Establishment of a training school for nurses (1860)' and 'Refining the social support system for the poor (1862-1867)' were chosen and 12 modern day complex problems in the health fields in Japan which are analogous to problems solved by F. Nightingale were selected as the subjects of this study. Background research of each accomplishment and modern day complex problem was conducted and structural commonness of those 2 phenomena was identified. We finally integrated those structural commonness and found the way of analogy to solve the problems by learning from F. Nightingale's work.

Results: The ways of analogy to solve the problems by learning from F. Nightingale's work were as follows.

1. Based on Natural Law and believing in human potential.
2. To compare the background of each problem to grasp the historical process and structural cause of the problem and to deduce an action plan.
3. Use scientific epistemology as a standard when implementing the plan.
4. In case of unexpected accidents, put top priority on securing the safety of human beings, inquire into the cause and prevent recurrence.

Conclusion: Although the community and health care services are facing systemic financial troubles, it has been suggested that by extracting a way of solving problems as hypothesis by using this analogy, we can realize a human centered healthier society based on the unique philosophy of nursing.

Does Transformational Leadership of Nurse Managers Change Over Time?: A Longitudinal Study

Tarja Kvist, PhD, MSN, BSN, RN, Finland

Katri Vehviläinen-Julkunen, PhD, Lic HC, MSc, RN, RM, Finland

Abstract

Purpose: The purpose of this study was find out the differences in nurse managers' transformational leadership perceived by the nurses between years 2008, 2010 and 2013 and examine the relationship between nurse managers' transformational leadership and study years and nurses' background variables.

Transformational leadership has been a paradigm of nursing leadership for over 20 years. According to the previous studies transformational nurse managers have characteristics like visible, visionary, innovative, accessible, supportive, and knowledgeable. In recent years especially Magnet Hospital studies has recognized the special importance of transformational leadership as a one component of Magnet Model (Borman & Abrahamson 2014, Kvist *et al.* 2013, Sanders *et al.* 2013). The study hospital had leadership development work according to Magnet principles and in addition it went through organizational changes between years 2008 and 2013.

Methods: Perceptions of nurses in a Finnish university hospital were surveyed longitudinally in years 2008, 2010 and 2013 using a web-based version of the Transformational Leadership Scale (TLS) questionnaire (Eneh *et al.* 2012, Kvist *et al.* 2013). TLS questionnaire has 43 items of nurse manager's transformational leadership and ten background questions. In total 1053 nurses responded. Differences in transformational leadership subscale scores between years were tested with one-way analysis of variance, and relations between background variables and subscales were analyzed by analysis of covariance.

Results: Transformational leadership scores were highest in 2010 and lowest in 2013. The subscale scored most highly was support for professional development, while giving feedback and rewarding received the lowest score. In 2008 and 2010 day workers rated all subscales of transformational leadership more highly than shift workers, but the opposite patterns were detected in 2013, except for support for professional development. The importance of development work and changes will be highlighted with the results.

Conclusion: Nurse managers need systematic leadership and support programs to develop their transformational leadership skills. It is important to strengthen nurse leaders' visibility through systematic, longitudinal interventions to enhance Magnet Hospital endeavor.

Importance of Palliative Care in End-Stage Liver Disease: A Rising Global Issue

Renee Pozza, PhD, MSN, RN, CNS, CFNP, FAASLD, USA
Bonita Huiskes, PhD, RN, FNP, USA
Anna Marie Hefner, PhD, MSN, BSN, RN, MaEd, CPNP, USA

Abstract

Background and Significance: Despite the dramatic improvements in disease management and treatment options for individuals with hepatitis C there remains an increasing incidence globally of individuals suffering from end stage liver disease (ESLD). While liver transplantation is a potential option for some individuals, many die waiting for organ availability while others are deemed not a viable candidate for various reasons. End stage liver disease patients have multiple symptoms such as ascites, pain, fatigue, confusion and gastrointestinal bleeds which impact their health related quality of life and require intensive medical management. Mortality rates are 50% at 5 years and often require frequent clinic visits and hospitalizations. There is little to no guidance in the liver disease management guidelines for palliative care and end of life care for these individuals.

Heart failure guidelines were first published in 1994. In the following decades significant therapy options such as the emergence of left ventricular assist devices (LVADs) offered advanced therapy for end stage patients. Many of the guidelines have seen a steady increase in end of life and palliative care content concurrent with medical advances. Liver disease management has been focused on early identification and therapy intervention to reduce the impact on the functioning of the organ; however, late stage end organ damage remains common, especially in the setting of non-alcoholic fatty liver disease (NAFLD/NASH) with prevalence rates skyrocketing across the world. The nursing professional is a key provider of care to these patients and families and is in a vital position to make a difference in the quality of life.

Purpose: The purpose of the study was to trace the development of palliative care content in heart failure guidelines during a period of remarkable progress in treatment with a focus on development of palliative care content in end stage liver disease guidelines.

Methods: Sixteen major North American and European heart failure guidelines published between 1994 and 2016 were examined for palliative content and compared to end stage liver disease guidelines as published by the American Association for the Study of Liver Diseases (AASLD) and the European Association of Liver Diseases (EASL). Keywords and content domains were determined from the guidelines. Characteristics of end stage heart failure and end stage liver disease were also compared in order to determine which content domains in the heart failure guidelines concerning end of life and palliative care apply to end stage liver disease.

Results: Content domains addressed in the health failure guidelines include prognosis, provider/patient/family communication, advance directives, identification of end stage therapies, symptom palliation, device deactivation, family/caregiver support, hospice/palliative care and advance therapies. The majority of these content domains are applicable to the end stage liver disease individual. However, most of the liver related guidelines do not address these content domains for the end stage individual.

Conclusions: The study allows for the assessment of models for possible integration of palliative care used in heart failure to inform the management of the end stage liver disease individual. Further palliative guideline development in the ESLD patient will require research to build an evidence base, to foster translation into practice, and to help ensure this need in the setting of ESLD is met.

RSC PST 1 - Research Poster Session 1

Efficiency of Authentic Leadership on Turnover Rate of Nursing Staff

Li-Chu Lee, MBA, RN, Taiwan

Abstract

Purpose: In Taiwan, medical institutions are faced with the dilemma of manpower management. Dimission has always been the most troublesome problem for organizations, especially in the medical fields where the turnover rate of nurses increases year by year. According to 2013 statistics, the average turnover rate of 303 hospitals in Taiwan was 12.00%. The turnover rate of this unit in 2014 was 13.8%, outclassing that of the entire Taiwan.

To evaluate efficiency exerted by authentic leadership for the turnover rate of nursing staff, job satisfaction, and patient satisfaction to serve as references for leadership styles of management of hospitals.

Methods: 83 nurses from clinics of the Precision Medicine Center were participated and opinions of 2288 outpatients were collected for the satisfaction survey. The subjects got involved in the project of authentic leadership in 2015. The project arranged job contents according to interests of nurses in clinics, facilitated flexible working hours and shortened labor-hour, added personnel for assisting nurses, scheduled presentation of new knowledge of specialties for two hours per week, face-to-face communication for rendering affirmation and appraises twice a week and advancement practices of professional competences. In the current study, Cronbach's alpha for satisfaction reliability ranged from 0.898 to 0.963, which was mostly acceptable.

Results: After involving in the project of authentic leadership in 2015, the turnover rate of nursing staff decreased by 9.9% (13.8% vs 3.9%) and the number of personnel increased from 82 to 103 with 0% vacancy rate, comparing results of 2014 to that of 2016. As to the job satisfaction, the degree of satisfaction to leadership of management and communication channels increased by 6.32% (80.05% vs 86.37%). The satisfaction of outpatients increased by 3% (88% vs 91%; $p = 0.000$) and the complaint cases of patients decreased by 23 (39 vs 16).

Conclusion: The authentic leadership possesses significant and positive correlations to psychological capitals, organizational commitments, job satisfactions and organizational citizenship behaviors. The more satisfactions that nurses have for the work environment and leadership styles of medical institutions, the lower their turnover intention would be. Therefore, nurses shall share events and frustrations in daily life to maintain a positive attitude. Nurses shall give play to speciality. They shall be affirmed via appreciative inquiries and criticism shall be avoided. Management shall use constructive words to stimulate staff and encourage them to explore new knowledge and construct visions so as to find out the core of a positive revolution. Consequently, changes stem from "spontaneity" rather than oppression of external forces. Influence building includes the application of power, the understanding of own goals and clear transmission of messages so that all colleagues of the unit could be influenced. It is suggested that governors of medical institutions shall treat each employee with sincerity and jointly create a better future based on the critical point for undertaking development.

Different Perception of Necessity of Management Skills Between Presidents and Nurse Administrators

Kyoko Shida, MS, RN, Japan

Hiroe Takahashi, RN, CNA, Japan

Makiko Muya, PhD, RN, Japan

Abstract

Purpose: To explicit the difference by comparing the perception to necessity of management skills for nurse managers between top managers and the nurse manager.

Methods: Quantitative approach was demonstrated. Anonymous questionnaires were distributed towards the top manager and the manager of nursing division working at all healthcare facilities in Osaka prefecture. The contents of questionnaire were 1) the facility's attributes: the number of beds and the type of organization, 2) the top manager's attributes: the age and the gender, the degree of cooperation between the top manager and the nurse manager(5 degree), 3) the nurse manager's attributes: the age and the gender, the academic status, the certification status, the degree of cooperation between the top manager and the nurse manager (5degree), 4) in terms of 53 items of AONE nurse manager competency instrument(NMCI)(Chase,2010), the top managers and the nurse managers were asked how is necessity for nurse managers with 5-Likert scale, such as very important=5, important=4, fair= 3, not so important=2, not important at all=1. The lists of NMCI were categorized to 7, such as 1) Financial Management (FM), 2) Human Resource Management (HRM), 3) Performance Improvement (PI), 4) Foundational Thinking Skills (FT), 5) Technology (T), 6) Strategic Management (SM), 7) Clinical Practice Knowledge and Skills (CP). As the compliance to ethical considerations, study approval was obtained from review board of Osaka Nursing Association.

Results: Statistical analysis was conducted. As the descriptive statistics, the number of completed couple of response was 72, while the total number of distribution was 955. Almost of respondents of top managers percept the cooperative degree was more than 4(good), on the contrary, perception of nurse managers was divided into two groups. As the perception gap between the top manager and the nurse manager, there was a correlational relationship with CP only ($p<.05$). Nurse managers recognized more necessary to HRM, PI, FT, RT, SM than top managers. As for the characteristics of facility, the size of hospital was significantly different with FM, HRM, FT, T, and SM of nurse managers' perceptions by analysis of variance($p<.001 \sim .05$). The organization type was also significantly different with FM, PI, FT, T and SM of nurse managers by Mann-Whitney U test ($p<.01 \sim .001$). As for the characteristics of nurse managers, to be a certified nurse administrator or not was significantly different with FT of nurse managers' perceptions by Mann-Whitney U test ($p<.05$).

Conclusion: As the typical similarity between top managers and nurse managers, the importance of clinical knowledge and skills was depicted. There was no significant difference with the importance of NMCI categories in terms of the age, the size, the type of organization among top managers. Meanwhile, nurse managers recognized the importance of some NMCI categories compared to top managers. These categories were related to essential management skills. Perception of the degree of cooperation between top managers and nurse managers divided into two groups. It is implied the difference of degree of cooperation is the key of promoting nursing management skills.

Professional Identity in the Lived Experience of Hospital Nurses

Tullamora T. Diede, MN, RN-BC, CNL, USA

Abstract

Purpose: The purpose of this study is to explore the phenomenon of the lived experience of nurses working with patients in hospitals and, with that information, to identify meaningful themes and patterns of how their workplace environment impacts their sense of professional identity. The specific aim of this study is to describe, interpret and, therefore better understand the lived experience of nurses working with patients in a hospital environment and the meaning of this phenomenon as it relates to their professional identity.

Rationale/Background: Over three million nurses currently holding active licenses to practice in the U.S. (U.S. Bureau of Labor Statistics, 2015); An estimated 30% of nurses leave their job within the first year and 27% report bullying in the last six months (Breau & Rheame, 2013; Johnson & Rea, 2009). Attrition is a common issue in the nursing workforce. Nurses experience oppression in their relationships with physicians and other health professionals (Risjord, 2010) as well as through lateral violence or bullying from other nurses (Johnson & Rea, 2009; Purpora, Blegen, & Stotts, 2012). Nurses play an essential role in a hospitalized patient's healthcare team providing skilled care and assessment. However, nurses have commonly been viewed as a less important, submissive healthcare team member when compared to other members of the healthcare team (Olofsson, Bengtsson, & Brink, 2003). Moreover, compared to physicians, nurses are considered less intelligent and less competent (Institutes of Medicine, 2011). Paradoxically, an annual poll by Gallup (2015) consistently identifies nursing as a highly trustworthy profession by the general public. This dichotomy of simultaneously being considered incompetent yet holding a high level of trust may leave nurses to question their own professionalism. Historical, political, and sociological factors contribute substantially to this view of nursing within the present health care culture (Roberts, 2000). Because of nursing's struggle for respect in conjunction with their rates of attrition and bullying, there is a critical need to understand the work of a professional registered nurse.

Methods: Philosophical hermeneutics will be used as the methodology to study this phenomenon. Researchers from this philosophical perspective seek to gain knowledge by interpreting the everyday experiences of those being studied in an effort to better understanding their world and to identify what shows itself as meaningful. Ultimately, philosophical hermeneutics believes that there is revealed truth in every human experience, not simply one universal truth to be revealed (Willis, 2007). Therefore, this methodology seeks to reveal a deeper understanding of how nurses create a professional identity for themselves in the work that they do with their patients through the narratives or voices of interviewing the nurses themselves.

Results: This dissertation is currently in the pilot stage with preliminary results to be presented.

Conclusion: The results of this study, when shared with nurses and other health care professionals, will yield a better understanding of the profession of nursing as explicated in the real work of nurses.

Supporting Nurses to Speak Up for Patient Safety Using an Employee Engagement Survey

Nicole Hall, MSN, MBA, RN, USA
Cheryl Graf, MSN, USA

Abstract

Purpose: The purpose of this research study is to further develop the understanding of factors that influence patient safety as they relate to nurses speaking up when faced with concerns through examination of archival employee engagement survey results.

Methods: The planned site for procurement of data for this research study is ABC hospital, a privately owned healthcare organization located in the United States that provides both inpatient and outpatient services. The employee engagement survey data that will be examined is from 2015 and had an overall 96% response rate at the research site. The target population for this study was registered nurses but the data set only allowed isolation of respondents who were either nurses, nursing assistants or unit secretaries. The data set did not permit the researcher to isolate only registered nurses.

An explanatory sequential research design was chosen for this study because of its incorporation of both quantitative and qualitative inquiry. This mixed methods study not only allows for identification of variables that influence nurse willingness to speak up through quantitative analysis of archival Employee Engagement survey results, but it then enables exploration of these findings through interviewing. To further understand those variables on the employee engagement survey that were associated with willingness to speak up, the qualitative interviews will allow the researcher to explore the phenomenon being studied by posing open-ended questions with the goal of learning from the interviewees' more about the variables of focus. After carefully considering the quantitative findings, a small number of key interviewees will be hand selected.

Results: The results of this research study will be finalized the spring of 2017 with quantitative analysis concluding in January 2017 and qualitative analysis concluding in March 2017. The results will include identification of variables on the employee engagement survey that impact nurse willingness to speak up through quantitative analysis. Interviewing allows for elaboration on these findings and aids interpretation of the data. Lastly, recommendations will be made, based on the quantitative and qualitative findings, for ways that healthcare organizations can support nurses to speak up when they observe something that may negatively affect patient care.

Conclusion: Conclusions for this study are not yet available though they are part of a doctoral research study that is currently being pursued. By identifying predictor variables, from an employee engagement survey, that support or conversely inhibit nurse willingness to speak up in these situations, the healthcare industry can better comprehend the phenomenon, plan ways to increase its frequency, and support its practice.

Prevalence, Virological Status, and Improvement of Depression Symptoms During a One-Year HIV Cohort Study

Yeow Chye Ng, PhD, MSN, BSN, BSE, RN, FNP-BC, NP-C, AAHIVE, USA
Sandra C. Jones, MSN, RN, APN, CPNP, USA

Abstract

Purpose: Depression is reported as one of the most common co-morbidities of HIV infection (Simoni et al., 2011). Currently, the estimated prevalence of major depressive disorder among the HIV population ranges from 20 percent to as high as 37 percent (Bing et al., 2001; Valente, 2003). Persons who experienced an increase in depression symptoms also reported increases in viral loads (Kalichman, Difonzo, Austin, Luke, & Rompa, 2002). Available evidence supports that depression has a high association with non-adherence to HIV medication, missed medical appointments, and health status deterioration during HIV disease progression. The team investigated the prevalence of depression symptoms, the relationship of PHQ-9 scores with HIV virological status, and further explored possible measures to estimate times needed to improve PHQ-9 scores over the course of a one-year study.

Methods: Patient Health Questionnaire-9 (PHQ-9), a standard instrument for diagnosing depression in primary care was implemented with all patients seeking care at one non-profit organization in northeast Alabama, United States. Patients participated in PHQ-9 screenings during each medical appointment prior to meeting with the medical provider. The survey mechanism was integrated as part of the patient's initial intake questionnaire. All responses were reviewed and recorded in the patient's electronic medical records. Four hundred and eighty patients met specific criteria and participated in the study during the period from 1 January 2015 through 31 December 2015.

Results: Fifty-five percent of the total participants recorded a PHQ-9 score of 10 or above. Interestingly, the group also achieved 90% of HIV viral suppression rate. An increase in PHQ-9 scores were found not to be statistically correlated with viral load and CD4. The Kaplan-Meier plot revealed that PHQ-9 improvements were noted approximately 160 days after the first PHQ-9 measurements were conducted.

Conclusion: This study emphasizes that depression is still an under diagnosed condition. Implementation of PHQ-9 screening at the clinical level could be the first step to alleviating this concern, regardless of the patient's current virological status. Results from the screening will provide valuable insight into the patient's emotional well-being. If warranted, proper depression medication treatment and multiple follow-up visits should be integrated as part of medical management services.

Functioning and Personal Experience Predict Job Satisfaction of Dedicated Nurses Working in Infection Isolation Rooms

Semyon Melnikov, PhD, RN, Israel
Shoshana Phridman, MA, RN, Israel
Esther Shalom, MA, RN, Israel
Ilya Kagan, PhD, RN, Israel

Abstract

Purpose: Job satisfaction, as a factor affecting the retention of nurses, is under extensive research and a focus of healthcare systems leadership. The aim of this study was to elucidate the effect of personal practice experience, sense of loneliness, perceived knowledge of KPC, and professional functioning, on job satisfaction among nurses working as dedicated carers of KPC infected patients hospitalized in isolation rooms.

Methods: In a study with a cross-sectional design, a convenience sample of 87 registered nurses working on medical-surgical wards answered a self-administered questionnaire about (a) job satisfaction, (b) perceived knowledge of KPC infection, (c) personal experience of working in dedicated isolation rooms, (d) sense of loneliness, (e) the respondents' perception of their professional functioning on the ward. Data were analyzed by descriptive statistics, Pearson correlation coefficients, *t* tests, a one-way ANOVA, and multiple regression analysis.

Results: Nurses reported a slightly positive experience of working in isolation rooms, average levels of feeling lonely at work, good functioning on the ward, and high levels of perceived knowledge about source infection and job satisfaction. Nurses were more satisfied with their job when their perceived knowledge of infection control was better, their personal experience of working in KPC isolation rooms was more positive, and they perceived their professional functioning as more effective and productive. The higher the nurses' sense of loneliness the poorer their experience of working with a KPC cohort and the poorer their self-reported professional functioning on the ward. Personal experience of working in KPC-source isolation rooms and perceived level of professional functioning on the ward predicted the dependent variable, explaining 33% ($R^2=.327$) of the variance in nurses' job satisfaction.

Conclusion: The job satisfaction of nurses working as dedicated carers of KPC-infected patients is affected by perceived knowledge of infection control, their personal experience of working in KPC isolation rooms, and perceived professional functioning. The current study emphasizes the importance of nursing management's addressing psychosocial aspects of working as dedicated nurses in the in-ward 'bubble' in hospital settings.

Health Failure Self-Management Support

Anna Dermenchyan, MSN, RN, CCRN-K, USA

Lynn V. Doering, PhD, RN, USA

Abstract

Purpose: Heart disease is the leading cause of death for both men and women in most ethnicities in the United States. It accounts for one in four deaths and costs \$32 billion annually (CDC, 2016). Heart failure (HF) is the final common pathway for heart disease and all cardiovascular diseases and 50% of individuals diagnosed with HF die within five years (CDC, 2016). Despite the advances in medical knowledge and technology, HF continues to be a major burden to the healthcare system due to the high rates of morbidity, mortality, and cost. This literature review synthesizes current approaches and outcomes of HF disease management support programs, with a focus on multidisciplinary teams, telemonitoring, and patient adherence. The goal of this review is to identify components of HF self-management support programs that can be incorporated into the health systems to improve key patient outcomes, including hospital readmissions and mortality. A second focus is to identify gaps in the literature that will be explored in future research.

Methods: The literature review was conducted using relevant electronic databases and search engines, including, PubMed, CINAHL Plus, and Web of Science, to locate appropriate articles for “health failure self-management support” or “self-management support for heart failure.” Search filters were set for Humans, English language, and date range of five years. However, some older articles were later discovered in the readings of original research as landmark studies and were also included. The search criteria yielded 429 articles, in which the following keywords were used to narrow down the search: heart failure, chronic disease model, self-management support, self-management, self-care, disease management, disease management program, quality of life (QOL), outcome measures, telehealth, and telemonitoring. From the 429 articles, 43 were selected for analysis based on the above criteria.

Results: The intensity (number of clinic visits and provider contacts) of the multidisciplinary team approach is not necessarily better. The landmark study by Rich et al. (1995) highlighted the significant impact of nurse-led, multidisciplinary disease management intervention for HF patients by demonstrating improvements in readmission rates, quality of life, and cost (Rich et al., 1995). Since then, many programs have adopted evidence-based practices by instituting a comprehensive education plan for patients prior to discharge, and adopting ambulatory, multidisciplinary, self-management support programs (Otsu & Moriyama, 2011, 2012). Despite the general agreement that HF disease management programs work in improving outcomes, some questions remain about operationalizing the interventions for all patients (Desai, 2012). Specifically, the lack of standardized definitions and the variability of program design limit the generalizability and actionable evidence for self-management program development (Sochalski et al., 2009). Furthermore, many of the trials are not statistically powered to evaluate clinical outcomes, and consequently, large numbers of studies are aggregates of individual or single site trials (Desai, 2012).

While telemonitoring is an emerging trend in health care delivery and has potential to be cost-effective, telemonitoring alone is not effective as a self-management support tool in the context of HF. Most HF self-management support programs require face-to-face follow-ups with an outpatient provider and/or care coordinator (Fonarow et al., 2010). However, this becomes a limitation for some patients due to time, access, and cost. In the last decade, Internet Technology (IT) solutions have become popular health care tools for patient self-management. Nonetheless, all the latest HF trials of IT-based interventions have revealed mixed results in patient outcomes. Numerous systematic reviews continue to show improved outcomes in mortality and hospitalization (Inglis, Clark, McAlister, Stewart, & Cleland, 2011; Inglis, Clark, Dierckx, Prieto-Merino, & Cleland, 2015), but these studies tend to be in single centers with smaller sample sizes (Ong et al., 2016). The larger RCTs on telemonitoring in the United States (1653 and 1437 patients) and Europe (710 patients) have shown little or no significant benefits (Chaudhry et al., 2010;

Koehler et al., 2011; Ong et al., 2016), but patient adherence rates seem to be low (ranges 40-60%) with device usage.

Patient adherence to self-management recommendations is important for improved clinical outcomes. Patient adherence is a problem for many self-management support program studies. Unfortunately, evaluating the influence of patient adherence on other variables, such as family support, psychosocial factors, and disease severity scores, has been minimal (Fountain, 2016). Most chronic disease management programs are designed to increase adherence to evidence-based treatment therapies because there is evidence that patients' knowledge and acceptance of their condition improved their adherence to recommended. Providing too much information at the time of diagnosis is not helpful to patients because they experience disruption and need time to process their diagnosis (Desai, 2012). Some patients require seven months to process the information given to them, which can be an issue for patients' in following through with discharge instructions and follow-up appointments (Otsu & Moriyama, 2011). Therefore, it is important to provide patients with ongoing self-management support and individualized evidence-based treatments for improved adherence.

Conclusion: The focus of this review was to synthesize the state of the science regarding effectiveness of HF self-management support programs with potential to be incorporated into health systems and to improve patient outcomes, such as, hospital readmissions and mortality. However, the literature review yielded mixed results. Numerous studies failed to improve key patient outcomes, including readmissions and mortality. These results may be due to multiple causes, including low adherence rates to the recommended therapy, the type of technology used, and lack of patient engagement in self-care. Future research should identify sub-populations of HF patients, who are most likely to benefit from specific self-management support interventions.

This review led to the identification of several gaps in the existing literature. Specifically, none of the studies in this review looked at risk tools to identify individual HF patient's likelihood to respond positively to specific self-management support interventions, such as telemonitoring and to test stratification (high to low responsiveness). Most studies did infer that stratification is needed for decision support and targeted self-management support interventions, but none really suggested specific study designs or tools. Future studies should investigate risk stratification of patients based on the combination of medical and social scores as an approach to 1) identify specific subgroups who are likely to benefit from specific self-management support interventions, and 2) test the effect of stratification strategies on improvements in patient outcomes.

Effectiveness of Visual Inspection With Acetic Acid in the Detection of Cervical Neoplasia Intraepithelial

Nancy Griselda Pérez Briones, MSN, RN, Mexico

Kerena Hernandez, MSN, RN, Mexico

Raul Adrian Castillo-Vargas, MSN, RN, Mexico

Mireya del Carmen González Álvarez, PhD, RN, Mexico

Alejandra Muñoz Morales, PhD, RN, Mexico

Abigahil Valdés Rivera, BSN, RN, Mexico

Abstract

Introduction: In Mexico every two hours a woman dies of Cervical Cancer, it's the second leading cause of death from malignancies, and it is estimated that about 4, 000 deaths occur every year. Currently to reduce the impact of the disease there are several tests for the early detection and timely treatment, the most used is the Cervical Cytology (CC), however it is not a definitive diagnostic method alone, a more efficient and effective strategy is the screening by Visual Inspection with Acetic Acid (VIA) at 5%, as it is a simple test, accessible and reliable, with immediate results regarding the probable existence of a precancerous lesion test.

Purpose: Determine the effectiveness of VIA as a screening test compared to the CC in Cervical Intraepithelial Neoplasia Detection(CIN).

Methods: The study population consisted of 74 women between 15 and 49 years attending outpatient clinic at a rural hospital in the city of Ramos Arizpe, Coahuila. CC underwent colposcopy and simultaneously. The sampling was performed using CC Ayre spatula and endocervical brush. Colposcopy was performed using acetic acid solution at 5% then with Lugol solution. In patients who were positive for either test, underwent biopsy of the lesion.

Results: VIA has greater sensitivity in detecting CIN as 74 women, 36 were found positive, compared with only 5 positive results by CC. It is noteworthy that high specificity was found because of the 36 biopsies were ratified 34 dysplastic lesions, including one patient with Cancer in Situ result.

Conclusion: Los resultados obtenidos en este estudio confirman, el alto número de falsos negativos de la CC en comparación con los del IVAA. Con ello, se concluye que la IVAA es adecuada para ser utilizada como alternativa a la CC, ya que así la paciente obtendrá un diagnostico temprano y tratamiento oportuno.

The results obtained in this study confirm the high number of false negative CC had compared with VIA. With this, we conclude that VIA is suitable for use as an alternative to CC, as this patient get an early diagnosis and timely treatment.

What Pregnant Adolescents Think About Antenatal Care: A Contemporary Review for Midwives

Deborah M. Ireson, PhD, MMid, RN, RM, CHN, IBCLC, Australia

Abstract

Purpose: Infrequent or delayed attendance for antenatal care is likely to exacerbate the health risks associated with pregnancy in adolescence. (Muhwava, Morojele, & London, 2016). Poor health literacy and inadequate understanding into the role midwives have in maintaining healthy pregnancy, can result in an erosion of midwifery support. (Docherty, Bugge, & Watterson, 2012). The result of this is a failure for this group to make optimal use of midwifery services provided. In this context potential alienation from midwives may further increase risks already associated with entrenched health behaviours resulting in poor ongoing outcomes for individuals, pregnancies and child development (Kim, Connolly, & Tamim, 2014). Taken from the authors PhD studies, this presentation will discuss the experiences and cultural behaviours of a group of pregnant adolescents that displayed the ways in which they made sense of their pregnancy health needs. Examining the resulting knowledge may assist midwives to plan equitable approaches to antenatal care and create occasions that strengthen engagement strategies with adolescents (Guliani, Sepehri, & Serieux, 2014). Furthermore the integration of this knowledge into midwifery practice may potentially exert positive influences to reduce the continuing cyclic health risks to this group of often marginalised women and their children (Hadley, 2016).

Methods: The qualitative approach of interpretive ethnography was utilised incorporating participate observation as a means of data collection. The author was for nine months positioned alongside pregnant adolescents in the waiting area of a dedicated “young women’s” antenatal clinic. Observations and cultural behaviours recorded during this time were supported by personal stories and validated using in-depth interviews at spaced intervals. Data collection and analysis was a concurrent approach following Spradley’s (1980) systematic approach to research development. This methodological analysis exposed four major themes influencing adolescents’ health related actions during pregnancy:

1. State of mind. This theme was generated from actions prior to pregnancy disclosure, pregnancy discovery, incidents that occurred during antenatal clinic attendance and the social influences prevalent at the time.
2. Searching for information. Adolescents are not different from other primiparae in wanting information relevant to their pregnancy, however, this theme identified where information was sourced by adolescents, where it was ‘given’ and the means by which the information was provided.
3. Sources of support. Support took different connotations for individuals. Adolescence is a time of life with varying levels of parenting support i.e. very young to independent living. Adolescents often were estranged from supportive relationships, neither were they always exposed to consistent relationships. What adolescents considered to be essential support was distilled in this theme.
4. Engaging with pregnancy. This theme took the context of ‘developing a mothering role’. Considering stage of life, cognition, social determinants and ability to plan for their future mothering, were included in this theme.

Results: The information gained from these themes includes reasons why adolescents delayed their pregnancy disclosure, the sources of information they considered to be of most use to them and who they relied upon for guidance during pregnancy. The traditional medicalised structured approach to antenatal care had little influence on adolescents’ reasons to attend for antenatal care. Midwifery contact was a polarising experience for some adolescents and the manner in which they were provided services strongly influenced their continued antenatal attendance. Personal and emotional milestones within their pregnancy were pivotal to their engagement with their pregnancy and as such identified moments of increased connectedness.

Conclusion: This presentation will build on what are known barriers and enhancements to providing antenatal care to adolescents, further the presenter will provide new insights into how influential antenatal care may be delivered to adolescents. While this research was conducted in Australia its message is very applicable globally to midwives wishing to enhance their approach to providing effective antenatal care to this group.

Neonatal Autonomic Function and Outcomes at 12-Months in Infants With Congenital Heart Disease

Tondi M. Harrison, PhD, RN, CPNP, FAAN, USA
Roger Brown, PhD, USA

Abstract

Purpose: Infants with complex congenital heart disease (CCHD) have impaired autonomic nervous system (ANS) function.¹⁻³ Impaired ANS function is a known predictor of morbidity and mortality in adults with acquired heart disease.^{4,5} Relationships between early ANS function and outcomes in infants with CCHD is unknown. The purpose of this study is to examine relationships between ANS function during the initial hospitalization of newborn infants with CCHD and growth, development, and survival over the first year of life.

Methods: Continuous 24-hour electrocardiographic (ECG) recordings from 55 newborn infants, hospitalized at birth for treatment of CCHD, will be used to calculate heart rate variability (HRV) as an index of ANS function.⁶ ECG waveforms before and after surgical intervention were obtained from Philips bedside monitors, equipped with the Excel Medical Electronics Bedmaster research export tool, stored in the hospital's central server, and exported to an encrypted research server. Raw ECG waveform data were then imported into the GE Healthcare MARS ECG analysis and Editing System (General Electric, Inc.) for HRV analysis. Each ECG complex was identified and characterized as to morphology by the computer software. This preliminary analysis is currently being verified by the PI to assure proper labeling of heart beats and artifact. Interbeat intervals associated with ectopic beats, non-sinoatrial node-initiated complexes, and artifact will be excluded from analysis. Power in three frequency domains will then be calculated: very low frequency (reflecting effects of thermoregulation and neurohormones on heart rate), low frequency (reflecting the combined effect of sympathetic and parasympathetic influences on heart rate), and high-frequency (reflecting parasympathetic influences on heart rate). Data related to growth (weight-for-age Z-scores), development (Bayley Scales of Infant Development III; occupational, physical, or speech intervention), and survival over 12 months will be obtained from the electronic medical record. Relationships among neonatal HRV and growth and development over 12 months will be analyzed using latent growth models with adjusting covariates. Relationships between neonatal HRV and survival at 12 months will be analyzed using logistic regression.

Results: We expect infants with more regulated ANS function during the neonatal time period will demonstrate improved growth and development. In addition, we expect markedly impaired neonatal ANS function to be associated with mortality within the first 12 months.

Conclusion: Identification of a non-invasive marker for morbidity and mortality in infants with CCHD will stimulate feasibility testing and implementation of low-cost, low-risk nursing interventions known to enhance autonomic function, such as skin-to-skin contact, comforting touch, and breast-feeding. Although these interventions are considered to be standard of care in neonatal intensive care units, they are rarely used in pediatric cardiac intensive care units where the majority of infants with CCHD currently receive care. Increasing our knowledge of relationships between early patterns of development of the ANS and later outcomes has the potential to improve nursing care and, ultimately, improve the quality of these infants' lives.

Private Mobile Phones as a Source of Nursing Team Interruption During Medication Division and Administration

Polina Rozenberg, MBA, MA, RN, Israel
Elleonora Shnaiderman, MHA, BA, RN, CCRN, Israel
Svitlana Rudenko, MA, BA, RN, CCRN, Israel

Abstract

Purpose: To estimate the relative rate of distractions that caused by audio notifications by mobile phones while focusing on long term distractions. We wanted to check whether there is a connection between the frequency and the relative rate of distractions that came from audio notifications, and especially the long term distractions, to the staff personnel's age and their youngest child's age. Moreover, we wanted to check if there is a connection between the perception of mobile phone as a cause of disturbance, to the frequency and relative rate of distractions that caused by its audio notifications.

Methods: The study was conducted in two major hospitals in Israel. We made direct observation on 100 nurses during preparation and distribution of medications. After observation period every observed participant filled out a questionnaire designed to measure his perception of mobile phones as a cause of disturbance.

Results: Distractions caused by audio notifications constitute at least 25% of all distractions during preparation and distributions of medications and of that, 20% are long term distractions. A negative connection was found between the perception of mobile phones as a cause of disturbance and long distractions, but not with the overall distractions stemming from audio notifications. The age of the participants and the age of their children have a negative connection on the frequency of distractions stemming from audio notifications, and especially long term distractions. The research findings raised a concern that using mobile phones has to be connected to the department safety policy.

Conclusion: The market penetration of mobile phones is rising in every industrial sector and professional field. The perception of mobile phones as a cause of disturbance during activities that require concentration may limit the use of mobile phones, or at least limit extended use of them. A program of assimilation of new workers needs to emphasize the negative influence of using them during activities that require concentration. Additionally, in future research, it is important to consider creating coherent policies for the use of mobile phones in the workplace and beyond.

Clinical Outcome of Comprehensive Care for Teenage Pregnancy in Ramathibodi Hospital

Nitaya Rotjananirunkit, MNS (NsgAd), RN, Thailand

Abstract

Purpose: This study aims to compare the number of complications of teenage mothers between the control group and the experiment group.

Methods: This is a quasi-experimental research. The purposive sampling was recruited from the postpartum teenage mothers who had delivery in the obstetric ward at Ramathibodi Hospital during January 2007 - December 2014. All participants were classified into 2 groups. The first 878 teenage mothers were assigned to the control group and cared by the conventional intervention, while the rest 529 postpartum teenage mothers were assigned to the experimental group and cared by the clinical and nursing practice guideline for comprehensive care for teenage pregnancy. Intervention tool for this study was the clinical and nursing practice guideline for comprehensive care for teenage pregnancy developed by clinical health care team. It included a clinical and nursing practice guideline for teenage pregnancy during antepartum, intra partum and post-partum period. The content validity was examined by three experts. Measuring tool was the check list sheet for complications occurred during antepartum, intra partum and post-partum collection. Data were analyzed by descriptive statistic and independent T-test for comparison complication between two groups.

Results: Results demonstrated that there were significantly different in number of complications between experiment and control group. After using the clinical and nursing practice guidelines, the experimental group had significantly lower number of complications than the control group. The number of complications during antepartum are anemia ($p = .000$), preterm labour ($p = .001$) and preterm premature rupture of membrane ($p = .006$). The number of complications during intrapartum is pregnancy induced hypertension ($p = .000$). The number of complications during postpartum is postpartum haemorrhage ($p = .008$).

Conclusion: The results of this study support that the clinical and nursing practice guidelines for comprehensive care for teenage pregnancy is certainly helpful for teenage mothers. It should be further developed this guidelines for reducing complication of teenage mothers.

Comparing Outcomes Between Vascularized Lymph Node Transfer and Lymphovenous Anastomosis in the Primary Lymphedema

Chia Yu Lin, MS, RN, Taiwan
Hsueh-Erh Liu, PhD, RN, Taiwan

Abstract

Purpose: Primary lymphedema is a devastating, debilitating disease. Much of the current treatment options demonstrate evidence in the treatment of secondary lymphedema. This study is to investigate the outcomes between vascularized lymph node (VLNT) transfers and lymphovenous anastomosis (LVA) in the treatment of primary lymphedema.

Methods: A total of 17 patients were recruited to the study with a total of 19 lower limbs with primary lymphedema at Chang Gung Memorial Hospital. All patients reported a non-hereditary occurrence of lymphedema history that originated at birth. All patients were treated with either VLNT or LVA. Postoperative quality of life and serial circumferential limb measurements were compared. Group comparisons were performed using Mann-Whitney U test for circumference comparisons, and the Wilcoxon test for pre and postoperative group comparisons. This study was approved by the Institutional Review Board (IRB) at Chang Gung Memorial Hospital and performed in accordance with the Helsinki Declaration ethical standards.

Results: 15 limbs received VLNTs and had an average of 3.8cm reduction above knee, 3.6cm below knee and 4cm above ankle. An average total reduction was 3.7cm. 4 limbs received LVA treatment and had an average of 1.3cm reduction AK, 3.0cm BK and 1.5cm AA, giving an average total reduction of 1.9cm. Patients in the VLNT group had an average drop from 5.2 episodes preoperatively to 0.1 episodes postoperatively. Patients in the LVA group reported an average reduction in cellulitic episodes from 5 preoperatively to 0.8 postoperatively. In the VLNT group, an average significant improvement in quality of life was noted by 2.5 points. In the LVA group, an average improvement in the quality of life score was seen by 2 points.

Conclusion: In conclusion, primary lymphedema can be treated adequately with improvements in both functional and quality of life outcomes if treatment options are chosen correctly. VLNT when used in severe cases of lymphedema, can provide greater relief with more impactful outcomes in both functional restoration and quality of life outcomes.

RSC PST 1 - Research Poster Session 1

Substance-Abusing Patients' Perceptions of Nursing Care

Christina M. Mertz, BSN, RN, USA

Abstract

Purpose: Existing research consistently documents that most nurses have negative attitudes toward patients who are substance abusers. These attitudes tend to be even stronger in non-psychiatric facilities, where substance-abusing patients are often admitted with a main diagnosis other than their substance abuse and are typically cared for by non-psychiatric nurses who may lack the knowledge and experience necessary to provide high-quality patient care to this population. These patients, then, may receive care that is less comprehensive and of a lower quality, which can significantly influence their outcomes and their opinions regarding their hospitalization experiences. However, there is little to no research on how substance-abusing patients themselves perceive the nursing care that they receive during hospitalization. Patient satisfaction is a crucial aspect of healthcare management and of direct nursing care, and there is a great need for further research regarding patient satisfaction in this particular population.

Methods: This research study will use a mixed-methods design and will mainly collect information via a survey whose questions will provide both quantitative and qualitative data. These questions will gather data on the circumstances of subjects' hospitalizations, their perceptions regarding their hospitalization experiences, and the interactions that they had with their nurses. These questions will specifically focus on themes of pain management, call bell response, direct patient care, therapeutic communication, and patient advocacy. To qualify, research subjects must be substance-abusers and must have either visited an emergency department or been hospitalized in a non-psychiatric unit within the last year. Medical hospitals, inpatient psychiatric hospitals and units, and substance-use therapy groups may all be investigated as potential sites for research subject recruitment and for potential further snowball sampling.

Results: Because this study has not yet been conducted and the existing research base is extremely limited, the results are still unknown. However, the results of this study can provide an invaluable addition to the nursing literature and can help non-psychiatric inpatient nurses to provide better care for this patient population. Using the results of this study, then, nurses will be able to use an evidence-based framework to better treat their substance-abusing patients.

Conclusion: Nursing literature on substance-abusing patients focuses on nurses' perceptions of these patients and not on how the patients themselves perceive the care that they receive. The data, results, and conclusions from this study will add to the nursing knowledge base and can be used to allow nurses to provide a higher quality of evidence-based care to this patient population.

Global Utilization of Fertility Services in Developed Nations

Jamie R. Kanehl, BSN, RN, USA

Abstract

Purpose: To identify factors that lead to discrepancies of utilization of artificial reproductive technology (ART) worldwide and understand the impacts liberal and strict country regulations have on cross border care and overall reproductive health and infertility rates.

Methods: A literature search for global infertility, assistive reproductive technology and cross border care was completed. Data from the search was gathered and analyzed. Visual graphs for 18 different countries were created to help visualize the differences in number of ART cycles, pregnancy rates and ART utilization based on population. Laws and regulations of each country were researched. Regulations in each country were compared with rates of ART utilization, and ingoing and outgoing cross border care.

Results: Regulations and laws for ART varied worldwide such as regulations dependent on marital status, age of woman, age of man, and sexual orientation. Countries with liberal regulations in which they do not impose as many strict regulations such as age limits typically have higher incoming cross border care and higher utilization of ART. Countries with strict regulations that impose requirements such as heterosexual marriage typically have higher outgoing cross border care and lower ART utilization. However, some countries such as the United Kingdom have liberal regulations but still have high outgoing cross border care rates likely due to their long wait lists and lack of appropriate access to care. Other countries such as Ireland do not have public access to ART and therefore have no regulations or public financing in place and very low utilization of ART.

Conclusion: The growing phenomenon of cross border reproductive care highlights the problem with infertility throughout the world. Restrictive laws, lack of public financing and wait lists all contribute to patients seeking legal, more affordable and better medical care in other countries. The utilization of ART has not met the growth in technology for infertility treatment and poses a threat to the population of infertile persons. The data should continue to be examined to fully determine the factors contributing to the increase in this form of medical tourism to further help the utilization of ART.

RSC PST 1 - Research Poster Session 1

A Qualitative Study on Nurse Mental Health Consumer Empathy Experiences During Conflict or Discord

Eimear Caitlin Muir-Cochrane, PhD, MNS, BSc (Hons), RN, GradDipAdEd, CMHN, Australia
Debra O'Kane, MSN, RN, Australia
Adam Gerace, PhD, Australia

Abstract

Purpose: Empathy, the process of taking another person's psychological perspective and experiencing emotional reactions to their experiences, is considered a core component of nurse-consumer relationships. It has been identified as particularly important in acute mental health care settings, where conflict is likely to occur due to involuntary hospitalisation and aggression or violence. However, there is confusion regarding what *exactly* is empathy in nursing; and there is little direct research into the ways in which nurses empathise with consumers and the unique challenges in thinking about and feeling for a consumer during a conflict situation. The purpose of this study was to investigate the empathic processes that operate during a nurse-patient conflict situation. In particular, the aims were to examine how nurses take the perspective of a patient in a conflict situation and experience empathic emotion; to investigate the perceptions of patients regarding empathic responses toward them by nurses; and to examine how empathic processes contribute to nurse and patient satisfaction and positive outcomes.

Methods: In semi-structured interviews, nurses (n=13) and consumers (n=7) discussed how they experienced empathy during conflict situations such as aggression, absconding, and medication refusal. Thematic analysis was used to analyse the data, and a theoretical model (Davis, 1994) was applied to the data to understand the antecedents, processes, and outcomes involved in a nurse-consumer interaction.

Results: Responsibilities in managing risk and safety on the unit determined nurses' empathic response to consumers during conflict situations, including how they took the consumer's perspective and experienced sympathy and compassion. The processes used and emotions felt often differed from those reported in literature outside of nursing. Empathy was demonstrated to consumers by nurses being there, engaging in specific interpersonal behaviours, and seeing them as more than their illness, which decreased consumer experience of stigma, depersonalisation, and anxiety about their admission

Conclusion: Mental health nurse-consumer relationships have unique aspects that influence the nature of the nurse's empathic response, and how consumers feel (or do not feel) understood during their admission. I will discuss ways that mental health nurses and other health professionals may improve their understanding of consumers, including self-reflecting on their own experiences, and enacting specific behaviours during nurse-consumer interaction. Evidence-based teaching and learning approaches to facilitate this skill improvement will be examined.

RSC PST 1 - Research Poster Session 1

Systematic Analysis of the Global Nursing Trust Research Literature

Lynn M. Varagona, PhD, MSN, MBA, RN, PMHCNS-BC, USA

Abstract

Purpose: Many articles in the nursing literature speak to the importance of trust in promoting favorable clinical outcomes. Abel and Efid (2013) found that patient trust in the healthcare provider predicted medication compliance. Wong and Giallonardo (2013) found that greater nurse trust in nurse leadership was associated with lower frequencies of adverse patient outcomes. Nilsson et al. (2011) found that when children trust their nurse to perform trauma wound dressing changes, the children can focus on distraction that enhances their pain management.

Additional outcomes related to trust were found in the nurse trust literature. Clarke et al. (2012) found that appreciative inquiry builds trust among staff involved in unit to unit transfers and improves communication and quality of care. Bobbio and Manganello (2015) found that servant leadership was positively associated with nurse trust in nursing leadership, which was negatively correlated with emotional exhaustion, burnout, and cynicism among nurses. Lehmann-Willenbrock et al. (2012) found that nurses' trust in co-workers significantly predicted nurse well-being and team commitment. Tang et al. (2013) found that respect and trust affected physician-nurse collaboration. Kalisch et al. (2012) found that staff on units with low levels of missed nursing care trusted each other more than staff on units with high levels of missed nursing care.

If nursing is going to continue to espouse the importance of trust in promoting positive clinical outcomes, research framed around theory and theory development needs to be conducted and what is known about EBP pertaining to trust needs to be identified, disseminated, and applied to practice. However, upon reviewing the research literature pertaining to nursing and trust, only one systematic review was found (Leslie & Lonneman, 2016). With a narrow focus on the home healthcare registered nurse-patient relationship, the generalizability of this review to broader nursing care is questionable. In addition, a search of PROSPERO in June 2016 revealed no published protocols pertaining to a systematic review or meta-analysis of nursing trust research.

Not being able to summarize the state of knowledge of the nursing trust research literature impairs nursing scholars in understanding what has been found to date, and therefore in conducting studies to build on what is currently known to systematically advance the body of knowledge.

The purpose of this global systematic review is to understand what is currently known in the nursing trust research literature. Clarity regarding the state of the nursing trust research literature will enable nurse scholars to plan studies that will systematically advance the knowledge of how trust can promote favorable clinical outcomes. A well thought out plan to advance the nursing trust research literature will enable nursing science to make greater strides. By understanding nursing and trust, evidence-based practices can be identified, disseminated, and applied in order to favorably influence clinical outcomes. For these reasons, a systematic review of the global research literature pertaining to nursing and trust was undertaken.

To achieve the purpose of this systematic review, literature evaluating the association between nurses, trust, and clinical outcomes—from both peer-reviewed published scientific literature, and relevant unpublished documents such as scientific publications from popular press, blogs, conference proceedings and presentations categorized as “gray literature”—was identified. To this end, the following research questions were explored.

1. What is currently known in the global nursing trust research literature regarding antecedents, attributes, and consequences of trust?
2. What constructs did trust emerge as an (a) antecedent, (b) attribute, (c) consequence, (d) theme, or (e) subtheme of?
3. If trust was found to relate to other constructs, how might these constructs be related?

4. Which nursing trust antecedents, attributes, and consequences are *similar* across type of nursing relationship (nursing student to faculty/preceptor, nurse to nurse peer, nurse to non-nurse peer, nurse to subordinate, nurse to superior, patient to nurse, family member to nurse)?
5. Which nursing trust antecedents, attributes, and consequences are *different* across type of nursing relationship (nursing student to faculty/preceptor, nurse to nurse peer, nurse to non-nurse peer, nurse to subordinate, nurse to superior, patient to nurse, family member to nurse)?
6. What theoretical frameworks were used in the nursing trust research literature?
7. What can we conclude from the qualitative studies?
8. What would a preliminary model of nursing trust antecedents, attributes, and consequences look like for various types of nursing relationships (nursing student to faculty/preceptor, nurse to nurse peer, nurse to non-nurse peer, nurse to subordinate, nurse to superior, patient to nurse, family member to nurse)?

Methods: To generate search terms for retrieving published peer reviewed articles from PubMed, Scopus, PsycINFO®, and Cumulative Index of Nursing and Allied Health Literature (CINAHL), the Medical Subject Headings (MeSH) database was searched for vocabulary related to “nurse” and “trust” on October 31, 2016. Articles were retrieved from inception of these databases to 2016. Searches were limited to literature published in English and on human subjects. Literature retrieved from all sources were combined and catalogued in one library for further review based on defined inclusion or exclusion criteria.

To develop a comprehensive list of search terms and to identify the body of literature potentially available for systematic review, a preliminary search was conducted in PubMed Health with the search string “nurs* and trust” on November 27, 2016; 7,424 articles were identified. To ensure consistency in inclusion and exclusion of literature in the review and data abstraction process, a random 1% sample of the categorized literature will be re-reviewed and classified by a reviewer other than the initial reviewer. Discrepancies in the review process will be resolved through discussion. A meta-analysis will be conducted on the quantitative data abstracted from the identified relevant literature. Qualitative data abstracted from the relevant literature will be summarized.

Results: This poster will present the findings of a global systematic review of the nurse trust research literature. Preliminary data has been collected, the research is ongoing, and data are being retrieved for analysis.

Conclusion: Pending final analysis of data.

Somatic Countertransference Experiences of Nurse Therapeutic Touch Practitioners: A Content Analysis, Part 1: Body

Doris Ezomo, MSN, MPA, CSN, RN, USA
Catherine Jirak Monetti, PhD, RN, CNE, QTTP, USA
Dorothy Nwosonyiri, MSN, RN, USA

Abstract

This qualitative study describes somatic countertransference (SCT) experiences of nurse Therapeutic Touch practitioners. Defined by Orbach and Carroll (2006), SCT is “the therapist’s awareness of their own body, of sensations, images, impulses, and feelings that offer a link to the client’s healing process” (p. 64).

Purpose: Use of purposeful sampling recruited eight experts. Audiotaped sixty-minute face-to-face in-depth interviews were conducted using a semi-structured interview guide with six open-ended questions. Sandelowski’s (2010)

Methods: Preferred method of latent content analysis produced codes and subcategories grounded exclusively in the saturated data (Krippendorff, 2004). Ten subcategories and three categories were inductively generated. Consensus on coding and data analysis led to the emergent theme, “A Language for Healing Trauma.” Consistent with social science communication research (Krippendorff, 1989),

Results: SCT was found to be a factor in the healing of trauma, experienced during the verbal and nonverbal communication of one group of nurse TT practitioners in interaction with traumatized clients.

Conclusion: The results of this study demonstrate the phenomenon of SCT is indeed real and that it occurs in nurse TT practitioners. Importantly, it can be articulated and conceptualized as a language to describe a process of nonverbal communication whereby useful clinical information is garnered from clients’ somatic memory. In other words, TT can access the knowledge of the body beyond the use of words. The findings validate Leddy’s (2004) conclusion that actual physical touch and exchange of energy are not needed for energetic healing. This further articulation of SCT increases the limited expression of the non-linear experience of TT (Samarel, 1992). Given the multitude of trauma experiences in the clinical population, these findings contribute to knowledge about the phenomenon of SCT and the significant role TT plays in trauma treatment. Of course, further description of SCT is needed, as well as related outcomes.

RSC PST 1 - Research Poster Session 1

Using e-Health Technology to Establish a Tailored Survivorship Care Plan for Breast Cancer Survivors

Yu-Lin Wang, BSN, RN, Taiwan
Su-Ying Fang, PhD, RN, Taiwan

Abstract

Background: As breast cancer survivorship increases, patients still have many unmet needs even when they already finished active treatment, including physical symptoms and psychological distress such as lymphedema, fear of recurrence, anxiety, depression and so on. It's a big challenge to provide survivorship care that meet the expectation of patient under limited human resource for health and time. E-Health technology could be applied to develop individualized information and provide convenient, tailored supportive care to them.

Purpose: This study will examine the effect of using e-health technology to establish survivorship care plan in breast cancer survivors.

Methods: Guided by the Cognitive-Social Health Information Processing Model and breast cancer survivorship care guideline, the study establish "Healthy Living with Breast Cancer", an application on smartphone and also a website for breast cancer survivors. In this study, 270 female breast cancer survivors with TNM stage I to III will be recruited. Participants were randomized to intervention group (received a tailored survivorship care plan by using "Healthy Living with Breast Cancer" plus usual care) or control group (received usual care). Unmet needs, fear of recurrence, symptom distress, anxiety, depression and quality of life will be measured at the beginning of the study then we will follow them at 5 weeks and 3 months later between the two groups. The secondary outcome will explore the patients' satisfaction of using e-health technology and factors related to effects of the intervention.

Results: Until now we enrolled participants included intervention (n=15) and control (n=18) group in the trial and got the baseline data. We will continue to enroll more patients in this study and follow-up to compare the care needs, fear of recurrence, symptom distress, anxiety, depression and quality of life between the two groups.

Conclusions: We expect using e-health technology as breast cancer survivorship care could decline care needs, fear of recurrence, symptom distress, anxiety and depression in breast cancer survivors then improve their quality of life and will keep track of the effect.

Validation of the Chinese Short-Form Cancer Survivor's Unmet Needs (CaSUN-SF) for Women With Breast Cancer

Su-Ying Fang, PhD, RN, Taiwan

Abstract

Purpose: It was necessary to assess women's needs in advance to develop their survivorship care plan more effectively. However, too many items and not specific for breast cancer women were the limitation on the current scales for evaluating these survivors' unmet need. The aims of the study were to modify the Cancer Survivor's Unmet Need (CaSUN) Scale to be a short form (CaSUN-SF) and then test its psychometric properties of the scale specific for breast cancer survivor in Taiwan.

Methods: By conveniences sampling, recruited breast cancer survivors were separated into 2 samples (sample 1, n=150, and sample 2, n=162). Three phases were used to validate the CaSUN-SF. First, we translated and modified the CaSUN to take care of the cultural adaptation and the CaSUN-SF was developed. Second, we used statistical methods to eliminate some items, and conducted an exploratory factor analysis (EFA) using sample 1 (n=150) to explore the factor structure of the CaSUN-SF. Finally, we conducted a confirmatory factor analysis (CFA) using sample 2 (n=162) to confirm the structure suggested by EFA, and tested the concurrent validity and known-group validity of CaSUN-SF.

Results: Four factors including information, physical /psychological, medical care and communication needs were identified in the CaSUN-SF and each factor had acceptable internal consistency reliability in which Cronbach's Alpha was between .61 to .82. The concurrent validity was supported by the significant correlations between the scores on unmet needs and fear of recurrence and depression. The result of known-group comparison which revealed that women who survived more than 5 years had fewer physical/psychological needs than those less 5 years also demonstrated the validity of CaSUN-SF.

Conclusion: The CaSUN-SF demonstrated acceptable reliability and validity for assessing unmet needs among breast cancer survivors in Taiwan. Using this simple assessment tool to target the individual needs of these survivors can help health care professionals to provide more personalized care efficiently.

The Diurnal Patterns of Fatigue in Patients on Hemodialysis: A Pilot Study

Ann Horigan, PhD, RN, USA

Abstract

Purpose: Fatigue is one of the most common symptoms patients on hemodialysis experience. With a prevalence rate of 60-97%, it affects both mental and physical functioning. While fatigue is a frequent and often debilitating problem for patients on hemodialysis, there is little research regarding the patterns of fatigue that patients experience. The purpose of this study is to (a) determine the feasibility of measuring fatigue in patients on hemodialysis 4 times daily for one week using a self-report method, and (b) investigate the diurnal patterns of fatigue in relation to the dialysis session over one week, from Sunday to Saturday.

Methods: Twenty-five hemodialysis patients over the age of 21 years will be recruited for this study. A longitudinal, correlational design will be used to investigate the diurnal patterns of fatigue and how they are related to the dialysis session and demographic and physiologic variables. The Lee Fatigue Scale will be used to measure levels of fatigue throughout the day and demographic and physiologic variables will be collected from the patient chart. The feasibility of measuring fatigue four times daily for seven days in patients on hemodialysis will be assessed by success of participant recruitment and completion of data collection.

Results: Research is ongoing at this time

Conclusion: Research is ongoing, however it is expected that participants will have a higher level of fatigue after the dialysis session that will last for varying amounts of time, possibly until the morning of the day after dialysis. It is also expected that fatigue levels will be lower or possibly non-existent on non-hemodialysis days. While it is difficult to predict the outcome of feasibility, if there are gaps in data, it is anticipated that those gaps will occur on dialysis session days when fatigue and travel are most likely to interfere. This work will be the basis for larger studies that will deepen our knowledge regarding the patterns of fatigue and its associated factors.

RSC PST 1 - Research Poster Session 1

Hot Flash-Related Daily Interference Scale Short Form

Janet S. Carpenter, PhD, RN, FAAN, USA

Abstract

Purpose: The Hot Flash Related Daily Interference scale (HFRDIS) is a widely used, psychometrically sound, 10-item, self-report questionnaire assessing the impact of hot flashes, a cardinal symptom of menopause, on a woman's life. The scale has been translated to 12 languages, cited over 150 times in journal articles and textbooks, and was included as an outcome measure within the National Cancer Institute Physician Data Query Cancer Information Summaries for Supportive and Palliative Care (Coping with Cancer). The HFRDIS is sensitive to change over time and documented reductions in interference have been observed with pharmacologic treatments, dietary supplements, and behavioral therapies. Because a shorter version may be desirable in certain situations and because cutpoints and minimally important differences have not previously been established, this study aimed to address those gaps. Our purposes were to shorten the HFRDIS into a shorter form termed the Hot Flash Interference (HFI) scale, establish cutpoints for both scales, and establish minimally important differences for both scales using psychometric analyses.

Methods: We analyzed baseline and post-randomization patient-reported data pooled across three randomized trials aimed at reducing hot flashes in 899 midlife women. Trials were conducted across five clinical sites between July 2009 and October 2012 as part of a United States National Institutes of Health funded research network. We eliminated HFRDIS items based on experts' content validity ratings and confirmatory factor analysis. We established cutpoints and minimally important differences by mapping HFRDIS and HFI to symptom and quality of life measures including daily diary-reported hot flashes, the Menopause Quality of Life Scale, Pittsburgh Sleep Quality Index, Insomnia Severity Index, and Generalized Anxiety Disorders-7 questionnaire.

Results: The short HFI consisted of 3 items related to interference with sleep, mood, and concentration. The HFI demonstrated strong internal consistency (alphas of 0.830 and 0.856), showed good fit to the unidimensional "hot flash interference factor", and strong convergent validity with HFRDIS scores, diary-recorded hot flashes, and menopausal quality of life. For both scales, cutpoints of mild (0–3.9), moderate (4–6.9), and severe (7–10) were associated with increasing sleep and anxiety problems as expected. The average minimally important difference for HFRDIS was 1.66 and for HFI it was 2.34.

Conclusion: The HFI is a brief assessment tool that will be useful in busy clinical practices to standardize hot flash assessment or in research studies where response burden may be an issue. The scale cutpoints and MIDs should prove useful in targeting those most in need of treatment, monitoring treatment response, and interpreting existing and future research findings.

Collaborative Work of Patients and Providers: Symptoms, Challenges, Shared Meaning, and Planning the Work

Donald E. Bailey, PhD, RN, FAAN, USA

Ruth Anderson, PhD, RN, FAAN, USA

N. Marcus Thygeson, MD, MPH, USA

Abstract

Purpose: Patients with CHC face treatment regimens that worsen the already unpleasant and sometimes debilitating symptoms they experience from the disease, including fatigue, depression fever, poor appetite, nausea, vomiting, abdominal and joint pain (Fusfeld et al., 2013). We used the Adaptive Leadership Framework for Chronic Illness to explore how healthcare providers work with patients to share treatment information and examine whether the way it is shared influences patients' symptoms and self-management over time. The Adaptive Leadership framework, originating in business (Heifetz) has recently been applied in healthcare to describe technical challenges as ones that have known technical solutions that can be mediated by the expertise and authority of a clinician (Adams, Bailey, Anderson, & Thygeson, 2013; Bailey et al., 2012). On the other hand, adaptive challenges are complex in nature, are easy to deny, and require a the patient to adapt, learn or change their behavior in some fashion (Thygeson, 2013). In earlier work, we expanded the framework specifically for chronic illness to reflect the dynamic nature of symptoms and challenges and to characterize the events that create the need for patients and families to engage in adaptive work (Anderson et al., 2015). Adaptive work is defined as developing and using the skills and actions required to change behavior and overcome adaptive challenges (Anderson et al., 2015). Our framework also proposes that the best plans of care for self-management can be developed through collaborative work, defined as patients and family members working together with the provider to jointly develop the most effective approaches for adaptive work by monitoring symptoms, assessing the challenges, verifying shared understanding of symptoms and challenges, and planning the work. The purpose of this study was to explore how healthcare providers interact with patients to share treatment information (collaborative work) and whether the way it's shared influences patients' symptom self-management.

Methods: This descriptive mixed methods study was part of a longitudinal case study of patients and their providers as they engaged in aggressive treatment for Chronic Hepatitis C. Data includes patient participant interviews following the initial and final clinical encounter; these office visits were recorded and transcribed verbatim. Follow-up interviews were conducted by telephone over the 12-24 weeks of treatment. The patient also completed a measure of patient activation at each time point. We interviewed the provider following the initial encounter and after the final clinic visit where treatment results were shared with the patient. Textual data reporting provider notes and records of phone contacts with the patients were abstracted from the electronic medical record. Data collection is complete.

We are analyzing the data of patient provider interactions using responses from patients and providers during these encounters and interviews following these encounters. We are identifying the conditions under which we see examples of patient/provider collaboration (collaborative work) and coding these using the concepts from our framework. They are: 1). monitor symptoms, 2). assess challenges, 3) verifying shared understanding of symptoms and challenges, and 4). plan the work. We will further describe the collaborative work for depth by quantizing the data, using a Likert type scale. For example, collaborative work that is limited to monitoring symptoms only would be scored lower than collaborative work that included higher levels of engagement such as assessing challenges and joint planning. We are also analyzing the scores from the Patient Activation Measure (PAM) collected at each data collection time point.

Results: Our 20 cases include 13 men and 7 women participants with an average age of 55 (Range 42-65.) The sample was 50% (10) African American. Healthcare provider participants were 5 MD, 3PA's and 2NP's. In our preliminary analyses we found multiple examples of patient participants and their healthcare providers monitoring symptoms. However we found few examples of providers assessing these symptom

challenges for their patients and even fewer examples of providers and patients verifying share understanding of challenges and interacting to plan the work of self-management during treatment. Preliminary analyses scores on the Patient Activation Measure (PA) varied across the treatment period. Most participants reported a downward trajectory on the PAM suggesting that as symptoms increased, patient's ability to self-manage decreased. A small number of participants reported a mixed trajectory e.g., as symptoms fluctuated, patients' ability to self-manage increased or decreased. Quantizing of the qualitative data is underway and will be completed and presented in this paper.

Conclusion: This study is the first to explore the collaborative work of patients and their healthcare providers while undergoing treatment for CHC. Findings from this study underscore the importance of developing new self-management interventions and care models for mobilizing support for monitoring symptoms, assessing challenges, and planning the work.

Catheter-Associated Urinary Tract Infection (CAUTI) Prevention Strategy Using Education in an Intensive Care Unit (ICU)

Laura M. Locke, BSN, RN, USA

Cynthia Louise Grissman, BSN, RN, USA

Rita Denise Crasta, MSN, RN, OCN, BMTCN, USA

Gisele Nicole Bazan, BSN, RN, USA

Kari Love, BS, RN, MSHS, CIC, FAPIC, USA

Cindy Ford, PhD, MSN, BSN, RN, CNE, USA

Jamie K. Roney, DNP, RN-BC, CCRN-K, USA

JoAnn D. Long, PhD, MSN, MA, BSN, RN, NEA-BC, USA

Abstract

Purpose: The purpose of this study was to measure the clinical impact of an evidence-based educational strategy on urinary tract infection (UTI) rates in a 900+ bed acute care facility located in a southwestern state. The research team sought to answer the question, "Will a focus on staff education in the intensive care unit (ICU) on the proper placement techniques, care, and early removal of urinary retention catheters reduce incidences of catheter-associated urinary tract infections (CAUTIs) in an ICU setting?" Indwelling urinary catheters are frequently used in critically-ill patients worldwide. Hospital-acquired infections from indwelling urinary catheters are associated with increased morbidity, length of stay, and healthcare costs (World Health Organization [WHO], 2016). Urinary tract infections acquired during a hospitalization account for 40% of all hospital-acquired infections (HAIs) with 80% of UTIs being associated with use of urinary retention catheters (Quinn, 2015). HAIs from indwelling urinary catheters are associated with more than 113,000 deaths annually in the United States (Ternavasio-de la Vega et al., 2016). Review of peer reviewed literature demonstrated various strategies to decrease CAUTIs, including computer reminders and evidence-based guidelines for urinary catheter care and maintenance. One 301-bed non-academic hospital in the northeastern United States demonstrated a 50% reduction in CAUTIs one year after introducing a nurse-driven process designed to daily question the need for a urinary catheter through use of nursing assessment and targeted clinician education (Quinn, 2015). Hospital acquired infection rates have declined in the United States except for CAUTIs, which rose 3% from 2009 to 2012 (Knudson, 2014). Clinicians in this study sought to implement specific opportunities for improvement in CAUTI rates in an ICU unit through reduction of urinary catheters used, implementation of urinary catheter insertion and maintenance best practices, and timely nursing assessment for need leading to urinary catheter removal if indicated through a structured educational strategy. Additionally, this study measured the impact on CAUTI incidence after implementation of the project intervention. Knudson (2014) reported analyzed data from 1,653 ICUs found that CAUTI prevention strategies were followed 27-67% of the time, thus informing the need for implementation and adherence measures for CAUTI prevention in this ICU. Evidence-based protocols designed to decrease urinary catheter associated infections may not capture point of care practices contributing to this significant problem. In response to this significant issue for critically ill patients, a targeted education intervention was developed and implemented by the infection prevention CAUTI team and the cardiac intensive care unit (CICU) nursing staff.

Methods: The intervention of a targeted, evidence-based educational program was implemented to raise nursing staff awareness and uptake of evidence-based protocol and point of care practices designed to decrease risks of catheter-associated urinary tract infections (CAUTI) in CICU patients. A descriptive design was used. Sampling was made at the unit and not the individual level. The CICU was selected by infection prevention CAUTI team members to implement specific nursing staff education focused on urinary catheter insertion hands-on training using low fidelity simulation, daily catheter care best practices, and timely nursing assessment of early urinary catheter removal. Targeted education and training was initiated December 2015. One hundred percent of CICU staff nurses ($N = 76$) received hands on training for insertion and care of urinary retention catheters. Periodic rounding in CICU by infection prevention CAUTI team members was performed to assess 100% of patients with an indwelling urinary catheter. The infection prevention team checked for daily care compliance by nursing staff, nurse assessment for necessity of continued urinary catheter placement, proper urinary catheter securement

devices in use, and appropriate positioning of closed drainage units. “Just in time” coaching and recognition was provided by the assessment team as needed.

Results: Catheter induced infection rates dropped significantly after training was initiated for the CICU staff. For FY2015, a total of 16 CAUTIs were recorded for the CICU with a rate of 3.91 per 1,000 device days and 2.22 per 1,000 patient days. For FY2016, the current total for CAUTIs reported in CICU is 4, reflecting a 75% reduction in the number of CAUTIs for CICU. The infection rate per 1,000 device days is currently at 1.15 and the rate per 1,000 patient days is 0.69. The incidence of improper care was reduced significantly with the periodic rounding by the infection prevention CAUTI team nurses.

Conclusion: With regular use of urinary retention catheters in ICU settings, patients are at increased risk for developing a CAUTI. Working in partnership with experts outside nursing units improved collaboration across disciplines in this CICU. Use of an infection prevention CAUTI team aided in increasing staff education and awareness of CAUTI nurse-led prevention strategies in this ICU. With targeted evidence-based education for the nursing staff and routine rounding by the infection prevention CAUTI team, a reduction in the number of CAUTIs have resulted in this ICU setting. The significance of this project to nursing practice and patient clinical outcomes is demonstrated in the reduction of CAUTIs through nurse-driven monitoring and processes. Further research is recommended to fully demonstrate the impact of targeted evidence-based clinician education and nurse-led protocols on CAUTI rates in the CICU setting.

RSC PST 1 - Research Poster Session 1

Families and Surrogate Decision Makers of Critically Ill Patients in Saudi Arabia

Omaimah A. Qadhi, MSN, BSN, RN, USA

Abstract

Critical illness often results in serious physical and / or psychological impairments (Brummel et al., 2012; Granja, Amaro, Dias, & Costa-Pereira, 2012) . The critical care professional will often require a proxy or a surrogate decision maker, especially for incapacitated individuals (Azoulay, Kentish-Barnes, & Nelson, 2016a). The experience of being responsible for making serious decisions regarding someone else's health can be a challenging trajectory (Hickman, Daly, Douglas, & Clochesy, 2010). Healthcare providers should give more attention to this phenomenon. Not only for critical illness survivors who suffer from physical and mental problems, but there is vast evidence that families and proxies demonstrated to have a high rate of depression, anxiety and Post-Traumatic Stress Disorder (PTSD) (Azoulay et al., 2016a). Researchers support that psychological disturbances may prevent the affected person from thinking appropriately or being unable to take the right decision. Failure to provide these families and decision makers with the adequate support and care may result in endangering patients` lives (Azoulay et al., 2016a; Fortunatti, 2014; Wendler & Rid, 2011). We as care providers tend to use medical terminology that is not easy for the families of patients to understand (Azoulay, Kentish-Barnes, & Nelson, 2016b; Lamas, 2014). Lots of the families report their lack of understanding regarding the patient`s prognosis (Azoulay et al., 2016b; Peigne et al., 2011). Families who are not aware of the patient`s health preferences report more dissatisfaction with patient`s outcomes than families who knew the patient`s preferences before the onset of the illness (Azoulay et al., 2016b; Wendler & Rid, 2011). The decision taken by the surrogate may conflict with the patient`s preferences (Wendler & Rid, 2011). There is a lack of information about how families and decision makers of critical illness survivors in Saudi Arabia report their lived experience of having their loved ones in the ICU and needing to make serious medical decisions for them. The official language for the medical healthcare providers in Saudi Arabia is English. However, some of the Saudi families don't understand English, which may cause language barriers and impose more of a burden on them. Understanding how these families live the experience will help us to provide the appropriate intervention. This research is trying to explore and understand the experience of having a loved one in the critical care unit and being delegated to make the decision for them. The findings will help nurses and other healthcare professions to understand the concerns of this population to efficiently address them. Meeting the needs for the families of the critically ill patients will contribute in promote clinical and patients`outcomes.

Purpose: to understand how the Families of patients report their experience of having critically ill patients and making decisions for them Saudi Arabia.

Methods: Structured open ended-question interviews

Results: in progress

Conclusion: It is crucial to understand how families in Saudi Arabia describe their experience of having critically ill patients and the experience of being responsible to make decisions for them. This study will help to understand the phenomenon and contribute in promoting the clinical outcomes for the patients in the ICU by supporting their families in the decision-making process.

Effects of Acupression on Pericardium 6-Point With Wrist Band on Postoperative Complications of Patients

Nurten Kaya, PhD, RN, Turkey
Meryem Ünüdü, MSN, RN, Turkey

Abstract

Purpose: This study was done to evaluate the effects of acupression on the pericardium 6 point on the wrist with a wrist band on prevention of nausea and vomiting, decrease the anxiety and increase the patient comfort in the postoperative period with this randomized and controlled experimental study.

Methods: The study was conducted on 97 individuals (experiment group, n:47; control group, n:50) who had underwent gynecological operations (Operations of A, B and C groups) except cesarean section at an obstetrical hospital in Bursa. Data were collected in the forms of Patient Information Form, Nausea and Vomiting Surveillance Form, State-Trait Anxiety Inventory, Perianesthesia Comfort Scale and General Comfort Scale and the data obtained were analyzed using SPSS program.

Results: No statistically significant differences were found between the groups in the specifications that might affect the postoperative nausea and vomiting status of the patients (age, type of operation, nausea and vomiting experience in prior operations, status of cigarette smoking, history of car sickness, body mass index, preoperative state-trait anxiety points, and type and duration of anesthesia; $p>0,05$). Application of acupression on the point of P6 in 0-48 hours after the operation was identified to be as effective as pharmacological methods on the prevention of vomiting, while it was even more effective on the severity of nausea and was equally effective on vital signs compared to the pharmacological methods. Median duration of hospitalization of the individuals, perianesthesia comfort points, postoperative state-trait anxiety points and General Comfort Scale were 4 days and 5 days, 5,33 and 4,87 points, 46 and 44 points, and 156 and 148 points in the experiment and control groups, respectively. These data obtained demonstrated that the duration of hospitalization was shorter, state-trait anxiety was decreased further and general comfort was better in the experiment group compared to the control group.

Conclusion: In conclusion, acupressure application on the P6 acupuncture point on the wrist with a wrist band is as effective as pharmacological methods in the prevention of nausea and vomiting which develop during the postoperative period. On the other hand, this study suggested that absence of nausea and vomiting might have provided comfort and thus comfort of the individual might have resulted in the decrease of anxiety level.

Effects of Activity Group Therapy for Children With ASD on Social Skills and Self-Esteem

Tomokazu Sugaya, MSN, RN, Japan

Tomoko Shimada, RN, Japan

Kaori Ogiwara, RN, Japan

Akio Sakurai, RN, Japan

Hayato Anzai, BN, RN, Japan

Fujiko Kudo, RN, Japan

Momoko Aoki, MD, Japan

Chizuru Mori, PhD, RN, Japan

Abstract

Introduction: In recent years, there has been an increase in consultation of Autism Spectrum Disorder (ASD) children at medical field. Diagnostic and Statistical Manual of Mental Disorders Fifth Edition (DSM-5) said that the essential features of ASD are persistent impairment in reciprocal social communication and social interaction, and restricted, repetitive patterns of behavior, interests, or activities. Children with ASD suffer from isolation and friendship at school because of their impairment in reciprocal social communication and social interaction. Because they do not understand the difference from typical development children, they deepen the sense of alienation and isolation. In this way, children with ASD cause maladjustment at school and often become school refusal, so the necessity of support is pointed out. Children with ASD are difficult to acquire social skills naturally, so it is necessary to experience various interpersonal experiences and acquire social skills. It is pointed out that self-esteem of Japanese children is lower than that of children of other countries (e.g., United States, China, Korea, Netherlands, Germany, Finland and Turkey). Furthermore, it has been pointed out that children with ASD have lower self-esteem than Japanese typical development children. Therefore, it is necessary to raise self-esteem of these children.

Activity group therapy (AGT) is one of group psychotherapy advocated by Slavson. In AGT, it is possible to express emotions, re-experience early conflict of development, by providing an acceptable environment and playing with groups. We thought that participation in AGT enables children with ASD to experience interpersonal communication and interaction. We thought that in AGT with same interests by utilizing restricted patterns of interests which is one of the essential features of ASD, participants who are not good at interpersonal relationships are easy to participate and can actively participate in group activities. In addition, we thought when we are carrying out AGT of their interesting theme, they could experience being recognized by others and increase their self-esteem.

In this study, we chose railway as interesting theme. Railway has orderliness, predictability, consistency, arrangement of numbers (e.g., rail timetable), arrangement beauty, symmetry and regularity of tracks and sleepers, and unique driving sound. Because those features are fit in their interests, it is pointed out that railway is very attractive for them. It is also reported that some people with ASD are interested in the railway picture books and some children remember and memorize in the rail timetable in detail. Therefore, we thought that conducting AGT of railway was useful for children with ASD.

Purpose: The purpose of this study is to clarify the utility of AGT with same interests for children with ASD.

Methods: Subjects - 9 subjects who were inpatients or outpatients at the adolescent psychiatry in Japan were recruited in the present study. They were children with ASD and from 5th-grade to 9th-grade. They participated in AGT of railway, it's called "RAILWAY FRIENDS".

Framework of AGT called "RAILWAY FRIENDS" - AGT "RAILWAY FRIENDS" was conducted once a week for 1 hour, and it was conducted 10 sessions a course. Until the 9th session, they got conversations and consultations on railway, appreciation of railway magazines and DVD, demonstration and driving of

their own railway models at the playroom in the hospital. They went to a day trip outside the hospital using railway at the 10th session. The staff participated in 2 nurses (1 is conductor and 1 is co-conductor), 1 psychologist (co-conductor), and 1 medical doctor (co-conductor). AGT "RAILWAY FRIENDS" period was from August 2014 to January 2016.

AGT assessment - In order to verify the utility of AGT "RAILWAY FRIENDS", we conducted a self-administered questionnaire survey before and after AGT "RAILWAY FRIENDS". The questionnaire we used was a Basic Communication Skills Scale for Junior High School Students for measuring social skills and a Japanese version of the Rosenberg Self-Esteem Scale for measuring self-esteem. A Basic Communication Skills Scale for Junior High School Students has 24 items and 4 subscales (Behavioral Expression, Emotional Regulation, Cognitive Decoding, and Cognitive Monitoring). A Japanese version of the Rosenberg Self-Esteem Scale is 10 items and one factor. Demographic information (age, gender, grade, and the treatment situation) was investigated from medical record in the hospital.

Wilcoxon signed-rank test were used to detect the difference before and after AGT "RAILWAY FRIENDS". The Statistical Package for Social Sciences (SPSS) version 22, at the 95% confidence level was used.

Ethical consideration - This study was approved by Ethics Committee of University of Tsukuba Faculty of Medicine, and Research Facility. Informed consent was obtained from participants and their guardian caregivers before the initiation of any research procedures.

Results: The subjects are 2 elementary school students and 7 junior high school students, 5 inpatients and 2 outpatients, and all boys. The average attendance rate of the participants was 93.3%. Univariate analysis showed no significant difference in social skills (before AGT: $M=44.78$ $SD=10.97$, after AGT: $M=48.44$ $SD=8.02$, $p=.057$), and the effect size was large ($r=.634$). In the subscale of social skills, there were no significant differences in Behavioral Expression (before: $M=16.33$ $SD=4.72$, after: $M=18.11$ $SD=3.59$, $p=.172$), in Emotional Regulation (before: $M=11.11$ $SD=3.62$, after: $M=10.56$ $SD=2.65$, $p=.670$), in Cognitive Decoding (before: $M=7.33$ $SD=2.35$, after: $M=8.22$ $SD=2.17$, $p=.074$), and in Cognitive Monitoring (before: $M=10.00$ $SD=4.03$, after: $M=11.56$ $SD=2.74$, $p=.104$). Effect size in Behavioral Expression is medium ($r=.455$), in Emotional Regulation is small ($r=.142$), in Cognitive Decoding ($r=.595$) and in Cognitive Monitoring ($r=.542$) are large. There is no statistically significant differences in Self-Esteem (before: $M=22.78$ $SD=6.85$, after: $M=26.44$ $SD=4.64$, $p=.065$), and effect size is large ($r=.614$).

Discussion: In this study, there are no statistical differences in social skills and Self-Esteem. However, because the significant difference is influenced by the sample size, in this study, the number of subjects was 9, which was considered to be related to this result. On the other hand, since the effect size does not change depending on the sample size, it can be considered that the effect of this research can be examined by the effect size.

It was suggested that participation in AGT "RAILWAY FRIENDS" improves social skills. Considering from effect sizes of Cognitive Decoding and Cognitive Monitoring are large, it was thought that they could think about the thought of others and themselves by participating in AGT "RAILWAY FRIENDS" and interacting with members of the same interest. Also, in Behavioral Expression effect size is medium, it was thought that participating in AGT "RAILWAY FRIENDS" and having experience of communicating one's own thoughts to others makes it possible to appropriately convey their feelings and thoughts to the others. It is pointed out that improving self-esteem is not so easy, but in this study, effect size of self-esteem is large, it was thought that it was possible to improve their self-esteem by participating in AGT "RAILWAY FRIENDS". In this AGT "RAILWAY FRIENDS", attention was focused on the subject's interests, which is a feature of ASD, and we conducted activities using those characteristics. Therefore, it was thought that their self-esteem was improved as a result of using the biological elements of participants with ASD, performing their favorite activities with others and getting positive feedback.

Conclusion: The purpose of this study is to clarify the utility of Activity Group Therapy with same interests (Railway) for children with ASD. Comparison of before and after has been carried out on social skills and self-esteem. There are no significant differences but effect sizes were medium to large.

Comparison of Skin Temperature and Bed Climate of Bedridden Elderly Patients in Summer and Winter

Aino Hayashi, MSN, RN/PHN, Japan
Aki Ibe, PhD, RN/PHN, Japan
Yoko Aso, PhD, RN/PHN, Japan
Masako Miyajima, PhD, RN, Japan
Megumi Katayama, PhD, RN/PHN, Japan
Kaori Fujimoto, MS, RN, Japan
Mihoko Ishizawa, PhD, RN, Japan
Tomoyuki Haga, BE, Japan
Kazuhiro Takeda, LLB, Japan

Abstract

Purpose: Peripheral skin temperature fluctuations are susceptible to the external environment. When exposed to a low-temperature environment, usually the peripheral blood vessels quickly contract to prevent heat dissipation and a lowering of the body temperature. However, because elderly people have lower thermoregulatory functions than younger people, such reactions are sluggish, heat is deprived, and the skin temperature decreases. Therefore, covering behaviors, which is one behavioral thermoregulation, are critical. However, since it is difficult for bedridden elderly patients to cover themselves with blankets, nurses must adjust the bed climates (temperature and humidity). Failure to properly control the peripheral skin temperature also increases the risk of pressure ulceration due to insomnia or peripheral circulation failure caused by getting chilled. In our previous study, we confirmed the change in skin temperature caused by placing blankets on healthy elderly people, but the actual situation remains unknown for elderly who are bedridden. In addition, due to the obvious climate difference between summer and winter, we must adjust the bed's climate based on a hot and humid environment in the summer and winter's low-temperature environment. Unfortunately, few studies have clarified this point. Therefore, to examine the adjustment method of the covering environment for feet, we compared the skin surface temperature and the humidity of the feet of bedridden elderly patients covered by a blanket in summer and winter.

Methods: 1) Participants: 20 hospitalized, bedridden patients who required assistance in excretion, eating, and changing their clothes. 2) Experimental period: August-October 2016 (summer) and December 2015-February 2016 (winter). 3) Procedure: After resting for more than 15 minutes without a blanket covering their lower feet and legs, they rested for 30 minutes with a blanket covering their whole body, and then rested for 15 minutes with their legs uncovered below the knee again. We measured the temperature and the humidity of the feet's soles and bed climate by a temperature/humidity data logger called Maxim ibutton Hygrochron (DS1923). We attached a temperature/humidity data logger to the three locations on the subject's feet and at the foot of the bed and measured the values every minute. The material of the used blankets is feathers in the summer, and down and feathers in the winter. We calculated the average of the temperature and humidity data of following period: for 30 minutes that the feet were covered by blanket and for 15 minutes after removing the blanket. The values are expressed as mean (SD).

Results: Our analysis included 20 participants (6 males, 14 females), 84.6 (5.7) years old in the summer experiment and 18 participants (5 males, 13 females), mean age 83.3 (8.7) years old in the winter experiment. The mean temperature at the bed's measurement location was 26.2°C (0.03) in summer and 24.2°C (0.2) in winter, and the mean humidity was 53.6% (0.1) in summer and 35.1% (0.4) in winter. Regarding the temperature and humidity under the blanket, the mean temperature 30 minutes after being covered was 26.4°C (0.1) in the summer and 24.5°C (0.3) in the winter, and the mean humidity was 54.8% (0.3) in the summer and 38.4% (0.7) in the winter. The mean temperature for 15 minutes after removing the blanket was 26.4°C (0.08) in the summer and 24.4°C (0.4) in the winter, and the mean humidity was 52.3% (0.6) in the summer and 34.8% (1.0) in the winter. The mean temperature of the feet's soles for 30 minutes covered by a blanket was 31.6°C (0.3) in the summer and 30.3°C (0.6) in the

winter, and the mean temperature 15 minutes after the blanket was removed was 31.1°C (0.3) in the summer and 30.0°C (0.6) in the winter. Regarding the humidity, the mean of the feet's soles covered by a blanket for 30 minutes was 67.1% (0.9) in the summer and 53.2% (2.3) in the winter, and the mean humidity in the 15 minutes after the blanket was removed was 64.1% (1.0) in the summer and 51.0% (2.1) in the winter. The changes in the skin temperature of the feet's soles reached an equilibrium state 30 minutes after being covered in the summer 17 minutes after being covered, whereas in the winter, the skin temperature continued to rise continuously for 30 minutes after being covered. Even after being uncovered, equilibrium was reached in eight minutes in the summer, but it continued to decrease for 15 minutes in the winter. The feet's soles temperature rose by 1.0°C for 30 minutes after being covered in the summer and decreased by 1.1°C in 15 minutes after the blankets were removed. It increased by 2.0°C in 30 minutes after being covered and decreased by 1.6°C in 15 minutes after the blankets were removed in the winter.

Conclusion: The changes in the skin temperature of the feet's sole due to the presence or absence of a blanket were small in the summer after it was removed, and fluctuation in the winter was large. The time required for the temperature change also quickly reached an equilibrium state in the summer, but it continued to change during the measurement time in the winter. In other words, warming up was more difficult in the winter than in the summer, and cooling off was also easier in the winter. In our previous studies on healthy elderly people, the skin temperatures of their feet were about 2°C higher in the summer and 3°C higher in the winter than in this paper's subjects. Effective warming is necessary to adjust the bed climate of bedridden elderly patients, especially in the winter. In the future we will continue to discuss concrete methods for adjusting the covering environments of the feet.

A Neglected Subject in Nursing: Eye Care

Nuray Turan, PhD, RN, Turkey

Hatice Kaya, PhD, RN, Turkey

Gulsun Ozdemir Aydin, MSc, RN, Turkey

Abstract

Purpose: In a healthy individual, the eyelids create both a physical and a mechanical barrier against trauma and dryness. However, loss of consciousness, giving respiratory support, sedation and the administration of muscle relaxant drugs lead to insufficient closure of the eyelids, reduction in blink reflex, and the emergence of problems with the eye. Accordingly, problems with the cornea, complications such as keratitis, conjunctival edema and dry eye may occur.

Methods: In this article, nursing interventions applied for the prevention of eye dryness were discussed by examining the literature and research findings, and application-oriented suggestions were proposed.

Results: The application of evidence-based nursing care standards is the most basic element in the prevention of eye dryness. However, nursing care applications for eye care are not performed based on evidence in our country, only the medicines prescribed by the physician are applied, and applications are started after a problem related to the eye has been detected. In studies carried out based on eye care protocols, it is seen that problems such as keratopathy, conjunctivitis and keratitis have been focused, eye dryness that can be avoided by a simple protocol before it has been neglected. In the prevention of eye dryness, eye hygiene should be ensured, tears should be protected or replaced, and the open eye should be closed. The use of tear preparations without preservatives and eye pomade, closing of the eye with polyethylene cover forming a humid chamber, isotonic-soaked or dry gauze bandage and eye protective pads are recommended. In a research carried out in our country, it has been stated that closing eye with polyethylene cover is more effective in preventing eye dryness.

Conclusion: One of the most important responsibilities of the nurse is to prevent the development of complications in the individual. In this context, nursing practices should be based on evidence in the prevention of advanced problems that may arise due to the eye dryness and further studies should be carried out in this field.

Mother's Anxieties Before the Proton Beam Therapy of Child

Noriko Ozawa, MSN, RN, Japan
Kayuri Furuya, DNSc, RN, PHN, Japan

Abstract

Background: Proton beam therapy is one of the radiation therapy in pediatric cancer treatment. Proton beam therapy is expected to reduce the late complications. However, there are only a few centers offering this promising therapy in the world. The largest centers in the world in Japan, but there are still only four centers that are treating children. Patients and their families usually need to travel to a proton center and stay for approximately 2 months in order to avail of it. It has been studied that there are the family impacts by environmental changes (Amy et al., 2012).

Radiation therapy itself is a noninvasive treatment, but it can be stressful and challenging for the children. Children are exposed to an unknown large radiation equipment and the new medical staff such as radiologists. Additionally, the children have to remain alone in the treatment room during treatment. These factors can cause the children stress and anxiety, so anesthesia is often used in radiation therapy for children's safety.

However, preparation programs for children to receive radiation therapy has been studied in some countries, and they have been shown that it is possible to reduce the amount of anesthetic. So we have created a program with reference to previous research, and carried out for the children to receive proton beam therapy in Japan. Through this program we were able to reduce the amount of sedatives (Mizumoto et al., 2015).

The radiotherapy treatment process involves interactions with the most advanced skills in pediatric oncology care, so there is a need to continue to improve the preparation program. Although There are few studies have investigated the child's and the parents' view of this particular procedure, a study reported the parents have various uneasiness due to radiation therapy (Charlotte et al., 2015). Parent's mental stability has been reported to lead to mental stability of the child (David, et al., 2013). Therefore, we thought that incorporation of parent intervention in the program of children receiving proton therapy would lead to a more effective program.

Purpose: The purpose of this study is to clarify anxieties encountered by parents of children who will receive proton therapy, before the treatment.

Methods: Our study subjects were mothers of children they received the proton beam therapy after implementing the current preparation program. Our study's target facility was one of the proton therapy center in Japan.

We conducted Semi-structured interviews after the treatment. We carried out content analysis, we found codes, subcategories, and categories.

The current preparation program: At the center nurses and radiologists care the children using the preparation program. The preparation program starts at 1~2 days before the CT scanning for the proton beam therapy and continue during treatment. First they explain to the children about treatment using picture book or pamphlet. Next they invite the children to facility for become familiar with the treatment room and staff before starting the treatment. Then the children practice to stay a treatment bed with mothers, and little by little they practice to stay alone using favorite DVD or music for their relaxation. Nurses and radiologists play with the children every time after practice and we give them the stickers of the reward.

Ethical considerations: Our study obtained the ethics committee's proposal of the organization. We explained to participants about the purpose and method of this study, the participation is free, and keeping anonymous in document. Participants signed on consent form.

Results: 5mothers participated in our study. Their children are 3male and 2 females, 4-13years old. 4 of the children could receive proton beam therapy without sedation.

We found 4 categories such as [Anxiety whether children can overcome proton beam therapy], [Anxiety as to whether you can receive similar care as hospitals so far] ,[Anxiety about mothers themselves after transference] ,[Anxiety what happens to other family members by mother's absence].

The mother was concerned that the child could successfully overcome it. Before the child 's preparation program, they could not understand how the child' s proton beam therapy will proceed specifically. They had few opportunities to encounter new medical stuff until they moved to the hospital, so they could not hear the way of care and could not figure out what they could do for their children. Besides, mothers were concerned that there might be a change not only in proton beam therapy but also in normal cancer care by moving through the hospital, too.

And also they had to leave the house as they had to accompany the child for proton beam therapy. So mothers expressed anxiety about changes in their lives and changes in the lives of other families, too.

Conclusion: The proton beam therapy is an unknown treatment not only for children but also for mothers. From the background that it is often necessary to transfer to receive proton beam therapy, it is expected that the mother will be transferred to the proton beam treatment center without information and the mother's anxiety will increase after the transfer. The current children's proton therapy preparation program has been found to reduce children's anxiety and deepen their understanding. However, unlike normal radiation therapy, it often requires metastasis. As a result, the time available for children's preparation program is limited.

Until now, it has been shown that the mental state of mother influences children. In order to do effective care in a limited time, it is thought that it is necessary to consider not only children but also programs incorporating mother's preparation. It is suggested that it is necessary to provide information on proton therapy and information on a new medical environment in advance.

Exploring the Relationship Between Docetaxel-Induced Peripheral Neuropathy and Quality of Life in Breast Cancer Survivors

You-Wun Jheng, MS, RN, Taiwan

Ya-Jung Wang, PhD, RN, Taiwan

Chih-Jung Wu, MS, RN, Taiwan

Abstract

Purpose: Docetaxel is benefit breast cancer survival demonstrated by numerous randomized trials. Docetaxel-induced peripheral neuropathy (DIPN) is one of side effects which is not easy to be aware and negatively influences women's physical, psychological, social status and quality of life (QOL). There are many studies to survey the phenomenon of peripheral neuropathy in other countries, but it's no study investigating its impact on Taiwanese women with breast cancer. The primary purpose of this study was to investigate the distribution and relationship among peripheral neuropathy and QOL in women with breast cancer after docetaxel treatment.

Methods: This study utilized a cross-sectional study design and purposive sampling. Women with breast cancer received at least one treatment with docetaxel were recruited in this study from a medical center in northern Taiwan. Instruments included Patient Neurotoxicity Questionnaire, Total Neuropathy Score-clinical version, and Functional Assessment for Cancer Treatment-Breast and Taxane. The data were analyzed utilizing mean, standard deviation, frequency, percentage, independent-samples t test, one-way ANOVA, Chi-square test, and Pearson correlation.

Results: The average age of 111 subjects was 50.78 years. The TIPN subjective measure found sensory and motor symptoms were 67.6% and 62.2%, respectively. Nearly half of the participants were with slight symptoms but only 4.5 to 7.2% of them were with a severe degree. The objective method indicated that 82.9% had peripheral neuropathy. Moreover, two of the most common symptoms were the deterioration of sensation on pinprick and vibration tests. PNQ sensory and motor scores were significantly higher in patients are undergoing docetaxel therapy compared to therapy has been completed. Women were keep exercise more than three times a week who got TNSc higher scores. There was a positive correlation between subjective and objective DIPN ($\rho=0.495$, $p<0.001$), a negative correlation between subjective DIPN and quality of life ($\rho=-0.552$, $p=0.001$), and then a negative correlation between objective DIPN and quality of life ($\rho=-0.407$, $p<0.001$).

Conclusion: Women with breast cancer after docetaxel treatment induced peripheral neuropathy negatively affected QOL. Oncology nurses are expected to have skills utilizing the TIPN subjective and objective tools to early detect and timely manage the DIPN. Therefore, the quality of life in this population is able to be advanced.

Feeding Behaviors for Premature Infants Who Received Extended Tube Feedings

Rosemary C. White-Traut, PhD, RN, FAAN, USA

Abstract

Purpose: The overall prevalence of feeding problems occurs in 25 - 35% of children, peaking by 6 months. Feeding problems are more common and more serious in infants who have had extended tube feedings and lead to delayed oral feeding, growth failure, and disengagement with the caregiver, leading to less optimal parent-infant interaction. The study was guided by the Developmental Science Model. For hospitalized infants who have long term exposure to tube feedings, we prospectively identified the range of early feeding behaviors encompassing the infant's feeding experience through hospital discharge to address the question: What are the early feeding behaviors of infants who receive extended tube feedings and do these behaviors change with maturation?

Methods: The research was conducted at a Level IV Neonatal Intensive Care Unit in the Midwest, USA. Premature infants were enrolled if they were expected to receive a minimum of two weeks of tube feedings. Non-surgical or surgical (non cardiac) infants who required a minimum of 2 weeks of tube feedings, may be receiving oxygen and IV therapy, or previously treated for sepsis, pneumonia, or assisted ventilation were eligible to participate. Infants experiencing current sepsis, pneumonia, on assisted ventilation, or IV only intake, had congenital anomalies of the oral cavity, chromosomal abnormalities, were in opiate withdrawal, or not neurologically intact (e.g. seizures) were not eligible to participate.

A prospective design estimated changes in feeding behavior over time and their variability. Infants were video recorded weekly for 30 minutes before feeding, during the tube feeding, and for 30 minutes after the feeding. The video recordings were later coded for feeding behaviors. Orally directed feeding behaviors (mouthing, swipes at mouth, hand to mouth, sucking on hand, sucking on tongue, empty sucking, tonguing, rooting, and yawning) and behavioral state (asleep, awake, drowsy, or crying) were evaluated through the in-hospital weekly video recorded sessions.

Results: Thirty-five infants were enrolled. Analyses will include GEE/GLM and predictive models. The sample demographics and orally directed feeding behaviors data have been analyzed on 14 infants. The final analysis for orally directed behaviors and behavioral state will be completed by April 2017. For the first 14 infants, the mean gestational age at birth was 28.85 weeks, mean birth weight was 1060.71 grams, mean Apgar Score at 5 minutes was 6.81, eight participants were male, 12 were delivered by Cesarean section, and 4 infants were still tube feeding at hospital discharge. The highest mean frequency of orally directed behaviors occurred in the 5 minutes immediately prior to the beginning of feeding (mean .67) followed by the first five minutes of feeding (.59). The mean frequencies for mouthing and tonguing were highest over the course of hospital stay. During the 15 minutes prior to feeding, tonguing occurred at the highest frequency (mean 5.7) followed by mouthing (mean 4.4). None of the infants exhibited sucking on hand, which is a more mature behavior. Fewer behaviors were exhibited post feeding. When orally directed behaviors were combined by age, younger infants between 30-33 weeks postmenstrual age (PMA) exhibited a higher mean frequency of all orally directed behaviors (17.5) when compared with infants between 34-36 weeks (15.4) prior to feeding and (19.7 vs 15.2 respectively) during feeding.

Conclusion: For infants between 30 and 36 weeks PMA, the frequency of orally directed behaviors was highest during feeding and did not increase with maturation as was expected. The findings suggest that extended tube feedings may influence the decrease in orally directed behaviours. Interventions are required to address the lack of maturation of orally directed behaviors and alleviate the long term consequences of oral feeding difficulty.

Invisible Nature of Self-Care: Clinical Issues Raised By People With Multiple Long-Term Conditions

Kim van Wissen, PhD, RN, New Zealand

Denise L. Blanchard, PhD, RN, Australia

Abstract

Purpose: People with illness are involved in their own care on a daily basis, constantly varying care according to the peaks and troughs of their illness experience. Despite people's important role in self-care, their work remains obscure and under-researched, hence a clearer picture is required of what work patients undertake. This presentation aims to typify the work of people with illness requiring self-care in community settings. Extending this line of thinking, our research indicates how managing illness at home requires an accomplished level of expressed self-care.

The invisible nature of self-care and the signs and symptoms of long term illness have been made more perceptible, for example fatigue as an invisible symptom often managed by the person themselves. Identifying invisible aspects of illness as a disease, may not always identify the needs of people striving for independence and consequently instigating self-care. Our research provides insight into how people with illness trivialise their role as the principal provider of their own care.

To clarify, self-management is that care that is directed by a health professional, while self-care is controlled by personal choices and accommodations made when living with illness. To attain levels of well-being through efforts that are largely imperceptible, people with illness make compromises. Unless health professionals examine people's input into their health status closely, important cues are missed in terms of the extent of how self-care has become entrenched in a person's life living with illness.

Methods: Interpretive description was instrumental to ensure our research remained orientated to the person-with-illness. Twenty nine participants were individually interviewed nine months after they had been discharged home from hospital, following an acute coronary syndrome event. All participants had sustained high blood glucose at the time of admission to hospital, indicating prediabetes, in addition to their cardiovascular disease (CVD). This combination of conditions is now clearly identified to have a shared pathogenesis and subsequent illness sequelae, which is why this group of people was specifically targeted.

Results: Findings highlight that invisible self-care persists as absent in patient assessments and conversations. Participants in our research described in their interviews how prediabetes frequently remained in the background, concealed by ongoing manifestations or treatments of CVD. In addition, participants had visible and less visible conditions that required ongoing monitoring and management, such as arthritis and hypertension. Consequently there was a notable indifference to the invisible work undertaken by participants to self-care for ongoing health issues arising from multiple long term conditions.

Conclusion: Nurses in any clinical setting are working with people with multiple long term conditions such as CVD and diabetes. To reduce the burden of evolving disease and subsequent illness, nurses are in an ideal position to provide support and partnership for those undertaking self-care. Professional nursing practice should elucidate self-care with people at every turn, to make the invisible work of caring for one-self with illness an important feature of nursing assessment and clinical judgement.

An Analysis of Maternal Near Misses and Failure to Rescue Using Two National Data Sets

Fuqin Liu, PhD, RN, USA

Peggy J. Mancuso, PhD, RN, CNM, USA

Patti Hamilton, PhD, RN, USA

Elizabeth B. Restrepo, PhD, RN, USA

Abstract

Purpose: The aim of this study is to use a population-level approach to identify and quantify maternal near misses and failure to rescue in the United States from 2012 through 2015 with data derived from 96.2% of deliveries and maternal deaths during the period.

Methods: We will use a descriptive, epidemiological, cohort design and will analyze Birth and Multiple-Cause of Death records available from the U.S. National Center for Health Statistics to identify vulnerable groups and vulnerable locations where failure to rescue occurs. We will calculate failure to rescue using an approach endorsed by the National Quality Measure Clearinghouse and the Agency for Healthcare Research and Quality, but tailored to fit the care of mothers during pregnancy, birth, and the puerperal period. Data documenting seven specific complications (maternal morbidities) will be extracted from national birth records for 2012-2015. These records describe births in 47 states, the District of Columbia, Guam, Puerto Rico, and the Northern Marianas. While some states do not use the 2003 revised birth certificate, variables that are comparable across various versions of the birth certificate are included and flagged. These data represent approximately 4 million births, annually (16 million births over the four-year period). All deaths processed by the National Center for Health Statistics are included in the national multiple-cause death files. We will analyze only death records having ICD-10 Maternal Death codes (O001-O999) as the underlying cause of each maternal death as well as the Record Axis codes corresponding to the maternal morbidities in the birth records. Each of the four years will include approximately 1000 maternal deaths for a total of 4000 cases analyzed during the study period.

Results: Preliminary analyses are derived from a population cohort comprised of all women who delivered a live-born infant in the U.S. in 2014 and died in that period as a result of the pregnancy, a condition occurring during the pregnancy, the birth, or in the postpartum period. The 2014 birth data were comprised of 3,998,175 births representing mothers for whom a U.S. certificate of live birth was submitted. Mothers giving birth in 2014 ranged in age from 12 to 50 years, with the greatest percentage of births occurring to women in the age range of 25 – 29 years and the least percentage occurring to those under 15 and in the 50-54 year range (0.1% and 0.0%, respectively). Race/ethnicity data indicate that for 3.3% of the maternal population, these data are missing. For the remaining mothers in the data, 23.0% were Hispanic and 76.3% were non-Hispanic (including origin unknown). Regarding marital status, 59.8% of the mothers were married and 40.2% were unmarried at the time of the birth. Mothers in 2014 had from 1 through 17 children still living from previous births. The majority of mothers (39.1%) had no living children at the time of the birth in 2014. Thirty two percent had one living child at the time of the birth, 16.7% had two living children, 7.0% had three living children, and 2.7% had four living children. Two percent of mothers had from 5 to 17 children alive at the time of the birth in 2014, and for 0.3% of the mothers, the number of children living at the time of the birth is unknown or unstated. For mothers giving birth in 2014, 98.3% had no children dead from a previous live birth, 1.0 % had one child dead from a previous live birth, and 0.1% had two children dead. The remaining mothers (0.0%) had between 3 and 12 children dead from a previous live birth. For 0.5%, it is unknown or unstated as to whether the mother had children dead from previous live births.

Regarding other terminations of pregnancy, 73.5% of mothers did not have a prior other termination of pregnancy, while 16.5% had one prior other termination of pregnancy, 5.5% had two prior other terminations, and 1.9% had three. The remaining 2.6% of mothers had between 5 (0.3%) and 29 (0.0%) prior other terminations. For 1.4%, information for prior other terminations is unknown or not stated. For approximately 3.6% of the population, data for the month of pregnancy in which prenatal care began are

missing. For the 96.4% of mothers who had prenatal care data, the breakdown by month prenatal care began indicated that 1.5% of the mothers had no prenatal care. The plurality of mothers began prenatal care in the second month of pregnancy (38.4%). Regarding participation in the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), approximately 41% of the mothers received WIC. Concerning the socioeconomic indicator, principal payment source for the delivery, 3.6% of the maternal population had missing data. Removing the missing data from consideration, the principal payment source for the delivery was private insurance (47.3%) or Medicaid (43.2%). Regarding place of birth, the majority of the population (98.5%) gave birth in a hospital. Another 1% gave birth in a residence, and 0.5 % gave birth in a free-standing birthing center.

Conclusion: This will be the first population-level study to identify and quantify maternal near misses and failures to rescue across ethnic and sociodemographic groups and across counties and states - focusing especially on Medically Underserved Areas and Health Professional Shortage Areas in the U.S.

RSC PST 1 - Research Poster Session 1

Care Models of Individuals With Dementia and Properties of Care at the Home

Nurten Kaya, PhD, RN, Turkey
Nuray Turan, PhD, RN, Turkey
Gulsun Ozdemir Aydin, MSc, RN, Turkey

Abstract

Purpose: As with population ageing, increasing older individuals are affected by dementia in the world. The dementia brings new behavioral problems in the lives of individuals with this disorder. These problems, both health team member who are caring for individuals with dementia and their caregivers makes it difficult to continue the process of care and reduces the quality of life.

Methods: This article examines literature and research findings about the dementia, care models, home care, nursing care and discusses the importance of subject.

Results: Dementia is a generic term indicating diseases that involve a loss of cognitive function. In the future, the number of individuals with dementia in the world is expected to be 115.4 million in 2050. Over the last two decades, there has been a growing interest in how to provide the best care for individuals with dementia. The models have developed in order to directly address this gap, by providing a theoretically driven, yet pragmatically focused framework to guide optimum dementia care practice. Therefore there are few well defined models to guide long-term dementia care. They are; Person-Centered Care, The Dementia Care Mapping/Planning, Need-Driven Dementia-Compromised Behaviour Model, Treatment Routes for Exploring Agitation, Progressively Lowered Stress Threshold Model, Elderly Abuse and Neglect on Care Models and Other Nursing Models. Those that are most widely used, such as individual centered care, aren't always well understood by care providers, leading to inconsistent implementation and a discrepancy between philosophy and practice. Researches have shown that, compared with other patients, individuals with dementia have added risks and poorer health outcomes. Especially home care of individuals with dementia are more comprehensive than other individuals. The home care of individuals with dementia includes; home health service delivery, support health care, personal care/self-care services, household services, social support, food and nutrition services and consultancy services.

Conclusion: Many of the day-to-day caregiving responsibilities for individuals with dementia are performed by either family or care givers of long-term care settings. Health care team members have an important responsibility especially home care of individuals with dementia. Individual care is a holistic alternative to conventional care practices that can moderate the effects of malignant social psychology and help personhood to persist as dementia develops.

Restorative Justice in Mental Health Communities: The Importance of Interagency Cooperation

Susan L. Adams, PhD, RN, NP-BC, USA

Elizabeth I. Rice, PhD, RN, PMHNP-BC, USA

Abstract

Purpose: Standard community criminal justice procedures are ineffective in reducing the high rates of recidivism by offenders diagnosed with severe mental illness (SMI). With limited access to community based mental health programs and the closure of institutional settings that serve people with mental health problems, jails and prisons have become the de facto institutions for people who suffer with severe mental illness across the United States. Adults diagnosed with SMI are overrepresented in our criminal justice system nationally (10-20%) and community-based interventions vary greatly in access and design. Beyond the human suffering, there are financial costs to this high incarceration rate. Housing an inmate with a severe mental health problem ranges between \$31,000 to \$168,000 (US)/inmate/year. Despite this high cost, the mental health needs of this population are not being adequately served. Recent national research in the United States indicates that many people with severe mental illness fail to receive minimally adequate mental health treatment in prisons (Wilper, et al. 2009).

The development of offender courts for persons with mental illness have changed this dynamic. The success of these programs is dependent upon the availability of appropriate community based services and treatment, therapeutic oversight from the courts and an interprofessional collaborative that is highly motivated to contribute to the success of the program. This presentation will focus on a model program, the California Support and Treatment After Release (STAR) program developed in Marin Co. in northern California, United States.

Methods: This comprehensive community intervention was designed using a public health evidence-based practice framework.

Results: In 1998, California State Sheriffs worked with the legislature to create Senate Bill 1485 to fund pilot demonstration programs to reduce the recidivism rate of mentally ill offenders in local jails. A call was sent to local governments to submit applications for the 3-year grant funded Mentally Ill Offenders Crime Reduction Act (MIOCRA) program. SB 1485 required counties to form Strategy Committees comprised of the sheriff or department of corrections director; chief probation officer; county mental health director; a superior court judge; representatives of local law enforcement agencies and mental health provider organizations; and a client from a mental health treatment facility. The assumption was that local governments have a better understanding of the nuances of local criminal justice issues than a one size fits all statewide approach. Marin County, California was one of the recipients of the grant and developed the STAR program for severely mentally ill offenders.

Leaders in Marin Co. identified that a primary factor in the program would be an interprofessional collaborative form of leadership to advance the program. Too often, divergent interests between mental health professionals and the criminal justice system cause promising programs to fail. In Marin, important elements in the STAR program included implementation of an array of mental health services, pharmacologic management, safe housing, job training, oversight by the courts and the probation department for a one to two-year period and regular case management meetings with the interprofessional team. The program was implemented as volunteer entry by the offenders. Offenders regularly check in with the overseeing judge and the court team to monitor the progress with treatment. With completion of the program, offenders were able to petition for expunging their record of the offense, thus reducing the problem with stigma surrounding a mental health diagnosis.

Over a 10 year period, Marin demonstrated a reduction in recidivism by more than 80% and psychiatric emergency visits by more than half. Today the Marin County jail is one of the few jails in the State of California that can boast of empty jail beds. In summary, the positive outcomes of this program include

reduction in recidivism, decreased use of psychiatric emergency visits, empty jail beds, employed and housed people, expansion of community-based services and a more humane way to treat people with mental illness who had become involved with the criminal justice system.

Conclusion: The Marin Co. program is a model that has focused on interprofessional collaboration and can be replicated to develop programs that serve people with severe mental illness.

Discrepancies in Necessary Support for Long-Term Care From Perspective of Patient's Family in Japan

Tomoko Ito, PhD, RN, Japan

Abstract

Purpose: Cerebrovascular disease is the primary reason to need long-term care in Japan, and family caregiver will face their caregiving at home with uncertainty (Byun, Riegel, Sommers, Tkacs, & Evans, 2016) or burden (Camak, 2015). At patient discharging, support for family caregiver has come general, however, its quality has not been sufficiently controlled yet (Lutz, Young, Creasy, Martz, Eisenbrandt, Brunny, & Cook, 2016). This study aim was to find family caregiver's own requests for support by interview survey at 1 year later than their patients' discharge and to discuss for clinical discrepancy between actual and ideal support.

Methods: This study was conducted at one hospital located in northern Kanto field of Japan. This hospital is a general hospital that advocates over 30 departments, and it is an acute care hospital for tertiary emergency care. Study subjects were family caregivers of whom patients were collected with inclusion criterion as following, 1. Diagnosed as cerebral infarction or atraumatic intracranial hematoma; 2. Discharged at 1 year ago; 3. Age at admission was 40 or more; 4. Modified ranking scale at discharge was 3, 4, or 5. The final criteria for collection was to be stable in their symptom and physician allowed their participation. In the interview survey, researchers visited the subjects for whom the consent of research participation was obtained, and asked questions including structured and unstructured items. This study was approved by the ethical review board of the field hospital.

Results: We found six respondents who had informed and consent. There were three males who were husband of patients. Among three females, the relationships to patients were wife in 2 cases and daughter. In the one case, a subject lost the patient. They showed their requests for support at discharge including advice about financial supports or utilization of long-term care services. One said "I had known nothing about long-term care. Completely I relied on social worker or care manager, but their support was never enough. They never told us what we wanted."

Conclusion: We found comments meaning clinical discrepancies in necessary support for long-term care through interviews for family caregivers. At that time to be family caregiver, they were concerned only "I do not know," but in retrospect, they made feelings closed to the indignation of "why did not you tell me." This feeling seemed to be appeared after a certain period (more than 1 year in this study) from injury. It was suggested the assessment for problems among family caregivers was needed with estimation for their future caring.

Anemia is Associated With Rehospitalizations of Patients With Heart Failure

Youn-Jung Son, PhD, RN, CCAPN, Korea, Republic of (South)
Youngye Park, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: Anemia is a frequent comorbidity in patients with heart failure (HF). However, the exact incidence of anemia in patients with HF varies widely and little attention has been focused on the relationship between anemia and hospital readmissions or emergency department (ED) visits, and on its health consequences in patients with HF. We aimed to identify the prevalence of anemia and its influence on hospital readmissions and ED visits in outpatients with HF.

Methods: A cross-sectional study design was used. We enrolled 298 patients with HF from outpatient cardiology clinics at an academic-affiliated hospital in Cheonan, South Korea. The institutional research board of Soonchunhyang University Hospital in Cheonan approved the study protocol. We obtained socio-demographic and clinical information, including frequencies of readmissions and ED visits, using face-to-face interviews and medical record reviews. In this study, anemia was defined for adult men and women according to the criteria of the World Health Organization as a hemoglobin concentration lower than 13.0 g/dL in men and 12.0 g/dL in women. The data were analyzed using SPSS version 23 (IBM Corp., Armonk, NY). P values of <0.05 were considered statistically significant. In order to investigate the association between anemia and readmission or ED visits, we adopted a multiple logistic regression model adjusting for age, gender, job, duration of diagnosed HF, NYHA class, hyperlipidemia, use of angiotensin-converting enzyme (ACE) inhibitors, and EF.

Results: The prevalence of anemia as assessed using modified World Health Organization guidelines was 111/284 (39.1%) in outpatients with HF. Anemia was significantly more prevalent in patients who were aged 65 and older ($p < 0.001$), those who had no monthly income ($p = 0.004$), those whose HF was diagnosed for one year or longer prior to their visit ($p = 0.014$), those with chronic renal failure (CRF) as a comorbidity ($p = 0.012$), and those with less than 40% of the EF of patients without anemia ($p = 0.019$). Anemia was also significantly more prevalent in patients with BMI ($p = 0.001$) and diastolic blood pressure (DBP) ($p = 0.002$), and those with higher BNP ($p = 0.024$), BUN ($p < 0.001$), and Cr ($p < 0.001$) levels than patients without anemia.

In adjusted multiple logistic regression, anemia was 8.04 times more prevalent (95% confidence interval [CI], 2.19-29.54) in patients readmitted to hospitals. Anemia was also 2.37 times more prevalent (95% CI, 1.22-4.60) in patients visiting the ED.

Conclusion: In conclusion, although cardiovascular nurses and allied professionals are aware of the importance of the assessment and treatment of anemia in patients with HF, their specific knowledge on this subject could be improved. Thorough nursing assessments and appropriate nursing interventions are imperative in safeguarding patients with HF presenting with anemia. Future prospective studies targeting interventions to improve anemic conditions are needed to determine whether anemia influences readmission rates and ED visits.

"Gift of Life": Comparing Factors Involving Non-Directed Kidney Donor Motivation for Social Workers and Nurses

Cheryl K. Giefer, PhD, MSN, BSN, APRN, FNP-BC, USA

Abstract

Purpose: This research examines donor motivations using a research design from earlier investigations evaluating the persuasiveness of the National Kidney Foundation's (NKF) altruistic "gift of life" frame. Earlier studies produced mixed results, showing, in particular, substantially more support for material incentives among an international sample of nursing professionals as compared to a convenience sample of college students. The purpose of this exploratory study is to compare nurses and social workers on each of three measures used as indicators of kidney donor motivation: 1) social distance between donor and recipient; 2) support for material incentives as a component of motivation to undergo a living kidney donation; and 3) self-ratings concerning compassion fatigue and worker burnout as possible factors influencing donor motivations among nursing and social work professionals. A total of 159 social workers and nurses participated in a survey that addressed not only the relationship between material incentives, social distance and motivation to donate; but also work-related burnout and compassion fatigue as structural factors that might reduce donor motivation. This study does not shy away from a debate surrounding "cash for organs" and other controversial ideas. Instead, ethical concerns were incorporated into the research model in an effort to explore what motivates an individual to undergo living kidney donation surgery.

Methods: The data for this research are based on a self-administered, self-reported survey using a non-representative sample of convenience administered at the National Kidney Foundation (NKF) 2015 Spring Clinical Meetings to social workers, nurses, and other healthcare professionals. The study assessed the willingness of NKF member nurses and social workers to undergo a living kidney donation with a modified version of the Bogardus Social Distance Scale (Bogardus, 1925; 1933), which is regarded as a valid measure of the level of comfort individuals have in associating with individuals who are increasingly "distant" or dissimilar on various key traits. The researchers also used a cumulative summated-rating scale linking various material rewards to willingness to donate. This ethical-motivation scale (EMS) was developed in accordance with ethical issues raised in the literature on donor compensation and consists of nine items of increasing monetary or material value. To measure compassion fatigue, an 11-item summated rating scale was utilized, again using issues raised in the literature on burnout and compassion fatigue. SPSS 22 was utilized for the statistical analysis of these data. Percentages and simple cross tabulations were used for nominal and ordinal variables to observe bivariate relationships. Descriptive statistics, including means and standard deviations, were used for the three ordinal-level scales. A Cronbach's alpha was used to test the reliability and internal consistency of the ethical-motivation scale and produced $\alpha = .82$. The Cronbach's alpha for the modified Bogardus Social Distance Scale was $\alpha = .72$. A Spearman correlation technique was used to examine the relationship between the social distance scale and the ethical-motivation scale.

Results: The nurses and social workers in this study were compared on each of three measures used as indicators of kidney donor motivation: 1) social distance between donor and recipient; 2) support for material incentives as a component of motivation to undergo a living kidney donation; and 3) self-ratings concerning compassion fatigue and worker burnout as possible factors influencing donor motivations among nursing and social work professionals. With respect to social distance, a modified Bogardus Social Distance Scale based on the hypothesis that those with the least social distance from the respondent would elicit the most willingness to donate. The data supports the hypothesis that as social distance increases, the willingness of respondents to donate a kidney decreases. 95.8% of nursing, social work, and other healthcare respondents indicated they would donate one of their kidneys to an immediate family member. Regarding a family member, 74.4%, or 21.4% less, were willing to donate a kidney to a member of their extended family. Regarding donation to a friend, 71.3%, or 24.5% less, were willing to donate a kidney to a close friend. In contrast to the high willingness associated with donations to immediate and extended family, however, only 22.9% of nursing, social work and other healthcare

respondents were willing to donate a kidney to an acquaintance and only 14.5% were willing to donate to a stranger. Hence, 81.3% fewer respondents were willing to donate a kidney to a stranger than to an immediate family member. This result is statistically significant at $p > .001$. A comparison between nurses and social workers on the Bogardus Social Distance Scale supports the hypothesis that social workers are more altruistic. Compared to nurses, social workers are 6.3% more willing to donate when it comes to donation to an immediate family member; 9.6% more willing when it comes to an extended family member; and 11.7% more willing when it comes to a close friend. In addition, despite the low level of willingness to donate to unrelated others among both groups, social workers are 23.8% more willing to donate to an acquaintance than are nurses, and 22% more willing to donate to a total stranger. Thus, the range of difference in willingness to donate to related and unrelated others is much greater in nurses at 89.6% ($p > .09$ 2df) as compared to 73.9% for social workers ($p > .001$, 2df). To examine the amount of support associated with material incentives of increasing value, a nine-statement ethical-motivation scale developed by Humphries et al (2009) was utilized. The results indicate nursing and social work respondents agreed that living donors should be compensated for medical expenses, both groups also agreed that donors should be compensated for lost wages and should receive a federal tax deduction. High agreement was also expressed for non-compensated altruistic giving in the nursing respondents as well as the social work respondents.

Conclusion: To assess the persuasiveness of the NKF's altruistic "gift of life" frame among member nurses and social workers, this research design was developed by a team member and included a measure of compassion fatigue as well as work-related burnout. Results from the use of the Bogardus Social Distance Scale confirm, consistent with prior research studies, that respondents are more willing to donate a kidney to a close other (e.g., a member of their immediate family) than to a distant other (e.g., a stranger). Thus, this research, considered in conjunction with prior research, provides strong empirical evidence that, regardless of target population, social distance is the single most important motivating factor in altruistic living kidney donation.

Additionally, a comparison of nurses and social workers using the Bogardus Social Distance Scale reveals that nurses are less willing than social workers to participate in a living kidney donation. For nurses, these findings are consistent with earlier research and support the hypothesis that nurses are "pragmatic" in their orientation. In contrast, the greater willingness among social workers to donate a kidney supports the hypothesis of an "idealistic" orientation. However, on the ethical-motivation scale item that suggests donating a live kidney should be a "free-will donation and purely altruistic", nurses express somewhat more agreement than social workers. Both nurses and social workers expressed low support for cash payouts and other high-value rewards. Furthermore, on the compassion fatigue scale, both nurses and social workers reported that while they "feel physically and emotionally exhausted at the end of the work day," they found work personally rewarding and were not "burned out." Compassion fatigue also does not appear to explain the greater social distance expressed by the current sample of nurses in that the results on the compassion fatigue scale are comparable for both nurses and social workers. This may be due to cultural rather than structural factors, such as the different professional worldviews and socialization experiences of nurses and social workers. Despite lack of support for high-value material rewards, results from the ethical-motivation scale show strong support among both nurses and social workers for limited material incentives in the form of compensation for medical expenses, lost wages, and a federal tax deduction. These findings suggest that the "gift of life" frame is not persuasive when it comes to motivating individuals to undergo a live kidney donation, particularly when it involves an unrelated other. Specifically, the results show that unless the recipient has a close relationship to the donor, there is a low willingness to donate. Given this, the research team is in favor of re-framing living donation to emphasize both justice and rights. Specifically, these authors argue that material compensation could be construed as a just reward that preserves the rights of a selfless donor to autonomy, integrity, and dignity. In the view of these authors, this restorative frame avoids the perception of "cash for organs" that lacked resonance with the nurses and social workers in this study.

Regular Sport Activity Is Positively Associated With Biopsychosocial Outcomes in Adults With Congenital Heart Disease

Hsiao-Ling Yang, PhD, RN, Taiwan

Abstract

Purpose: The purpose of this study was to explore whether adults with congenital heart disease (CHD) engaged in regular sport, and to examine whether participating in sport activities on a regular basis was associated with increase exercise capacity as well as better quality of life in adults with CHD.

Methods: From March 2014 to July 2014, a total of one hundred and thirty adults (82 female, 48 male, 18 -61 years) with various CHD were included in this study, twenty four (18.5%) with simple CHD, seventy four with moderate CHD (56.9%), and thirty two (24.6%) with great complexity CHD. Participants completed two self-report scales and cardiopulmonary exercise test. Self-report scales including the Health Behavior Scale-Congenital Heart Disease (HBS-CHD) and the Satisfaction with Life Scale (SWLS) were used to assess whether adults with CHD practiced sport activity regularly and to evaluate their quality of life respectively. Cardiopulmonary exercise test was conducted to evaluate patient's exercise capacity using the Ultima™CPX. Data were analyzed using SPSS version 16.0 (SPSS Inc., Chicago, Illinois, USA).

Results: Most adult patients with CHD (n=87, 66.9%) did not participated in sports activities regularly. Age, education level, complexity of the heart defect and comorbidities were not related to patients whether practiced sport regularly ($p>0.05$). However, female significantly reported less regular sport activities than male (22.0% vs. 51.1%, $p=0.01$). Both exercise capacity and quality of life of patients who participated sport regularly were better than patients who did not practiced sport regularly (Peak O₂ consumption: 24.56 ml/kg/min vs. 20.69 ml/kg/min, $p<0.001$; METs: 7.00 vs. 5.93, $p<0.001$; percentage of the predicted: 68.60 value vs. 60.33, $p=0.016$; SWLS score: 26.19 vs. 23.59, $p=0.035$).

Conclusion: Most adults with CHD did not perform regular physical sport, especially female adults with CHD. The results provided evidence that regular physical sport is positively associated with not only physical function, exercise capacity, but also psychosocial domain, quality of life. The future study should examine the causal relationship between regular sport activity and exercise capacity and quality of life in patients with CHD. However, continued efforts are needed in early intervention to promote patient with CHD to do sport regularly.

The Emerging Adults' Lived Experience of Perinatally Acquired Human Immunodeficiency Virus (PAHIV)

Angela Marie Wright, MSN/Ed., ARNP, FNP-BC, USA

Abstract

Background: Globally, Human Immunodeficiency Virus (HIV) continues to be a serious health issue. In 2015 there were 2.1 million new cases; an estimated 36.7 million people were living with the disease; and 1.1 million people died from the disease around the world. Of these amounts, 25.6 million people were living with the disease in Sub-Saharan Africa which also accounted for two thirds of new HIV infections globally in 2015. Between 2000 and 2015, new HIV infections fell by 35% and AIDs related deaths fell by 28% globally. There is an estimated 150,000 new infections in children globally in 2015, a significant decrease from 2008 where 430,000 children were born with HIV. In 2012, approximately 2.1 million adolescents were living with HIV worldwide. Between 2005 and 2012, HIV-related death among adolescents increased by 50% while the global number of HIV-related deaths decreased by 30%.

Since the first cases of HIV infections in the United States were diagnosed in 1980, an estimated, 1.8 million people in the U.S. have been diagnosed with the disease and 658,992 have died from the virus or other related diseases. Although the incidence of HIV in the U.S. has decreased, it has remained steady at approximately 50,000 new cases each year. Presently, more than 1.2 million people in the United States are living with HIV infection. In 2009, an estimated 10,834 persons who were diagnosed with HIV when they were under the age of 13 were living within 46 of the U.S. territories. Of this amount 9,522 (88%) were infected perinatally. There has been a 90% decline in the number of children perinatally infected with the HIV virus in the United States since the 1990s; however, in 2010, 162 or 75% of children under the age of 13 who were diagnosed with HIV were infected perinatally; and at the end of 2012, an estimated 7,300 adolescents and 33,334 young adults were living with HIV in the U.S.

Advancement in drug therapy, research, development and healthcare workers preparation has decreased the incidence of HIV infections and seroconversions among infants in high resourced countries drastically. This has changed the face of HIV and acquired immune deficiency syndrome (AIDS) from being a terminal disease to a chronic one. It has been difficult to track long-term complications and survival of the Perinatally Acquired HIV (PAHIV)-infected or seroconvert infants through global and national data systems because they are not reported on or accounted for as a sub-category. In the United States there are approximately 10,000 PAHIV emerging adults who have emerged as a growing population of whom very little knowledge exist.

This growing population of survivors is faced with the same challenges as their HIV negative peers; however, there is a paucity of information on the population, the developmental stage and the barriers to achieving the benchmarks of this developmental stage that they may encounter. Further studies are needed in resource poor regions; where success in the fight against HIV/AIDS are not as evident as in North America and Europe; utilizing the resources that are available in those regions, to provide evidence based appropriate programs and services to meet the needs of the PAHIV emerging adults in those regions.

Purpose: The purpose of this qualitative study is to explore the emerging adult's lived experience of perinatal acquired HIV.

Research Question: What is the emerging adult's lived experience of perinatally acquired HIV?

Methods: A phenomenological process will guide the proposed study. A purposive sample of 20 PAHIV emerging adults receiving care in a major Metropolitan city will be used to explore their lived experience of PAHIV. Study data will be collected via demographic questionnaire; individual conversational audio-taped interviews and follow-up interviews (45-60 minute); participant's journal; and researcher's reflexive journal. The data will be analyzed into themes; composite depictions of common qualities experienced by

the individual participants; and the narrating or drawing of unique combinations of all data from all co-researchers. The results of the proposed study may inform nursing education, nursing practice, further research and public health policy.

Results: Pending

Conclusion: Pending

Someone to Watch Over Me: Feeling Safe and Cared for in Clinical Settings

Madeline Marie O'Donnell, DNP, RN, USA

Inge B. Corless, PhD, RN, FAAN, USA

Lisa Quinn, PhD, OCN, USA

Catherine Griffith, PhD, RN, USA

Margie Sipe, DNP, NES-BC, USA

Patrice Kenneally Nicholas, DNSc, MPH, RN, ANP, FAAN, USA

Abstract

Purpose: The purpose of this exploratory study is to identify what makes patients feel cared for and how caring behaviors and feeling safe contribute to feeling cared for in clinical settings.

- To determine whether there is a significant relationship between:
 - patients' perceptions of caring behaviors and feeling safe.
 - patients' perceptions of caring behaviors and feeling cared for.
 - patients' perceptions of feeling safe and feeling cared for.
- To investigate whether participants' responses vary by demographic factors, the length of the current hospital stay, whether the patient can identify a primary nurse caregiver, and the length of time the patient has been receiving care at the current facility other than the current hospitalization.
- To identify themes in the open-ended questions regarding feeling safe and feeling cared for.

Methods: After Institutional Review Board approval of the research, this mixed methods pilot study will be conducted on three medical and three surgical units in a tertiary care facility. Patients who have been hospitalized from 3 to 12 days, are English speaking and reading, and indicate a willingness to participate will be given an explanation of the study and their rights, an informed consent document for review of their rights, the questionnaire, and a return envelope addressed to the Principal Investigator. The questionnaire will be collected at a time convenient for the patient. It will be emphasized that current and future care at the tertiary care facility will not be affected by the decision regarding participation in the study. Completion of the questionnaire will imply consent. The questionnaire for this study is comprised of the CBI-24 (Wu, Larrabee & Putnam, 2006) that was reduced from the 42-item instrument (Wolf, 1986). The CBI-24 is preceded by a socio-demographic section containing questions on gender, age, ethnicity, education, length of hospital stay, identification of a primary nurse, and length of time receiving care at the tertiary care facility (other than the current stay). This is followed by questions on current physical and psychological status, perceptions of social support by family and friends, as well as perceptions of social support by nurses while hospitalized. The visual analog scales, measured on a 1-10 metric, assess self-perceived physical status, psychological status and social support and have been used multiple times in previous studies (Coleman, et al., 2006). Slight modifications to these scales query social support from nurses, feeling safe, presence of nurses in feeling safe, and presence of relatives in feeling safe. The next sections of the questionnaire contain the CBI-24 questionnaire and two variations of this instrument addressing feeling safe (CBI-24-FS) and feeling cared for (CBI-24-FCF) while hospitalized. The instrument also contains open-ended questions where participants can express their views about feeling safe and feeling cared for while in the hospital.

Results: If the data demonstrate an overlap between caring and feeling safe, this in itself has implications for both nursing education and practice. First, this formulation resolves the discrepancy in the caring literature where nurses emphasize the psychosocial aspects of caring given that technical proficiency is assumed as a requisite for providing safe care. Nurses can take pride in caring for patients knowing that their technical, as well as their psychosocial, skills are essential for caring for the patient and should be acknowledged as contributing to the patient's well-being. Further, identification of what makes patients feel cared for will be useful to nurses in practice as well as for nurse educators who strive to help their students achieve these skills.

Conclusion: The findings of this study will reinforce the importance of making explicit to patients what nurses take for granted, namely, their technical and monitoring activities. Nurses doing so as a part of providing care will help patients feel more secure in the clinical setting. With this as a foundation, much like Maslow's hierarchy, nurses then can address the other needs of patients confronting a health issue; a health issue with ramifications for other aspects of a patient's life and well-being. Finally, the findings of this study will contribute to the patient's knowing "I have someone to watch over me" which we contend is essential to patients feeling safe and cared for in the clinical setting.

Developing Clinical Guidelines to Improve Home Care for Patients After Prostatectomy

Hui-Tzu Chen, BS, RN, Taiwan

FangHua Hsu, MN, RN, Taiwan

Miaofen Yen, PhD, RN, FAAN, Taiwan

Abstract

Purpose: This study aims to develop clinical guidelines for both patients and their families with regard to taking care of those with prostatectomy home care (PHC). This would help to improve the quality of PHC and reduce the re-admission rate due to the complication of hematuria.

Methods: This study was an action research. The subjects were post-prostatectomy patients without complication. A task force was composed of three urologists, five nurses, and two administrators. The postoperative care procedure was analyzed by the task force using a quality control circle approach, while references were cross-checked and charts were reviewed. The care processes used were carefully examined. Regular meetings were held among the five nurses and three urologists to delineate the care quality indicators. Three dimensional models were applied to analyze the care process, staffing, and patient characteristics. An analysis of the results showed three factors related to poor quality care: (1) with regard to the process, there was lack of monitoring standards for postoperative care quality; (2) with regard to the nursing staff, there was a the lack of coherence and integrity in the content of the guidance guidelines; and, (3) with regard to the patients, there was a lack of knowledge about hematuria, and thus greater anxiety. We thus develop a guidelines for caregiver education, including an innovative urinary color card and educational tools. Interventions include: (1) The development of clinical guidelines for post-prostatectomy care, focusing on six aspects, such as diet, exercise, Foley care, incontinence care with Kegel exercise (pelvic floor), urine color differentiation (for hematuria), and re-scheduling for subsequent diagnosis. (2) The innovative design of a urine color education card (UCEC) for urine color differentiation. And (3) organizing in-service education on prostatectomy home care (PHC)

Results: A total of 525 subjects were included from February 2014 to May 2016, and an analysis of their data showed the completion rate of PHC was 99.5% (with the threshold set at 90%). Meanwhile, the percentage of telephone consultations for home care service after discharge was 10%, down from 25%, indicating an improvement of 60%. The re-admission rate for hospitalization due to hematuria in the 14 days after discharge was 2%, down from 9%, indicating an improvement of 78%.

Conclusion: This research focused on the development of clinical care guidelines for PHC. Care service quality could be closely monitored and regularly checked for improvement. The innovative urine color education card designed as part of this work could be applied in the home care guide for post-prostatectomy patients, in order to effectively improve self-care and reduce the re-admission rate due to hematuria. The development of guidelines for home care education had the following benefits: (1) Integration of disease care service for more comprehensive post-discharge care; (2) preparation of the urine color education card, inspiring creativity in health care workers and providing a standard tool for educating patients; and (3) from the perspective of risk management, the introduction of clinical care guidelines could identify individual cases at high risk of re-admission and so assist the medical team in establishing systematic preventive measures, and serve as a reference for the effects and quality of post-prostatectomy home care services.

Abstract

Purpose: The aim of this study was to evaluate the use of Standard Operating Procedures in the professional practice of the nursing team as well as identify fragilities and potentialities after their implantation in health institutions.

Methods: This is an evaluation research, with a quantitative approach, structured in two stages: documentary analysis and subsequent application of a questionnaire to the nursing professionals who work in the Health Units of a city in São Paulo state, Brazil, from April to June 2015 (this questionnaire was previously elaborated and validated by a judges' committee). The questionnaire applied is divided into two segments: sociodemographic characterization of the subjects and items referring to the use, potentialities and fragilities of the protocols implemented. Furthermore, 14 operating procedures were implanted into the locals of study in mid-2012 (nasogastric and nasoenteral catheterization protocol, catheterization by cystostomy, bladder catheterization for relief and delay, vital signs measurement, venous puncture, blood's sample collection, capillary glycosimetry, intestinal and gastric lavage, tracheostomy cannula care, airway aspiration, medication administration and dressings). The educational process of nursing professionals' training began on the same occasion. Thereunto for a theoretical reference this study used the evaluation triad of the proposed health services which is composed by: structure, process and results. The study was attended by 247 nursing professionals (nurses, technicians and nursing assistants) who worked in the Basic Health Units, the Family Health Units and the Prehospital Care Service, selected in order to meet the stipulated inclusion criteria: two years of prior contact with the protocols at least. In these circumstances, it should be noted that those nurses, technicians and nursing assistants who were on vacation or medical absence during the period of data collection were excluded from this study. All statistical tests were performed with a significance level of 5% ($\alpha=0.05$).

Results: More than half of the interviewed professionals consulted the procedures protocols basis daily, reporting that they were used at least once in the twelve months preceding the survey. There was a statistically significant difference between the variables "professional category" and "daily use of protocols" ($p=0.000$), as well between "professional category" and "consultation protocols in the last 12 months" ($p=0.000$), indicating the existence of an association between them. The professionals reported changes in the execution of nursing interventions after the implementation of the operational procedures. Concerning to the association between the knowledge of nursing professionals' improvement and the participation in the training related to the protocols, a statistically significant result ($p=0.009$) was obtained, as well as the result derived from the comparison between the intervention interventions ($p=0.025$). It reinforces the importance of education's actions in the quality of care improvement because these actions generate positive results. The main fragilities of the implanted protocols pointed to the reduced number of professionals, inadequate physical structure and lack of materials. Among the potentialities were the standardization of materials and the concern about professional and patient safety. Considering the contemporary scenario of health, the triad model structure, process and result is intended to provide subsidies for the systematic practice of evaluating the quality of services provided. In this context, the process component of this study encompassed the potentialities and fragilities perceived by professionals in the services and procedures performed from the implantation, training and use of the protocols. Regarding the evaluation of results established by the same model, the incorporation and subsequent execution of operational procedures showed implications for the clinical competence of

nursing professionals, compliance with patient safety standards, quality of care provided and satisfaction of the customer. Concerning to the structure, the research emphasized the importance of the structural preparation of the health units, emphasizing the need to adapt the facilities in terms of organization and resources for the training related to protocols and subsequent development of interventions in the daily practice of nursing professionals.

Conclusion: According to the results found in the study and based on the health service evaluation framework the reassessment of the protocols is necessary as well the adoption of the strategy of permanent education of the professionals. The introduction of the educational action may have improved the quality of nursing care evidenced by the detection of changes in the way interventions are implemented, the knowledge improvement and the increase in the number of services offered by health units.

Use ISBAR Communication Tool to Reduce the Rate of Unplanned Endotracheal Extubation in Neonates

Shun-Lin Chen, BS, RN, Taiwan

Abstract

Purpose: Patients with unplanned endotracheal extubation have a higher mortality rate if re-intubation is required. We expect unplanned extubation is reduced to 0% after implementation of quality improvement in our neonatal intensive care unit.

Methods: Implementation of quality improvement included: 1. Reform the fixation method of endotracheal tube. Elastic adhesive tape is divided into 3 phalanges or 2 phalanges with different length. We set up a table by weight to decide the number and length of phalanges, and take a video to demonstrate how to fix endotracheal tube by different phalanges of elastic adhesive tape. We replace a new elastic adhesive tape every 2 days or when wet tape is noted. 2. We revise "endotracheal tube care guide book", and also formulate "security of endotracheal tube assessment form", to promote the nursing staff to confirm the depth of the endotracheal tube and to perform auscultation of breath sounds. 3. Promote the nursing staffs to use "N-PASS: Neonatal Pain, Agitation and Sedation Scale" to evaluate pain, restlessness for intubated babies. If N-PASS is ≥ 3 points, the physician is called to deal with this condition. We also use ISBAR tool at hand-off communication every shift. 4. Set up neonatal positioning guide and also encourage the use of pacifiers to achieve greater comfort of each intubated infant. 5. Consider early extubation according to VAP Buddle daily assessment. 6. Arrange education and training of patients' safety.

Results: There is improvement of the care of endotracheal tube after implementation of quality improvement. However, we found out that evaluation of N-PASS was difficult to be applied because attending physicians is worried that sedation analgesics easily lead to neonatal respiratory depression, which may result in delayed extubation. They recommended to use "containment" and oral sugar to pain relief. if fail, we will further consider use of sedatives.

After implementation of quality improvement, we still did not reach the target value of 0%. In February 2016, there was an unplanned endotracheal extubation occurred in the night. The physician assessed that there was no need for re-intubation, and nasal continuous positive pressure was decided to use. We carried out this case by RCA approach to explore the reasons and found that we did not have an endotracheal extubation program guideline. Therefore, this will be the future direction of improvement.

Conclusion: The project will continue to work to reduce unplanned endotracheal extubation, which aims to maintain patient safety, and improve quality of care, enhancing the communication and collaboration between healthcare teams.

Systematic Review of Cyberbullying Interventions for Youth and Parents

Elizabeth N. Hutson, MS, RN, PMHNP-BC, USA

Stephanie Kelly, PhD, RN, FNP, USA

Lisa K. Militello, PhD, MPH, RN, CP, USA

Abstract

Purpose: Cyberbullying is a relatively new risk factor for the well-being of pediatric populations in which research is growing worldwide. Consequences of cyberbullying include both physical and mental health concerns such as depression, anxiety, and somatic concerns. Adolescents who have been victims of cyberbullying and consequently developed physical and mental health problems are often recommended to visit their pediatric or psychiatric provider to obtain effective, evidence-based treatment. To date, no interventions exist in the healthcare setting for adolescents who are victims of cyberbullying. The purpose of this project is to review interventional studies on cyberbullying that have components for adolescents who have been involved with cyberbullying and their parents and to provide recommendations on effective intervention components with the goal of guiding clinical practice.

Methods: A systematic review was conducted using the Institute of Medicine guidelines. A comprehensive electronic literature search was completed targeting interventions of cyberbullying in any setting. As cyberbullying is a new phenomenon, no date limits were used. Literature was searched in MEDLINE, Cumulative Index of Nursing and Allied Health Literature (CINAHL), PubMed, Communication and Mass Media Complete, Education Information Resource Center (ERIC) and PsycINFO databases. The following search terms were applied “cyberbullying” + “intervention” or “treatment” or “therapy” or “program”. Only articles with a pediatric population of 18 and younger were selected for review.

Results: Sixteen cyberbullying intervention programs in 23 articles were found to meet the search criteria. A globally representative sample was found with intervention programs from 11 countries across four continents. The most frequently used components included coping skills, education on cyberbullying for the adolescent and their parents, and digital citizenship. Past systematic reviews on this topic have focused on interventions in the school setting. To date, no interventions exist in the healthcare setting for adolescents who are victims of cyberbullying. No studies examined specific interventions that can be utilized by individual adolescents and their parents dealing with cyberbullying.

Conclusion: As more youth present for with symptoms related to cyberbullying, effective interventions are needed to guide evidence-based practice. Since cyberbullying is a global phenomenon with both short and long-term negative consequences, evidence-based clinical guidelines are urgently needed.

Factors Predicting Readmission Among Coronary Artery Disease

Rapin Polsook, PhD, RN, Thailand

Yupin Aunguroch, PhD, RN, Thailand

Abstract

Purpose: Coronary artery disease is a serious, chronic, progressive of symptom, unpredictable exacerbation, and incurable medical condition that are a major cause of mobility, mortality, and high readmission rates. Especially heart failure and myocardial infarction are growing epidemic and affects many people world wide. Hospital readmissions for heart failure and myocardial infarction are a major clinical problem and associated financial burden. Additionally, readmission in the hospital is a drain on the health care system and recognized as a maker of quality of care and a significant contributor to rising health care cost. Despite the fact that readmission is a marker of quality of care, prior studies have found that readmission rates vary between 15 % and 30% respectively, within 30 to 60 days post-discharge and between 25 % and 50 % within 6 months after the first hospitalization as well as increasing 80% within one year and account for approximately 70% of the health care cost. Various reasons are given for readmission, such as other medical health problems, nonadherence to health recommendations such as medication adherence, diet, fluid restriction, emotional or mental factors such as pain anxiety, depression, substance abuse and cognitive disorder, environment, and inadequate discharge planning. Thus, readmission remains an important health problem which is frequent, costly, and life threatening event were associated with quality of care. So, the purpose of the study was to examine the predictive ability between selected factors and readmission among Thai coronary artery disease patients.

Methods: A descriptive –correlational study was conducted to examine whether the potential factors can predict readmission among coronary artery disease. A total 77 patient with heart failure and myocardial infarction were recruited from all regions of Thailand. The participants who met the inclusion criteria were approached and requested to participate in the study, creating a purposive sample. All research instruments used showed adequate validity and reliability. Preliminary data analysis was analyzed using descriptive statistic and multiple regressions.

Results: The overall regression model shown Multiple R (.465) and R^2 (.216), followed by the adjusted R^2 (.161) and the standard error of estimate (1.946). Five factors were correlated with readmission ($R^2 = 0.216$), explaining 21.6% of the variance of the criterion variables. The overall F ratio for this analysis was 3.919 ($df=5,71$, $p=0.003$). Thus, the independent variables as a group were significantly correlated with the dependent variable, readmission. The coefficient for depression was significant beyond the .05 level which is consistent with other literature. Co-mobility, symptom severity, social support, and quality of life were not significant.

Conclusion: The preliminary analysis examined the predictive ability between selected factors and readmission and found that only one predictor- depression explained readmission among Thai with coronary artery disease patients. However, the influence of depression on readmission in this preliminary data analysis was consistent with previous studies.

Disclosure of Mental Health Symptoms: A Concept Analysis

Tamar U. Rodney, MSN, RN, PMHNP-BC, USA

Abstract

Purpose: This is an analysis of the concept disclosure of mental health symptoms. The assessment of mental health symptoms is primarily dependent on the individual experiencing them sharing their experience of symptoms with a healthcare provider. The social consequences of revealing such symptoms are often negative and prevents early assessment and treatment provision for these individuals. Disclosure have been defined to capture “a telling of the unknown”. It has previously been defined in the context of cancer (Sun & Knobf, 2008), HIV (Eustace & Ilagan, 2010), and as a general concept (Saiki & Lobo, 2011). However the disclosure of feelings, emotions and concerns during a mental health interview captures new meaning because of the potential impact of having shared that information with a nurse.

Methods: A computer search of the following databases was conducted to capture the meaning and processes of HIV disclosure among HIV-positive individuals: PubMed, CINAHL and PSYCINFO. Only English language journals were used. Publication dates of the literature review ranged from 2006 to 2016. The following key words were used: mental health symptoms, psychiatric symptoms, diagnosis, and disclosure. The Walker and Avant (2004) concept analysis model (Strategies for Theory Construction in Nursing, Pearson Prentice Hall, River, NJ, 2005) was used to guide the analysis process. The defining attributes to disclosure of information relevant to psychiatry and mental health were explored as unique aspects to analysis of the concept.

Results: The concept analysis revealed that mental health symptoms disclosure is a process that can have positive and negative implications for the individual. This dichotomy influences the time to disclosing these symptoms and is characterized by the following attributes: self-interpretation of changes in behavior and emotions, re-experiencing symptoms, vulnerability, trust, timing, fear, expectation of change.

Conclusion: The exploration of this concept highlights the differential experiences that needs to be considered when assessing individuals with mental health concerns. The approach to mental health assessment should reflect a process of non-judgmental inquiry. The subsequent implications include the need to develop approaches that protect individual and encourage an environment receptive to early disclosure of symptoms to allow for timely treatment planning.

RSC PST 1 - Research Poster Session 1

Evaluating Differences of Implementing Fall Prevention Strategies on Low and High Risk of Falling Inpatients

Yueh-Li Yu, MSN, RN, Taiwan
Shu-Yuan Lin, PhD, RN, Taiwan

Abstract

Purpose: To investigate the differences of implementing fall prevention strategies between the two groups of high and low fall risk inpatients.

Methods: This is a prospective survey study. Data collected from a convenience sample. A total of 380 inpatients were recruited from 12 medical / surgical wards in a medical center located in south Taiwan. Inpatients selected in this study were met criteria of having an age above 20 years old, admission to hospital within 3 days, and fall risk as identified by the Hendrich II scale (Fall Risk Score ≥ 5). Inpatients were excluded if they were long-term bedridden, severe/ moderate impaired without ambulation capability, and critical ill or absolutely bed rest by doctor orders. Structured questionnaires including personal demographic information, the Hendrich II scale, Peninsula Health-Fall Risk Assessment Tool (PH-FRAT), of which composed the "risk factor checklist" and "strategies for patients at risk of falling". Questionnaires and intra-hospital electronic information system were used to collect data and this survey conducted during Nov 5, 2015 to Feb 26, 2016. Totally 375 valid questionnaires were analyzed. Descriptive statistics and Chi-square test are done via SPSS 19.0 software.

Results: The mean age was 69.1 years old for all inpatients. Approximately 60% of inpatients were male, and 71% admitted to medical wards. Patient who had a score higher than 11 on the risk factor checklist of the PH-FRAT was assigned to the high risk group (23.8%). Their counterparts were assigned to the low risk group (76.2%). Six fall prevention strategies were implemented 100% for both group patients, they were "optimize environmental safety," "regular equipment and aids maintained," "obtain details of previous fall to determine any pattern," "document in nurse care plan," "place fall alert identifier in chart and nurse care plan," and "medication review in the last month". Not any patient in two groups received the following fall prevention strategies: vision or hearing tests within the last year, communication with gestures, cues and assistances from family members, referral to speech therapists, evaluation an appropriate incontinence management plan and referral to urologic or gynecological clinics. Results of Chi-square tests showed there were significant differences of eight fall prevention strategies implementing between two groups. They were: ensure the wheelchairs as safe ($p=.04$), evaluate causes of a patient's anxiety and agitated behavior ($p < .01$), referral to dietitian ($p < .01$), offer nutritional supplement ($p < .01$), monitor the heights of beds and chairs ($p < .01$), consider removal of gait aid if patient consistently used in unsafe manner ($p < .01$), and consider engagement in physical activities or other activities ($p < .05$).

Conclusion: The results showed there were differences existed on implementing fall prevention strategies between inpatients with high falling risk and low falling risk. The high risk group received more fall prevention strategies than the low risk group. Fall prevention strategies, of which had not received by any patient, deserved more concern. Eight fall prevention strategies that implemented differently between two groups needed more attention. An improvement of selecting appropriate fall prevention strategies in nurses is suggested. The results would be a reference for training nurses to consider the feasibility of fall prevention strategies in the future.

Effectiveness of Small-Bore Pigtail Catheters for Management of Spontaneous Pneumothoraxes : A Meta-Analysis

Mei-Chin Huang, BSN, RN, Taiwan

Yueh-Yen Fang, PhD, RN, Taiwan

Chih-Hsing Shen, BSN, RN, Taiwan

Hui-Chuan Chen, BSN, RN, Taiwan

Abstract

Purpose: Spontaneous pneumothorax (SP) can be a life-threatening condition. It can be primary and caused by unknown reason, or secondary from acute or chronic lung diseases. It was estimated that the SP affected over 20,000 patients and accounted \$130 million health-care costs in the United States. The primary management of SP is to remove air from the pleural space. The recommendations of SP management differ across guidelines. Though the trend tends to suggest the use of less invasive small catheters, applying a large chest tube is still common. To validate drainage methods for SP, we compared the effectiveness of a small-bore pigtail catheter with the traditional chest tube in the management of SP.

Methods: A search of studies comparing the effect of a small-bore pigtail catheter and a traditional chest tube for SP management was conducted using three Chinese databases (CEPS, the Chinese Thesis/Dissertation database, and the Chinese Journal database) and four English databases (CINAHL, Medline, PubMed, and the Cochrane Central Register of Controlled Trials). The search was up to April, 2016. Evaluations of study quality were conducted by the 2011 Oxford Centre for Evidence-Based Medicine-Levels of Evidence and the Cochrane Collaboration's tool for assessing risk of bias. Meta-analyses were performed by the random effect model. Pooled effects of drainage failure and length of hospitalization were calculated to present the effectiveness of tubing methods.

Results: Eleven studies involving 783 subjects were identified from 110 citations. Among included studies, only three studies are randomized controlled trials. All studies were unclear or high in risks of random sequence generation, allocation concealment, and blinding of participants and personnel. No difference in the risk of drainage failure was found between the pigtail method and the chest tube method (OR=.67, 95%CI=.41-1.09, $p=.10$). Among the secondary SP subjects, the length of hospital stay did not differ between two methods as well (OR=-.3, 95% CI=-.68 - -.08, $p=.12$).

Conclusion: Findings of this study support the use of small-bore pigtail catheters to manage SP. The application of small-bore pigtail catheters is suggested to promote patient compliance and comfort.

Risk Factors of Pressure Ulcer Development During Spinal Surgery

Chun-Chen Lin, MSN, RN, Taiwan
Yueh-Yen Fang, PhD, RN, Taiwan
Yi-Pei Chien, BSN, RN, Taiwan
Pei-Chun Chung, BSN, RN, Taiwan
Yi-Ping Wang, BSN, RN, Taiwan

Abstract

Purpose: Healthcare related pressure ulcer is an important quality indicator for nursing care. The cost of its treatment was estimated around 2,000 to 3,000 US dollars per patient in the United States. It may extend the length of hospitalization and cause pain and discomfort in patients. Uncontrolled infections of the ulcers may even contribute to the presence of sepsis or death. The prevalence of pressure ulcers in surgical patients is between 12 to 66%. Among these events, 25% were developed during surgery. Surgery related pressure ulcer is an unresolved problem in the operational theatre. It is common in long-hour operation. This study intended to identify risk factors related to pressure ulcer development during spinal surgery. It is expected that the identification of risk factors may contribute to the prevention of surgery related pressure ulcers.

Methods: OR records of spinal surgery between year 2012-2016 from one acute care hospital in Taiwan were reviewed. 394 patients received spinal surgery were identified. Risk factors of pressure ulcer development during surgery were retrieved, including categories of surface stress factors, blood perfusion factors, and oxygenation factors. Descriptive statistics and logistic regression were used to describe characteristics of study subjects and identify risk factors of surgery related pressure ulcers.

Results: All 394 subjects took a prone position on a pressure reducing mattress placed over a circulating water bed. The temperature of the water bed was controlled at 37°C. The range of surgical time was between .8 to 11.5 hours. Age of patients ranged from 32 to 95 years. Nine patients were found to develop intraoperative pressure ulcers with the severity from 1 to 2 degrees. The injured sites were on the front chest and cheek. Age of these patients ranged from 43 to 95 years old. The operation time was more than four hours, with an average of 6.21 hours. Risk factors of surgery related pressure ulcers identified were high BMI, hypertension, smoking history, and blood loss more than 500 cc.

Conclusion: This study had identified risk factors that contributed to development of surgery related pressure ulcers. Clinicians may manage these factors prior to or during the surgical procedure to prevent surgery related pressure ulcers.

Characteristics of Mortality Cases With Advance Care Planning Issues

Anna Dermenchyan, MSN, RN, CCRN-K, USA

Wendy Simon, MD, USA

Abstract

Purpose: The UCLA Department of Medicine (DOM) Rapid Mortality Review (RMR) is an innovative in-person, near real-time review of all deaths to capture the unique insight of the care providers into aspects of end-of-life care quality that otherwise go undocumented and unreported. The purpose of this study is to examine characteristics of mortality cases that are more likely to have advance care planning (ACP) issues identified during RMR.

Methods: This study is a primary analysis of a mortality database that is used in tracking patients who expired in the medicine wards and intensive care units from October 2012 to May 2016 at the Ronald Reagan and Santa Monica UCLA Medical Centers. The data elements were obtained through chart abstraction as well as during the RMR meetings with the primary medical team. Descriptive statistics and logistic regression was performed. The study sample is 498 patients, 299 males (60.0%) and 199 females (40.0%), with a mean age of 69.6 (range 21-105, SD 16.51). The dependent variable is the identifiable ACP issue and covariates include demographic and clinical characteristics of the sample, such as, age and length of stay, primary and secondary reason for mortality.

Results: In a sample of 498 mortality cases, issues with ACP were identified in 112 cases (22.49%).

Goals of care discussions took place at multiple outpatient and inpatient settings: outpatient (12.7%), hospital admission (50.0%), clinical deterioration (62.7%), and the day of death (18.7%). From the total sample, 131 (26.3%) were Do Not Resuscitate/Do Not Intubate (DNR/DNI) at the time of admission and 422 (84.7%) were DNR/DNI at the time of death. In addition, 352 (70.7%) were placed on comfort care with 196 (39.4%) receiving palliative care consultation.

The results of logistic regression examined characteristics of mortality cases that are more likely to have ACP issues. Strong associations were seen for female gender (OR: 1.601; 95% CI: 1.011-2.536; p=.045), longer length of stay (OR: 1.014; 95% CI: 1.003-1.025; p=.016) and primary reason for mortality infection (OR: 2.02; 95% CI: 1.144-3.567; p=.015) or acute medical (p=.04). All other variables were not significantly associated with ACP issues, including older age, transfer patient, preventability, UCLA patient with primary care physician, goals of care discussion in the outpatient setting, DNR/DNI at admission and time of death, and palliative care consult.

Conclusion: The findings of this primary data analysis demonstrate some characteristics of mortality cases that will more likely have ACP issues. Gender (being female), length of stay (longer), and primary reason for mortality (acute and infection) were all strongly associated with the cases that had ACP issues. Further study could investigate the etiology of the gender association, whether improved ACP reduces lengths of stay, and the potential benefit of more universal ACP.

Perspectives of Emergency Nurses With Overcrowding State in Taiwan

Chun-Chih Lin, PhD, RN, Taiwan

Li-Chin Chen, MSN, RN, Taiwan

Chin-Yen Han, PhD, RN, Taiwan

Chiung-Jung (Jo) Wu, DrHlthSc, MN (ICU), BN, RN, FACN, Australia

Abstract

Purpose: The purpose of this presentation is to provide an overview of emergency registered nurses' perceptions and express their work identity within an overcrowded emergency department.

Methods: A qualitative approach with symbolic interactionism was used to allow participants to express their own individual experience. Data collection was undertaken by semi-structured interviews was used to collect data between May and November, 2014 in a tertiary hospital in Taiwan. Purposeful sampling was performed and forty nurses were recruited as saturation of data reached. The interview data were analyzed by adopting grounded theory approach, including open, axial and selective coding. The credibility, transferability, dependability, and confirmability were carried out to ensure the trustworthiness throughout the data collection and analysis process.

Results: Main themes of *seeking and keeping within boundaries* were identified supporting by perceptions of being an emergency nurse as working and continually enduring within a state of overcrowded environment. . The identified themes have been supported by three categories, including *identifying herself, searching for possible solutions, and going on the situation*. The first category was further supported by *defining the role of emergency department, characterizing overcrowding and interacting work within an overcrowded environment*. The second category was reinforced by *searching for possible* within multi-factorial emergency in overcrowding, nurses' experience about their professional social behaviors. The last category was, *going on the situation*, illustrated by the consequences of nurses' work and clients' satisfactions, as well as leading to a psychosocial distress.

Conclusion: The findings fill a gap in knowledge about how emergency nurses working and searching for their work role within the overcrowded emergency state. The results informed that emergency nurses' perceptions of working in an overcrowding situation. Consequently, three strategies are recommended to support emergency nurses facing the overcrowded state, including using a bed –transferring manager position, considering to modify current government health insurance policy; and decreasing the nurses-clients ratio .

Neuropathic Pain and Related Factors in Patients After Lumbar Spine Surgery: A Prospective Study

Feng-Ling Chen, MSN, RN, Taiwan

Hsiao Fen Chang, BSN, RN, Taiwan

Su-Ying Fang, PhD, RN, Taiwan

Abstract

Purpose: Neuropathic pain exists even after receiving lumbar spine surgery. These painful conditions often reduce the quality of life and limit the activities of daily living. However, the prevalence of neuropathic pain (NP) before and after lumbar spinal surgery among patients with degenerative lumbar diseases is still unknown. The purpose of this study was to understand the prevalence, characteristics of neuropathic pain and related factors among patients receiving lumbar spine surgery. This study also aimed to identify the risk factors related to NP and compare the clinical outcomes after surgical treatment between patients with and without NP.

Methods: Prospective and observational study design as well as convenience sampling will be used in this study. Patients scheduled for lumbar spinal surgery will be recruited from neurosurgical ward in one medical center in South of Taiwan. According to the number of inpatients suffered degenerative lumbar diseases in the neurosurgical ward each year, we will recruit 200 patients in this study. Inclusion criteria are as follows: age over 18, patients with degenerative lumbar disease who are scheduled for lumbar spine surgery. Exclusion criteria are patients have another source of NP such as diabetes mellitus, herpetic zoster, traumatic injury, amputation, cancer, stroke, and AIDS. Structured questionnaire including demographic and disease questionnaire, Numerical Rating Scale, and the simplified Chinese Identification Pain Questionnaire will be given to the patients in pre-operative day 1, post-operative day 3, week 3, month 1 and month 3 to measure wound pain, neuropathic pain and related factors.

Results: This study has been approved by institutional review board of the hospital. Results in this study will help us understand the prevalence of NP among patients with lumbar spine surgery as well as identify related factors of NP.

Conclusion: This can help health care professionals to develop an appropriate intervention to strengthen future pain control for patients with lumbar surgery and thus enhance patient comfort and quality of life.

RSC PST 1 - Research Poster Session 1

Hope and Health-Related Quality of Life of Older Women Who Have Had Heart Attacks

Alice Mary Kelly-Tobin, PhD, RN, GNP-BC, USA

Abstract

Purpose: Examination of the relation of hope and HRQoL of older women with history of heart attacks. Heart disease is the number one cause of death and leading cause of disability in adults in the United States and worldwide (Centers for Disease Control and Prevention [CDC], 2013). Coronary heart disease (CHD) is the most common form of heart disease with heart attack as its acute manifestation. Health Related Quality of Life (HRQoL) is a multidimensional concept of self-perception of physical, emotional health, and overall sense of well-being (Stewart & Ware, 1992; Centers for Disease Control and Prevention [CDC], 2012). Hope, an inner process focusing on maintaining physical and mental well-being, is considered necessary for survival of chronic illnesses, such as CHD (Herth, 1993; Duggleby, et al., 2012).

This study is significant because it focused on older women who have had heart attacks and it examined the relationship between HRQoL, as multidimensional assessment of health perceptions and hope, as an inner process related to physical and mental health. The population of women over age 65 is growing and they are a vulnerable group because they are likely to live alone and in poverty. The incidence and prevalence of heart attacks is greatest among women, age 65 and older, as approximately 200,000 women die from heart attacks in the US annually (CDC, 2013). However, there are few research studies that focus upon women who have had heart attacks, their consequent perceptions on the quality of their lives or their perceived levels of hope. Healthy People 2020 and the Institute of Medicine have identified HRQoL as a focus of the US health agenda (Healthy People, 2013).

Previous studies of HRQoL have focused upon adults of all ages and gender with specific diseases such as heart disease, cancer, arthritis and diabetes mellitus type 2 (Khanna, et al., 2011; White, Wheelwright, Fitzsimmons & Johnson, 2012; Williams, et al., 2012) or adults living in long term care facilities (Kanwar, et al., 2013; Van Malderen, Mets & Gorus, 2013). There is a gap in research studies from 1990's and 2014 that focuses upon women, heart attacks and the relationship between hope and HRQoL.

Methods: Older women with history of heart attacks (N=91) volunteered for this quantitative non-experimental correlational study. Instruments: demographic questionnaire, SF12 (HRQoL), Herth Hope Index (HHI). Parameters for inclusion in the sample of 84 voluntary participants are female gender, age 65 years and older, history of a heart attack, living in community, ability to speak and read English without need of interpreter services, no diagnosis of cognitive impairment and ability to independently complete questionnaires with minimal prompting.

The HHI is a 12 question tool measured on a 4 point Likert scale in which the higher scores represent the greater level of hope. The HHI questions probe inner thoughts and feelings about outlook on life, goals and fears. Scores can range from 12 to 48, with 12 as the lowest score and 48 as the highest. One point is assigned to responses of "strongly disagree" and four points is assigned to responses of "strongly agree." Lower scores represent less hope and higher scores represent more hope.

The SF 12 is a 12 question tool measured on a 4 point Likert scale in which higher scores represent a higher level health related quality of life (HRQoL). Scores can range from 0 to 100, with 0 as the lowest score and 100 as the highest. Lower scores indicate lower health related quality of life and higher scores indicate higher health related quality of life.

Results: Marital status correlated to HHI scores, $t(90) = -2.70, p = .041$, married participants having greater mean score (40.87) compared to singles (38.39). General Health, $r(89) = .244, p = .02$; Mental Health, $r(89) = .352, p = .001$; Vitality, $r(89) = .221, p = .035$; Social Functioning, $r(89) = .333, p = .001$ and Role Emotion, $r(89) = .223, p = .034$ correlated with HHI. Marital Status, $t(89) = 2.07, p = .041$ and Mental Health, $t(88) = 3.40, p = .001$.

Conclusions : Registered nurses and advanced practice registered nurses who include evaluation of hope and HRQoL when performing comprehensive assessments of older adults will uncover health problems and unmet needs such as low vitality in women under 70, pain management in Non-White women and risk for depression. This information will serve as the bases for comprehensive plans for health and wellness.

Gaps in Palliative Care Provision in Saskatchewan, Canada: Learning From Palliative Care Management

Susan Eva Fowler-Kerry, PhD, RN, Canada

Louise Racine, PhD, RN, Canada

Abstract

Purpose: This study is part of an ongoing project to develop a working knowledge about the long-standing uneven development and delivery of palliative care in Saskatchewan, Canada; subsequently providing a foundation for continuing study and facilitating practical improvement of palliative care programs.

Methods: The results to be presented are based on the current stage of this project, the analysis of longitudinal survey data which were collected from the management personnel of palliative care in each health region in 1998, 1999 and 2002. The three surveys are composed of both close-ended and open-ended questions, therefore both quantitative and qualitative analysis are conducted

Results: The results in this study have shown that 1) the disproportion of palliative care services among health regions and between rural and urban areas have been persistent from 1998 to 2002; 2) there has been no significant improvement in terms of the undersupplied and/or understaffed services in vast majority of the health regions throughout the survey period, for example, pain/symptom management, physician and nurse support, and designated funding are the top three on the list; 3) there have been several prominent concerns regarding the palliative care system, such as, lack of palliative care training programs or clear guidance for nurses and physicians, ineffective communication between facilities as well as communities due to geographic distance, and a lack of functional collaborations within palliative care team or advisory committee. Nevertheless, the analysis is also able to identify some primary strategies adopted by the palliative care management to improve palliative care in their regions, for instance, organizing activities to enhance community involvement and public awareness, establishing an information center to collect resources from all health regions, and developing systematic networks for palliative care support with other health regions especially the resourceful metropolitan health regions. Despite the rich information obtained from the current study, some major knowledge gaps can be identified: for example, surveys were only designed to target the palliative care management personnel thus perspectives from palliative care providers, patients and their family caregivers have been largely ignored; the differences between rural/remote and urban areas especially in terms of palliative care accessibility and portability are not directly addressed; information related to culturally-diverse health practices in palliative care has been missing in all current

Conclusion: The current study provides the knowledge base and inspiration for a new study, which is not only comparable with the current longitudinal data but also able to generate critical new information which has been neglected in the current data. Upon completing this project, both the current and new study would provide practical knowledge to inform health professionals regarding the current situation and prominent issues regarding palliative care in Saskatchewan, and to allow health policy makers to develop feasible educational and service programs to enhance accessibility, portability, and cultural-safety in palliative care delivery to meet the professional and public demands.

Improving Care for the Veteran Population Through Respectful Interprofessional Collaboration: One College's Experience

Susan B. Connor, PhD, RN, USA

Paula Byrne, DNP, RN, USA

Abstract

Purpose: The purpose of this study is to determine the impact of a novel educational offering on the interprofessional knowledge and attitudes related to health care of the rural veteran. With roots back in the 1960s, the interprofessional education (IPE) movement did not become energized in the United States until 2009 when six national education associations of schools of the health professions formed the Interprofessional Education Collaborative (IPEC) followed in 2010 when the World Health Organization's (WHO) proposed a global framework for implementing IPE and collaborative practice. Yet, Bankston and Glazer (2013) and even the American Nurses Association (2013) ponder why despite concerted efforts by some institutions of higher learning and healthcare systems, many future health care providers are not educated to provide cost-effective, patient centered coordinated care as part of an integrated team. Challenged by resource shortages, many smaller colleges continue to funnel future health care students through fast-paced, highly technical, and specialty focused curricula or silos. However, as Hudson, Sanders and Pepper (2013) detailed, there is only a limited amount of evidence to help nursing educators break these silos and enrich the future practice of nursing students.

Methods: Spearheaded by the school of nursing, a modular program of study was developed based on the Interprofessional Education Collaborative (IPEC) core competencies and focused on the veteran population. In order to include different disciplines into this nursing-centric course, four free standing modules were developed that focused on ethics, roles, communication, and teamwork. This design enabled the various disciplines to schedule their students around their discipline-specific calendars, space, credit, and grading requirements. Students from The College's Health Sciences (e.g., health informatics, physical therapy, occupational therapy, and social work) attended the course as their clinical rotations allowed. In each class there was a mixture of student health care professions. Nursing was the only constant group throughout the course. Using the veteran population as exemplars throughout each module helped to generate active interprofessional classroom experiences and bridge educational silos. Each module offered didactic, group activities focused on shared interprofessional values, collaboration and evidence-based practice, complex interprofessional simulation and case studies, and guest speakers from the veteran community. Course work was patient/client centric and did not emphasize any one particular profession. Measurements of interprofessional knowledge and attitudes were used to determine the impact of the education program. Attitudes were assessed before and following each 15 week course.

Results: Ninety-eight students completed the first set of pre- and post-surveys. Preliminary findings suggest that education grounded in Benedictine values at a liberal arts college and tailored to the needs of a large rural population of veterans resulted in increased attitudes toward ethical components of teamwork and improved knowledge of and communication with various health professionals and veterans related to healthcare. The attitudes that significantly improved were related to collaboration. Attitudes related to professional ethics and values were unchanged. Course evaluations and student reflections exemplify the importance of respectful collaboration. As an unintended result, many of the health clinics where students worked added a question about uniformed service on their health history forms. Due to student feedback, enthusiasm and interest in continuing this course grew.

Conclusion: IPE and respectful collaboration is the future of healthcare. The state of the science is limited for educators interested in developing curricula to help future health care professionals collaborate with patients and their families to cut cost, improve their health experience as well as their overall health as outlined in the Triple Aim (2016). This unique educational experience will add to the literature and may inform future IPE curriculum development at smaller institutions challenged by costs, credit loads, and faculty availability.

Applying Social Network Analysis to the Spread of Moods and Emotions Among Graduate Nursing Students

Patricia M. Schmidt, PhD, RN, USA

Christine E. Kasper, PhD, RN, FAAN, USA

Patrick D. Finley, MA, USA

Greg Lambert, MS, USA

Abstract

Purpose: Turnover costs average 21 percent of an employee's annual salary in healthcare.

Organizations invest more for the turnover of specialized employees. Hospitals expend thousands of dollars annually hiring and training new staff. Healthcare workers spend a significant percentage of time at work. Heavy workloads and long hours, burn out and turnover are a continued concern. Relationships in a nursing environment are complex and highly integrated. Affect is the experience of moods and emotions, and is influenced by behavior and interactions. Affect influences performance, decision making, safety, turnover and absence, prosocial behavior, and negotiation and conflict resolution which may impact on patient outcomes. Affect contagion, the transfer of moods and emotions in groups, occurs with interaction. It's existence is well established in corporate and industry settings to influence workplace outcomes. Understanding how relationships impact affect, behaviors, and cognition can lead to a healthier work environment therefore improving patient outcomes. Workplace affect can be of critical importance. An individual's work affect is influenced by those around them. Affect contagion, the transfer of affect between individuals, is well documented. Affect transmission has been studied in healthcare. The purpose of the study was to observe and describe the spread of affect in a group of military graduate nursing students using social network analysis.

Healthcare affect contagion research has occurred on the dyadic level or as a single time point, identifying the presence of collective affect but does not account for the dynamic capabilities of affect to evolve and change. Using social network methodologies to examine affect contagion provides a conduit to understand affect contagion as an environmental phenomenon. Social network analysis (SNA) identifies important individuals, channels of affect flow, the dynamics behind positive and negative self-reinforcement, and the impact of network topologies on the effectiveness of affect-oriented interventions.

Methods: The Kelly and Barsade middle range theory of moods and emotions in small groups and work teams was used to develop the design of the study, find valid measurement tools, and conduct analysis. There were 35 participants from a closed network of 60 advanced practice nursing students. Social network surveys established relationships among the participants. Student's affect was surveyed twice daily 14 times over the course of a semester to measure changes in affect. Affect expressivity and susceptibility to the affect of others was measured. This study utilized social network analysis and linear statistics to identify and visualize relationships among graduate nursing students during an academic semester. The relationships were correlated with the affect of participants to determine the impact of individual moods and emotions on those with whom they interact.

Results: Using assortative mixing calculations, affect among participants was correlated with their identified "friends" at four time points and affect similarity was correlated with academic specialty program and the amount of time spent with classmates. Stimulus exposure on three data collection days changed the affect of exposed participants. The students exposed to the stimuli demonstrated a change in affect, and assortativity correlation demonstrated similar affect. Environmental events occurring during the semester were identified and associated with changes in affect among the participants. Affect contagion occurs in advanced practice nursing student networks and affect influencing stimuli have the potential to influence the exposed individual.

Conclusion: The moods and emotions of nurses are impacted by the events of the day and those whom they spend much of their time. Developing environments that support and facilitate high positive affect and low negative affect of nursing staff should improve the quality of patient care. Utilizing advanced statistical methods, like social network analysis, promotes comprehensive quantification of the relationship that exists among group members. An understanding of the behaviors exhibited by group members related their affective state may facilitate development of methods to decrease negative affect and increase positive affect as a means to promote a healthy productive environment.

Health-Related Quality of Life and Treatment Outcomes for Individuals With ESRD Treated By Hemodialysis

Chiung-Yu Huang, PhD, MSN, RN, Taiwan

Hui-Ling Lai, PhD, MS, MSN, RN, Taiwan

Chun-I Chen, PhD, Taiwan

Abstract

Purpose: This research investigated risk factors and support style on health-related quality of life (HrQoL) and depressive symptoms (DSs) in adults with end-stage disease (ESRD). Previous studies focused on the psychosocial correlations studies or the presence of DSs but not on the specific causal antecedents that lead to DSs or HrQoL.

Methods: A descriptive, correlational design was used to examine related factors and social support on health outcomes. This study was conducted at the dialysis center in a general hospital. A convenience sample of 178 adults with ESRD aged 20 or above was recruited. Data were collected by a self-reported questionnaire and physiological examination. Using the structural equation modeling technique analyzed all relationships among factors, mediators, and health outcomes.

Results: The average age of the participants was 62.9 years (± 11.5), the mean time since dialysis was about 57 months (± 40.2), and most were males. Over 70% individuals with ESRD have sleep disturbances. The results revealed younger, more education, lower pain, more appraisal support, and better sleep quality of individuals with ESRD are more likely have better physical quality of life and lower depressive symptoms. All four types of social support (emotional support, appraisal support, informational support, and tangible support) were negatively correlated with depressive symptoms. Moreover, sleep disturbances are negatively related to both physical and mental quality of life. The best fitted SEM model included individual demographics and disease characteristics, and social support as significant predictors on depressive symptoms, with social support acting as a mediator in this relationship. Subjects' characteristics and social support both contributed substantial indirect effects on depressive symptoms and physical and mental related quality of life.

Conclusion: Identifying risk factors and the mediators of support are an integral part of disease management. This integrated model provides a whole understanding of how factors and mediating effects of support influence HrQoL and DSs in individuals with ESRD. If people with ESRD perceived themselves with more support, they were more likely to report less depressive symptoms and better physical quality of life.

RSC PST 1 - Research Poster Session 1

A Frontline Approach to Investigating Nurses' Handover: A Focus on Content and Structure

Verna A. Sitzer, PhD, RN, CNS, USA

Rhea A. Eusebio, BSN, RN, CMSRN, CBN, USA

Julianna M. Timmerman, BSN, RN, CMSRN, USA

Karen Reavis, PhD, RN, ANP-BC, USA

Lynn E. Marder, MSN, RN, CNS, CCNS, PCCN, USA

Abstract

Purpose: The aims of these multi-phased studies was to describe the content of nurses' handwritten patient notes used during change of shift report, design an electronic medical record (EMR) generated handover tool and evaluate the impact of a handover structure.

Background: Miscommunication is a frequent root cause in safety errors particularly during handovers (World Health Organization, 2007). Nurses play an essential role in the transfer of patient information among and between providers and particularly at the change of shift. A standardized structure has been recommended to improve handover communication and patient safety (Agency for Healthcare Research and Quality, 2012). Electronic solutions (templates and summary screens) have been shown to be insufficient requiring handwritten notes. However, information technology such as electronic medical records can be leveraged to support the handover process and effectiveness (Smeulders, Lucas, & Vermeulen, 2014; Staggers & Blaz, 2012)).

Methods: Born from an organizational Delphi study to identify nursing research priorities in a Southern California non-profit community hospital, novice investigators learned the research process to conduct multi-phased, IRB-approved research studies on a top priority result – patient safety at change of shift. Delphi qualitative results together with organizational quality report data were used to refine the research focus. Following an extensive literature review, the research team, comprised of frontline clinical nurses and research mentors, determined a multi-phase approach was needed to fully investigate the clinical issue. The first phase (Phase 1) was a descriptive, cross-sectional design using a convenience sample of bedside nurses who voluntarily submitted their patient assignment notes (aka report sheets) for content analysis. The second phase (Phase 2) was a quasi-experimental design using a convenience sample of bedside nurses working in the intervention and the control unit. The intervention was a newly developed and EMR-generated handover tool. Development of this tool was based on Phase 1 content analysis findings. The handover tool was generated from the EMR and included pre-populated patient information as well as “white space” for customized handwritten notes. Intervention unit nurses agreed to use the EMR-generated handover tool during the study period. Satisfaction with the handover tool and process was measured pre and post implementation of the handover tool in the intervention and control units using an investigator-developed satisfaction survey. The survey included 9 items on the handover tool and handover process with a 5-point Likert-like response set ranging from strongly agree to strongly disagree. Additionally, feedback was obtained from the intervention unit on the handover tool content and structure. Basic quantitative and qualitative methods were used to analyze Phase 1 and Phase 2 data. The third phase and final study is in progress which is an interrupted time-series design to evaluate the impact of a structured nursing handover process at change of shift on patient safety outcomes and is mentioned to illustrate the complexity of the clinical issue and the investigative strategy.

Results: Phase 1. Findings from the Phase 1 study yielded patterns from clinical nurses on what was handwritten in their patient notes or report sheets. A convenience sample of 103 RNs from 11 patient care units submitted their report sheets over a 24-hour period. There were 26 different report sheets submitted customized with more than one color or type of writing implement (41%), emphasis markings (87%), and symbols (100%). The majority of content included in the report sheets consisted of: patient identifiers (i.e., name 99%, room 85%) physician names (99%), diagnosis (84%), systems review (78% - 92%), and task reminders (99%). Isolation status (48%), fall risk (38%), hospital-acquired pressure ulcer risk (8%), other risks (20%), and vaccination status (12%) had low percentages of handwritten presence on report sheets. These finding were congruent with subsequent analyses of 29 matched handover sheets (same patient, different RNs) where percent agreement between content were highest with patient identifiers (i.e., name 87%, account number 70%) and lowest with safety and risk information (i.e., fall risk 27%, pressure ulcer risk 17%, vaccination status 0%).

Phase 2. A convenience sample of 138 RNs assigned to either an intervention unit or a control unit participated in the study. Satisfaction: Although perceptions improved for all nine items on the handover satisfaction survey, the Mann-Whitney U test found no statistically significant difference in satisfaction levels within and between the intervention unit and control unit, pre (n=79) and post (n=59) implementation of the EMR-generated handover tool. Handover Tool Feedback: Content analysis of feedback obtained from nurses (n=28) in the intervention unit revealed themes related to content, structure and context. Nurses had positive comments on prepopulated information including patient identification, allergies, provider names, reason for visit, vital signs, last bowel movement and labs. The ability to trend patient data such as vital signs and labs were recommended. Added sections for plan of care priorities and pre-identified tasks were not seen as useful. Numerous recommendations were provided for font size, flow, and space allocation for certain sections and white space. Comments often referred to previous report sheet formats. One example was to add the anatomical figure and the lab values diagram. Suggestions to add patient population specific information were also provided.

Conclusion: What is handwritten on report sheets can be interpreted as important to nurses in the care of patients and communication at shift change. Phase 1 analysis revealed report sheets and content were neither standardized across the organization nor within a unit. Content and structure favored the medical model. Although rich in patient specific medical and nursing care task information, notes often lacked common safety or risk related information. This finding may indicate a discrepancy between organizational and bedside nurse priorities for patient care. The sample of report sheets submitted show handwritten symbols, emphasis markings, tasks and activities which may indicate the sheets are used as a mnemonic device. This supports previous research on the need for nurses to interact with, and modify their report sheets (Hardey, Payne, & Coleman, 2000). While Phase 2 analysis had insignificant findings in nurses' satisfaction with the EMR-generated handover tool and process, perceptions on the survey items improved after using the tool and rich qualitative information was provided. The positive feedback on the EMR-generated, printable, pre-populated report sheet and designated white space supports previous research on the need for report sheets to be adaptable and contextual (Staggers & Blaz, 2012). A standardized handover tool and a structured process have been recommended to improve handover communication. In order to standardize to one handover tool, it was important to determine what nurses write about on their report sheets. The patterns can then be used to design a user-friendly handover tool that meets nurses' needs for accurate and up-to-date information, personalization and portability (Hardey, Payne, & Coleman, 2000). The results of these multi-phased studies assist the investigators in further improving the handover content and structure. A modification to the EMR-generated tool will facilitate the goal of standardizing handover content and structure to improve nurses' satisfaction and more importantly, communication and patient safety. In a technologic age, a handover tool can be generated from the EMR and contain the information that nurses want as well as critical information to influence and promote transparency, quality and patient safety.

Effects of Lower Extremity Strength Training on Physical Recovery in Patients Underwent Total Knee Replacement

Yu-Hua Lin, PhD, RN, Taiwan

Su-Ying Lee, MSN, RN, Taiwan

Chia-Chan Kao, PhD, RN, Taiwan

Abstract

Purpose: Patients with knee of osteoarthritis (OA) after surgery had experienced physical function decrease and impact their quality of life. However, they always lack a long-term, home-style, and continuous legs exercise training methods, and rare study to explore the effects on physical recovery and quality of life after exercise training. The purpose of this study was to examine the effects of lower extremity muscle strength training on patients' physical recovery and quality of live underwent total knee replacement.

Methods: The quasi-experimental design was conducted, and using a simple randomize sampling (as patients admission priority order) to collect participants' data. Eligible sample recruited from a hospital in Tainan. Inclusion criteria were above 20 old, and will be received total knee replacement (TKR). Outcome measurements included the Knee injury and osteoarthritis outcome score (KOOS, including pain, symptoms, active daily life [ADL], sport & recreation, and quality of life five subscales), disease related variables, and personal demographics. Participants were distributed into with a lower extremity muscle strength training and the training started before surgery (experimental group, n=100) or with usual care (control group, n=100). The lower extremity strength training was conducted by a nurse practitioner. We examined outcome indicators before surgery (T1) and follow up at two weeks (T2), one month (T3), two months (T4), and three months (T5) after TKR.

Results: The KOOS subscales scores showed that all the two groups' patients experienced physical function (ADL and sport & recreation) and quality of life decreased at the two weeks after received TKR, but all the subscales scores gradually increased from one month to third months after TKR ($p < .001$). The generalized estimating equation (GEE) tests showed that both group and time were significantly different, indicated that both group patients experienced physical function and quality of life improvement, however, the exercise group physical function and quality of life was early recovery and better than no exercise group physical function and quality of life after TKR.

Conclusion: The study confirmed that after lower extremity muscle strength training exercise helps to improve the quality of life and physical function recovery in patients who undergone TKR. This results recommend for the healthcare staff embed this training into pre-surgical nursing care and patients' discharge plan in care of TKR patient as a continuous daily rehabilitation activity at home.

Right Time in Medication Administration: A Multifaceted Concept

Juliana J. Brixey, PhD, MPH, MSN, RN, USA

William Scott Erdley, DNS, RN, CHSE, USA

Abstract

Purpose: The medication administration process is a five-step procedure entailing prescribing, transcribing, dispensing, administering, and monitoring. Medication administration involves giving a pharmacological agent, such as a drug, to a patient or client. Within medication administration the patient expects the right medication, in the right dose, to be at the right time, and by the right route. 'Right time', which is clearly identified as an important component of the medication administration process, should therefore be clearly defined as well achievable. 'Right time' also implies a measurable period of time. The literature does not clearly define 'right time' instead defining through linking to, for example, a prescribing provider's order or the most recent administration. The purpose of this study was to review the literature to determine themes, trends, and definitions of 'right time' of medication administration.

Methods: A retrospective review of the literature was conducted to identify themes and trends of 'right time' of medication administration.

Results: A specific definition of 'right time' was not readily discovered in the literature. The following trends were identified from the literature. For example, 'right time' is coupled with an exact time such as an hour for administration (e.g., at 0600). Moreover, 'right time' is intimately related to frequency. For example, twice a day at 0900 and 1700. 'Right time' may also be coupled with a range in hours. For instance, every two hours or every six hours. What is more, 'Right time' can be extended to a seasonal event. For example, the 'right time' to receive the flu vaccine during the flu season. Right time is teamed with vital signs. For example, administer acetaminophen every 6 hours as needed for temperature greater than 100 degree F. 'Right time' is also coupled with laboratory values. Administer Warfarin 5 mg for INR < 1.5. Additionally 'right time' is frequently denoted with a specific parameter such as with food or without food. These attributes should ultimately be based on drug action, distribution, absorption, metabolism, and excretion.

Conclusion: A definition for 'right time' medication administration needs to be explicitly stated. This research study indicates 'right time' is a multifaceted concept without a clear and precise definition. This research begins development of a taxonomy of 'right time' drug administration.

Outcomes of Study on Quality Life and Perception of Dyspnea: Patients With Advanced Lung Cancer

Barbara A. Roces, PhD, NP, RN, USA

Abstract

Purpose: This study was proposed to help fill the gap in knowledge regarding quality of life and dyspnea perception in the advanced lung cancer population. The overall purpose of this study was to examine the relationship between quality of life and perception of dyspnea in a group of advanced lung cancer patients.

Methods: This was a descriptive correlational, cross-sectional study. Quality of life was measured using The Assessment of Quality of life at the End of Life (AQEL). Perception of dyspnea was measured using the Cancer Dyspnea Scale (CDS). The participants were 22 patients in a hospice care setting diagnosed with advanced lung cancer that reported dyspnea.

Results: The aims of this proposed study were formulated to address the research questions of whether relationships existed between relevant demographic variables, the subscales component of AQEL and CDS, and the total score for both the Assessment of Quality of Life at the End of Life and the Cancer Dyspnea Scale. The findings supported the literature review suggestions that there was indeed relationship between the subscales, AQEL, and CDS measurement total scores. In the sample of advanced lung cancer patients in the hospice care setting, results revealed the AQEL subscales (basic function, activity, cognitive function and perception of care) had a significant correlation to the AQEL total score. In addition, the physical symptoms (pain and bowel movement) indicated a strong inverse relationship to the AQEL total score. As indicated by prior research, analysis revealed the CDS subscales (discomfort, anxiety, and sense of effort) had a strong significant relationship to the CDS total score. Furthermore, it is important to note that the result geared toward the second aim of this research study, indicated no significant relationships between the participants demographics, AQEL total score, and CDS total score.

Conclusion: Precipitants of dyspnea included both physical and emotional sensations triggered by immediate reactions connected to participants' experience of dyspnea perception amongst advanced lung cancer patients in the hospice setting. Therefore, The need to explore numerous interventions in lung cancer and dyspnea is imperative. It is vital that the healthcare team work therapeutically with patients and family to help them live better with illness and its manifestations.

Travel Motivation and Influencing Factors of Travel Decision Making in Hemodialysis Patients

Wan-Chen Lo, MSN, RN, Taiwan

Abstract

Background: Hemodialysis patients suffered physical and psychological stress come from chronic disease. Patients may experience troubling symptoms, such as fistula puncture related pain, nausea, vomit, fatigue, diet and fluid restriction, time constrained of dialysis. Studies showed that leisure activities can relief stress, anxiety, depression, and improve patient's health. Traveling is one of the leisure activities. However, previous studies focused on obstacles and related factors about traveling in dialysis patients, seldom explored travel motivation and factors influencing travel decision making.

Purpose: 1. To explore the travel motivation and factors influencing travel decision making in dialysis patients.

2. To analyze the relationship between demographic characteristics, travel motivation, and travel decision making in dialysis patients.

Methods: A cross-sectional study and recruited dialysis patients by purposive sampling. Participants were aged 20 and above, conscious clear, able to communicate and willing to join study. Questionnaire was self-designed by referencing literature, include travel motivation and factors influencing decision making dimensions. Total 27 items and calculated by 5-point Likert scale, higher scores mean higher travel motivation and more important influencing factor of travel decision making. Content validity index were 0.95 and 0.90, Cronbach's α were 0.875 and 0.825 respectively.

Results: One hundred dialysis patients were recruited, most of them were 41~60 year-old (46%) followed by over 60 year-old (41%), male and married. Dialysis years in average was less than 5 years (65%). At travel motivation, relaxation (4.00 ± 1.19), maintain physical and mental health (3.91 ± 1.01), and experience local natural environment (3.90 ± 1.25) were the major motivations. In terms of travel decision making, the influencing factors were dialysis schedule (3.97 ± 1.26), tourist destination image (3.83 ± 1.18) and travel motivation (3.60 ± 1.10) in sequence. The relationship between demographic data and travel motivation was no significant, but younger patients tend to have higher travel motivation. On the travel decision making, there was significant relationship between age and travel decision making. Younger patients believed the importance of traveling and most of factors influenced the travel decision making.

Conclusion: Study results revealed that relaxing, maintaining health and experiencing local natural landscape were the major motivation to travel. Those travel decision making would be influenced by dialysis schedule. Younger patients have higher travel motivation and deem travel was very important. As a clinical nurse, feasible dialysis schedule will help and promote patients to arrange travel activities. Though older patients have lower motivation, we should encourage them and join the travel activities.

RSC PST 1 - Research Poster Session 1

An Early Rehabilitation Intervention for Enhancing Oxygenation and Recovery From Lung Cancer Surgery

Tsae-Jyy Wang, PhD, ARNP, RN, Taiwan

Wei-Ling Hsiao, MSN, NP, RN, Taiwan

Abstract

Purpose: The purpose of this study is to test the effects of an early rehabilitation intervention on oxygenation, postoperative complications, and recovery from lung cancer surgery.

Methods: The study uses an experimental design. Ninety patients scheduled for lung cancer surgeries was recruited from thoracic surgery units of a medical center in Taiwan. Patients were randomly assigned to the intervention or the control group. The intervention includes a 5-day preoperative home-based rehabilitation and a 5-day postoperative in-hospital rehabilitation. The main components of the rehabilitation were aerobic and strength exercises as well as breathing training by using an incentive spirometry. Peripheral capillary oxygen saturation (SpO₂) was measured in the morning of the preoperative day and of the 4 consecutive days from postoperative day one to four by using the Nellcor™ OxiMax N-65 Portable Pulse Oximeter. The SpO₂/FiO₂ (S/F) ratio was then calculated to assess patients' oxygenation. Data on postoperative pulmonary complications and durations of chest tube drainage were collected from the patients' charts.

Results: The patients' demographics and baseline measures were equivalent between groups. Results of GEE showed a significant group by time interaction effect on S/F ratio. As for the parameter estimates, from postoperative day 1 to day 4, the S/F ratio improvement in the intervention group was 74.49 (Wald $X^2 = 46.42$, $p < 0.001$) more than in the control group. Result of Chi-square test showed that the number of postoperative lung complications in the intervention group ($n = 1$) was significantly less ($X^2 = 8.39$, $p = 0.004$) than it in the control group ($n = 10$). Result of t- test showed that the duration of chest tube drainage in the intervention group (2.00 ± 1.00 days) was significantly shorter ($t = -2.32$, $p = 0.022$) than it in the control group (2.56 ± 1.25 days).

Conclusion: The study results support the effects of the early rehabilitation intervention on enhancing oxygenation, preventing complications, and promoting recovery from lung cancer surgery as indicated by shortened the duration of chest tube drainage. Surgery to remove the cancer is one of the primary treatment options for non-small cell lung cancer. However, lung cancer surgery may result in decreasing lung capacity and expansion; therefore, increase risks for postoperative pulmonary complications. Pulmonary rehabilitation designed to enhance lung expansion and ventilation may help to reduce postoperative lung complications and promote patients' recovery from lung cancer surgery.

The Important Factors to Improve Nurse's Self-Confidence in Utilizing of Nursing Information Systems (SIMKEP)

Dewi Sartika Asril, MKep, NS, Indonesia

Tutik Sri Haryati, SKp, MARS, Indonesia

Abstract

Purpose: A phenomenology study was carried out to explore nurse's experience about self-efficacy in utilizing nursing information system (SIMKEP) in Bunda Mother and Child Hospital Jakarta, Indonesia, included response, self-confidence, adaptability, factors, barriers, and expectations.

Methods: The method of data collection was the in-depth interview to ten nurses who utilizing SIMKEP in Bunda Mother and Child Hospital Jakarta. Participant recruitment process carried out through cooperation with the Manager of Nursing and Head Nurses in each room. The method used in this research was in-depth interview which was conducted for about 30-45 minutes at the participants. The central question posed in-depth interview were with open-ended question. This question topic was developed based on the dimensions of self-efficacy included magnitude, strength, and Generally. The main tool for collecting data in this study was researchers themselves. The tool used for data collection was a voice recorder to record the verbal expression of participants and handy camcorder to record the participants' nonverbal expression, which was used by permission of the participants. Other tool used was field notes or field notes to help researchers gain an overview of all the events during the process the interview took place. Each completed in-depth interviews with participants, researchers directly create documentation through verbatim transcript and field notes. Furthermore, researchers conducted a data analysis by using Colaizzi. The validity of research data was conducted by credibility, confirmability, transferability and dependability.

Results: The study found theme about the factors that improve the nurse's self-confidence in utilizing SIMKEP, covering the factors of the nurses, the factor of co-workers. About reward can improve the self-confidence of nurses in utilizing SIMKEP. The newly found in this study were the emergence of self-confidence in utilizing SIMKEP, shape constraints of co-workers, and expectations about reward can improve the self-confidence of nurses in utilizing SIMKEP.

Conclusion: Recommended to the nurses to improve their self-confidence by increasing the interest to the SIMKEP, learning SIMKEP, often using SIMKEP, and training with co-workers. To the nurse manager is expected to optimize the role and management functions for improving the self-confidence of nurses in utilizing SIMKEP by granting rewards.

Life Meaning in Patients Diagnosed With End-Stage Liver Cancer: An Interpretive Phenomenological Approach

Dinah Hernandez, MSN/Ed, RN, PHN, CRN, USA

Abstract

Purpose: The purpose is to present a synthesized review of the literature regarding the occurrence of existential needs for meaning and purpose in end stage liver cancer patients.

Methods: Meaning in life, liver cancer, cancer, end of life, palliative, hospice were key words used to search for the English research articles in CINAHL, EBSCOHost, Medline, and Medscape. Ninety peer-reviewed publications of cancer patients with respect to life's meaning were found, none in end stage liver cancer patients. Based from the inclusion and exclusion criteria, forty-seven studies were eliminated in the search. The remaining forty-three peer-reviewed articles were included in the synthesis that met the inclusion criteria: cancer patients that are terminally diagnosed who are seeking purpose and meaning in life.

Phenomenology brings to the fore the perceptions of human persons regarding essential truths that are grounded in the lived experience. Interpretive Phenomenology allows for the description of the phenomena surrounding human existence and facilitates the understanding of persons' internally experienced and processed meaning. The focus is not on the objective measures but on the uniqueness of one's experience and its corresponding meaning or meanings. The French Existentialist Gabriel Marcel (1189-1973) envisions the human person as *homo viator*, one who is on a journey, a traveler, a pilgrim. Life is a kind of pilgrimage that goes beyond the present world and ultimately leads to God. This is transcendence. As a philosopher of transcendence, Marcel professes that the intrinsic value of the human life is a gift of God that is meant to be shared with others. The human person thus, makes a personal choice for an intimate communion with God and for the genuine dialogue with others in an inter-human relationship. While the human is very much present in the world, he/she recognizes the reality of something more than what this world and life can offer. Death is not the end. Authentic existence here on earth gives human person hope, a bridge to go beyond a deeper and fuller intimacy in the afterlife with the Divinity. But at the same time the human person is not on a journey alone. For Marcel, to exist is to co-exist. Existence thus means presence for others and for the Other. He/she is a *being-in-the-world- with others*, totally engaged in an actual and conscious communion with Being (God) and with other human beings through love, hope, fidelity, and availability.

Jean Watson's Caring Science exemplifies the act of caring in an interpersonal way, stands for values that honor and respect human capacity, preserving human dignity, spirituality, and wholeness in the midst of threats and crises of life and death. All of which transcend illness, diagnosis, condition, setting that were, and remain enduring and timeless across time and space, and changes in systems, society, civilization, and science.

- One of the basic assumptions of Jean Watson's Caring Science is the intersubjective human-to-human process that teaches the individual to be human by identifying oneself with others, whereby the humanity of one is reflected in the other.
- The caring moment becomes transpersonal when two persons (nurse and other/patient) together with their unique life stories and phenomenal field (perception) become a focal point in time, from which the moment has a field of its own that is greater than the occasion.
- This conveys a concern for the inner world and subjective meaning of another who is fully embodied and goes beyond the ego self and the given moment, thereby reaching to the deeper connections of the spirit and the broader universe.
- It also implies the uniqueness of self and others, of the moment and the coming together as mutual and reciprocal, each fully embodied and capable of transcending the moment and being open to new possibilities.
- Nurses participate in the patient's realm of experience in finding meaning and purpose, in a way that the patient and nurse are "in tune" with each other and are aware of the uniqueness of each other.

Significance

Patient care necessitates not only the knowledge of the medical condition but one must be able to look beyond the patient's diagnosis, see the person as a whole, and understand the meaning that the

experience holds for him/her. The search for meaning in life can contribute to the development of meaning-based interventions in the context of cancer. The knowledge generated can be used in the planning of holistic care services; and this may increase the awareness among healthcare professionals in honoring the remaining precious moments of dying patients by respecting their humanity, preserving dignity, ensuring comfort, and advocating optimum palliative care. Such knowledge may empower healthcare providers to assist individuals that are approaching death and their families to do so in a way that is meaningful rather than simply tolerable. Nurses and other healthcare providers may assist patients for necessary referrals to counselors and chaplains who could provide strength and comfort during life's final stages.

Results: Meaning in life is a multi-dimensional concept involving the value and purpose of life, and the motivation to find both. It is a matter of living authentically, that is, with a certain quality, depth, abundance, and intensity thus, making life worth living. The way a person becomes aware of the changed circumstances of his/her life, as being diagnosed with liver cancer for instance, and how he/she deals with this awareness is decisive for the way the individual continues to live. Hope has been found to be a dominant component when terminally ill patients describe their lived experience. A higher sense of meaning has been associated with greater social, psychological, emotional adjustments, and has exhibited to have a positive impact on the quality of life of these patients. Existential meaning-focused interventions have also shown to effectively improve well-being. A successful search for meaning may contribute to one's ability to cope with suffering. Regardless of the coping mechanism, patients attempt to find meaning, inner peace, and hope during the uncertainty inherent to the fight against cancer.

Implication

Understanding how individuals attach meaning to their experience would enable the nurses to help patients adjust to difficult situations such as approaching death in liver cancer patients. Research findings can contribute to the identification of concepts and subsequent development of quantitative tool to measure identified constructs in patients with same illness and prognosis and profile. The results can aid in future clinical research related to the meaning in life and the predictive factors in patients with cancer. Findings of this type of research can be used to develop continuing education programs for nurses and healthcare providers related to the meaning in life.

Conclusion: Life's meaning is a multi-dimensional concept associated with greater social, psychological, and emotional adjustments that relate to the quality, depth, abundance, and intensity of life. Hence, the best supportive care for end-stage liver cancer patients should include efforts to assist them in search for meaning.

Considering the meaning in life for the dying patients as the essence of this research and intuiting that the end stage liver cancer patients would in general be affirming the value of hope and the greater purpose in continuing to live despite inevitability of death, Marcel's existential phenomenological approach is a fitting philosophical framework that can dialogue with Jean Watson's nursing framework in caring for the dying.

A Holistic Wellness Program for Low-Income Women: A Pilot Study

Debra Henline Sullivan, PhD, MSN, RN, CNE, COI, USA

Deborah Weatherspoon, PhD, MSN, RN, CRNA, COI, USA

Abstract

Purpose: It is well documented that the health of women in the United States (US) is declining primarily due to the high rates of obesity and sedentary lifestyle. In 2014, 66.2% of women in the US were overweight or obese and 38.1 obese (Center for Disease Prevention and Control [CDC], 2015b). These women are also inactive, with only 50% of the population participating in leisure-time and muscle-strengthening activities. Obesity and inactivity are known causes for chronic disease and premature death (Booth, Roberts, & Laye, 2012). Another complication is that low-income women are less likely to have resources to combat obesity and inactivity consequently; we see high rates of obesity in the population (CDC, 2015b).

The state of Tennessee (TN) ranks as the ninth highest adult obesity rate in the nation with 32% of women falling in the obesity range in 2012 (Segal, Rayburn, & Martin, 2016). Adult Blacks rank the highest in TN with 43% of the population, making it 4th in the nation. Latinos were 27.6% ranking 40th in the nation and whites were 31.5% and 7th in the nation (Segal et al., 2016). Higher rates of overweight and obesity are correlated with low-income adults in TN (Tennessee Department of Health, 2010) Due to this serious health problem in TN, a holistic health program was developed to offer low-income women the opportunity to receive lifestyle coaching. Coaching in nutrition, exercise, and empowerment are offered through a scholarship program. Each year 350 women receive these scholarships. A holistic wellness program has produced excellent results with positive health outcomes, and offers a wealth of information for further study. Participants have decreased diabetic and high blood pressure medications, controlled eating, and increased overall health and vitality (The New Beginnings Center, n.d.).

The purpose of this poster is to outline a pilot study to look at the progress of this unique program to determine if positive health outcomes of the program could be applied to a larger community population, which could be managed by nurses.

Methods: A pilot study is designed to research the correlations in participant outcomes.

Results: Results are not complete as of this date.

Conclusion: Conclusions have not been drawn as of this date.

Clinical Alert System to Reduce Hospital Unexpected Cardiac Arrest Event

Chi-Hsuan Asphodel Yang, PhD, RN, Taiwan

Lee-Ling Huang, MSN, RN, Taiwan

Abstract

Purpose: The purpose of the paper was to determine whether clinical alert system led by nurses prompted by clinical instability in a patient could reduce the incidence of unexpected cardiac arrest in hospital.

Methods: A retrospective analysis of data extracted from medical records was performed to compare the incidence of UAC before and after the implantation of the CAS. The study was conducted at a 350-bed teaching hospital in central Taiwan area. Medical records of all adult patients admitted to the non-ICU wards of the hospital from January 1, 2010 to December 31, 2015 were reviewed. Patients who had signed do-not resuscitate order were excluded. We measure the incidence of unexpected cardiac arrests that occurred outside of the intensive care unit and occurred over the study period.

Results: There were 557 CAS calls during the study period. In the 36 months before the CAS began, the overall unexpected cardiac arrest was 0.020% per month. In the subsequent 36 months, that UAC rate was 0.021% per month. A slightly increase of UAC incidence was noted. A Bai-Perron method was used to test if there was any structure break appeared in the UAC rate of the 72 months. The analysis of Bai-Perron method identified the structural break date to be the 4th month of 2015 ($F = 26.1732, p < .01$), that after April 2015, the trend of UCA rate was shifted to a lower rate. In addition, the result of a order logistic regression showed three possible determinants of clinical outcomes after CAS; they were comorbidity ≥ 4 ($p = .0054$); presentation of neurological sign and symptom ($p = .0000$) and presentation of cardio-pulmonary sign and symptom ($p = .0000$).

Conclusion: While it may take up to 16 months to see the positive effect, the deployment of a clinical alert system may help in early recognition and response to patients' deterioration to further *prevent UCA*. Nurses should familiarize with the important clinical alerting sign and symptoms of patients; so that nurse could initiate early response to patients' deterioration and could further help *prevent UCA*.

Status of Foot Care for Chronic Dialysis Patients and Issues With Implementation

Sachiko Tamura, PhD, RN, Japan

Abstract

Purpose: We are developing a foot care that will prevent foot lesions for chronic dialysis patients. As the first step, we conducted a survey of the actual conditions in order to grasp the status and issues with implementation.

Methods: Head nurses at all dialysis facilities in one prefecture were posted question sheets we prepared, which were later collected.

Results: Responses for these question sheets were obtained from 33 of the 40 facilities targeted. Foot care was carried out on all dialysis patients at 46% of the facilities. The implementation period was during dialysis for 76% of the facilities, while a foot care checklist was used at 70% of the facilities. The most common types of care were observation of the foot and walking (91%), provision of knowledge of foot diseases and assessment of lifestyle (65%), instruction for how to care for one's own feet and the application of ointment (61%), cutting and filing toenails (52%), and foot baths (48%). Issues with the implementation of foot care included problems with ensuring enough time (86%), lack of knowledge and skills for foot care (73%), lack of a proper environment for foot care (50%), and the burden of recording in checklists, etc. (47%).

Conclusion: There is a high level of interest in foot care among dialysis nurses. In many facilities, a foot check chart is used alongside observation and care, but in terms of preventing foot lesions, there are issues with a lack of assessment and implementation of care, and in support for self-care. In order to prevent foot lesions in patients undergoing chronic dialysis, it is necessary to further enhance assessment and care, and it is very important to use a simple yet effective checklist to that end. Recording in checklists and so on needs to be improved to allow it to be done on a daily basis without it causing a burden.

Using a Bundle Prophylactic Approach in Post-Operative Total Knee and Hip Arthroplasty

Haofei Wang, DNP, RN, NEA-BC, USA

Patrick G. Ryan, MS, RN, CNS, ANP, CCRN, USA

Abstract

Background: Evidence is limited on which prophylactic intervention(s) to prevent post-operative VTE is/are optimal or suboptimal in TKA and THA population.

Objectives: To examine the different types of prophylactic interventions (pharmacological and mechanical), patient age and BMI, bleeding tendency and renal function, and type of surgeries (TKA and THA) in relation to VTE incidence.

Purpose: Deep vein thrombosis (DVT) is a blood clot that occurs in a deep vein of the body; pulmonary embolism (PE) occurs when a clot breaks free and enters the arteries of the lungs (CDC, 2015). Both DVT and PE comprise venous thromboembolism (VTE), which is a serious condition associated with prolonged duration of hospitalization and mortality. Each year in the United States, an estimated 350,000-900,000 people develop incident VTE, of whom approximately 100,000 die (CDC, 2014). Patients who undergo major orthopedic surgeries such as total hip arthroplasty or total knee arthroplasty are at the highest risk for postoperative VTE due to coagulation activation from tissue and bone injury, venous injury, reduced venous emptying intra-or post-surgery, and prolong immobilization (Florescu et al., 2013). The incidence of DVT varies from 42% to 57% after hip arthroplasty and from 41% to 85% after knee arthroplasty; the incidence of PE varies from 0.9% to 28% after hip arthroplasty and from 1.5% to 10% after arthroplasty (Januel et al., 2012). **Methods** of VTE prophylaxis include mechanical interventions such as compression stockings, compression device, or ambulation, and pharmacological intervention such as oral or subcutaneous anticoagulation agents. The purpose of this study is to look at the rates of VTE between those that received mechanical intervention only, pharmacological intervention only and those that received both mechanical and pharmacological interventions in the post-operative total hip and total knee arthroplasty patients.

Methods: A retrospective chart review study on a total of 135 adult patients underwent TKA ($n = 66$, 49%) and THA ($n = 69$, 51%) between October 2015 and December 2015 was conducted at a large tertiary Academic Medical Center. A convenient sample of the charts of all patients who underwent total hip or total knee arthroplasty and discharged from the hospital from October 2015 to December 2015 was pulled from the electronic medical record using the International Classification of Disease (ICD-10) code. Information was extracted including: age, gender, race, ethnicity, body mass index (BMI), surgery type, VTE risk factors, bleeding risks, mechanical measure used, pharmacological prophylaxis used, and duration of the mechanical measures used. The inclusion criteria included all adult patients greater than 18 years of age who underwent hip and/or knee arthroplasty procedures from October 1, 2015 to December 31, 2015. Exclusion criteria included patients with a documented VTE at the time of the surgery, past medical history of VTE and a past medical history of malignancy.

Results: None of the patients developed post-operative VTE complications during the hospitalization. Compliance rate of using both pharmacological and mechanical prophylaxis was 99%. Majority of the patients were on either Rivaroxaban ($n = 54$, 40%) or aspirin ($n = 63$, 46.7%) and mechanical intervention(s). Sixty-three percent of patients received early mobilization therapy within 24 hours of the surgery.

Conclusion: Use of a bundle prophylactic interventions, both pharmacological and mechanical, improved venous circulation and prevented the likelihood of VTE development in postoperative TKA and THA patients. Aspirin used along with mechanical intervention(s) might be as effective as an anti-coagulant agent. Strategies to improve practice compliance are crucial in efforts to prevent post-operative VTE. Future clinical trials of multiple VTE prophylactic interventions involving different types of pharmacological and mechanical approach for TKA and THA population and evaluation of the relative risks and benefits of these interventions are needed.

Using Barthel Index and Performance Status Scale to Predict Inpatient Bowel Preparation Quality

Yu-Chi Kuo, BSN, RN, Taiwan

Ming-Wun Wong, MD, Taiwan

Ning-Hsin Lee, BSN, RN, Taiwan

Tzu-an Hsu, RN, Taiwan

Wei-Chen Lin, RN, Taiwan

Chun-Han Cheng, MD, Taiwan

Abstract

Purpose: Bowel preparation, cecal intubation rate, and adenoma detection rate influence the quality of colonoscopy and interval cancer rate. Adequate bowel preparation is first and essential step for not only procedure safety but also lesions deflection ability. According to literature, several factors affect inpatient bowel preparation such as age, socioeconomic class, opiate/ tricyclic antidepressants use, and physical status classification system by American society of anesthesiologists. However, there was still lack of general predicting model. Under hypothesis that patient's activity may be related to bowel movement then influence the bowel preparation. Thus we tried to predict inpatient bowel preparation by activity scoring system: Barthel index and performance status scale by eastern cooperative oncology group that routinely assessed in our inpatient nursing work. This study was aimed to evaluate predicting power of Barthel index and performance status scale by eastern cooperative oncology group for inpatient bowel preparation. We also investigated the cutoff values of scoring systems for inadequate bowel preparation.

Methods: All consecutive patients hospitalized for colonoscopy at the gastroenterology ward between 2016 May to 2016 June were retrospectively analyzed. We used Aronchick scale for bowel preparation evaluation. The level "excellent" and "good" were defined as adequate; "fair" and "poor" were defined as inadequate. All patients' activity statuses were assessed by Barthel index and performance status scale by eastern cooperative oncology group. The results were tested by receiver operating characteristic curve. Final the cutoffs were calculated by Youden's index.

Results: During the period of study, 100 hospitalized patients were retrospectively reviewed. The adequate bowel preparation rate was 70%. In addition, adenoma detection rate was 35%; cecal intubation rate was 99%. In receiver operating characteristic curve, area under curve of Barthel index was 0.798; area under curve of performance status scale by eastern cooperative oncology group was 0.824. Both of them were good discrimination for bowel preparation. After Youden's index calculation, we found 82 was cutoff for Barthel index and 1 was for performance status scale by eastern cooperative oncology group.

Conclusion: Both Barthel index and performance status scale by eastern cooperative oncology group were valuable to predicting inpatient bowel preparation. In daily practice, cutoffs let medical team pay more attention to possible inadequate bowel preparation.

PTSD in Neurology Nurses Coping With Verbal and Physical Abuse From Patients and Families

Roy Trahan, PhD, RN, USA

Abstract

Purpose: The purpose of the study was to assess the incidence, intensity, and impact of verbal and physical abuse experienced by neurology nurses from patients and families, identify current coping strategies of neurology nurses, and explore the relationships between selected demographic characteristics, high and low abuse from patients and families and coping strategies.

Methods: A descriptive, exploratory research design utilizing an anonymous online survey was used for this study. The sample consisted of registered nurses living in the United States currently employed full or part-time in direct care roles with neurology patients.

A total of 112 participants were recruited from three sources: 1) a contact population of 5000 neurology nurses via email using purposive sampling design techniques through an online database service specializing in healthcare marketing and research, 2) three metropolitan hospitals with full IRB reviews and 2) invitations submitted to nursing directors at local and regional hospitals.

Data was analyzed using descriptive statistics, tests of differences (analyses of covariance), and correlation (Pearson's and Spearman's rho and partial correlations). A statistical significance of $p < .05$ was the standard used for this research.

Results: Results of the study enriches the current literature by confirming the occurrence of verbal and physical abuse against neurology nurses, as well as contributing new data on intensity, impact and coping strategies of neurology nursing as it relates to verbal and physical abuse by patients and families. In addition, predictors of PTSD symptomatology and differences in genders on types of violence and the effects of verbal and physical abuse on coping strategy utilization were identified.

Conclusion: The findings of the study enrich the current literature by confirming the occurrence of verbal and physical abuse against neurology nurses, provided a forum for this nursing population to join in the discussion as legitimate victims of healthcare abuse, as well as contributing new data on intensity, impact and coping strategies of neurology nursing as it relates to verbal and physical abuse by patients and families.

Uncertainty and Depression as Mediators of Quality of Life in Patients With Heart Failure

Ting-Yu Chen, RN, Taiwan

Chi Wen Kao, PhD, RN, Taiwan

Abstract

Purpose: Based on the Mishel's uncertainty in illness theory (UIT), this study is to investigate the mutual relationships among uncertainty in illness, depressive status (DS) and health-related quality of life (HRQoL) in the patients with heart failure (HF).

Methods: In this cross-sectional observational study, 147 patients with a primary diagnosis of HF completed six self-report questionnaires: demographic and clinical characteristic, Mishel's Uncertainty in Illness Scale (MUIS), Beck Depression Inventory-II (BDI-II), Social Support Scale, Heart Failure Symptom Distress Scale, and Minnesota Living with Heart Failure Questionnaire. In this study, the AMOS 8.0 software package was used to conduct Structural Equation Modeling (SEM) analysis.

Results: The majority of subjects were male (54.4%), with a mean age of 71.04 ± 13.29 years. The left ventricular ejection fraction (LVEF) is between 10% and 80%, with an average of 46.42% (SD=17.20). The mean score of MUIS was 73.5 (SD=18.55), BDI-II was 19.42 (SD=11.29), and MLHFQ was 54.41 (SD=21.24). According to Mishel's UIT, the full model incorporated education, NYHA, LVEF, symptom distress, emotional support, and depressive status set up as measured variables. Uncertainty in illness and HRQoL were the latent variables. The final model has good fitness (/df 2.60, GFI 0.93, AGFI 0.85, CFI 0.96, RMSEA 0.10). Symptom distress, LVEF, education and emotional support explained 40% variance of uncertainty. Symptom distress, emotional support and uncertainty explained 56% variance of depressive status. Symptom distress, emotional support, uncertainty and depressive status explained 89% of HRQoL. Examination using Sobel's test found that uncertainty was the mediator between symptoms distress and HRQoL (Z value = 3.12 ; p value < 0.01), depressive status was the mediator between symptoms distress and HRQoL (Z value = 2.38 ; p value < 0.01), depressive status was also the mediator between emotional support and HRQoL (Z value = -2.25 ; p value < 0.01).

Conclusion: Our study identified uncertainty and depressive status as mediators between symptoms distress and HRQoL in HF patients. Therefore, we suggest that the clinicians should identify the patients' uncertainty and depressive status in clinical care, and providing non-pharmacological management strategies to improve patients' uncertainty and depression.

Assessment of Human Trafficking Awareness

Karen L. Hoblet, PhD, MSN, RN, CNL, USA

Abstract

Background: Human trafficking is modern day slavery. INTERPOL, the world's largest police organization reported that human trafficking is a multi-billion dollar enterprise (2016). The Federal Bureau of Investigation in the United States reported that human trafficking may be the "third largest criminal activity in the world" (2016). The Ohio Department of Health reported that human trafficking is one of the fastest growing criminal industries in the world (2016). Literature identified nurses and other healthcare workers in working in emergency departments, physician offices, and urgent care centers as being positioned to identify and rescue victims of human trafficking (Peters, 2013). Currently there is limited if any content that included in curriculum in medicine and nursing to inform these healthcare providers about how to identify victims of human trafficking and then how to effectively access or provide support for victims of human trafficking.

Purpose: This study was conducted to assess Toledo, Ohio area emergency department nurses and physician knowledge of indicators of human trafficking and resources to help rescue victims of human trafficking. The study design also educated participants about indicators of human trafficking and about available resources to rescue and help victims.

Methods: The quantitative study was approved by the University of Toledo Social and Behavioral Science Institutional Review Board. Reciprocal institutional approval was obtained from a large health care corporation with multiple acute care facilities with emergency departments in the Toledo, Ohio area. Data collection took place in local Toledo, Ohio area emergency rooms. Once informed consent was obtained participants were given a 14-item instrument, The Human Trafficking Awareness Survey. This instrument was developed after a review of literature from 2004-2014 using a key word search which included: human trafficking, emergency departments, assessment, signs, symptoms, healthcare providers, sex trafficking, trafficking, minors, knowledge, and protocol. The instrument included six demographic items and eight items specific to human trafficking and took approximately ten minutes to complete.

Results: Data are currently being analyzed using SPSS23 and results will be available prior to the conference.

Conclusion: Human trafficking is modern day slavery and a multi-million dollar global industry. Emergency department nurses and physicians are positioned to identify, rescue, and help these victims. Unfortunately, not all nurses and physicians working in emergency departments are educated to enable them to identify and help victims of human trafficking. This study provided a means to not only assess the knowledge level of nurses and physicians working in Toledo, Ohio area emergency departments about indicators of human trafficking and available resources to help rescue victims, it also provided a means to educate these professional about indicators of human trafficking and available resources as well. The benefits of this work is self-evident. If one more person is identified, rescued, and helped than it was a meaningful work.

RSC PST 1 - Research Poster Session 1

Validity and Reliability of the Social Adjustment Scale for Adolescents With Tourette Syndrome

Mei-Yin Lee, PhD, RN, Taiwan

Abstract

Purpose: Tourette syndrome is a childhood-onset neurodevelopmental movement disorder, characterized by unwanted multiple motor and vocal tics, and lasting longer than a year. The unpredictable and abnormal tics result in negative effects on the physical, psychological, social, and academic domains of adolescents with Tourette syndrome. Worse still, they suffer difficulties in interpersonal interactions and drawbacks in adulthood. Therefore, developing a social adjustment scale suitable for adolescents with Tourette syndrome will facilitate the evaluation of their social adjustment and future studies. The objective of this study is to evaluate the reliability and validity of the social adjustment scale for adolescents with Tourette syndrome.

Methods: The in-depth interviews of this qualitative study are held with 16 adolescents with Tourette syndrome to explore their social adjustment experience. Meanwhile, the dimensions and items of the scale are based on relevant academic papers. In this study, 5 experts are invited for expert validity testing regarding the appropriateness, comprehensiveness, and relevance of the scale. Moreover, 100 adolescents with Tourette syndrome are taken as the samples for analysis of the reliability and validity of the social adjustment scale for Adolescents with Tourette syndrome.

Results: The mean content validity index of this study was 86.4%. Originally, the questionnaire consisted of 26 items; however, after item analysis, correlation analysis, and factor analysis, only 22 items were retained, and a higher score indicated stronger social adjustment. According to the factor analysis and the maximum variance method, four dimensions formed the best mode, including "Academic performance", "Familial relationship", "Peer relationship", and "Self-disease relationship", which could explain 52% of the variances. Cronbach's alphas of the social adjustment scale for adolescents with Tourette syndrome were 0.81. The Stress Index for Children or Adolescents with Tourette Syndrome was adopted to test criterion-related validity, and the result indicated negative correlation.

Conclusion: The social adjustment scale for adolescents with Tourette syndrome is a self-management tool developed according to the understanding of the social adjustment experience of adolescents with Tourette syndrome, and is designed to evaluate the social adjustment of adolescents with Tourette syndrome. The scale features high expert validity, inner consistency, and construct validity. The results of the scale can be taken as the basis for understanding and evaluating the social adjustment of adolescents with Tourette syndrome. The social adjustment scale for adolescents with Tourette syndrome is an ideal tool to evaluate social adjustment, and can serve as reference for the design and development of interference measures of clinical medical workers, relevant counselors, and educators.

RSC PST 1 - Research Poster Session 1

Improving Door-to-ECG Time for Patients Presenting With Chest Pain in the Adult Emergency Department

Barbara Maliszewski, MS, RN, USA

Heather Gardner, MS, RN, USA

Diana Lyn Baptiste, DNP, MSN, RN, USA

Cathleen Lindauer, MSN, CEN, RN, USA

Abstract

Purpose: The American Heart Association/ American College of Cardiology guidelines recommend rapid door-to-electrocardiography (ECG) times for patients who present with chest pain. Reducing ECG-to-door time is important so that health care providers adhere to the recommended door-to-balloon times (less than or equal to 90 minutes) for patients who present with ST-segment elevation myocardial infarction (STEMI).

The objective of this quality improvement project was to measure the mean time that it takes to obtain an electrocardiography (ECG) for patients who present to the emergency department with complaints of chest pain. The goal of this project was develop and evaluate an intervention that promote meeting the American Heart Association/ American College of Cardiology standard for ECG-to-door time of less than 10 minutes upon patients' arrival to the emergency department (ED).

Methods: We implemented a door-to-ECG protocol that included moving the ECG station to a specialized area in triage, where patients can quickly receive an ECG upon arrival to the ED. Patients who presented to the ED with complaints of chest pain were provided with a red heart symbol as an indicator for clinical technicians to identify those in need of an ECG, and process them quickly. Pre and post intervention data was collected over a six-month period.

Results: Prior to the intervention, the mean door-to-ECG time was 21minutes among (N=292) patients over three months. After the intervention, the mean door-to ECG time for (N=701) patients was 10.6 minutes, over the next 3 months. Initially, the percentage of compliance with door-to ECG standard was 26% and improved to 73% after implementation of the door-to ECG protocol. We found that door-to-EKG times for patients who walked in to the ED were relatively shorter than those who arrived via ambulance.

Conclusion: The overall door-to-ECG compliance improved by 47% in the post intervention period. By implementing a door-to ECG protocol, we not only improved door-to ECG-times, potentially decreasing door-to-balloon times for patients who presented with STEMI. Door-to-EKG times may vary among method of arrival. Further investigation is warranted to evaluate door-to-balloon times for patients with STEMI, and for development of strategies to improve door-to-EKG times for patients arriving via ambulance.

A Prospective Study to Explore Pain, Anxiety, and Acute Confusion in Patients With Abdominal Surgery

Kalaikai Patzukele, MSN, RN, Taiwan

Ya-Jung Wang, PhD, RN, Taiwan

Abstract

Purpose: Abdominal surgery is a very stressful process for patients. Pain, anxiety and acute confusion were common complication during surgery. Unfortunately, Acute confusion adverse outcomes, including longer hospital stay, and higher mortality. In Taiwan, most studies utilized a cross-sectional study design to respectively explore pain, anxiety and acute confusion in patients with surgery. Former studies lack of focus on trends of pain and acute confusion as well as predictors of acute confusion during pre-post operation. Therefore, this study were designed to search trends and predictor of pain, anxiety and acute confusion at pre-operative period(T1), 24 hours within post-operation (T2), and 72 hours after post-operation.

Methods: A prospective, observational, repeated-measure, correlational design was adopted. From August 2014 to May 2015, there were 60 patients with abdominal surgery who admitted to intensive care unit were recruited from a medical center in the northern Taiwan. Inclusion criteria were patients aged twenty and above, and with a Richmond Agitation Sedation Scale score between -3 and +4. This study assessment of acute confusion using confusion assessment method for the ICU (CAM-ICU), and Pain assessment using the critical-care pain observation tool in Chinese, and anxiety measurement tool using heart rate variability.

Results: Using generalized estimating equation analysis, results showed that the change of pain and acute confusion were significantly different over the three time points. The highest pain score was at T2, and then it decreased at T3, and also predicting acute confusion. The highest incidence was at T2, and then increased as time passed by. The change in anxiety through the pre-post operation was not significantly different. The different domains of heart rate variation were all with downward trends at T2, and then followed upward curves at T3.

Conclusion: Results of this study help to understand the change of pain, anxiety and acute confusion over the pre-post operation period, and pain level and anxiety were predictors of acute confusion in patients with abdominal surgery. Recommendations from this study results are (1) to include the acute confusion assessment within the routine nursing care, and (2) to monitor predictors of acute confusion in patients with abdominal surgery during their pre-post operation period.

Is There Gender Difference in Maintenance of Peritoneal Dialysis: Analysis Using Competing Risk Model

Hsiao-Ling Chen, MS, RN, Taiwan

Jin-Lain Ming, MS, RN, Taiwan

Abstract

Purpose: Peritoneal dialysis (PD) is one choice of renal replacement therapies in patients with end-stage renal disease (ESRD). Gender difference was known with involving long-term outcome of nursing care such as quality of life among ostomy patients. However, little is known about the gender difference of PD usage and maintenance. This retrospective study aimed to clarify the gender effect on withdrawing PD.

Methods: ESRD patients, who had received PD catheter insertion, were enrolled in a tertiary hospital in northern Taiwan. The clinical data were reviewed and analyzed for the outcomes of PD-withdrawing time and events using competing risks regression model. Receiving renal transplantation or death was considered as a competing risk for the outcomes of withdrawing PD. Univariate analysis model was used to investigate the relationship between each independent variable, while multivariate analysis model was used to determine the independent variables that continued to be associated with outcomes after inclusion with significant variables in univariate analysis. Subdistribution hazard ratios (SHR) of covariates of competing risks regression were expressed with respective confidence intervals of 95%. Data were analyzed using the software Stata 12.0. *P*value less than 0.05 is considered statistically significant.

Results: A total of 514 patients receiving PD were enrolled for analysis between 2001 and 2013. One hundred and four patients (26%) had events of PD infection or malfunction and received removal of the PD catheter. Forty patients had received renal transplantation and avoided PD thereafter. Eighty-three patients had mortality events and 79 of them died with functioning PD. In the competing risk regression model, female patients had fewer events to remove PD catheter than male (SHR 0.67, 95% confidence interval 0.48-0.94, *p* = 0.019).

Conclusion: Male is a risk factor to have episode for removal of their PD catheters. Women may keep longer duration of PD usage and gender difference affects maintenance of PD catheters. Caring PD catheter is essential for ESRD patients and requiring self-care education. Gender difference for the maintenance of PD should be considered for further patient education and individual care.

The Relationship Between Magnet® Hospitals and Nurse-Driven Patient Outcomes

Amelia M. Joseph, PhD, MBA, RN, USA

Abstract

Purpose: Magnet® hospitals were established as a standardized program in 1990 by the American Nurses Credentialing Center to allow hospitals to be designated as excellent places for nurses to practice. Hospitals with this designation have the reputation of improved nurse-driven patient outcomes due to the structures and processes that support the organizational culture. However, the evidence does not conclusively support the effect that this designation has on patient outcomes. The aim of this study was to use publically available Medicare data to compare nurse-driven patient outcomes in Magnet® hospitals versus non- Magnet® hospitals across the United States.

The term “magnet” was first applied to hospitals following a 1983 study commissioned by the American Academy for Nursing to determine why certain hospitals easily hired and retained nurses. Forty-one hospitals were found to have specific characteristics that were especially attractive to nurses which created the idea of Magnet® hospitals ([McClure, Poulin et al. 1983](#)). In December, 1990, the American Nurses Association Board of Directors established the Magnet® Hospital Recognition Program which designated specific hospitals that demonstrated a work environment that encouraged and rewarded professional nursing. The first hospital was named in 1994. The program was renamed in 2002 to the Magnet® Recognition Program and is directed by a nine member, voluntary governing body made up of representatives from national nursing organizations as well as nurse managers and direct care nurses ([Morgan, Lahman et al. 2006](#)). Designation of Magnet® status is voluntary for hospitals and involves a multifaceted, peer review evaluation system. Final determination is made by the governing body. Designation is conferred for four years at which time, the facility must re-apply and undergo the same rigorous review. In the past five years, the standards have focused more on outcomes than on structure and process ([Morgan, Lahman et al. 2006](#), [Goode, Blegen et al. 2011](#)).

The evidence for the effect that this designation has on patient outcomes is mixed. A multi-site study using the Agency for Healthcare Quality and Research (AHRQ) data among 60 Magnet®, 720 non-Magnet®, and 19 Magnet® aspiring hospitals found a lower incidence of central nervous system disorders, hospital acquired pneumonia, and hospital acquired urinary tract infections in Magnet® hospitals when compared to non-Magnet® hospitals. Magnet® aspiring hospitals also had a lower incidence of central nervous disorders and hospital acquired pressure ulcers than non-Magnet®. However, non-Magnet® facilities had lower incidence of deep vein thrombosis/pulmonary embolism, failure-to-rescue, and pulmonary complications. There was no difference among the three groups for mortality, sepsis or surgical infections ([Carlson 2009](#)). Goode and colleagues used University Hospital Consortium data to measure patient outcomes in 19 Magnet® and 35 non-Magnet® hospitals based on patient safety indicator software published by AHRQ. Non-Magnet® hospitals had better outcomes for infections, post-operative sepsis, and postoperative metabolic derangement. Only pressure ulcers showed a lower incidence in Magnet® hospitals ([Goode, Blegen et al. 2011](#)). Among surgical patients treated in Magnet® hospitals, 7.7 percent were less likely to die within 30 days and 8.6 percent were less likely to die after a postoperative complication than in non-Magnet® hospitals ([Friese, Rong et al. 2015](#)). Among emerging Magnet® hospitals, 30-day mortality decreased by 2.4 fewer deaths per 1000 patients during an 8 year period. Failure-to-rescue decreased by 6.1 fewer deaths per 1000 patients during the same period ([Kutney-Lee, Stimpfel et al. 2015](#)). Using AHRQ Cost and Utilization data, no significant difference were found between Magnet® and non-Magnet® hospitals among pressure ulcers and failure to rescue ([Mills and Gillespie 2013](#)).

A systematic review of studies of patient outcomes among Magnet® hospitals found that the evidence for the effect of Magnet® designation on patient outcomes is inconclusive. Among the 141 studies that were screened, only ten met the inclusion criteria. This small sample was due to the methodological heterogeneity and poor quality design of studies. The sample was too small to allow for any strong conclusions to be reached by the investigators ([Daniel and Regnaud 2015](#)).

Methods: This is a retrospective, descriptive study using three different data sources. The first data source is from the Centers for Medicare and Medicaid (CMS) web-site using hospital compare data. These data are the results of the efforts of the Hospital Quality Alliance in collaboration with CMS. A

variety of different data sets are available for use. For the purposes of this study, data on hospital acquired infections and hospital acquired conditions were selected. Only variables thought to be sensitive to nursing care were considered using indicators established by the National Quality Forum ([Naylor, Volpe et al. 2013](#)). Catheter associated urinary tract infections (CAUTI) and central line blood stream infection (CLAB) were selected from the data set on hospital acquired infections and are reported over a 24 month time period, July, 2009 through June, 2011. Pressure ulcers, falls, and glycemic control were selected from the hospital acquired conditions set and are reported over the same time frame. Hospitals that did not report data for all of the five selected variables were excluded. The final sample contained data from 2780 hospitals.

The second is a list of Magnet® designated hospitals which was obtained from the American Nurses Credentialing Center (ANCC) web site. The ANCC is the arm of the ANA that administers the Magnet® Program. Three hundred fifty-eight hospital names were downloaded. These were then matched with data from the Medicare Compare web-site. Children's hospitals were excluded as were any hospital which was obviously a specialty care hospital based on the name (orthopedics, spine, eye, etc.). International hospital and hospitals with the Department of Veterans Affairs were excluded as they do not accept Medicare assignment and are not required to report data to Medicare. Critical Access Hospitals were also excluded as they are exempt from reporting data. Some hospitals could not be matched to hospitals in the Medicare data set by name or address and these were excluded leaving a total of 290 Magnet® hospitals.

The final data set that was used was data from the American Hospital Association web-site which provided information on the type of hospital ownership: private (voluntary private church based (VOLNPCHU); voluntary private (VOLNPPRI); voluntary private other (VOLNPOTH), public: federal government (GOVFED); hospital district (GOVHOSDIS); local (GOVLOC); or state (GOVST), or proprietary (PROP). Hospitals were also classified into geographic region as follows: New England (NE); mid-Atlantic (MA); Atlantic-south (AS); deep south (DP); great plains (GP); great lakes (GL); Rocky Mountains (RM); southwest (SW); and Pacific area (PA).

The dependent variable is Magnet® hospital status which is defined as any hospital that is listed on the ANCC web site.

The independent variables are:

- Central line associated blood stream infection (CLAB) which is measured in number of infections per 100 discharges;
- Catheter associated urinary tract infections (CAUTI) which is measured in number of infections per 100 discharges;
- Glycemic control (BS) which is blood glucose greater than 180 mg/Dl per 100 discharges;
- Hospital acquired pressure ulcers (PU) is the incidence of severe (stage 3 or 4) pressure ulcers per 100 discharges;

Falls are an unanticipated contact with the floor per 100 discharges.

Descriptive analysis was done on the full data set. As each variable performs independently of the others, that is the possibility of developing a pressure ulcer is not related to experiencing a fall, t-tests were used to compare the mean scores of Magnet® versus non-Magnet® hospitals for each variable.

Results: Ten percent of the 2780 hospitals that were reviewed held Magnet® designation at the time of the study. The Great Lakes region had the most designated hospitals. The overwhelming majority of designated hospitals fell into a voluntary ownership status at 82.7%.

There was no significant difference between the rates of pressure ulcers and glycemic control between Magnet® and non-Magnet® hospitals. Rates of CAUTI and CLAB were found to be better in non-Magnet® hospitals. Only the rate of falls was significantly better among Magnet® hospitals.

Conclusion: The evidence to support improved patient outcomes in Magnet® hospitals is inconsistent. This most recent study adds little to our knowledge. Glycemic control has not previously been reported in the literature related to Magnet® designation and findings from this study do not support a relationship. Although lower hospital acquired pressure ulcer rates have been reported in Magnet® hospitals ([Mills 2008, Goode, Blegen et al. 2011](#)), this association could not be confirmed. Evidence of a lower rate of hospital acquired urinary tract infections in Magnet® hospitals could neither be confirmed or denied as this measure is not the same as catheter associated urinary tract infections which was the variable that was used in this study. Only the findings for falls were consistent with the published literature ([Lake, Shang et al. 2010](#)).

Factor Influencing Satisfaction about Using PCA of Postoperative Patients a General Ordered Logistic Regression Analysis

Wonhee Baek, MSN, RN, Korea, Republic of (South)

Mir Moon, BSN, RN, Korea, Republic of (South)

Abstract

Purpose: The aim of this study was to identify the factor that influence the satisfaction about using patient controlled analgesia of postoperative patients.

Methods: A descriptive design was selected for this study. The participants were abdominal surgery, limited to GS surgery, that included gastrectomy, colectomy, lobectomy, pancreatectomy and so on. And the patients who received the patient controlled analgesia treatment after surgery. The type of the patient controlled analgesia are intravenous or epidural patient controlled analgesia. A total of 2724 patents were participated. The survey was conducted between May 2014 and August 2015 in severance hospital. Pain has been measure using the Numeric Pain Rating Scale. To estimate patient controlled analgesia consumption, researchers measured the patient controlled analgesia residual dose after removing patient controlled analgesia. The patient satisfaction of patient controlled analgesia was measured by Likert scale. Statistics analysis was conducted using SPSS 23.0 and STATA 13.0. Researchers used to ANOVA and chi-square to identify the impact factor of patient satisfaction. In addition, researchers used the generalized ordered logistic regression to investigate the factor influencing the patient satisfaction about using patient controlled analgesia.

Results: Comparing of the patient satisfaction depending on passage of time, it was significantly decreased when the patients' pain was increased. In the 6 to 24 hours after surgery, the lower level group of satisfaction score was decreased satisfaction further than the higher level group. In the lower level group of satisfaction, the nausea and vomiting didn't significantly affect the patient controlled analgesia satisfaction. However, in the higher level group of satisfaction, the nausea and vomiting were effect the patient satisfaction. In all groups, patient satisfaction is significantly decreased when the patient experienced dizziness and headache. The patient controlled analgesia consumption affected the patient satisfaction.

Conclusion: The postoperative patients pain management using the patient controlled analgesia is important to improve patient satisfaction. It would be able to contribute to affect the postoperative pain management resulting in patient satisfaction promotion.

The Effects of Music on Anxiety of Hospitalized Psychiatry Patients

Chyn-Yng Yang, PhD, RN, Taiwan

Abstract

Purpose: Music could be used as a non-invasive therapeutic tool to relieve the anxiety of patient. But less study is designed to compare the role of music therapy on the level of anxiety in Taiwan. The purpose of this study was to explore the effectiveness of music relaxation therapy in reducing anxiety in hospitalized psychiatric patients.

Methods: We used a single-group experimental repeated measures design and allocated the 22 enrolled participants. Based on the severity of the patient's anxiety divided into mild, moderate and severe three levels, who received 20 minutes of music relaxation therapy for 10 consecutive days. Soft music was played to patients using CD player and headphones. We administered the Beck Anxiety Inventory (BAI) and measured skin temperature, alpha brain waves and beta brain waves to determine anxiety level before, during, and after intervention.

Results: The results showed that the anxiety scores among the three levels had significant difference after music relaxation therapy ($p = 0.0339$). Each level of anxiety compared pretest and posttest anxiety scores have decreased, ranging from 3-12, also reached significant difference ($p = 0.0277$). After the music relaxation therapy, 50% of patients with mild anxiety had returned to normal, and 37.5% of patients with moderate anxiety had returned to normal. In the severe anxiety group, 16.7% of patients had returned to normal, 16.7% had returned to mildly anxiety and 33.6% had recovered to moderate anxiety. Three levels of anxiety demonstrated a significant difference in the pre-test and post-test differences in the alpha EEG percentage ($p = 0.0435$) and the beta EEG percentage ($p = 0.0147$).

Conclusion: Our results showed that music relaxation therapy can relieve on different levels of anxiety. During the listen to music, the patient's alpha EEG percentage increased, that confirming the patient in a relaxed state. Therefore music relaxation therapy can be recommended to relax relieve anxiety symptoms as non-drug effective interventions.

Women's Experience of Perinatal Loss: A Collaboration to Develop a Learning Resource for Nurses

Gerri C. Lasiuk, PhD, RPN, RN, CMHPN(C), Canada

Susan E. Fowler-Kerry, PhD, RN, Canada

Angela Bowen, PhD, RN, Canada

Carla M. Ransom, MN, BScN, RN, Canada

Wendi N. Stumborg, BScN, RN, Canada

Abstract

Purpose: The death of an infant is a profound and devastating experience for women and families. Nurses who work in emergency departments; obstetric, neonatal, and pediatric units; and in public health settings are likely to encounter women who experience a miscarriage, stillbirth, or infant death. These nurses are responsible to address women's physical, psychosocial, and instrumental needs, however the existing research suggests that many feel ill prepared to do so and there is limited research evidence to guide nurses on how to best do this. **Our purpose is to collaborate with women to describe their experience of perinatal infant loss and develop a learning resource to help nurses effectively support bereavement.**

Methods: Purposive sampling will be used to recruit 10-12 English-speaking women who have experienced perinatal infant death, in hospital, during the previous two years and provide informed consent. In phase 1 of the study, women will be interviewed about their experience of perinatal infant death. The interviews will be recorded, transcribed verbatim, and analyzed for themes using Interpretive Description. Phase 2 of the study will employ photovoice, a participatory action method, which invites participants to collaborate with researchers to document significant aspects of their everyday lives in photographs and descriptive texts. Participants and researchers will meet five times as a group to discuss and refine the themes identified in the interviews; take photographs that reflect the themes; and write about the meaning of the photographs. Through consensus, the group will then select photographs and textual descriptions to develop a learning resource for nurses.

Results: Although the study is ongoing, it is clear that women who have experienced the loss of an infant can offer a unique perspective on the experience of perinatal loss and bereavement.

Conclusion: Targeted efforts to educate nurses about these experiences will help them to provide compassionate and competent care.

Preschool Children: What They Know About Asthma and How They Learn

Adaya A. Troyer, BSN, RN, USA

Tami Wyatt, PhD, RN, USA

Abstract

Purpose: Childhood asthma is a growing societal problem that causes suffering for children and families. Asthma currently impacts 6.8 million children in the United States, with as many as 50-80% developing symptoms before the age of five (Beydon et al., 2007; National Heart, Lung, and Blood Institute, 2007). Short of finding a cure, the best way to address this health concern is to give children with asthma the resources they need to control their condition. Unfortunately, research and resources for young children with asthma are lacking. The authors hypothesize using age-appropriate education via technology, which promotes self-regulation with psychosocial elements, could decrease exacerbations and establish healthy habits.

Methods: This qualitative, descriptive study uses in-depth semi-structured interviews and direct participant observation to explore preliterate children's (3-5 years) understanding of asthma causes, symptoms, and treatments and educational strategies for this age group. Preliterate children who meet at least 3 out of 4 of the National Asthma Education and Prevention Program (NAEPP) criteria are interviewed to determine cognitive development and understanding of asthma and are then allowed a free-play period to help determine the children's preferences for entertainment and educational tools.

Results: A systematic evaluation of texts (e.g., field notes, transcripts) will provide qualitative data to categorize and identify themes. Additional analysis will determine what elements of the entertainment tools are most attractive to children in this age group by evaluating time spent with the toys and children's physical and verbal responses during the play period.

Conclusion: Research suggests that children can begin learning to regulate their health behaviors within the first few years of life and that early self-regulation leads to better health and socio-emotional outcomes later in life; therefore, educating preliterate children on how to self-manage their asthma is a key step to decreasing asthma exacerbations and healthcare costs (Archibald et al., 2015; Bandura, 2005; Fraley et al., 2013; Lieberman, 2001; National Heart, Lung, and Blood Institute, 2007; Yang et al., 2010). Early management of asthma also has the potential to minimize stigma placed on the child due to their chronic disease, thus decreasing feelings of social isolation (Stewart et al., 2011). The ability to use a unique and effective education tool for this aggregate of children would be a significant benefit for the child experiencing asthma and for the healthcare professionals providing care. These data are the foundation to develop future educational materials that enhance cognitive understanding and health-related behavioral regulation in preliterate children diagnosed with asthma.

Pain-Me-Free: A Video Game to Improve Geriatric Pain Management Using a Multi-Discipline Approach

Martha Martinez, MN, RN, USA

Sandra Sanchez-Reilly, MD, USA

Jeanette Ross, MD, AGSF, FAAHPM, USA

Abstract

Purpose: In response to the IOM report the Association of American Medical Colleges (AAMC), Accreditation Council for Graduate Medical Education (ACGME) and American Association of Colleges of Nursing (AACN) recognized the importance adequately preparing healthcare professionals to care for elders and developed minimum geriatrics competency guidelines grounded in evidence-based principles of quality care for older adults. Despite its prevalence, evidence suggests that pain is often poorly assessed/managed, especially in the elderly. The **PAIN-ME-FREE (Pain Activity for Inter-professional Nursing and Medical Student Education Focusing on Response, Effectiveness and decreasing side Effects among elders)** educational intervention aims to promote collaboration and patient-centered best practices by educating health care trainees in the assessment, diagnosis, and safe treatment of total pain for elders, as an integral part of an inter-professional team.

Methods: This interactive game includes video, audio, and text to gain a general history of the patient the learner will be caring for. Intervention targeted nursing (NL) and medical learners (medical students: MS and fellows: F) at a teaching institution. Pain Game had 3 pain-related scenarios (Older Adult (OA) at home, hospitalized OA after fall and OA at rehabilitation facility). Pain Game has questions related to pain assessment, management and opioid side effects. Scores were compared between learners' groups.

Aim 1. To evaluate the educational effectiveness of a geriatric chronic interactive pain video-game comparing different types of learners from different disciplines and educational levels.

Aim 2. To evaluate the effectiveness of this teaching tool by the learners.

Results: Current data presents: N: 77, 78% female, Ethnicity: 36% Hispanic, 33% Caucasian, 4% African American. When comparing NL vs. MS/F; there were no significant differences related to rating or classifying pain. When asking about naming physical, emotional, social and spiritual factors influencing "total pain" when a patient was suffering, 89.5%F were knowledgeable as compared with 77.8%MS and 47%NL ($p=0.02$). When deciding on a specific pharmacological pain regimen, 100% MS/F had accurate recommendations vs. only 54% NL ($p=0.03$). When discussing side effects, 100% MS knew opioids caused constipation and how to treat it vs. only 60% NL ($p=0.04$).

Conclusion: Incorporating chronic pain education into clinician's curriculum will greatly improve the management of chronic pain for Older Adults. An innovative intervention such as the Pain Game could be ideal to gain such expertise, and is much needed for all learners, including nursing: the forefront of patient care. Reaching to MS and NL early in their education and providing them with the skills and specialized training to treat chronic pain in Older Adults will improve patient satisfaction and overall quality of care.

Does 3D Technology Have Clinical Application in Nursing Assessment of Wounds in Adult Care Settings?

Martina Mendoza, MSN, BSN, RN, CWOCN, USA

Joyce Elaine Emery, MSN, BSN, RN, CDE, USA

JoAnn D. Long, PhD, MSN, MA, BSN, RN, NEA-BC, USA

Abstract

Purpose: The purpose of this project is to describe the state of nursing science using 3D imaging as an adjunct for pressure injury documentation and subsequent clinical care.

Background: Pressure injuries present a major health care challenge worldwide

(http://www.woundsinternational.com/media/issues/64/files/content_24.pdf).

Pressure injuries are considered a “never event” by the Center for Medicare and Medicaid Services (Soban et al, 2016). Accurate measurement of wound size is vital in monitoring the wound healing process and is a central concern in the practical management of wounds and the development of new treatment preferences. Additionally, the United States Centers for Medicare and Medicaid Services and insurance companies require accurate wound surface dimension data (Martin et al, 2011). Data is used to determine reimbursement for specialized treatment such as negative pressure therapy, specialty surfaces, and bioengineered skin substitutes. Wound measurement methods need to be accurate, reliable and feasible if they are to be useful in evaluating the wound healing process. A factor affecting the accuracy of wound measurement is definition of the wound boundary, which is often difficult to identify (Jorgensen et al, 2015). The National Pressure Ulcer Advisory Panel recommends at least a 1.5-3 megapixel digital camera for photographing wounds as an adjunct to support written wound documentation (Bryant et al, 2015). Problems with current digital imaging, resulting in underestimation of the wound area, include: poor lighting, location and size of the wound, differences in camera angle, user error, inaccurate recording of wound dimensions, documentation errors, and ineffective internet connectivity to upload into EMR (Jorgensen et al, 2015). Digital imaging is time consuming from the instant the image of the wound is captured by the camera until the wound area is estimated by the software. Recent advances in 3D imaging may help to overcome obstacles related to precise wound measurement; however, the efficacy of this technology as a tool in nursing assessment of wounds is not fully known.

Methods: An integrative literature review was conducted using PubMed; Google Scholar; CINAHL; Cochrane Database of Systematic Reviews. Key Words included: Stereophotogrammetry (SPG), 3D scanning; Instruments to Measure Pressure Ulcers; stereophotogrammetry technique and wounds; instruments to measure pressure ulcers; wound documentation; stereophotogrammetry and 3D photographs, legal costs of pressure ulcers, use of 3D scanners in wound assessment, Pressure ulcer Assessment; pressure ulcer documentation, , measuring wounds, wound assessment, 3 D photography, digital planimetry. All peer-reviewed articles published to date were included. The following were included: adult care settings, wounds and pressure injuries. Children and animals were excluded. Eleven articles were initially located and five were included in the final sample. Data were extracted and synthesized.

Results: One level one meta-synthesis (Jorgensen et al, 2015); One level three comparative study (O'Meara, S.M. et al, 2012); One level four qualitative study were included (Hammond, C.P., & Nixon, M.A. 2011). In the past decade various 3D imaging from a volume perspective have appeared on the market, however none of the reviewed technologies have yet had a major impact due to low accuracy, high cost and difficulty in handling the system setup. Only a few of the studies provide data on wound selection criteria, thus reducing the generalizability of the results (Jorgensen et al, 2015). The SilhouetteMobile, Aranz Medical, included five wounds and was found to have low intra-and inter-rater variation and with approximately two minutes were required to capture photographic documentation (Hammond, C.P., & Nixon, M.A. 2011). Twelve studies were included, however no definitive conclusion could be reached in regards to the diameter or depth of the wounds (O'Meara, S.M., et al 2012).

Conclusion: The use of digital planimetry or digital imaging may be a solution for wound measurement if a high accuracy is required, however, the methods can also be time consuming for everyday clinical practice. Absence of a Gold Standard method for wound area and volume measurement against which other methods can be tested is a current concern. Currently there is little evidence to recommend clinical guidelines. Technological advances in digital imaging may help to advance the science underpinning wound care and more research is required to find ways to better validate wound volume measurement.

RSC PST 1 - Research Poster Session 1

Innovative Use of Video Telerounding to Improve Patient Satisfaction and to Expedite Discharge

Ginger S. Pierson, RN, CCRN, CCNS, USA

Joseph F. Burkard, DNSc, MSNA, BSN, RN, CRNA, USA

Abstract

Purpose: The purpose of this study, is to evaluate the intervention of remote presence, video telerounding as the real-time, virtual physician discharge visit, on patient satisfaction and acceptance of this technology, to expedite the time to hospital discharge.

Methods: This prospective, quasi-experimental study will enroll 36 eligible post-procedure cardiac patients who consent to this study, to serve as the intervention group for telerounding. The control group, who had a traditional face-to-face hospital discharge visit, will be created from patients who meet study criteria in the three months prior to the telerounding intervention, from two Electrophysiologist (EP) cardiologist partners. The telerounding intervention group will plan a pre-established, morning timeframe for the patient to receive a virtual, remote discharge visit from their EP/cardiologist on the anticipated day of discharge. Telerounds will be collaboratively facilitated with the telemetry unit charge nurse at the patient's bedside, with the EP cardiologist on the remote presence, video conferencing robot- for real-time, interactive, discharge evaluation rounds. The nurse researcher will collect observational data and time measures during each telerounding interaction, but will not actively participate in the discharge process. Patient satisfaction data targeting hospital and discharge experiences will be completed for the intervention group, after the telerounding intervention, prior to discharge, utilizing the 20-item *Patient Judgment of Hospital Quality*, a psychometrically sound questionnaire- which includes 11 items specific to telerounding (Ellison, Pinto, Kim, Ong, Patriciu, Stoianovici, Rubin, Jarrett & Kavoussi, 2004). The control group will retrospectively complete nine items of this same patient satisfaction questionnaire, excluding the telerounding questions, and will mail their consent and study surveys back to the researcher in a pre-addressed, stamped envelope. A short, five-item phone survey regarding the two-week post-discharge time period, conducted by the nurse researcher for both groups, will aim to capture any stated, unplanned need for medical evaluation, emergency services, or hospitalization due to any concern for a post-discharge complication. Both groups will have been admitted, cared for, and discharged from the same cardiac telemetry unit. One EP/cardiologist will perform all intervention group telerounding discharges. Patient satisfaction and time measures related to the hospital stay and discharge, including demographic data obtained from the Electronic Health Record (EHR), will be compared to the pre-intervention control group, who received the traditional, face-to-face physician discharge visit.

Results: Study in progress; results pending. The data analysis plan will include the use of current SPSS statistical software. Descriptive statistics will be used to analyze frequencies of categorical outcome variables, including patient satisfaction scores for each group. Independent *t*-tests will be used to compare patient demographic characteristics and satisfaction scores between the two groups. Chi-square testing will be analyzed for significant associations of categorical variables between groups as appropriate. Logistic regression analysis will be performed for continuous outcome variables of satisfaction. Confounding variables, for patients who may differ in co-morbidities or need for additional discharge consultations, will be evaluated for correlation with specific identified delays in discharge.

Conclusion: Study in progress; results pending. Telerounding allows for real-time, two-way audio/visual, and physical assessment telecommunication between the patient, nurse and physician. There is a gap in the literature regarding the use of telerounding as a strategy to expedite the hospital discharge process. This innovative approach may improve patient satisfaction, acceptance of this technology for future use, and improve discharge efficiency.

Nursing Care Technology and Patient Safety

Nuray Turan, PhD, RN, Turkey

Gulsun Ozdemir Aydin, MSc, RN, Turkey

Hatice Kaya, PhD, RN, Turkey

Turkinaz Asti, PhD, RN, Turkey

Abstract

Purpose: The general public believes that technology will improve health care efficiency, quality, safety, and cost. However, few people consider that these same technologies may also introduce errors and adverse events. Hospitals and health care organizations are under relatively little pressure to implement safety practices. Regulators and accreditors are pushing health care organizations to adopt various “safe practices” or to avoid particular adverse events that are considered wholly or largely preventable.

Methods: In this article, the literature and research findings regarding the nursing care technology and patient safety. This subject was analyzed, the importance of the issues was discussed and the suggestions for implementation were proposed.

Results: Patient safety has received increased attention in recent years, patient care technology has become increasingly complex, transforming the way nursing care is conceptualized and delivered. Over time, the nurses' unaided senses have replaced with technology designed to detect physical changes in patient conditions. Before extensive application of technology, nurses relied heavily on their senses of sight, touch, smell, and hearing to monitor patient status and to detect changes. Patient care technologies of interest to nurses range from relatively simple devices, such as catheters and syringes, to highly complex devices, such as barcode medication administration systems and electronic health records. While nursing care technology holds much promise, the benefits of a specific technology may not be realized due to four common pitfalls: (1) poor technology design that does not adhere to human factors and ergonomic principles, (2) poor technology interface with the patient or environment, (3) inadequate plan for implementing a new technology into practice, and (4) inadequate maintenance plan.

Technologies used by nurses offer the means for preventing errors and adverse events (e.g., medication errors, miscommunications, delays in treatment, and adverse events such as failure to rescue, nosocomial infections, pressure ulcers, falls, and complications of immobility). Implementation of new technologies offers nurses yet another avenue for ensuring safe and efficient use of technology. While technology has the potential to improve care, it is not without risks. Technology has been described as both part of the problem and part of the solution for safer health care, and some nursing educators warned of the introduction of yet-to-be errors after the adoption of new technologies. Selecting the wrong equipment and technology can be costly and expose the patient to errors and ethical issues.

Conclusion: Nurses providing direct patient care can ensure that the technologies they use meet international quality and safety standards and technical specifications needed to perform in the clinical environment in which they are used. Being informed consumers and users of technology in nursing care means that nurses be involved in the selection of new equipment, receive the proper training for its use, and monitor equipment safety and the effect of technology on patients and families on an ongoing basis. Therefore, nurses should be sensitive to developing and changing products with technology and develop themselves.

Kaori Fujimoto, MS, RN, Japan

Mihoko Ishizawa, PhD, RN, Japan

Kazuhiro Takeda, LLB, Japan

Abstract

Purpose: Nurses play an important role in the prevention of pressure ulcers. However, because the determination of stage 1 (the early status of pressure ulcers) is based on the appearances of such ulcers, nurses have difficulty determining their presence. In our previous study, one out of three Japanese nurses admitted having difficulty judging stage 1 by themselves. In addition, no simple device exists with which nurses can directly evaluate the status of skin blood perfusion. Given the leading role that blood flow plays in the transfer of body heat, we focused on the heat transfer efficiency of skin tissue, and developed a device for evaluating the blood perfusion. Heating in the local area of the skin surface, the skin-surface temperature response depends on the amount of blood perfusion. We estimated the skin blood perfusion by solving the bio-heat transfer equation with skin-surface temperature responses.

In this study, we experimentally tested the validity of evaluations made with our new device and compared its estimated skin blood perfusion with the measured values of the Laser Tissue Blood Flowmeter (OMEGAFLO, OMEGAWAVE, INC.) of the feet of participants covered by a blanket, which was a Japanese futon.

Methods: Twenty healthy elderly people participated (10 men and 10 women) wore 100% cotton pajamas and lay in bed in a climate chamber. The ambient temperature and relative humidity were controlled at 25°C and 55% RH. The subjects lay in bed for 30 minutes with their body and extremities covered by a blanket and for another 15 minutes without a blanket covering from their knees down. We measured the skin-surface temperature and the superficial blood flow by the flowmeter on the sole of feet at the following three times: just before the body and extremities were covered with a blanket (before), 30 minutes after being covered with a blanket (after being covered), and 15 minutes after it was removed from below the knee (without blanket). We estimated the blood perfusion with skin-surface temperature responses and compared it with the flowmeter value.

Results: The mean (S.D.) age of the subjects was 71.5 (3.6) years. The mean (S.D.) skin-surface temperature was 31.8 (1.8) °C before being covered, 33.7 (2.0) °C after being covered, and 31.7 (1.7) °C without a blanket. The mean (S.D.) estimated blood perfusion by the proposed device was 0.8 (0.3) before, 1.6 (1.6) after being covered, and 0.8 (0.2) without a blanket. The mean (S.D.) flowmeter value was 8.4 (4.4) before, 10.4 (5.3) after being covered, and 7.7 (4.6) without a blanket. Like the skin-surface temperature and the flowmeter value, the estimated blood perfusion significantly increased after being covered with a blanket and significantly decreased after it was removed. Positive correlations were observed between the estimated blood perfusion with the flowmeter value ($r=0.49$, $p<0.05$). But no relationship was observed between the ratios of the change (before and after being covered with a blanket) of the estimated blood perfusion and the flowmeter.

Conclusion: We confirmed the ability of our new device to evaluate skin blood perfusion. With it, we will be able to objectively and easily predict pressure ulcer developments. However, we found no relationship between the ratio of the change of the estimated blood perfusion and the flowmeter value. The validity of evaluating skin blood perfusion must also be investigated in further study.

Derek Hoy: The Legacy of the First Scottish Nursing Informatician

Siobhan O'Connor, BSc, CIMA, CBA, RN, FHEA, United Kingdom

Abstract

Purpose: Derek Hoy was a prominent Scottish nursing informatician. This paper aims to explore his career and its impact on nursing, patients and the health services in Scotland and beyond.

Methods: A literature review of Derek's academic research was undertaken to establish his contribution to nursing informatics as a field. An exploratory case study approach was adopted to explore his career in depth. A selection of people are being interviewed including his wife and close personal colleagues in the National Health Service (NHS), Glasgow Caledonian University where he worked and the Scottish Government among others. The qualitative dataset will undergo thematic analysis using the constant comparative method.

Results: Preliminary results show that Derek made a significant contribution to his field. He developed numerous electronic applications including AGNIS (A Generic Nursing Information System) to capture nursing assessments, interventions and care plans. He also worked on the Scottish Health Service EPPIC (Effective Purchasing and Providing in the Community) project to use minimum patient and nursing datasets in combination with mobile devices to improve care delivery. His most ambitious and successful eHealth project was the ALISS (Access to Local Information Systems to Support Self-Management, <https://www.aliss.org/>) which is still in use supporting people with long-term conditions in Scotland today. He also worked with international colleagues on numerous digital health initiatives such as International Classification for Nursing Practice (ICNP) a data standard for nursing and patient records. Derek also taught nursing and informatics to students at Glasgow Caledonian University and inspired many in the profession to pursue clinical careers that utilised technology to the fullest.

Conclusion: Derek Hoy's writing and work spans a 20 year timeframe from the early 1990's right up until his death in 2012. This demonstrates a clear commitment to developing nursing informatics as an important clinical and academic speciality in the United Kingdom and further afield.

Early Detection of Stage I Pressure Ulcers Identifying Non-Blanchable Erythema Using Electric Impedance

Masako Miyajima, PhD, RN, Japan

Aki Ibe, PhD, RN/PHN, Japan

Nanae Ikeda, PhD, RN, Japan

Masako Hirano, MS, RN, Japan

Kaori Fujimoto, MS, RN, Japan

Tomoko Tamaki, MS, RN, Japan

Abstract

Purpose: Early detection and identification of pressure ulcers is very important for the well being of patients as well as for controlling medical expenses. Under Japanese Society of Pressure Ulcers guidelines, either finger method or disk method is considered appropriate to identify such erythema or pressure ulcers, because non blanchable erythema(NBE) is not always clearly visible. Since electric impedance typically reduces resistance in interstitial fluids, measuring the impedance of skin tissue under erythema conditions can find evidence of whether Stage I Pressure Ulcer exists. The purpose of this study was to examine the relevance of impedance measurement for classifying complete NBE or partial NBE or blanchable erythema (BE) .

Methods: Subjects involved patients who were judged to have complete NBE, partial NBE, or BE by the disk method. Impedance data were collected by the two electrodes method using an LCR METER NF Corp.. One electrode sensor was placed on the edge of an erythema and another electrode sensor was on the opposite edge of erythema. The range of frequency was 1mHZ to 100kHz. The differences of impedance data between complete NBE , partial NBE, or BE and each opposite healthy local area to erythema were analyzed by ANOVA. Finally, to improve the accuracy of impedance difference, devised formula of total deviations which was removed erythema size effect were used .

Results: Subjects were 23 bedbound patients, and the local areas of erythema were the thigh, knee, heel, toe, sacrum, and spinal curvature. By the disk method, five patients were classified as having complete NBE, eleven as partial NBE and seven as BE. The mean (SD) size(mm) was 18.6(12.6) in complete NBE, 10.5(12.8) in partial NBE, or 11.9(6.1) in BE. As for ANOVA analysis, a significant difference was observed among complete NBE, partial NBE and BE($p<0.05$). Impedance difference for complete NBE is larger than normal control, while that for partial NBE was smaller than normal control. As there were observed a linear relation and a coefficient of determination, analysis by revised formula of total deviation, which removed erythema size effect, proved that three distribution of impedance values existed. The mean (SD) impedance data by revised formula of total deviation was 0.14(0.03) in complete NBE, 0.52(0.02) in partial NBE and 0.34(0.02) in BE, and a significant difference was observed ($p<0.001$).

Conclusion: The result of this work indicate that complete NBE can predict blood flow disturbance , while partial NBE can predict complicated skin tissue conditions of vessel dilation or increasing interstitial fluids, and there may be possibility of skin damage. Therefore, there is possibility of developing a new early detective and identifiable device of Stage I pressure ulcer using electric impedance. In the future ,we will use a larger sample size and clarify the difference between complete and partial NBE, additionally using a blood flow measurement and a digital erythema color instrument.

The Tele-Case-Management Program Improves Resilience, Symptoms Distress, Fatigue, and Depressive Symptoms in Heart Transplant Recipients

Chi Wen Kao, PhD, RN, Taiwan

Pai-Hui Lin, MSN, RN, Taiwan

Abstract

Purpose: Patients with severe heart failure (NYHA Fc IV) without effective responses to medical therapy have to receive the treatment of heart transplantation. Although patients may prolong their life after undergoing heart transplantation, they need to take immunosuppressive drugs lifelong. How to strike a balance between avoiding infection and preventing rejection causes patients both physiological and psychological distress. Due to the special conditions after heart transplantation, telehealth care could provide immediately and timely care, and reduce the degrees of anxiety and depression for heart transplant recipients. Therefore, the purposes of this study were to develop the Tele-Case-Management Program, and determine its effects on the improvements of the depressive and fatigue symptoms, resilience, and the symptom frequency and distress.

Methods: This study used experimental design with pretest, post-test. According to pretest of depression scores, we stratified and randomly assigned participants to the experimental group and control group. The heart transplant recipients in experimental group (n=31) received Tele-Case-Management Program intervention, and the recipients in control group (n=30) received the usual care. Each study participants was evaluated by Resilience Scale, Symptom Frequency and Symptom Distress Scale, Beck Depression Inventory-II Scale, and Fatigue Scale at pre- intervention (pre-test), and one-month and three-month follow-up. This study used independent t-test and chi-square test to evaluate the homogeneity of the characteristics between the two groups. The generalized estimating equation (GEE) was used to examine the effects of the Tele-Case-Management Program on the improvements of resilience, symptom frequency and distress, depressive and fatigue symptoms.

Results: The majority of participants were male (78.7%), with a mean age of 53.2 ± 12.28 years, and mean ejection fraction (EF) after heart transplant of $61.74 \pm 10.04\%$. The participants receiving the Tele-Case-Management Program intervention showed significantly greater improvement than those in the control group in the symptom frequency ($p= 0.029$) and distress ($p= 0.014$), and depressive symptom ($p=0.029$) at one-month follow-up. Furthermore, the intervention effects on resilience ($p= 0.001$), symptom frequency ($p= 0.001$) and distress ($p= 0.001$), and depressive symptom ($p= 0.001$) were significantly improved in experimental group compared with control group at 3-month follow-up.

Conclusion: The Tele-Case-Management Program is able to improve resilience, symptom frequency and distress, depressive symptoms in heart transplant recipients.

Effect of Massage Balls on Breast Engorgement for Taiwanese Postpartum Women: A Randomized Clinical Trial

Hsiu-Jung Lee, MSN, MA, Taiwan

Abstract

Purpose: The multitude of benefits that come from breastfeeding has been very well established and recognized. Breast engorgement, however, is a common problem of early postpartum breastfeeding, one that contributes to lower willingness to breastfeed. The development of effective strategies aimed at increasing milk secretion is, therefore, highly important, for it helps to prolong the duration of breastfeeding. It is incumbent upon health-care providers to find the best strategies in assisting women to both manage the discomfort of breast engorgement and increase milk secretion. The purpose of this study was to evaluate the efficacy of massage balls toward treating breast engorgement in postpartum women.

Methods: A quasi-experimental design was used. Participants were recruited from the postpartum ward of a regional hospital in northern Taiwan. They were all within seven days postpartum and gave informed consent. Participants were randomly assigned into two groups of 30 participants each. Participants in experimental group used the massage balls 30 mins per day for 3 consecutive days. Standard postpartum nursing was provided for the control group. Symptoms of breast engorgement were assessed via a self-report scale before and after the intervention. Data was documented and analyzed using SPSS version 22.0. Differences between two groups were evaluated by use of generalized estimating equations.

Results: The results showed that symptoms of breast engorgement (pain, swelling, heat sensation and discomfort) lessened in both groups, with more significant lessening in the experimental group. Differences between two groups reached statistical significance ($B = -13.46^{***}$).

Conclusion: This study demonstrated that the use of massage balls may be a more effective method in mitigating the symptoms of breast engorgement. This form of treatment helps mothers and health-care providers handle breast engorgement symptoms more effectively in primary care, which in turn promotes the length and quality of breastfeeding. This method provides an alternative for nurses to manage breast engorgement more effectively and thus increases the quality of care in early postpartum mothers and infants.

Adaptation to Curriculum Delivered via iPad Technology

Melissa A. Stec, DNP, APRN, CNM, FACNM, USA

Abstract

Purpose:

With the emergence of new and innovative technology, an evolution of nursing education must be considered. Traditional methods of teaching, while effective, cannot be expected to be successful with the new technology literate populations of students. Instead active learning strategies that utilize tablets and other technologies are becoming more of the norm than the exception. Initiatives incorporating tablets into educational programs are largely aimed at improving the student experience through increased engagement, collaboration, and interactivity (Wong, 2012; Bond-Raacke & Raacke, 2008). The thoughtful integration of emerging technologies throughout the teaching and learning environment relies on the successful diffusion of the innovations, and that diffusion depends on acceptance of change (Rogers, 2003). This study aimed to fill this gap by exploring student perceptions, attitudes, and skill levels related to iPad use before, during, and after the first year of the iPad Initiative.

Methods:

This convergent mixed methods study was designed to examine the skills and attitudes toward using an iPad to support curriculum for sophomore Bachelor of Science in Nursing (BSN) and Doctor of Nursing Practice (DNP) students at a Midwestern university. Data were collected using an investigator-developed survey to identify student perceived iPad skill levels and attitudes towards the iPad before, during, and after the first year of the implementation of a one-to-one iPad requirement (i.e., the iPad Initiative). We used focus groups to identify factors that contribute to students' attitude and skill levels. Initial data were collected from participants during the iPad orientations in August of 2013 (sophomore BSN n = 158; DNP n = 29). Follow-up sessions occurred at the end of fall semester 2013 (survey only) and spring semester (survey and focus groups) 2014. Qualitative and quantitative data were rigorously analyzed.

Results:

Significant improvement was seen in students' perception of their technology proficiency. However, students reported significantly less use of the iPad than they had predicted in the fall. Preliminary analysis of qualitative data resulted in a variety of themes including portability of the device and increased access to information. Students were concerned about the cost of the iPad and felt that the technology was under-utilized by their professors. Once data analysis from both sets of data concluded, the results were fully integrated in order to develop plausible conclusions. The overall findings of the study (meta-inference) was informed by all data sets from all participant groups.

Many themes emerged from the quantitative data that were divided into three subgroups. The first group described positive attitudes and attributes that are called drivers. The second group of themes articulate negative experiences or attitudes that were classified as speed bumps. The third and final group of themes were seen as moderators of both the positive (drivers) and negative (speed bumps) themes. These moderators must be carefully considered when planning a technology integrated curriculum. Additionally, the results of this study elucidated challenges inherent in being early adopters of technology in education.

Conclusion:

Meaningful technology integration requires a thorough understanding the the challenges that may be faced initially. Faculty use of technology was a strong moderator of the student experience. Thoughtful and well planned faculty development can be a useful first step to proficient use of technology in the classroom and therefore a positive student experience. This study identifies the challenge of being early adopters of technology and offers insight into the specific indicators to be considered in implementing a successful technology initiative.

Growing the Next Generation of Nurse Leaders in Palliative Care: An International Case Study

Kathryn A. Pfaff, PhD, RN, Canada

Linda J. Patrick, PhD, MSc, MA, BScN, RN, Canada

Laurie Freeman-Gibb, PhD, RN, ANP, Canada

Abstract

Purpose: There is a global need to address the growing palliative and end of life care needs of individuals who are living longer, and who also live with serious and complex life-limiting and life-threatening illnesses. This will require significant growth in point-of-care resources, including a sustainable palliative care workforce. More importantly, it will require a complement of nurse leaders who will play key roles in education, evidence-based practice change, care coordination, and program evaluation. This presentation summarizes the findings of an evaluation of an international exchange program in palliative care. The project's aim was to engage graduate students in nursing to develop advanced knowledge and leadership skills in palliative care. The program was funded by the Canadian government and was built on an existing collaborative academic relationship between the University of Windsor in Canada, and Keele University in the United Kingdom. It also leveraged the shared community relationships among four community hospices, one hospital-based palliative care unit, one community outreach program, and a cadre of clinicians who served as champions and mentors.

Methods: The study employed a descriptive single case study design (Yin, 2003) with three embedded units of analysis: scholars, universities, and organizations.

Results: The findings revealed three overarching project processes that supported the project's success. These were: readiness, engagement, and outcome achievement. Within these processes, a number of themes emerged from the data. These were: passion and perseverance, discovery and inquiry, committed mentors, partnerships, and unexpected synergies that span the Atlantic Ocean.

Conclusion: This project is a beginning step in developing global nursing leaders in palliative care. International exchange in palliative care enables the sharing of best evidence in palliative care. It requires the partnership of academic institutions and practice organizations who are willing to invest significant time, funds, and energy. The findings of this project suggest processes and strategies for successful international collaborations in palliative care education and leadership. Project expansion and sustainability will require new and ongoing resources.

Prelicensure International Immersion Illuminates Shared Professional Values and Discovery of Nursing Voice in Cultural Humility

Gina B. Diaz, DNP, RN, ANP, GNP, USA

Paula Byrne, DNP, RN, USA

Edna Imperial, MA, RN, Philippines

Abstract

Purpose: This project's purpose is to explore collaborative strategies for developing a sustainable international pre-licensure nursing educational experience. Nursing scholars and the International Council of Nurses (ICN) recognize that as our world becomes more culturally diverse, nurses will be the linchpin for transforming healthcare that is culturally flexible and responsive to the needs of patients and their families (ICN, 2013; Henly, 2016). The two goals of this project are (a) to deepen the student's understanding of shared professional values and (b) develop the nursing voice. This project is framed by the assumption that when students are immersed into healthcare systems different from their own, they witness how nursing leaders model the shared values of the profession and demonstrate intercultural and collaborative skills of respect and humility. Kumagi & Lypson (2009) describe how the ability of understanding and bracketing one's own assumptions, biases, and values, enables one to see care through different lenses and expand their perspectives on what constitutes the genuine art and science of nursing. Complex pre-licensure nursing curricula rarely offer pre-licensure students the opportunity to engage in actual patient care that occurs in different health systems, which may delay students' experiences with recognizing their own positionality and understanding the positionality of others.

Methods: This program involves a collaboration between a small Midwestern private college and a private nursing school which operates in a highly underserved community in Manila, Philippines. A collaboration was initiated by a faculty member at the Midwestern private college who is an alumna of the nursing school in Manila. Students initially meet before the two-week trip using social media and then travel to Manila to be immersed in clinical practice and community nursing projects. Filipino students are matched with American students in clinical to serve as translators and guides within the organizations. Experiences include OR, Labor and Delivery, ICU, ER, and medical surgical floors. In addition, there is a pre-school screening and family feeding project that enhances family nursing and developmental assessment skills. The aim of the immersion for the students of both colleges is to identify their shared professional values while practicing cultural humility during different nursing educational experiences. The aim for faculty and administration is to explore best practices in nursing education and evaluation that can support the growth of future international nursing leadership. Leaders from each college have visited alternate sites each year to exchange ideas and plan for the future. Fifty seven American nursing students aged 21-23 years have participated and shared their perceptions. The underlying framework of collaboration balances the prioritized educational needs of both colleges as identified by the leaders. This shared vision of the purpose of the immersion has allowed the pilot to expand the length of the trip and to offer faculty development opportunities.

Results: Students wrote reflective papers before and after the experience to examine their assumptions before the trip and to validate their growth upon their return. Critical reflection is one of the guidelines for culturally competent nursing care. Nurses shall engage in critical reflection of their own values, beliefs, and cultural heritage in order to have an awareness of how these qualities and issues can impact culturally congruent nursing care (Douglas et al., 2014). Reframing care delivery is the main theme gleaned from the students' reflections of the intercultural immersion experience. Reframing care delivery refers to application of therapeutic communication with cultural context, enhancing care through high human contact (touch), providing quality care despite low use or no technology used, and acute awareness of social justice within healthcare delivery systems.

American Student Reflection: "This course offered an amazing learning experience for me. I am so grateful to have had the opportunity to participate in this experience. I am able to evaluate personal, professional, and cultural values that impact clinical decision-making that are respectful of patients' values and preferences after participating in this intercultural exchange."

Filipino Student reflection: "The cultural differences adds up new dimensions in taking care of patients. We learn from them and they learn from us. And also a lot of Filipinos are very happy seeing them

because it unusual to be taken care by foreigners, they brought joy to the patients and also to the working area. The nurses enjoys talking to the CSS students even they are not so good in speaking English.”

Conclusion: Developing a sustainable international immersion experience allows both students and faculty the opportunity to examine cultural bias and practice openness and empathy in a diverse healthcare setting. Clarity in the vision regarding the outcomes for the immersion experience allows leadership to align each of their unique faith based missions and address curricula needs for highly desired cultural humility outcomes. The strength of the collaboration is catalyzed by the shared interests of alumna and alignment of faith based colleges. The sustained collaboration encourages the organizations to develop new initiatives; the most recent plan includes designing a synchronous semester long class focused on leadership and assertive communication techniques such as TeamSTEPPS (AHRQ, 2016) to promote patient safety. Integrated technology will narrow distances between students.

RSC PST 2 - Research Poster Session 2

Advancing Caring Science in Global Health: Assessment of Mental Health Needs in Bondeau, Haiti

Beth M. King, PhD, RN, PMHCNS-BC, PMHNP-BC, USA

Charlotte D. Barry, PhD, RN, NCSN, FAAN, USA

Abstract

Purpose: The purpose of this exploratory study was to investigate the mental health needs of adults living in Bondeau, Haiti, a rural community located in the southwest region of the country. The aims of the study were to: (1) develop collaborative partnerships and relationships to facilitate the study, (2) determine the severity of depressive symptomatology (measured by the PHQ-9 & Zanmi Lasante Depression Inventory Scale), (3) assess the degree of anxiety (measured by the PROMIS Anxiety scale), and (4) appraise resiliency (measured by Connor-Davidson Resilience scale) for participants in the study compared to the global community.

Significance: In 2011, the World Health Organization (WHO) called for a comprehensive, coordinated response to the global burden of mental disorders. The World Bank reports that 350 million persons are impacted by depression and is “the leading cause of disability world wide” (2016, para 1). Yet, assessment and treatment of mental health disorders remains limited, with estimates of 76% to 85% of persons living in low and middle-income countries receiving no treatment for mental health disorders (WHO, 2015).

Haiti, declared a priority nation by the Pan American Health Organization & World Health Organization (PAHO/WHO) in 2002 is the poorest and most vulnerable country in the Americas (PAHO, 2006, World Bank, 2016). With an estimated population of 10.4 million, only 40% of the population has access to health care (WHO, 2014). The country has no specific mental health policies or legislation and has only 2 mental health hospitals and .07 psychiatrists, .07 psychologists, .29 nurses, and .06 social workers per 100,000 populations to care for persons with mental health disorders (WHO, 2014).

Theoretical Framework: The Community Nurse Practice Model (CNPM) served as the framework for this study. Based in the values of respect, wholeness, and caring, the CNPM promotes community participation and intersectoral collaboration. The CNPM is grounded in the beliefs: respect for person, persons are caring, and persons are whole and connected to the community and environment (Parker, Barry, & King, 2015). In addition, services and activities are intentionally guided by the concepts of community participation/partnership, empowerment, access, essentiality, and intersectoral collaboration (World Health Organization, 1978).

Literature Review: Rasmussen et al. (2015) described the development of a 13 item, culturally sensitive, depression screening tool, the Zanmi Lasante Depression Symptom Inventory (ZLDSI) for use in Haiti. Using an emic-etic approach, the investigators developed a screening tool with construct and concurrent validity for depression. Wagenaar et al. (2013) asserts that mental health resources should be community based, as supported by the report that there were ten psychiatrists practicing in the public sector at the time of the earthquake mostly located in Port au Prince and mental health services were nonexistent in rural communities. The findings of their study revealed a lack of faith in biomedical providers and the high likelihood of seeking help from a local healer or religious leader for mental health problems. The authors supported the WHO’s initiative to scale up mental health interventions in low income countries by using trained community based health care providers who are not psychiatrists.

Barry, King, Goodman, Gullett, and Grumme (2016) identified overall health needs of the community in Bondeau, Haiti and the need to investigate the mental health needs of the community. Health disparities and limited access to health care in Haiti impact the mental health and well-being of persons. The authors asserted that competence, compassion and humility are needed to develop collaborative partnerships and relationships to explore the mental health needs and resources of the community.

Methods: The study design was a sequential (quantitative-qualitative) mixed methods design. Only the quantitative phase of the study has been conducted which assessed the severity of depressive symptomatology, anxiety and resilience of a convenience sample comprised of adults’ age 18-84 living in Bondeau, Haiti. Data analysis consists of descriptive statistics and correlational statistics (Pearson r , Spearman ρ) which compare the participants’ scores on the Promise Anxiety tool, PHQ-9, Zanmi Lasante Depression Symptom Inventory and Connors-Resilience scores to the participants’ demographics. IRB approval was obtained by the University IRB and written and/or oral consents were obtained by all participants.

Results: The study is in process and findings will be completed in 2017.

Conclusion: This study advances caring science in the discipline of nursing, arrived through intentional research focused on the relationship of caring to mental health and well-being of the whole person within the family and community. The critical role nursing plays in global collaborations and in attaining the United Nation's Sustainable Health Goals of "people-centeredness" healthcare programs (United Nations, 2015) was demonstrated in the study.

Changes in Providers' Viewpoint Eight Years After Implementation of a Neonatal Palliative Care Program

Debra Brandon, PhD, RN, CNS, FAAN, USA

Nancy Dias, PhD, RN, CNE, USA

Margarita Bidegain, MD, USA

Abstract

Purpose: Pediatric palliative care programs are integrated models of care in which curative and palliative interventions coexist (American Academy of Pediatrics Committee on Bioethics and Committee on Hospital Care, 2000). These programs are considered essential care for all infants and children with any life-threatening condition. One third of pediatric deaths occurs in the neonatal period and neonatal deaths occur primarily in critical care hospital settings (Brandon, Docherty, & Thorpe, 2007) and most admissions to the neonatal intensive care unit (NICU) are unexpected. Therefore, decisions to initiate life-sustaining treatments often must be made quickly following birth and sometimes without adequate input from parents (Pinter, 2008). Once life-sustaining interventions are initiated, decisions-making around withdraw of interventions are a source of distress for parents and neonatal providers alike.

Distress for neonatal health care providers is often manifested as moral distress (Brandon, Ryan, Sloane, & Docherty, 2014; Heffernan & Heilig, 1999), defined as conflict between the health care action and a providers' values. Source of moral distress among neonatal health care providers is associated with inappropriate use of aggressive care, providers lack of voice, and delays in transitioning to palliative care (Brandon et al., 2014). Provider moral distress affects the care of patients and palliative care programs may decrease moral distress (Brandon et al., 2014). Therefore, understanding providers' views of palliative care and the factors that impact their agreement with withholding and withdrawing life-sustaining interventions is essential to informing decision making and decreasing provider moral distress.

Therefore, the purpose of this study was to describe changes in neonatal providers' knowledge and comfort with integrated neonatal palliative care eight years after implementation. In addition, typologies of provider palliative and end-of-life decision-making and the relationship between the typologies and providers' moral distress were explored.

Methods: The study design was a cross sectional survey before implementation and 8 years after implementation of neonatal palliative care program. An on-line survey was sent to all neonatal providers in a Level IV neonatal intensive care nursery in the southeastern U.S. The setting was the Intensive Care Nursery of Duke Children's Hospital. The Birthing Center (BC) is a regional referral center with 3300 births per year and the Intensive Care Nursery (ICN) is a 67 bed level IV unit.

The goal of the Neonatal Palliative Care Program is to provide holistic, compassionate, supportive, coordinated, and consistent care to neonates with a life-threatening or terminal condition, and their families. The program is designed to serve families at any point from prenatal diagnosis throughout infancy and is based on four domains of neonatal palliative care: 1) infant and family needs including symptom management, psychosocial distress, spiritual issues, and family support, 2) ongoing reassessment and establishment of the infant's care needs in collaboration with the parents, 3) coordination of infant care across care settings including transition to home and community, and 4) grief and bereavement support for families and providers (AAP, 2000; Carter and Bhatia, 2001). In addition, the program is committed to ongoing education regarding palliative care issues for both neonatal providers and families.

The program developed a number of products to facilitate comprehensive care for the patients and their families. The products developed included a Potential Candidates List, Palliative Care Protocol, a Palliative Care Order Set, a Nursing Palliative Plan of Care, a Medication list, a Family Conference Record, and an Infant Withdrawal of Care Protocol. In addition, a pamphlet was designed that can be provided to families, which gives an easily understood description of palliative care.

Survey measures included: 1) a demographic information; 2) an investigator developed measure of Neonatal Palliative Care (NPC) knowledge attitudes with a Likert scale; and 3) a provider moral distress scale developed by Corley and colleagues (Corley, Elswick, Gorman, & Clor, 2001) and modified by Hamric and colleagues (Hamric & Blackhall, 2007). The modifications were to adjust the questions to specific provider types (physicians, nurses, and others). Further modification to align with the NICU setting was completed with permission of Dr. Hamric.

All primary neonatal providers (RNs, NNPs, Neonatologists, Fellows, Social Work, Developmental Specialists, Unit Clerks) were emailed an invitation to complete an anonymous online Redcap survey. The link to the survey was active for one month, and the sample of providers received weekly emails reminding them to complete the questionnaire.

Results: 124 and 114 respondents completed the survey in 2007 and 2015 respectively for a 54% and 43% response rate. Mantel-Haenszel Chi-Square was used to evaluate provider knowledge and attitude differences before and after program implementation. Most respondents were nurses (79.8%). There were no significant differences in providers' perceptions of their competence in providing NPC before and after program implementation. Providers perceived themselves to be either competent or extremely competent with providing comfort measures, managing pain and other symptoms (anxiety, gasping), recognizing impending death, and understanding the role of palliative care over 90%. However, talking with families about palliative care and dying was lower with about 70% of providers expressing competence. While providers generally felt they were competent at providing NPC the delivery of some aspects of NPC were viewed as more of a problem after program implementation. For example, reluctance of the health care team to discuss palliative and end-of-life care increased from around 50% before implementation to 85% 8 years after program implementation.

Latent class analyses were conducted around withholding or withdrawing 16 life-sustaining interventions. These interventions ranged from withholding or withdrawing nutrition and antibiotics to withholding or withdrawing mechanical ventilation and resuscitation. Three typologies of decision-making were present both before and after program implementation. Providers either *mostly agree*, *mostly disagree*, or had *selective agreement* with limiting or withdrawing life-sustaining interventions. Moral distress scores were moderately high. Nurses had significantly higher total moral distress scores (mean=94.33; SD=52.74) than physicians (mean=59.70; SD=42.07). In ordinary square regression analyses providers' moral distress predicted their decision-making typology ($p < 0.001$). Moral distress was highest among the providers in the *mostly agree typology* (median=116) and lowest in the *mostly disagree* (median=68) typology.

Conclusion: Providers' knowledge and comfort with neonatal palliative care was generally good at both baseline and 8 years following program implementation while problems with implementation of specific interventions were viewed as more problematic. One possible explanation for this finding could be the greater awareness of the importance of NPC and thus more concern or recognition that care was not consistently applied. This finding is consistent with our moderately high levels of provider moral distress. Provider moral distress over the use of certain interventions may impact the delivery of NPC and negatively impact the providers' well-being. Institutional support for both parents and care providers is essential for effective delivery of NPC.

Perceptions of Nursing Students of Study Abroad Experiences

Camille Payne, PhD, RN, USA

Genie E. Dorman, PhD, APRN, BC, FNP, USA

Abstract

Purpose: The purpose of this research study was to explore nursing student perceptions of study abroad experiences. The findings of this study may help to guide faculty in developing new opportunities, and increasing the meaningfulness of existing study abroad courses.

Methods: Basic qualitative methods were used to conduct the data collection and analysis for this study. Undergraduate nursing students who had participated in previous study abroad experiences were recruited by email invitation. The researchers scheduled individual, one on one interviews with the nursing student participants. At the beginning of the interview, participants were provided with consent forms, and any questions were addressed. The interviews were guided by pre-set, semi-structured, open-ended questions, and were conducted in quiet areas of the participant's choice. Interviews were audiotaped, transcribed, and checked for accuracy.

Results: Themes and categories of responses emerged through qualitative data analysis. Researchers initially reviewed and categorized data independently. After this, researchers discussed findings and collapsed categories. Data analysis revealed consistent patterns of responses in students. Results were shared with faculty colleagues who participate in the development and direction of study abroad programs.

Conclusion: The data revealed that students found overall that the experience served to help them better understand individuals from different cultures and different health care systems, as well as to explore different health beliefs. Students expressed a new understanding of cultures and geographic areas in which there is reduced access to high level health care and technology, but patient care needs are still met. Expecting to teach, and not to be taught, students were surprised at the ways in which they were themselves educated about other people and different cultures. Participants shared that these experiences have enabled them to create their own new world views, and will further enable them to provide health care that is more culturally sensitive and aware as future nurses. Specific recommendations will be directed for nursing education courses and programs.

Incontinence Associated Dermatitis Assessment Scale: Study of Inter-Observer Compliance

Gulsun Ozdemir Aydin, MSc, RN, Turkey

Hatice Kaya, PhD, RN, Turkey

Abstract

Purpose: This research was designed to adapt the Incontinence Associated Dermatitis Assessment Scale (IADAS) to Turkish and to show the usability of the scale in our country.

Methods: The study which was planned in the type of methodological research was carried out in two stages. In the first stage, the language equivalence of the scale was performed using translation-back translation techniques, it was submitted for the opinions of 5 faculty members who are experts in their fields to assess the Content validity, and the expert opinions obtained were assessed by the Content Validity Index. Then, nurses were asked to give points in accordance with the instructions of the scale by showing an image demonstrating the dermatitis development at different levels. This second stage was carried out with 65 nurses working in the neurology, neurosurgery, physical therapy and rehabilitation clinics of two university hospitals. ICC: Intraclass Correlation Coefficient was used in the inter-observer reliability assessment. The significance was assessed at the $p < 0.05$ level.

Results: The content validity index of the scale was determined as 1. It was found that the average of age of the nurses who participated in the research was 32.52 ± 5.80 , 87.7% of them had an occupational experience of 3 years and above, and 86.2% of them did not receive any training for the development of incontinence associated dermatitis. In the assessment made by the nurses using the sample image, the average of the point they get from the scale was 23.94 ± 3.92 . The inter-observer intraclass correlation coefficient (ICC: 0.867, $p = 0.001$) of the scale was found high ($p < 0.01$).

Conclusion: In line with these results, it can be said that the inter-observer compliance of the incontinence associated Dermatitis Assessment Scale (IADAS) is very high, it can be used effectively in determining and assessing the dermatitis in incontinence patients with high dermatitis development in our country. This scale is useful in nursing care.

Selecting Internationally Educated Nurses (IEN) to Participate in a Program of NCLEX-RN® Preparation

Susan T. Sanders, DNP, RN, NEA-BC, USA

Abstract

Purpose: Identifying appropriate IEN applicants to enter a prescriptive program of study to prepare for the NCLEX®-RN. The challenges for IENs to become licensed in the United States through the NCLEX®-RN have been chronicled in multiple publications. Squires (NYU, 2016) noted the decline in IEN pass rates on the NCLEX®-RN declined from 58% in 2004 to 32% in 2015. Language is one of the issues with IENs but cultural differences also create a gap in knowledge and/or ability to answer the NCLEX®-RN items (Richmond, 2013). Boshier and Bowles (2008) identified a 40% disparity in NCLEX®-RN pass rates despite academic performance.

Methods: A validation study will be conducted to determine admission into the prep program. In order to improve success rates for IEN on the NCLEX®-RN, a standardized test will be developed and administered to IENs. A score range will be established to determine recommended score(s) for successful completion of the NCLEX®-RN examination. Upon acceptance into the prep program a structured on-line course will be provided that includes content review, practice and standardized/benchmarked tests, language review, and a NCLEX®-RN review class will be offered to the students with appropriate entrance scores.

Results: The prep program is in use at this time without the use of the screening test. To date, the current students consisted of an initial 4 cohorts of 46 students who have completed the prep and review with a resulting 56.5% pass rate on the NCLEX®-RN. The IENs enrolled in this prep course have been working with mentors and faculty to complete the components of the program while working as nurses in their current country of residence. The goal to become NCLEX®-RN licensed is a strong motivator for these nurses to complete the prep program.

Conclusion: The hypothesis is that the student success rate will increase with the utilization of the screening test prior to admission into the prep program.

RSC PST 2 - Research Poster Session 2

Leveraging Statistical Simulations to Gain Insights From Data: A New Type of Simulation for Nurses

Alvin D. Jeffery, PhD, RN-BC, CCRN-K, FNP-BC, USA

Abstract

Purpose: Nurses scientists are finding themselves working with increasingly more quantitative data from a variety of sources and do not typically have the same degree of training in theoretical statistics that an epidemiologist or statistician might have. Even if nurse scientists were equipped with such training, they might still be uncertain of the best statistical approach for analyzing data under new or unknown assumptions. Statistical simulations can be beneficial, but do not appear to be frequently used by nurse scientists.

To illustrate the benefits of statistical simulation studies, this presentation will provide both a basic use case and a more complex exemplar. The first case compares basic statistical tests for differences in means and is intended to demonstrate the ability of simulation to illustrate rules and concepts taught in an introductory statistics course. The second case compares more complex statistical approaches to handling missing data in a clinical dataset as a way to demonstrate the ability of simulation to guide analysis approaches in real-life applications.

Methods: The first demonstration will compare the use of the Student's t-test, non-parametric Mann-Whitney U-test, and ordinary least squares regression for samples of varying sizes from populations with differing effect sizes. After creating 2 populations (N = 100,000) with differences in means ranging from 0 to 2 times the mean of the first population, we extracted sample sizes ranging from 6 to 400. For each effect size and sample size, we conducted 1,000 "studies." In each study, we tested for a difference in means using the aforementioned t-test, U-test, and regression approaches.

The second exemplar will illustrate a case study where the presenter used a simulation study to explore the preferred approach for handling missing data in a clinical dataset where some variables had a large amount of missing data. The simulation study comprised the following assumptions: (a) incidence of missing from 1% to 60%, (b) data missing completely-at-random, at-random, and not-at-random, and (c) missing associated with outcome and not with outcome. Imputation procedures included simple median imputation and multiple imputation with chained equations approaches. Analysis approaches included both a logistic regression and a Cox proportional hazards regression, and sample results were pooled and compared to true population values.

Source code for replicating the simulation studies and resources for learning the statistical software R will be provided to interested audience members.

Results: In the first example, graphical results demonstrate that: (a) the percentage of statistically significant findings [$p < 0.05$] increases with larger sample sizes and effect sizes and (b) the percentage of discordance among statistical tests becomes negligible at larger sample sizes and effect sizes. In the second example, graphical results demonstrate that multiple imputation with a model that includes the outcome variable obtained results closer to true values under most assumptions.

Conclusion: Statistical simulations leverage modern computing abilities to explore results of statistical approaches under a variety of assumptions. By creating a large population where true values are known and then analyzing multiple samples taken from the population, one can gain an idea of which analysis method(s) might be preferred based on the assumptions he/she is willing to make.

Assuming Caucasianess in Pressure Injury Research: A Literature Review

Neesha Oozageer Gunowa, MSc, DN, RN, QN, SPT, HEA Fellow, United Kingdom

Marie Hutchinson, PhD, RN, RM, Australia

Joanne Brooke, MSc, BSc, RN, CPsychol, United Kingdom

Debra Jackson, PhD, RN, FACN, United Kingdom

Abstract

Purpose: Systematically examine research literature about people with darkly pigmented skin in relation to pressure injuries.

A pressure injury, previously known as a pressure ulcer, is an injury to an area of skin and/or underlying tissue often on a bony prominence which may be caused by pressure, shear or other factors (EPUAP, 2016). Despite best efforts, pressure injuries are a significant cause of harm to patients, and in addition to the human suffering, which may include pain and psychological distress they cost the United Kingdom National Health Service billions of pounds a year (Dealey et al., 2012) The importance of effective skin assessment and early recognition of skin damage is an essential step in reducing the burden of harm to patients (NPUAP and EPUAP, 2009). Yet all current skin assessment strategies assume that a patient is Caucasian (NICE, 2014).

Methods: After establishing inclusion and exclusion criteria a comprehensive electronic database search was undertaken of PubMed, Cumulative Index for Nursing and Allied Health Literature, Cochrane and British Nursing Index between 1990 – May 2016. Variations of the following terms: 'pressure injury', 'pressure ulcer', 'deep tissue injury' 'bed sore', 'decubitus', 'ethnicity', 'race', 'skin tone' and 'skin colour' were used after being audited by a healthcare librarian.

Results: It was identified that there is a dearth of literature exploring pressure injury risk amongst people with darkly pigmented skin, as 12 relevant articles were identified through the criteria set. All the articles were quantitative studies mostly based on secondary analysis of data in the United States of America, using set categories of skin colour such as black or white. The studies incorporated a large number of subjects, one of which analysed data from 2,936,146 residents (Ahn et al, 2016)

Employing a component ratings assessment (National Collaborating Centre for methods and Tools, 2008) the studies were assessed as weak or moderate due to issues of reliability, tool validity and methodology. The focus of the research was statistical rather than acknowledging and exploring overall skin tone variances and individual experiences.

Conclusion: Most of the studies reviewed excluded early stage pressure injuries as the assumption of identification was seen to be difficult and often unreliable, particularly in people with darkly pigmented skin. A recurrent theme in the findings of these studies confirmed that people with darkly pigmented skin were more likely more likely to develop severe pressure injuries as they are seen to be difficult to identify. The literature review also revealed that there is very little empirical research to guide and support health professionals, patients and carers to reduce pressure injury in black and ethnic minority communities resulting in significant health inequalities and implications for nursing practice.

International Clinical Experiences for Required Clinical Contact Hours in U.S. Schools of Nursing

Tamara H. McKinnon, DNP, RN, APHN, USA

Joyce J. Fitzpatrick, PhD, RN, FAAN, USA

Anglea McNelis, PhD, RN, FAAN, ANEF, CNE, USA

Kathleen de Leon, MS, RN, USA

Abstract

Purpose: Background

Over the past decade, there has been an increase in interest and participation in international experiences and programs in United States Schools of Nursing as faculty are concerned with preparing future nurses as global citizens. In fact many schools of nursing have an explicitly stated commitment to international experiences and/or global citizenship as a component of their mission and vision. And the subject of international health may be integrated into the nursing curricula. Further, the ever-increasing multicultural population in the US poses a significant challenge to nurses for providing culturally appropriate and holistic care to their patients as many are unprepared or underprepared to care for diverse citizens. Nurses are required to be knowledgeable and understand cultural differences in healthcare values, beliefs, and customs. International clinical experiences provide an environment for developing knowledge, skills, and attitudes that promote culturally competent care. Despite increasing interest and strong philosophical and evidentiary support for international learning experiences, a recent national survey by the National League for Nursing (NLN) revealed that fewer than 50% of US schools of nursing have such programs, and faculty respondents identified significant obstacles to program development (McKinnon & McNelis, 2011).

Study Aims

Specific Aim 1: Describe the nature of international clinical experiences for required clinical nursing courses in RN pre-licensure programs in US schools of nursing.

Specific Aim 2: Obtain information about understanding of their state BON regulations regarding international clinical experiences from the program director/program administrator of RN pre-licensure programs in US schools of nursing.

Methods: This National Council of State Boards of Nursing funded study will include a national survey of all Registered Nurse pre-licensure programs in the United States including Associate Degree, Bachelor's Degree, Diploma, and Master's Entry programs. We will assess the use of international clinical experiences to meet required clinical content across all clinical content areas and clinical nursing specialties, determine facilitators and barriers to using international clinical experiences, and identify the basic understanding of State Board of Nursing requirements. While this national survey is limited to United States based schools of nursing, it is our intent to expand this work to address similar issues in other countries.

Results: Preliminary survey results will be presented.

Conclusion: Preliminary survey results and conclusions will be presented.

Ruth-Alma N. Turkson-Ocran, MPH, MSN, RN, FNP-BC, USA

Joanne Fitzpatrick, PhD, RN, United Kingdom

Anne Jones, MSc, PhD, PGCert, RGN, FHEA, United Kingdom

Abstract

Background: Nursing doctoral programs exist in varying models around the world. While there are many measures of success for these programs, one way is through the collaborative opportunities a program provides and the success of the students in maximizing these collaborative efforts (Edwards, Rayman, Diffenderfer, & Stidham, 2016). Doctorally prepared nurses value opportunities to learn from each other and form professional contacts as they prepare for their future careers (Jairam & Kahl, 2012). Seeking international peers through a web-based platform can be used to increase collaboration and peer support.

Purpose: The purpose of this presentation is to describe an international doctoral student seminar and the lessons learned in the first year in order to support the development of other international collaborative partnerships by 1) describing the establishment of the group and 2) identifying benefits and barriers to the process.

Methods: The International Doctoral Student Collaboration was initiated by two faculty members from King's College London (United Kingdom) following a meeting of The International Scientific Advisory Board (ISAB). After establishing an internal interest in the project, invitations were extended to Johns Hopkins University (USA) and University of Turku (Finland). These collaborators were initially chosen on the basis of their established links between the faculties at these institutions. A steering group comprised of doctoral students from the faculties of Nursing from each University was established to lead on this initiative. The inaugural seminar was held in September 2015 and hosted by King's College London with further seminars hosted in turn by University of Turku and Johns Hopkins University. Due to the success of these seminars, the collaboration has been extended to include doctoral students from University of North Carolina at Chapel Hill (USA). Meetings continue to be held in rotation, with topics of the seminars jointly determined by the participating Universities. The host University then identifies a suitable expert on the chosen subject to facilitate the seminar. Each seminar is conducted via videoconferencing. Between seminars, students continue to network and communicate via other multi-media platforms.

Results: Twenty-three students and faculty across the four universities participate in the seminar. Presentations in the first year have focused on how to build an international research profile, how to be involved with the peer review process in academic journals, and how to effectively engage in social media as a researcher. Benefits to the students have included being visiting scholars at each other's university, building a professional network, and utilizing peer support. Students have taken opportunities to meet each other through mutual attendance at conferences and trainings, further strengthening the collaborations. Additionally, the group is currently collaborating on a manuscript for submission. Some of the challenges encountered in the first year have included navigating international time zones and different academic schedules. Also, a lack of shared web-based conference platforms meant that as each institution hosted a seminar, a new system had to be accessed.

Discussion:

International student collaboration presents a unique opportunity by allowing the student to create a community of support, develop leadership skills, and form an international professional network (Rautenbach & Black-Hughes, 2012). Shared team leadership, with each university taking rotating responsibility for content, has been linked with higher success of virtual teams (Hoch & Kozlowski, 2014). Additionally, researchers have suggested a framework for the enhancement of international scholarship by collaborative learning through a web-based initiative (Wihlbord & Friberg, 2016). This collaboration

provides a unique opportunity for doctoral students to form an international professional network and a community of support among peers.

Conclusion: In the first year of this international doctoral student collaboration, key benefits to members have been the development of a professional network, leadership skills and peer support. Participation in the seminar encourages early engagement in career building with a focus on supporting international research.

RSC PST 2 - Research Poster Session 2

Disaster Response Preparedness and Training: A Capabilities Assessment of Asia Pacific Partners

Mary Catherine Goetter, PhD, RN, NEA-BC, USA

Susan F. Dukes, PhD, RN, CCNS, USA

Abstract

Purpose: The purpose of this study is to address a knowledge gap in understanding how military personnel involved in casualty transport would be able to function with their military and civilian counterparts in the event of a disaster involving multinational response. United States Air Force (USAF) personnel have accrued robust experience in patient evacuation employing en route care (ERC) systems and critical care air transport teams (CCATT) that were established, designed, and studied in wartime. In the event of a multinational disaster, this resource will likely be tapped; however, ERC and CCATT have not focused on scenarios outside of wartime. USAF personnel will need to work with host and volunteer nations to evacuate casualties, yet little is known about how military personnel of other nations train for disaster response. The need to seamlessly integrate with these military and civilian counterparts is a given, but there is a lack of knowledge and understanding on how that would operationalize. Disaster response preparedness is a critical issue for military and healthcare leaders. Major disasters have captured world attention: earthquake, tsunami, and resultant nuclear event [Japan 2012], Typhoon Hagupit [Philippines 2014], and most recently the earthquake in Nepal [2015]. Disasters on this scale require more than one nation's resources and response. The Asia Pacific Military Health Exchange (APMHE) is an annual military medicine event that combines the features of three previously separate medical, nursing, and leadership information exchanges into a single event. APMHE was developed to foster information and knowledge sharing between U.S. Department of Defense (DoD) and non-DoD entities to further shared aims. Disaster preparedness and response is a key commonality between U.S. and Asian military members, as well as civilians and non-governmental organizations (NGO) providing response and relief. Despite language or cultural differences, the need to rescue and evacuate casualties is a shared priority in disaster preparedness and response. This study will add knowledge to our understanding of how other nations train for disaster response preparedness, as well as assess disaster response preparedness training capabilities.

Methods: Program evaluation is a method that informs decision-making for a specific program, in this case, disaster response preparedness training and capabilities of member nations of APMHE. This method of inquiry and assessment aims to meet the evaluation needs of the various stakeholders. The capabilities assessment was a basic inquiry using survey method to gather demographic and factual information to determine how our military counterparts train for disaster response. The ultimate aim was to assess capabilities in the current system and inform future decisions related to the ability to work together with other nations to transport casualties in nontraditional ERC platforms.

A basic survey questionnaire using Survey Monkey® was distributed to all APMHE participants (members of medical, nursing, medical service corps) who actually attended the 2016 meeting, as well as those who were not selected to attend, but expressed interest and visited the APMHE webpage. Attendance to APMHE is limited due to fiscal and logistical constraints; many countries were limited in the number of attendees they could send, but military unit colleagues of the attendees would still have valuable input to be solicited. A link to the survey questionnaire was posted on the APMHE website and Facebook page, as well as emailed to the attendees on the distribution list of the meeting. Participants were asked to fill out a questionnaire gathering simple demographic information and facts about disaster response preparedness and training.

Results: Data collection is in progress and is expected to be completed by mid-2017. Descriptive statistics will be used to illustrate the sample and trends. Chi square analysis will be performed for subgroup analysis as appropriate. Results will be disseminated at future meetings of the APMHE.

Conclusion: This program evaluation of disaster response preparedness training and capabilities assessment will increase knowledge and understanding of this critical issue among military and civilian colleagues in the Asia Pacific region. Knowing the status quo of disaster response preparedness training will enable USAF leaders to narrow the knowledge gap of understanding of how evacuation and casualty movement could occur in a real world disaster in the Asia Pacific region. Knowing how our counterparts train, identifying common areas of disaster response training needs, and formulating concrete plans to close gaps will build international collaboration and improve the likelihood of saving lives. The

researchers plan to take the lessons learned from this study and further expand collaborations with African and European partners.

Safety Culture: Medication Adverse Event Tracking at a Pediatric Oncology Hospital in Guatemala

Liliana Zelaya, BSN, RN, USA

Emily Dray, MSN, RN, CCRN, CPNP, USA

Abstract

Purpose: The ECHO Project: Educacion de Cuidados Intensivos en un Hospital de Oncologia is a multidisciplinary educational collaborative between the Medical-Surgical Intensive Care Unit at Boston Children's Hospital and Unidad Nacional de Oncologia Pediatric (UNOP). The initial goal of the partnership was to facilitate the development of an acute care nursing orientation and continuing education curriculum for the hospital and has grown to encompass other strategic goals. In January of 2016 the ECHO Project team, consisting of two Boston Children's Staff Nurses and two Boston Children's Clinical Pharmacists, traveled to Guatemala for a quarterly site visit. The goals for this visit were to perform an assessment of pharmacy systems and evaluate processes already in place to ensure medication safety. The assessment uncovered the need for a comprehensive medication adverse event tracking system in the context of unknown error frequency or classification.

The Harvard Medical Practice Study demonstrates that medication errors are the most frequent type of medical adverse event; it is for this reason that we chose to focus on medication event tracking (Kaushal et al., 2004). It is well delineated in the literature that adverse drug events are preventable. Pediatric patients are a high risk group when it comes to medication adverse events for several reasons, including, but not limited to: weight-based dosing, dilutions to stock medications are needed to create appropriate dosing, and wide variations in organ function (Kaushal et al., 2004). Pediatric cancer patients are at especially high risk due to the potential for both toxicity and treatment failure with medication errors (Oberoi, Trehan, & Marwaha, 2014). There is a paucity of literature with regard to medication error rates among pediatric oncology patients, especially in low resources settings. This quality improvement project will contribute to the knowledge base while at the same time directly impacting the quality of patient care. The creation of safer systems has the potential to improve patient outcomes and decrease morbidity and mortality.

Methods: Using the Plan-Do-Study-Act method for quality improvement we will implement a hospital-wide medication adverse event tracking system in collaboration with a multidisciplinary team of Boston Children's Hospital experts and UNOP leaders.

- Identify key stakeholders at UNOP and at BCH to define the project team and leaders. Engagement of hospital leadership at UNOP.
- Perform a literature review to determine existing evidence on medication error frequency and tracking systems in low resource hospital settings.
- Design a reporting form that is easily accessible to all staff and user friendly.
- Design and implement Medication Adverse Event Tracking training for all levels of hospital staff.
- Tracking of medication adverse events to identify system strengths and weaknesses.
- Multidisciplinary root cause analysis to assess findings and implement changes based on institutional needs, resources, and limitations.

Results: Project continues to be ongoing.

Conclusion: Medication errors are a global health care issue and in low-resource settings there is a lack of infrastructure to support non-punitive identification and correction of systems errors that contribute to medication adverse events. This quality improvement project takes a systems approach to medication adverse events to identify medication error frequency, define systems strengths and weaknesses, and promote solutions to increase patient safety and reduce nursing and/or pharmacy workload. Collaboration with our colleagues at UNOP is essential to design a successful and sustainable system that meets institutional standards and needs.

Capacity Building: Writing Abstracts and Disseminating Research Through Video Conferencing From Different Countries

Anita Collins, PhD, RN, RM, Rwanda

Philomene Uwimana, MSN, BN (Hons), RN, Rwanda

Abstract

Purpose: An abstract is an essential part of a research article and the three areas of importance in it are the language, or the readability, the sequence of information, or the structure, and the typography, or the presentation. (Hartley J. 2000). One specific goal of student researchers is learning to write an accurate abstract. Writing accurate abstracts is a learned skill. Students need to learn to write an abstract which has one or more paragraphs that are unified, coherent, concise and able to stand alone. (Jester P. 2014). Technology can be used to increase the collaborative nature of training, but to build capacity and increase training effectiveness, technology must be implemented in a way to meet specific goals or used to deploy a learning element. (Askanase D, Berry A, Martone K and Swink R. 2016). Learning to write accurate abstract is a specific goal for novice nurse researchers that can use the implementation of technology such as video conferencing. They can be connected to experienced researchers presenting their abstracts with the help of Video conferencing.

Technology such as Online video sharing technologies is also a new and easier way for disseminating latest research findings and making it more accessible to a larger audience than the traditional academic journals. (Rokka J. 2016).

The purpose was to show case the use of technology for capacity building in research and in dissemination of research and collaborative training of MSN students

Methods: To achieve these two goals the postgraduate research student virtual scholarly event "Nursing and midwifery research across Europe" which was hosted by the STTI Upsilon XI at Large Chapter was used as a platform for capacity building of eighteen Rwandan students of the MSN program Medical Surgical track, and one Rwandan PhD aspirant at the University of Rwanda, East Africa.

Rwandan students benefited as they joined the post graduate nurse researchers from Edinburgh Napier University, United Kingdom, University of Gothenburg, Institute of Health and Care Sciences, Sweden, University of Primorska, Slovenia, and Bournemouth University, United Kingdom as presented their abstracts in a video conference. One researcher from Jordan was not able to join in due to problem with net connectivity. However she had sent her abstract by email which could be read by the students.

This was followed a short talk by Prof. Joy Merrell of Swansea University and President of the Chapter on the benefits of being in STTI.

Results: The Rwandan MSN students joining in, in this technological platform was to help these novice researchers to structure and present their own Master's dissertation abstract. It has helped them to broaden their minds and see for themselves that video conferencing involving several countries to disseminate their own Master's research findings, is a possibility in the near future.

Conclusion: Connecting MSN students from resource poor country to experienced nurse researchers across two continents, three countries and four universities to improve their abstract writing skills optimizes technology in nursing education

Children of War: Implementation of Non-Specialist Mental Health Interventions

Adria Spinelli, BSN, RN, USA

Jennifer Leeman, DrPH, MDIV, USA

Gillian Litynski, BSN, RN, USA

Abstract

Purpose: Over one billion children live in countries or territories affected by armed conflict or war. Of these, 88.9% of those events occur within Low and Middle Income Countries (UNHCR, 2015; Uppsala Conflict Data Program, 2015). A growing number of mental health interventions exist that reduce children's trauma symptoms with varied levels of effectiveness (Betancourt, Meyers-Phki, Charrow, & Tol, 2013; Barry, Clarke, Jenkins, & Patel, 2013). Frequently, nurses and other health care professionals who are not specialized in mental health are providing these interventions (Jordans, Pigott, & Tol, 2016). A possible reason for interventions' varied effectiveness is inconsistent implementation. The purpose of this review is to determine the extent to which implementation findings are reported, according to Fixsen's Core Components for Implementation, among interventions provided to children affected by armed conflict.

Methods: A search was performed using PubMed, CINAHL, and PsycINFO to identify empirical studies testing mental health interventions for children in conflict who experienced a traumatic event. The search combined key words and MeSH terms related to "conflict" or "war" or "refugee" with those for "mental health" or "psychosocial" "interventions". The date range for articles was October 2011 – November 2016. Studies were examined if they occurred in a Low or Middle Income Country and the study sample was children. Data were extracted on intervention type, study design, sample demographics, information on the intervention and outcome data. To describe implementation, data was extracted on implementation strategies (based on Fixsen's implementation components; e.g., training, coaching, staff performance evaluation); implementation outcomes (based on Proctor's taxonomy; e.g., fidelity, feasibility); and on contextual factors that influenced implementation (Fixsen, Blase, Naoom, & Wallace, 2009; Proctor et al., 2011).

Results: The initial search produced 450 studies of which 54 underwent full text review and 20 met inclusion criteria. The interventions occurred in Palestine, Sudan, Nepal, Rwanda, Democratic Republic of the Congo, Uganda, Burundi, Indonesia, Sri Lanka and Bosnia and Herzegovina. Countries included those in armed conflict and post conflict. The interventions included Cognitive Behavioral Therapy (CBT), Trauma-Focused CBT, Classroom-Based CBT, Writing Therapy and Child-Friendly Spaces. Authors provided only limited information on the strategies used to implement interventions, intervention outcomes, and contextual factors that influenced implementation. Less than half of the interventions reported activities that fall within Fixsen's Core Components for Implementation.

Conclusion: Few studies reported implementation strategies and none of the studies mentioned implementation theories or frameworks that guided the research. This is problematic because effectiveness of these interventions could increase if implementation strategies were used. For instance, effectiveness of mental health interventions in the U.S. has increased by using implementation techniques (Kilbourne et al., 2014). Prior to conducting research using implementation techniques, research is needed to understand which of those techniques are best suited for nurses and other non-specialized health workers. Ultimately, by using implementation techniques, intervention effectiveness will increase and could improve the well-being of children affected by armed conflict in Low and Middle Income Countries.

RSC PST 2 - Research Poster Session 2

Identification of Barriers, Facilitators, and Recommendations for Chiropractic Health Systems Change for Tobacco Cessation Activities

Kelly P. Buettner-Schmidt, PhD, RN, FAAN, USA

Mary F. Larson, PhD, MPH, LRD, CDE, CHES, USA

Brody Maack, PharmD, CTTS, USA

Megan Orr, PhD, USA

Becky McDaniel, MSN, RN, USA

Donald R. Miller, PharmD, FASHP, USA

Katelyn R. Mills, MPH, USA

Abstract

Purpose: The purpose of the focus group was to ascertain the barriers and facilitators related to adopting evidenced-based health system changes to address patient tobacco use and cessation, the clinical quality measures related to tobacco use, and to identify key factors for researchers to consider when developing and piloting a health systems intervention for chiropractors to address tobacco use by their patients.

Methods: Using a participatory research method (Israel, Eng, Schulz, Parker, 2013), specifically, a grounded theory (Cho, 2014) qualitative study using a focus group (Carver, 2014) with chiropractors (n = 4). The chiropractors were purposively selected to participate due to their leadership positions in the chiropractic community. One focus group session, lasting 45 minutes, was held on a university campus. Participants were provided informed consent prior to the start of the focus group. The focus group participants were asked four questions about the barriers and facilitators related to adopting evidenced-based systems change to address patient tobacco use and cessation, clinical quality measures related to tobacco use, and to identify key factors for researchers to consider when developing the intervention for the pilot study. The focus group was audio-recorded and transcribed verbatim. During the initial analysis three researchers read and analyzed the transcript separately. The researchers independently identified key content using a matrix method (Averill, 2002). The researchers then collaboratively reviewed the matrices to develop codes and themes through constant comparison and discussion. Using an inductive consensus-based analytic approach (Cho, 2014; Graneheim & Lundman, 2004), the authors agreed upon the results.

Results: The focus group participants identified facilitators, barriers, clinical quality measures, and identification of the most important factors to consider for development of this pilot study. The factors that facilitate evidence-based tobacco control strategies within chiropractic clinics included trusting relationships developed between chiropractors and their patients, accessibility of chiropractors due to their presence in multiple geographical locations, potential expansion of typical scope of practice and related potential reimbursement, wellness focus of chiropractic care is consistent with addressing tobacco use, knowledge of the connection between tobacco use and pain and healing, a responsibility or desire to help their patients, and the frequency of patient visits. Barriers included concerns of “confronting” patients regarding tobacco use may result in loss of positive relationships with patients, and subsequent loss of business, the chiropractor’s lack of knowledge, confidence, and skills to address tobacco cessation with patients in a positive manner, and lack of reimbursement. Clinical quality measures and benchmarks that were discussed by the chiropractors included Medicare, meaningful use of electronic health records, lack of the medical necessity of addressing tobacco use for musculoskeletal conditions, as well as being future-focused for how reimbursement is evolving, and the cost-benefit analysis of all quality measures. The economic business model is an important framework for chiropractor assessment of selecting quality improvement changes. Factors considered most important to the development of the intervention included ease of process, methods for engaging with patients free of confrontation, recognition of conflicting philosophies of chiropractors in relationship to pharmaceutical interventions.

Conclusion: These findings clarified the concerns that chiropractors practicing in a rural state in the USA have about incorporating evidenced-based health systems change to address their patients’ tobacco use within their clinics. The importance of making this economically neutral, that is, not cost a small business income, were also stressed by the participants. The findings from this study are being used to implement a collaborative, interdisciplinary tobacco systems change education program for chiropractors in a rural state in the USA. Results from this study emphasize the importance of addressing the unique needs of health care practitioners when implementing health systems changes to address tobacco use (CDC,

2014; CDC, 2016). As public health nurses often provide outreach and education of healthcare professionals on tobacco cessation, it is important to consider inclusion of chiropractors while being sensitive to their distinctive concerns. In addition, this study demonstrates the importance of interdisciplinary research, practice, and education to improve population health.

Structural Violence in Elderly With Functional Dependence

Anahi Ruiz-Lara, RN, Mexico

Jesus Acevedo-Alemán, PhD, Mexico

María de los Angeles Villarreal-Reyna, PhD, RN, Mexico

Ana Laura Carrillo-Cervantes, MSN, RN, Mexico

Abstract

Purpose: To determinate the effect of the intervention in nursing to prevent structural violence in dependent elderly families, . Neuman's System Model will serve as the theoretical background for this research.

Methods: Quasi-experimental design with repeated measurements and two groups: experimental group and control group; the experimental will participate in a psychoeducational program which consist in 8 sessions of two hours per session, the study population will consist of dependent elderly families from the city of Saltillo, Coahuila, Mexico. The central hypothesis of this project is that the families of elderly adults in functional situation participating in the experimental group will be sensitized to the problematic of structural violence and it consequences. Sampling will be for convenience. The outcome variables to be measured before, during, after and follow-up at of the experimental condition using validated instruments will be structural violence and functional dependency. The sample size will be calculated using ANOVA for repeated measurements with three levels (level of trustfulness 95%, potency =0.90) for the interaction time per group, and a size of the large effect. We will use the nQuery Advisor 7.0 software. The data collected will be analyzed with Statistical Package for Social Sciences 24.

Results: The outcome variables will be analyzed using repeated measures ANOVA and post hoc analysis to determine differences between groups and effect size; also will be describe the relationship between the study variables: structural violence and elderly dependent.

Conclusion: We will discuss the importance of the development of nursing interventions based on scientific evidence for the development of a nursing care plan to reduce and / or prevent, or both, elderly violence in organizational, institutional and community contexts, also we will discuss the importance of the nursing role as the spokesperson for recognizing that structural violence is a social and health problem and its effects are factors that affect the quality of life and the well-being of elderly population.

RSC PST 2 - Research Poster Session 2

The Role of Religion and Spirituality in Parent Decision-Making for Critically Ill Young Children

Melissa J. Kurtz, MSN, MA, RN, USA

Marie T. Nolan, PhD, RN, FAAN, USA

Jill Hamilton, PhD, RN, FAAN, USA

Abstract

Purpose: Approximately 85% of African Americans and 58% of Caucasians say religion is very important in their lives (Grossoehme et al., 2012). More specifically, significant literature cites parents' use of religious coping in pediatric decision making. However, what is still unknown is how parents of young children utilize religion and spirituality during the decision making process. A more in-depth exploration of the existing research that has explored religion and spirituality and parent decision making will inform the development of decision support interventions that promote parent engagement in complex pediatric decision making. Therefore, the purpose of this presentation is to systematically review the literature describing the role of religion and/or spirituality in critical care decision making for parents of children under 2 years of age.

Methods: Keyword searches of peer-reviewed literature investigating the relationship between spirituality or religion and parents' medical decision making for a critically ill child under 2 years of age were conducted using relevant databases, including PubMed, CINAHL plus, PsychInfo, and Embase. The review was limited to studies published between January 2004 and September 2016. Titles and abstracts for 141 nonduplicate records were screened. Thirty three of these full-text articles were reviewed and 20 published studies were included. Resulting quantitative and qualitative studies were summarized using thematic analysis.

Results: Twenty articles met final inclusion criteria examining the relationships among religion/spirituality and shared decision making. Resulting thematic categories included: 1) Finding meaning in the experience of caring for a critically ill young child; 2) Using spirituality and religion for guidance in medical decision making for a critically ill young child; 3) Using spirituality and religion as a coping strategy during the illness or after the death of a critically ill young child.

Conclusion: The review revealed that religion/spirituality is an important and primarily positive influence on shared medical decision making among parents of a critically ill child. Future research should explore how to facilitate health care providers' understanding of these religious/spiritual beliefs and to incorporate these beliefs into medical decision making for their critically ill child..

Exploration of Lesbian, Gay, Bisexual, Transgender, and Questioning Adolescents Experiences in Healthcare: A Cultural Examination

Stephanie C. Evans, PhD, RN, APRN, CPNP-PC, USA

Abstract

Purpose: Lesbian, gay, bisexual, transgender, and questioning (LGBTQ) youth are a new cultural group in healthcare settings that has unique physical, social, and psychological needs as compared to the typical adolescent or the LGBTQ adult population. A majority of the literature in medicine and nursing focuses on the LGBTQ adult, demonstrating a gap in literature on the needs and desires of the LGBTQ adolescent. In order to better understand the needs of LGBTQ adolescents in healthcare settings, descriptive studies are needed. The purpose of this study was to explore the healthcare experiences of lesbian, gay, bisexual, transgender, and questioning (LGBTQ) adolescents, with a focus on their perceived cultural disparities in the healthcare setting.

Methods: The study was approved by a university IRB board, and all participants signed consent and media release for audio recordings. This qualitative study was conducted using focus groups on a private university campus. Participants were recruited across campus with dissemination of flyers seeking voluntary participants. The principal investigator conducted focus groups of three to five participants. Each focus group met for one session lasting one to one and half hours. Each session was audio recorded and then transcribed with digital transcription software. The principle investigator completed a read back for accuracy of transcription. The principal investigator conducted the focus groups and conducted a short debrief session with participants after data collection was complete. Data analysis will be completed with NVivo software for themes identification.

Results: This study is currently in the data analysis phase and is not complete. Preliminary data analysis has revealed themes of education for providers related to LGBTQ lifestyle, heteronormative environments in healthcare settings, assumption of lifestyle by healthcare providers, and lack of privacy and confidentiality provided. Results are to be explored further and in-depth analysis in the next month.

Conclusion: Preliminary findings indicate that LGBTQ adolescents recognize their healthcare providers have inconsistent education about LGBTQ culture and how it impacts health. The participants verbalized a need for standardized preparation of healthcare providers to better equip them for personalized healthcare with LGBTQ adolescents. IN addition, the participants verbalized a concern for the assumption of heteronormative status. Assumption of heteronormativity decreased the participants desire to disclose and seek information from their providers. Further analysis will be completed.

Culturally Based Stressors and Depressive Symptoms for Latino/a Adolescents

Allison L. McCord, BSN, RN, USA

Abstract

Purpose: U.S. Latino/a adolescents suffer from significantly higher levels of depressive symptoms than Caucasian and African-American adolescents. In 2016, 35% of US Latino/a adolescents reported feeling so sad or hopeless on a daily basis that they were unable to participate in some daily activities (Centers for Disease Control and Prevention [CDC], 2016). When left untreated, these depressive symptoms can lead to a variety of other negative health consequences such as suicidal ideation and attempt (CDC, 2016) and substance use (Cano et al., 2015). In the U.S., Latino/a adolescents experience culturally-based stressors, which are threatening events uniquely experienced by members of a specific ethnic group. These stressors are above and beyond those universal stressors that all U.S. adolescents experience. Many studies have demonstrated that experiencing culturally-based stressors has contributed to the high levels of depressive symptoms in this group, but no study has integrated all of these findings into a cohesive picture of the specific culturally-based stressors that contribute to the development of depressive symptoms for Latino/a adolescents. Bronfenbrenner's (1994) Ecological Systems Model was used to frame the review by suggesting that the culturally-based stressors that Latino/a adolescents experience may occur on different sociocultural levels within the individual's environment. The purpose of this review was to identify the specific culturally-based stressors that are associated with the development of depressive symptoms in Latino/a adolescents.

Methods: Ganong's (1987) Integrative Review Method was followed in conducting this review. Twenty-nine articles meeting the inclusion criteria were retrieved from CINAHL, PsychINFO, PubMed, and SocINDEX databases from the years 2010-2016. Articles were included in the review if the authors (1) included Latino/a adolescent participants in the sample, (2) measured depressive symptoms, (3) measured a culturally-based stressor, and (4) determined the relationship between the culturally-based stressor and depressive symptoms. Articles were excluded from the analysis if (1) the focus of the study was on pregnant or parenting adolescents or (2) the study was conducted outside the U.S.

Results: The review revealed that discrimination, family culture conflict, context of reception, immigration stress, intragroup conflict, and acculturative and bicultural stress were culturally-based stressors that were associated with depressive symptoms for Latino/a adolescents. Discrimination was measured in twenty studies (69%) and was defined as unfair, differential treatment based on ethnicity, including negative behaviors such as derogatory remarks, prejudicial treatment, and violence. Family culture conflict was examined in eleven articles (38%) and was defined as disagreement with a family member related to a discrepancy between the cultural values of the family member and adolescent. Three studies (10%) discussed context of reception, which was defined as the perceived degree of openness and opportunity structure in the local community. Three studies (10%) examined immigration stressors, which were measured as the reported difficulties faced when leaving the home country, separation from a primary caregiver, and satisfaction with the decision to move to the U.S. Intragroup conflict occurs when an individual becomes the recipient of negative behaviors or remarks from another person within the same ethnic group and was associated with depressive symptoms in two studies (7%). The concepts of acculturative stress and bicultural were used interchangeably and refer to the stress that results from changing values as a result of coming into contact with another culture and navigating between the heritage culture and the host culture. Acculturative and bicultural stress were associated with depressive symptoms in six studies (21%). These findings should be interpreted in the context of the limitations of the body of literature reviewed, including a lack of consistent conceptual and operational definitions of culturally-based stressors and sampling from a limited number of U.S. states.

Conclusion: The findings suggest that culturally tailored strategies to treat depressive symptoms in this population need to occur on multiple levels. On a federal and state level, immigration policy changes will affect how Latino/a adolescents experience immigration stressors. These policy changes may also affect the perceived context of reception and discrimination that the adolescent experiences. Strategies to promote unity and racial/ethnic integration in schools may also decrease perceived discrimination and intragroup conflict. Since family culture conflict is a stressor strongly associated with depressive symptoms for Latino/a youth, mental health providers and those individuals working with adolescents should address the adolescents' experiences of family conflict related to cultural values and involve the family in mental health treatment. Individuals working with U.S. Latino/a adolescents at any level, in

healthcare, community, or advocacy settings, should recognize the complexities that Latino/a adolescents face in managing the stressors they experience in family, school, and community settings.

RSC PST 2 - Research Poster Session 2

Educating Healthcare Providers to Identify and Heal Victims of Sex Trafficking

Kupiri Ackerman-Barger, PhD, MSN, RN, TNAC, USA

Jann L. Murray-García, MD, MPH, USA

Ellen E. Goldstein, PhD, MFT, USA

Jerry John Nutor, MSN, BSN, RN, USA

Abstract

Purpose: Human trafficking is recognized as a gross violation of human rights that victimizes tens of millions of vulnerable women, men and children worldwide (Ahn et al., 2013). A United States Congressional Research Service report estimated the number of victims who are trafficked at any one time worldwide may reach as high as 27 million (Siskin & Wyler, 2013). Millions of trafficked victims are unaccounted for and remain invisible to law enforcement, medical providers and other professionals. A lack of awareness of this invisible population has meant missed opportunities to improve both the health of individuals, including minors, and population health. Sex trafficking, a specific type of human trafficking, is a priority health issue because of the physical and mental health risks and outcomes faced by the victims. Sex trafficking occurs when "...a commercial sex act is induced by force, fraud or coercion, or when the person induced to perform such an act has not attained 18 years of age (U.S Department of State, 2014, p. 29). Research suggests that sex trafficking victims, in many instances, have had contact with a health care provider. However, most health care professionals have difficulty recognizing and have limited education and training to appropriately respond to victims of sex trafficking.

Aims: This study aimed to 1) assess and increase knowledge, ability and confidence of healthcare providers to identify and heal victims of sex trafficking; 2) assess and build institutional capacity to appropriately and constructively serve victims of sex trafficking.

Methods: IRB approval was obtained prior to the workshop. A four-hour workshop was provided that featured the lived experience from a sex trafficking survivor; statistics and referrals from local nonprofit community organizations; trauma-informed primary care; and law enforcement actively working on mitigating and ameliorating the impact that sex trafficking has had on the lives of individuals. The structure of the workshop was intended to provide specific information to healthcare providers, but intentionally recruited community members, advocates and healthcare consumers to brainstorm and develop a collective effort to create structures, practices and resources to help and heal victims of sex trafficking. Paper pre- and post-event surveys with a 4-point Likert scale were administered to participants who identified as health professionals or health professional students to assess their perceived levels of knowledge, ability, and confidence during clinical encounters with patients who are victims of sex trafficking. Pre- and post- surveys with open-ended questions were administered to both health care professionals and non-health care professional participants to assess perceptions of institutional capacity. A brainstorming session was conducted to gather data regarding perceptions of potential solutions to better serve the needs of sex trafficking victims and survivors.

Results: Of the 67 participants who completed the questionnaire, 52 were healthcare providers and 15 were staff, administrators or community members. Pre-event distributions indicated that 47.8% (22) healthcare providers had heard that sex trafficking may be a problem, but did not know more than that. Results from the study indicated that the workshop increased knowledge, ability and confidence and promoted a desire to advocate on behalf of sex trafficking victims. The results of a thematic analysis of qualitative participant responses resulted in five prominent themes that included: training, community and institutional capacity, awareness and advocacy, knowledge of local resources, and coordination of care.

Conclusion: Although equipping individual healthcare providers with knowledge, awareness and confidence is critical, workshops like this will yield little without institutional support, resource availability, and community partnerships. The findings from this study add to the existing literature by demonstrating that building institutional capacity and collective efficacy are critical to provide and sustain optimal care for sex trafficking victims and to make critical change in the harm created by sex-trafficking

Low-Income Pregnant Women's Experiences With Prenatal Care Education

Amy McKeever, PhD, RN, CRNP, WHNP-BC, USA

Abstract

Purpose: The purpose of this presentation is to discuss the findings of a qualitative descriptive study exploring the perinatal experiences of low-income urban women with regarding their experience with prenatal care and prenatal education in the United States.

Methods: A qualitative descriptive study using focus groups was employed. Thirty women who gave birth within the last 10 years who were eighteen years of age or older were recruited and agreed to participate in the study. Participants were asked about their healthcare and health education experiences during their pregnancy, during childbirth, and during the postpartum period, and their recommendations for healthcare providers to improve the current state of prenatal care and education for childbearing women in the United States. Content analysis was used to analyze the transcribed interviews. Themes that emerged were identified and coded.

Results: Seven themes emerged from the analyses of the transcribed data. Trust, Respect, cultural perceptions, disparity in access to education, desire and readiness to learn, privacy, and models of care. Women provided recommendations that are critical implications for healthcare providers caring for childbearing women that are practice-based issues, healthcare provider issues, and larger healthcare systems issues.

The themes found in this study confirm what older seminal and more current qualitative studies found. Low-income women who seek prenatal care and education consistently have the same experience: they experience barriers with insurance access, barriers in accessing care at the point of prenatal care, they have poor interactions with healthcare providers and staff, the care they do receive is fragmented with long wait times which require missed time from work, and childcare interruptions, as well as issues with accessing transportation to receive care. In addition, the women perceived the relationship with their healthcare provider as not trustworthy, that their healthcare providers fail to understand specific cultural beliefs, fail to respect some level of knowledge that women possess, and fail to respect that women do have an interest in learning about prenatal education and caring for themselves and their baby even though they are low-income and minority.

Conclusion: Participants experienced widespread barriers to care, poor interactions with healthcare providers, and poor care coordination as well as limited to no prenatal education. However, consistent among the literature is that the model of prenatal care and education in the United States is antiquated, not women-centered, nor family-centered; is healthcare provider and health system centered, creates great barriers for women- particularly low-income minority women. Whether health systems, government, or healthcare providers want to take a serious look at the model warrants attention in the future health of the American childbearing woman. Given, that 90% of nurses are women, the authors suggest that nursing take a leadership role in champion change of this failing model of prenatal care and education care. As the United States maternal mortality ranking continues to worsen nursing is in a critical role to lead efforts for change at the point of care.

The Traditional Chinese Medical Body Constitution Status and the Related Factors of Coronary Artery Patients

Jun-Dai Lin, PhD, MSN, RN, Taiwan

Li-Li Chen, PhD, RN, Taiwan

Tung-Mei Chen, MS, RN, Taiwan

Abstract

Purpose: The purpose of this study is to understand the Traditional Chinese Medical body constitution (TCMBC) status and the related factor of coronary artery patients. On the expectation of achieving disease prevention through improving health condition and adjusting lifestyle by researching the difference and relevance of body constitution of Chinese medicine to identify personal health condition and further to serve as basis to improving health condition.

Methods: This is a cross-sectional correlation study with purposive sampling. Participants came from cardiovascular Intensive Care Unit (CCU) and general cardiovascular ward, in a medical center in central Taiwan, and was conducted with structured Body Constitution Questionnaire (BCQ) with 250 coronary artery patients. The BCQ has three parts, "yang-qi-Xu", "ying-blood-Xu", and "phlegm and stasis", and the Cronbach's α is 0.85, 0.88, 0.88, respective. The data were analyzed by *SPSS 22.0 Statistics Chinese Version*, descriptive statistics described the distribution of all of the important variables, and chi-square, binary logistic regression formula (LR) performed univariate and multivariate analysis.

Results: The study shows that the body constitution among coronary artery patients, 75.2% belong to the category of "yang-qi-Xu"; further examine with multivariate analysis and univariate analysis of variance indicate that: "Recurrence of coronary artery disease" is aggravating factor of yang-qi-Xu. "Kidney disease" is aggravating factor of ying-blood-Xu. "duty Shifting" and "Stress" are aggravating factor of phlegm and stasis. "No habit of exercise" is aggravating factor of yang-qi-Xu and phlegm and stasis. "Female" is aggravating factor of yang-qi-Xu, ying-blood-Xu and phlegm and stasis.

Conclusion: This study shows that coronary artery disease patients tend to have weak constitution, and the demography, lifestyle and disease factors will influence the physical performance. We recommendation that different body constitution could performed through diet, exercise guidance, daily living care and emotional care, to maintain the yin and yang balance of body, so that all parts of the body have encountered the normal operation.

A Multivariate Testing of Illness Perception, Self-Management, and Quality of Life of Taiwanese Cancer Patients

Fang-yu Chou, PhD, RN, USA

Abstract

Purpose: Cancer has been the leading cause of death in ethnic Chinese. Different cultural backgrounds can influence how patients perceive the disease, how they self-manage their health and disease process, and how these factors can influence their quality of life. Effective self-management is imperative to reduce possible complications and maintain treatment completion, control symptoms, and collaborate effectively with health care professionals. This paper tests a multivariate model to determine the associations among self-management, illness perception, and quality of life among a sample of Taiwanese cancer patients.

Methods: A sample of ethnic Chinese cancer patients (N = 159) were included in the multivariate model analysis. The data were from an international collaboration project conducted in 2011-2012 at northern Taiwan region. The sample included breast cancer and colon cancer patients. After consent, each participant completed a questionnaire booklet in which questions were included for demographics, illness perception, self-management practice, and quality of life. Illness perception was measured by Chinese version of the revised Illness Perception Questionnaire. Self-management practice was measured in the aspects of self-care efficacy, symptom self-care activity, and health maintenance resources. Quality of life was measured by the Quality of Life Scale. All questionnaires were available in bilingual versions. Data were analyzed in SPSS 23.0 and statistical significance was preset as Alpha = 0.05.

Results: The mean age of the sample was 55.55 years old, and 83% of the sample was female. The mean Karnofsky's Score was 78.43 (SD = 13.19). Seventy-two percent of the sample reported the religion preference was as Buddhism or Taoism. Thirty-three percent identified themselves as the primary caregivers. The overall sample reported moderate level of quality of life and self-care efficacy. On average, about five symptoms were reported from each participant. Stress and overwork were the common perceived causes of cancer reported in the sample. Walking and exercise were the commonly used daily health maintenance activities. The four-stage hierarchical multiple regression revealed that at stage one, demographic characteristics contributed significantly to the regression model ($F_{(9,12)} = 4.48, p < .001$) and accounted for 24% of the variation in quality of life. In step two, adding the illness perception subscale dimension variables explained an additional 18% of the variation in quality of life and this change in R^2 was significant ($F_{\text{Change}}(8,119) = 4.46, p < .001$). In step 3, adding self-care efficacy to the regression model only explained an additional 1% of the variation in quality of life and this change in R^2 was not significant. However, the overall model was statistically significant ($F_{(18,118)} = 4.85, p < .001$). The final model explained a total 43% of variance in quality of life ($F_{(19,117)} = 4.56, p < .001$). Among all variables, the dimensions of consequence and personal control from the Illness Perception Questionnaire, and Karnofsky's Score were the significant predictors in the model.

Conclusion: The overall results from this study showed that enhancing cancer patients' self-care efficacy and empowering patients to have positive personal control and attitude toward cancer and its treatment can significantly contribute to their quality of life. While the sample was focused on Taiwanese patients in this study, the proposed predicted model can be applied in other population. The emphasis of self-management in cancer patients' long-term quality of life has also been well established in the literature. Illness perception has also been supported to be the main covariate to quality of life in cancer patients can be employed to facilitate cancer patients for empowering their efficacy in self-management and active participation and planning for their adjustment with living with cancer. Further research can explore culturally-appropriate interventions to assist cancer patients to support their self-management. Variation in illness perceptions of cancer by different types of cancer should be considered in cancer survivorship planning and patient education.

Facilitators and Barriers Faced By Student Veteran Population Upon Transitioning From Military to Academic Life

Brittany M. Gannoe, BSN, RN, USA

Heeyoung Lee, PhD, APRN- BC, USA

Abstract

Purpose: As a result of the Post-9/11/2001 Veterans Education Assistance Act of 2008 and the benefits and financial assistance it offered to those who served in Afghanistan and Iraq, approximately half a million Veterans, National Guardsmen, active-duty personnel, and reservists used military education benefits to attend college and have difficulty in reintegrating their life to academic settings due to multiple deployments, a constant risk of injury and death, and repeated challenging homecoming transition. The present study explored the experiences of the student service member and student Veteran population upon transitioning from military life to academic life.

Methods: Recruitment was achieved through the dissemination of a flyer by a university's Office of Veterans Services on their website, their Facebook page, and emailed through their listserv. Additionally a Facebook boosted post advertising campaign was ran which reached approximately 1,600 targeted Facebook profiles containing the key terms "Veteran" and the name of the university. Word of mouth was also utilized, as well as an in person recruitment event at a Veterans meeting. This study made use of a qualitative interview with a structured interview guideline. Audio recordings of interviews were transcribed verbatim though the use of software (i.e., Soundflower 2.0b2 and Audacity 2.1.0) and then proofread line by line by the primary investigator for accuracy. The interview data was coded using thematic content analysis as outlined by Graneheim and Lundman. Meaning units were extracted and categorized into condensed meaning units, subthemes, and themes. Any discrepancy about code and themes were discussed and refined in order for mutual agreement.

Results: Six participants were recruited. All six participants were white males. They were between the ages of 25 and 40. Branches of service represented included Air Force (n=1), Army (n=2), Coast Guard (n=1), Marine Corps (n=1), and Navy (n=1). Years of service included 1-4 years (n=2), 4-8 years (n=2), and 12-16 years (n=2). College majors represented were Nursing (n=2), Public Service (n=1), Informational Science (n=1), Natural Science (n=1), and Administrator of Justice (n=1). 79 meaningful text units were described by the participants. Five major themes of facilitators were identified. Themes included social relations, competence, cultural accommodation, communication, and opportunity for personal growth. Four major themes of barriers included cultural differences, academic challenges, isolation, and juggling school and life.

Conclusion: The findings of this study provide insight into unique experiences beyond what would otherwise have been ignored. In particular, cultural differences need to be acknowledged and addressed in order to encourage student service members and veterans to adjust to academic life. Participants' military-related experience such as Posttraumatic Stress Disorder or Traumatic Brain Injury impacts their ability to balance their life and academic work. Therefore, student service members and Veterans may benefit from specialized academic and institutional services and supports to address aforementioned barriers. The need is presented for larger and longer studies in order to better inform policy regarding the challenges faced by the student service member and Veteran population.

Cultural Competence: Gaps in Knowledge of Navy Healthcare Personnel During Global Health Engagement Missions

Heather Cuniff King, PhD, CRNA, USA

Natalie Todd, BA, JD, USA

Patricia Watts Kelley, PhD, RN, FNP-BC, GNP-BC, FAANP, FAAN, USA

Abstract

Background: Military medical personnel assigned to United States (US) Naval hospital ships perform a wide range of humanitarian assistance (HA), disaster response (DR), and civic assistance (CA) operations worldwide. Collectively, these missions are called “global health engagement” missions and provide rapid coordinated relief to countries affected by natural/man-made disasters and endemic conditions. Global health engagement missions also contribute to strategic US policy aimed at improving political, economic, and international relationships (Chief of Naval Operations, Commandant of the U.S. Marine Corps, & Commandant U.S. Coast Guard, 2015; Joint Chiefs of Staff, 2015; Quinnan, 2016; Secretary of the Navy, 2012). Over the last nine years, fourteen global health engagement missions have occurred aboard US Naval hospital ships. These ships deploy to countries located in Southeast Asia, Central America, Latin American, and the Caribbean. Military healthcare personnel are integral members of the healthcare team on these missions and possess a vast amount of mission specific knowledge. However, capturing this knowledge to transfer to future deployed healthcare personnel has remained challenging.

Purpose: The purpose of this on-going study is to examine and capture first person accounts of experiential learning of military nurses, physicians, and corpsmen that have deployed on hospital ship based global health engagement missions. Although the overall study has identified over 22 codes, the need to possess culturally relevant knowledge to optimize the delivery of care is a prominent code identified by the research team. Many military healthcare participants in this study describe a lack of culturally relevant knowledge and competence to care for and interact with patients encountered during these missions. Further, many participants discussed the lack of cultural knowledge as a significant barrier to successfully accomplish the goals of the mission.

Cultural competence within healthcare systems has been defined as the ability to provide care for patients with diverse values, beliefs, and behaviors, including tailoring delivery to meet patients’ social, cultural, and linguistic needs (Betancourt, Green, Carrillo, & Park, 2005). Previous research reports that providing culturally competent care improves provider-client communication (Kelly & Papadopoulos, 2009), increases patient satisfaction with care (Alfred, Ubogaya, Chen, Wint, & Worrall, 2016; Stoneking et al., 2016), and improves patient adherence to lifestyle recommendations (Stoneking et al., 2016). Given the importance of enhanced international collaboration that can occur during global health engagement missions, the need for providing cultural competent patient care is paramount. This study highlights the need for targeted in depth cultural education to enhance cultural competence of future military nurses, physicians, corpsmen, and leaders who participate in global health engagement missions. The knowledge gained from this study will expand the understanding of care provided during global health engagement missions and will promote informed competent care for future military nurses, physicians, corpsmen, and leaders to function optimally on future global health engagement missions.

Methods: An interpretive, ethnographic method was used as described by Benner (Benner, 1994). Consistent with Dr. Patricia Benner’s approach to interpretive ethnography (Benner, 1994), our approach to gain meaning from narratives were guided by three central strategies: 1) identify paradigm cases, 2) identify themes within and across participant narratives of meaningful patterns, and 3) exemplars were used to represent common patterns of meaning, and common situations. Data collection consisted of face-to-face, and telephone semi-structured interviews with individuals or small groups aimed at eliciting detailed, narrative examples of experiences from military healthcare personnel who participated in previous global health engagement missions aboard US Naval Hospital Ships.

Sample: Data were collected between 2015 – 2016. The sample consisted of 141 participants (50 physicians, 50 nurses, and 41 corpsmen) recently deployed on US Naval hospital ships in support of a global health engagement missions.

Analysis: Descriptive statistics were conducted on demographic data. Codes and themes were identified inductively. After discussion and consensus by team members, a codebook was developed by selecting

interview excerpts that illustrated each code. Any ambiguities were discussed by the research team until a consensus was obtained.

Results: Demographic data by specialty is as follows: mean age in years for physicians, nurses, and corpsman was 39.7, $SD = 7.0$, 36.0, $SD = 8.0$, 28.8, $SD = 6.6$, respectively. Gender by specialty: physicians 75% male, 25% female, nurses 45.5% male, 54.5% were females, and hospital corpsmen 64.1% male, 35.9% female. Length of service in years for physicians, nurses, and hospital corpsmen was 12.5, $SD = 7.1$, 12.8, $SD = 8.3$, 8.3, $SD = 6.0$, respectively. The educational preparation of the sample was as follows: high school diploma, 2.4%, some college, 15.3% Associate's Degree, 6.9%, Bachelor's Degree, 26.7%, Master's Degree, 11.5%, and Doctoral Degree, 37.4%.

From the cultural competence code: Three sub codes describing culturally relevant gaps in knowledge emerged from the data: 1) cultural belief systems and practices which impact the delivery of healthcare, 2) cultural customs which effect patient evaluation for surgical procedures, and 3) military healthcare providers awareness of cultural practices in social situations.

Conclusion: Despite the accumulation of experiential knowledge among Navy physicians, nurses, and corpsmen to provide care during these missions; gaps in culturally relevant knowledge remain. This study highlights the need for targeted in depth cultural education to enhance cultural competence of future military nurses, physicians, corpsmen, and leaders who participate in global health engagement missions. Relevance to Nursing: As part of a multidisciplinary healthcare team, military nurses are integral in the success of these complex missions. It is critical that clinical and deployment knowledge is captured from these unique missions to insure the education and training of healthcare providers are culturally competent in the care they provide.

How Does Obesity and Intentional Weight Loss Impact Health Related Quality of Life in Adults?

Holly Kirkland-Kyhn, PhD, MSN, BSN, RN, FNP, USA

Abstract

Purpose: Over the past 30 years, the percentage of older adults who are obese has doubled; the most recent CDC data indicates that adults age 60 and over were more likely to be obese than were younger adults. The number of chronic health conditions associated with obesity increases with increasing body mass index (BMI) and in association with aging. Obesity-related chronic health conditions and their associated physical function–mobility limitations are the leading cause of diminished personal independence and diminished health related quality of life (HRQOL) for older adults. The aim of this study was to identify associations of BMI, gender, age and HRQOL with mental component summary (MCS) scores and physical component summary (PCS) scores, among adults with obesity who were enrolled in an intensive weight loss program, and at Week 17, after the intensive weight loss.

Methods: Six hundred and forty five participants (age: 18–79 years) completed the demographic data and HRQOL surveys at their first visit (baseline) and at Week 17 of an intensive weight loss program. The short form (SF–36) was used to measure the HRQOL for physical component summary (PCS), mental component summary (MCS), BMI, weight loss, systolic blood pressure (SBP), and diastolic blood pressure (DBP) were measured for between-group and between-gender comparisons. Further analysis was performed to evaluate Week 1–Week 17 outcomes and differences.

Results: From Week 1 to Week 17, all of the study participants lost weight. Average weight loss was approximately 47 pounds (21.36 kg) per person, or an average weight loss of 17% from baseline weight. BMI and the week in the program were statistically significant contributors to the PCS score. Participation in the program for 17 weeks was associated with an increase in the PCS score by 0.34% ($p = .000$) [$s^2 = .0724$, $p = .000$], and lowering the SBP increases the PCS score by 0.087% ($p = .000$) [$s^2 = .0166$, $p = .000$], and as SBP increases, the PCS score decreases. In other words, the SBP and the PCS score during linear regression or were inversely related.

Conclusion: Obesity and in turn weight loss are associated with HRQOL. This study is one of the few to explore the gender and age differences (to include patients with multiple chronic health conditions) in the HRQOL of individuals with obesity. The SF–36 is a self-rated measure of health; the instrument's scores are influenced by the respondent's perceptions, expectations, and interpretations regarding their health. This study provides comprehensive data that elucidate how obesity and intentional weight loss affect self-rated physical and mental health in younger and older adults; this information is pertinent to people who may or may not have chronic health conditions. The study found that, as an individual became older, their MCS scores tended to improve. In this study, females with obesity tended to have a lower MCS score than did males with obesity, and that PCS scores increase as weight and BMI decrease.

Balance Self-Efficacy: Does It Affect Psychosocial Well-Being in Older Adults?

Mercy N. Mumba, PhD, RN, CMSRN, USA

Ignacio Godinez, MBA, USA

Abstract

Purpose: The purpose of this study was to examine the effects of exercise on balance self-efficacy and to determine if there is an association between balance self-efficacy and performance on psychosocial outcomes.

There are 40.3 million people in the United States aged 65 and older. This is a drastic change from two decades ago when only 3.1 million Americans were older than 65 years of age. In 2010, over 38% of individuals over the age of 65 reported one or more disabilities including difficulties with walking, climbing stairs, and an inability to do regular errands alone. The older adults' bodies may not always respond in a manner they expect, making them more susceptible to falls and injury. The result is a decrease in balance self-efficacy, which then affects their willingness to participate in exercise and social gatherings. Social isolation subsequently leads to depression and decreased quality of life.

Methods: One-group pretest-posttest design. Approved by the IRB at University of Texas at Arlington. Convenience sample was used, recruited from the community. Power analysis required sample size = 64, total of 78 participants were recruited for the study. Participants engaged in 15-week exercise program that incorporated balance, strength, endurance, and flexibility training. Instruments used: Balance Self-efficacy Scale, EquiTest® computerized system (neurocom), Comprehensive Fall Risk Screening Instrument, and the Promis 29.

Results: Preliminary results: 78 total participants in the study. Ages ranged from 60 years to 89 years. 74% were female, over 60% had at least a bachelor's degree. 89% were caucasian. Comorbid medical diagnoses such as Arthritis (62%), diabetes (9%), hypertension (14%), thyroid problems (15%), cardiovascular problems (11%), and cancers (21%). 90% of participants use assistive devices, and 50% report falling within last 3 years. 46% use more than 4 prescription medications daily. Balance self-efficacy did not differ based on age, gender, ethnicity, pain interference, physical function, low back pain, or educational level. However, depression ($p = 0.044$) and anxiety/fear ($p = 0.025$) significantly predicted balance self-efficacy.

Conclusion: Depression and anxiety often go untreated in older adults. However, from this study, they are significantly related to balance self-efficacy. Finding ways to treat depression and anxiety in this population is imperative in order to foster social and community engagement in this population.

RSC PST 2 - Research Poster Session 2

Developing a New Cognitive Impairment Measure for Korean Cancer Patients

Hee-Ju Kim, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: The purpose of the present study was to evaluate the reliability (internal consistency reliability) and validity (concurrent, convergent, factorial, and known-group validity) of the Brief Perceived Cognitive-Impairment Scale in Korean cancer patients.

Methods: A total of 249 cancer patients from a university hospital (both outpatients and inpatients) in South Korea participated in the data collection from July 2012 to January 2014. The 3 clinical experts and 3 research experts evaluated content validity and the content-validity index was calculated. For internal-consistency reliability, Cronbach's alpha and item-total correlations were evaluated. For convergent validity, Pearson's correlations were tested with another validated cognitive impairment scale (The Functional Assessment of Cancer Therapy–Cognitive Function). For concurrent validity, Pearson's correlations were tested with Functional Assessment of Chronic Illness Therapy–Fatigue. For known-group validity, *t*-test was performed to evaluate whether the measured cognitive impairment differed the in treatment experience groups. For factorial validity, factor analysis was performed.

Results: The newly developed measure, the Brief Perceived Cognitive-Impairment Scale, showed high internal consistency, with a Cronbach's alpha of .92. Item-total correlations ranged from .76 to .81. In the content-validity index, all items were scored at higher than .80 and the scale was scored at higher than .92. The new measure was highly associated with another validated cognitive impairment measure (i.e., $r = .93$). The new measure showed moderate significant correlations with fatigue, a theoretically associated concept with the cognitive impairment ($r = .54, p < .001$). Factor analysis confirmed that the scale is unidimensional. The subjects undergoing treatment and the subjects expecting treatment statistically differed in the score of the Brief Perceived Cognitive-Impairment Scale ($p < .05$).

Conclusion: The findings indicate that the new instrument is valid and reliable, for assessing cancer patients' perceived cognitive dysfunction, particularly in concentration, memory, and executive functions. This instrument will be particularly useful in busy clinical settings and research studies examining multiple symptoms, because of its brevity.

Adolescent Success Promotion: Can Timelines Help?

Josie Weiss, PhD, MSN, BSN, FNP-BC, FAANP, USA

Abstract

Purpose: Career development is an important task that occurs during high school and is associated with positive post-graduation adjustment. Many adolescents have hopes of completing high school and college, living independently and having satisfying careers. However, adolescents often do not plan effectively in order to achieve these goals, hopes and dreams. A GPS (Getting Plans Started) Tool was developed to help adolescents think about their plans to achieve their goals for future success. The purpose of this presentation is to discuss a study that was conducted to determine the feasibility of using the GPS Tool in the future, in particular the ease of use and engagement of participants in completing the GPS Tool. The perceptions of the participants regarding the effectiveness of the Tool in helping them think about and plan for their future success was also assessed.

Methods: Thirty-one adolescents participated in this research. Each wrote the goals they hoped to accomplish within the next four years. Then they each completed GPS Tools which involved constructing personal timelines using labels, preprinted with tasks they hoped to achieve during the next four years. After completing their Tools, participants evaluated the effectiveness of constructing their timelines in helping them think about being successful in the future. They also evaluated their perceived likelihood of accomplishing the tasks they planned. Likert scales were used for both of these evaluations. The participants' written responses and labeled timelines were analyzed using both qualitative and quantitative measures.

Results: The participants found the GPS Tools effective in helping them think about their future success and they were confident they would accomplish their plans. The most significant goals written by the participants and labels used most often on the GPS Tools indicated strong desires and plans for graduating from college and becoming independent through satisfying employment and moving to apartments or homes of their own. However, analysis of written goals and labels used on the GPS Tools indicated that many of the envisioned plans would be difficult to achieve within the designated timeframes. The amount of time anticipated to achieve the goals planned was frequently unrealistic.

Conclusion: The GPS Tool is feasible to use. The participants were engaged in the process and found constructing their timelines to be effective in helping them think about and plan for their own future success. The GPS Tools were also helpful in identifying ineffective and unrealistic planning. These findings indicate that the GPS Tool could be used to promote more effective planning during career preparation. When combined with other measures, the GPS Tool could help decrease distractions such as risky behaviors that often derail plans for success.

An Investigation of the Personality Traits, Emotional Intelligence, Coping Behavior, and Job Stress Among Preceptors

Chiu Yen Lee, MS, RN, Taiwan

Abstract

Purpose: Preceptors play a critical role in onboarding new nurses. They build a bridge for new nurses to adapt to the working environment and play an important role in education, inspiration, and consultation. Moreover, they are heavily burdened with teaching responsibilities and are responsible for quality of care. Preceptors who are under such great stress are likely to experience burnout, leading to poor work performance and teaching quality, and job satisfaction. The purpose of this study was to investigate the correlations among personality traits, emotional intelligence, coping behavior, and job stress of preceptors.

Methods: A descriptive correlational design was used, and a purposive sample of 200 preceptors from a medical center, a regional hospital, and a district hospital located in Tainan City was recruited for this study. The instruments included the Personality Trait Scale, Emotional Intelligence Scale, Coping Behavior Inventory, and Job Stress Scale. Descriptive statistics, chi-square test, and stepwise multiple regression analysis were conducted to analyze the data using SPSS for Windows 19.0.

Results: There were significant differences in job stress in terms of the personality traits of neuroticism and conscientiousness, the emotional intelligences of use of emotion to facilitate performance and regulation of emotion in the self, and the coping behavior of emotion-focused coping. The demographic variables including education level and precepting experience, emotional intelligences of regulation of emotion in the self and use of emotion to facilitate performance, personality traits of neuroticism, openness, and agreeableness, and coping behavior of emotion-focused coping were important predictors of the job stress among preceptors.

Conclusion: The results of this study could serve as a reference for healthcare managers in cultivating talent. We expect that the results will make a significant contribution to the improvement of talent retention, thereby facilitating the retention of preceptors and improving the quality of nursing care and teaching quality, as well as Increase job satisfaction

Influencing Factors of Cultural Competence Among South Korean Clinical Nurses

Yunhee Park, PhD, RN, Korea, Republic of (South)

Duckhee Chae, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: As Korean society has rapidly become multicultural in the last few decades, health professionals and healthcare organization are needed to deliver care to culturally and linguistically diverse population groups. This study was to investigate individual and organizational levels of predictors associated with cultural competence among Korean clinical nurses.

Methods: This cross-sectional study included 401 clinical nurses from 21 hospitals in South Korea. Multilevel modeling was used to estimate effects of predictors at the individual and the organizational level. Individual-level variables included sociodemographic factors (age, gender, education, experience of staying abroad, foreign language speaking, and cultural competence training), job related factors (career length, job position, clinical unit, and caring experience of foreign patients), and professionalism. Organizational-level variables included the number of hospital beds, work environment, and organizational cultural competence. The data were analyzed with STATA software version 13.0 using multilevel analysis.

Results: Most participants were female (97.5%) and the mean age was 31.16 (SD=7.54) years. While majority (88.8%) had experience of caring foreign patients, only few participants (7.3%) received education for caring foreign patients. Mean number of hospital beds was 467.67 (SD=291.16). Multilevel regression analysis showed that professionalism ($p<.001$) and previous experience of staying abroad ($p=.001$) were significant factors at the individual level. When organizational-level variables were added as predictors, organizational cultural competence ($p<.001$) was significant while the significance of professionalism ($p<.001$) and previous experience of staying abroad ($p=.001$) were maintained. And the estimated interclass correlation coefficient (ICC) was 11.13% of the total variance in cultural competence of nurses.

Conclusion: By application of multilevel modeling, this study sought to identify individual and organizational level factors associated with cultural competence among Korean nurses. The results of this study indicate that differences in nurses' cultural competence were related to individual and organizational factors. In order to provide effective nursing care to culturally and linguistically diverse patients, efforts should be made to improve not only individual competence but also organizational cultural competence.

RSC PST 2 - Research Poster Session 2

Healthcare Provider Attitudes and Beliefs Toward Family-Witnessed Resuscitation in Saudi Arabia

Tara R. Belcher, MPA, RN, NEA-BC, Saudi Arabia

Arlene M. Minnock, MBA, RN, Saudi Arabia

Abstract

Purpose: Healthcare provider attitudes and beliefs towards family witnessed resuscitation (FWR) have been studied extensively in Western cultures¹⁻⁶. However, the literature shows little evidence of similar studies being conducted in Middle Eastern cultures⁷⁻⁸. The study was undertaken at a medium sized community hospital setting in Saudi Arabia. The authors hypothesize that overall attitudes and beliefs will not be in favor of family witnessed resuscitation as an option. However, there may be significant differences by nationality, unit, length of service, profession, age, gender, years qualified, and previous encounter with family witnessed resuscitation. The researchers sought to determine if healthcare providers in Saudi Arabia had similar attitudes and beliefs to those previously reported in the literature and to guide the healthcare system in developing an institutional FWR policy.

Methods: The research design is a quantitative cross sectional descriptive study using a survey method. A convenience sample of nurses, doctors, paramedics, and respiratory therapists working in emergency departments, intensive care units, operating rooms, day surgery areas, and general and pediatric wards were recruited. Recruitment was via blast e-mail with instructions on how to obtain a hard copy of the survey. Paper copies of the survey were provided in each clinical area. A reminder was sent via e-mail at week two. Extra hard copies of the survey were provided in each clinical area. Envelopes were left in pre-designated areas for collection and were collected periodically. Inclusion criteria included all doctors, nurses, paramedics and respiratory therapists working in general and pediatric wards, intensive care units, operating rooms, day surgery units, and emergency departments in all five facilities. Exclusion criteria included all allied healthcare personnel not employed in the aforementioned units. The Emergency Nurses Association's (ENA) Health Care Provider Attitudes and Beliefs Toward Family Presence Assessment Survey⁹ was used to address the study aims. The latest version of SPSS (23) was utilized for data analysis. Variables included age, gender, nationality, unit, profession, length of qualification, and duration of employment within the hospital system. The survey tool was utilized with permission granted by the ENA. There were 19 questions on the survey. Questions (Q) 1-10 were scored on a 5 point Likert scale with "1 = strongly agree" to "5 = strongly disagree." Q's 8 and 9 were reverse coded such that "1 = strongly disagree" and "5 = strongly agree". This was done to compensate for the somewhat negative terminology in the questions. Thus analysis and comparisons could be made with the other questions. Q's 11-16 were yes/no answers and Q's 13-19 had free text options although it was not analyzed for this paper. In addition to the ENA tool, seven demographic questions were included before the survey questions. The survey consisted of questions related to feelings and beliefs of healthcare providers in relation to FWR during invasive procedures and resuscitation. This study will focus on only those questions relating to resuscitation, therefore there was no analysis performed on questions relating to invasive procedures (Q3, 5, 12a, 14a and 15a). Four main themes were identified for analysis. Identified themes were feelings (Q1, 2, 4), beliefs (Q6-8), stress (Q9) and fear of litigation (Q10). Dependent variables analyzed were feelings, beliefs, stress, and fear of litigation. Independent variables analyzed were age, gender, nationality, profession, unit, and years qualified.

Results: Of the 799 surveys distributed, 393 were returned representing a response rate of 49%. The majority of respondents were female (70.9%), over 40 years of age (69.9%), of Middle Eastern descent (29.1%), and were from emergency rooms and intensive care units (53.2%). The profession which had the most respondents was nursing (82.1%). Most participants were qualified in their professions more than 6 years (87.7%) and had been working in the healthcare organization for 0-15 years (84%). Seventy-eight percent of respondents were in support of family having the option to be present if accompanied by a facilitator. The majority of respondents were Middle Eastern (29%) followed by European (19%), Filipino (15%), Indian (13%) and Sub-Saharan African (11%) with the remaining five nationalities making up slightly more than 12%. Gender was significant across all four themes ($p < 0.05$). Results of the analysis indicated a statistically significant difference between unit worked on and nationality and beliefs ($p < 0.05$) and stress ($p < 0.05$). Profession had a significant association with feeling comfortable providing psycho-social-spiritual support during FWR ($p < 0.05$). Years qualified and age had no significant association with beliefs, feelings, fear, or stress.

Conclusion: This study explored the views of nurses, doctors, paramedics, and respiratory therapists providing resuscitative care. Results of the study may be used to develop institutional policy regarding family witnessed resuscitation. Implementation of an FWR policy would enable staff to make informed decisions based on evidence-based practice. Additionally, policy implementation would prevent individual healthcare provider beliefs from impacting patient care decision-making. The organization in question does not currently have an FWR policy. One intention of this study was to provide evidence that a policy was required regardless of the outcome of the study. Policy development would also help reduce fears and tensions among healthcare providers during resuscitation. Implementing a structured policy would ensure healthcare providers were informed and aware of their role in assisting family members as well as the patient in order to improve outcomes.

RSC PST 2 - Research Poster Session 2

Family Situations and Sleep Disturbance of Chinese Elderly in Taiwan

Jong-Ni Lin, PhD, RN, Taiwan

Abstract

Purpose: This qualitative study aimed to describe sleep patterns and sleep quality from the perspectives of Chinese elderly, as well as gain insight into how family situations affect sleep appraisals by Chinese elderly.

Methods: Naturalistic Inquiry served as a philosophical framework to guide in-depth interviews of 50 Chinese elderly in Taiwan. Naturalistic inquiry, a special form of inquiry, emphasizes that the phenomenon needs to be studied in its natural ongoing circumstances. The interviews primarily were guided by a script and were initiated with a "grand tour" question. Probing and follow-up questions were asked to expand upon specific topics. **Convenient sampling and snowball sampling were used in recruiting the participants.** The strategies of content analysis were adopted to sort the interview texts. Four techniques were utilized to assess the trustworthiness of the interview data: peer debriefing, member checking, inter-coder agreement, and audit trail.

Results: Twenty-three Chinese men and 27 Chinese women aged 60 to 104 years were recruited. The mean age was 76.3 ± 11 . "Toss and turn," "difficulty falling asleep," and "poor sleep quality," were commonly used by the participants to describe their sleep complaints. The key themes represent family situations that influenced the sleep of Chinese elderly including family household size and configuration, living arrangements, filial piety, family roles and responsibilities, and family relationships. The most common family household in this study (46%) was the extended family, a unit including at least three different generations. From the viewpoints of 23 participants, the extended family household was a function of a traditional cultural norm. Twenty-six percent of the participants who lived with offspring in the same building, but on a different floor reported that such a living arrangement resulted in a less disturbing influence on sleep, compared to those who lived with their descendants on the same floor. They enjoyed living with their family members in such a household. Approximately 1/3 of all participants perceived that filial piety is associated with sleep disturbance because the failure to perform filial behavior causes negative moods, such as worry and unhappiness for the parents, who don't receive them, but the obligations of filial behavior cause stress for the children, who have to perform them. The participants living alone were more likely to report feelings of loneliness, poor sleep quality, and long sleep duration. The participants involved in a strained or demanding family relationship tended to report poor sleep quality and difficulty falling asleep. Interestingly, the majority of the participants in this study were reluctant to "air their dirty laundry" in public because disclosing negative family information to an "outsider" is thought to be shameful in Chinese society.

Conclusion: Family situations, including family household size and configuration, living arrangements, family roles/responsibilities, filial piety, and family relationships, may play roles in affecting the sleep quality of older adults. The influences of family situations on sleep are complex because family roles along with responsibilities, living arrangements, and family relationships naturally change over time when family events or crises occur. Thus, it is crucial for health care providers to take the multiple aspects of family situations into consideration in evaluating and treating sleep problems. The influences of family situations on sleep need to be studied ethnographically by including participants and family members in the research at different time points.

Do New Nurse Practitioners Support a Post-Graduate Residency for the Transition to Practice?

Julie C. Stuckey, DNP, MSN, RN, ANP, AANP, USA

Abstract

Purpose: The purpose of this DNP project was to describe the Nurse Practitioners (NP) perceptions of the Nurse Practitioner Residency (NPR) Programs effectiveness and impact on their transition to practice. The project was designed to determine the following questions related to the post-graduate Nurse Practitioner Resident (NPR); what were their perceptions of the residency program, determining the effectiveness of the program, and what impact the program provided towards the transition into primary care practice. The project also included the opportunity to identify any additional themes that could assist in further development of the NPs transition to primary care practice through the residency experience.

Methods: This was a pilot study that utilized a quantitative descriptive survey, with a nonprobability purposeful sample of Nurse Practitioner post-residency graduates from Community Health Clinics Inc. A Qualtrics survey was sent to fifty-six possible survey participants via email. Fifty-four emails were successfully delivered to the sample subjects. Nineteen completed the Qualtrics survey, with ten partially completing the survey. Twelve surveys were deemed valid. The participants answered a total of 145 questions on their perceived preparation for practice and the importance of that preparation in five different clinical areas: the specialty area of practice, specific disorders seen in practice, procedural skills, clinical skills preparation, and other elements of NP Residency training.

Results: The Pearson Correlation (2-tailed) and the Nonparametric Correlations using the Spearman's rho measured perceived preparation for practice and the importance of that preparation ($n = 12$, $r = 0.245$), showed that there was no relationship between the perceived preparation for practice and the importance of that preparation. The Nonparametric Correlations measuring skill preparation and the importance of the skills the Kendall's tau b ($\text{Tau-b} = 0.453$; 0.238) and Spearman's rho ($r_s = 0.393$; 0.383) show a possible low relationship but data still supports non-relationship. The survey reliability showed a Cronbach's Alpha of ($N = 81$, 0.990), ANOVA with Friedman's Test with a mean of (3.21), and Kendall Coefficient of ($W = 0.362$) providing a reliable and valid survey instrument for this pilot study.

Conclusion: The DNP project determined that NP Residences do not perceive a relationship between preparation for practice and the importance of that training post residency in the five areas surveyed. The sample was from a single residency program. From the potential sample size of 54 and the actual sample size ($N=12$) the survey participants may be exhibiting survey fatigue. This study did not compare post-graduate NP's who did not attend the additional year of residency to those who did. This study does not support the literature review.

New graduate NP's describe themselves as "ill-prepared for the expectations of their new role and lack of support to assume responsibilities in the high-acuity setting of primary-care" (Sargent & Olmedo, 2013, p. 604). They lacked the confidence, competence and mastery of the provider role to adequately fulfill the expectations of the primary care provider in a Federally Qualified Health Center (FQHC) (Flinter, 2005). Compounding this "only about one-quarter of frontline nurse leaders are fully satisfied with the new graduates' performance" (Advisory Board, p.3). Confident experienced primary care providers are difficult to find and expensive to replace, turnover in health care settings also disrupts continuity of care (De Milt, Fitzpatrick, & McNulty, 2009).

With the implementation of the Affordable Health Care Act (AHCA) (AHCA, 2010), the 2025 predicted physician primary care shortages are greater than 130,000 (Iglehart, 2014). Nurse Practitioners are slotted to fill these gaps in primary care (Green et al., 2013). In the Institute of Medicine report, "State boards of nursing, accrediting bodies, the federal government, and health care organizations should take actions to support nurses' completion of a transition-to-practice program (nurse residency) after they have completed a prelicensure or advanced practice degree program or when they are transitioning into new clinical practice areas" (IOM, 2003, Joint Commission [JC], 2010). The ACA includes grants for nurse-managed clinics and significant financial support for NP training (Iglehart, 2014). The National League of Nursing reported on March the 1st that the 2017 Federal budget proposes 229.472 million for nursing workforce development programs through Health Resources and services Administration (HRSA).

New healthcare environments demand "safe, timely, efficient, equitable, and patient-centered care in complex environments, with healthcare professionals functioning as highly collaborative teams" (AACN, 2004; IOM, 2010; Iglehart, 2014). Bush (2014) states, "nurse executives have the opportunity to

champion postgraduate NP training programs. Designing programs for recent NP graduates and experienced NPs transitioning to new practice settings can help ensure adequate retention and job satisfaction of a rapidly growing and important segment of the clinical workforce.”

Nurse Practitioner Residency programs continue to grow and further research of the NPR and the residency programs will need to be conducted. Longitudinal studies of the NPR who attend accredited residency programs will need to be assessed through the National Nurse Practitioner Residency and Fellowship Training Consortium (NNPRFTC).

Educational Strategies Applied to Facilitate Cultural Confidence to Care for a Refugee Population

Judith Ann Young, DNP, RN CNE, USA

Abstract

Purpose: The Institute of Medicine (2011) report entitled “The Future of Nursing: Leading Health, Advancing Change,” challenged academic settings to make curricular change to facilitate student preparation with the provision of culturally sensitive care. Professional nursing practice requires nurse graduates be culturally competent to care for and educate diverse patient populations, and work within multicultural interdisciplinary teams. Patient centered holistic care requires the nurse view care needs through the patient’s perspective, and adapt care delivery according to patient expectation (Campinha-Bacote, 2015). Cultural competence is also key to patient safety due to the potential for misperceptions and misunderstanding of patients, families of diverse cultures (Hamre, 2012). Being knowledgeable of the cultural and social attributes of culturally diverse patient population including values and needs also supports social justice and ethical practice. A nurse makes a moral commitment to care for all patients. Specifically the Code of Ethics for Nurses, Provision one states, “nurses practice with compassion and respect for the inherent dignity, worth and unique attributes of every person” and Provision three, “promotes, advocates for and protects the rights, health and safety of the patient” (ANA, 2015). The Office of Minority Health (2005) defines culture as “thoughts, communication, actions, and customs” that impact healthcare delivery and management. According to Jeffrey’s (2006) “Culture is a factor that can make the greatest difference in promoting wellness, preventing illness, restoring health and enhancing quality of life for all individuals” (p.xiii).

One program outcome for a Leadership course is to develop a “*culturally sensitive individual who provides holistic individual, family, community, and population-entered nursing care that will improve patient health outcomes.*” Educational activities must facilitate the integration of knowledge, skills, and attitudes to achieve program outcomes. The challenge for facilitating student achievement of cultural competency without the international travel and study abroad experiences is real as many cannot afford to “study abroad” and travel to third world countries is risky. It is therefore imperative that culturally sensitive learning opportunities be integrated within course content in the classroom setting. Course internationalization is “a process by which international elements are infused into course content, and international resources are used in course readings and assignments” (Schuerholz-Lehr et al., 2007, p. 70).

Methods: The pursuit of meaningful learning activities to facilitate student competency is an important focus. According to Jeffrey’s (2005) “Self-efficacy and skill development can be facilitated through education” (p. 24). An educational strategy such as a case study or problem-based assignment could facilitate experiential learning (Pfeiffer et al., 2013) as well as collaboration and innovative problem-solving skills.

The gap in needed resources challenges nursing faculty to facilitate student achievement of the desired program outcome of cultural sensitivity. Following a literature review, educational strategies were identified and utilized. One educational included an in class activity to facilitate self-awareness of bias and judgment. A caring manner is a fundamental component of the nurse-patient relationship. To build this trusting, caring relationship, the nurse must be self-aware of any judgmental feelings that could impair the development of a therapeutic relationship. Cultural sensitivity supports a non-judgmental viewpoint. A video and guest speakers also presented the refugee story prior to arrival in the United States and the challenges post arrival associated with transitioning into their new home. The unfolding case study facilitated synthesis of knowledge, skills and attitudes needed to provide care to members of a refugee patient population by raising awareness of health beliefs, values and practices of the Burmese culture and how culture affects patient-centered care planning. .

Results: Student confidence to care for a patient from a diverse culture would be evaluated at two time points, the start and end of the semester utilizing Jeffrey’s Cultural Competence Clinical Evaluation Tool – Student Version (CCCET-SV) and the Transcultural Self-Efficacy Tool. The tools, based on Bandura’s research, evaluate change in an individual’s perceived confidence associated with the cognitive, behavioral and affective domains of cultural competence upon completion of the leadership didactic and clinical courses.

Conclusion: Professional nursing practice requires culturally competence. Culture impacts healthcare delivery and management and awareness of cultural attributes supports social justice and ethical practice. Multiple evidence based educational strategies applied in the didactic and clinical settings effectively enhanced students' perceived confidence to care for a diverse patient population.

Promoting Mental Health in a Refugee Community Using the RHS-15 and Pathways to Wellness

Rebekah J. Salt, PhD, MN, RN, USA

Margaret E. Costantino, MA, LPC, USA

Emma L. Dotson, BSN, RN, USA

Abstract

Purpose: The purpose of this study was to pilot the Refugee Health Screener (RHS-15) and the Pathways to Wellness (PW) intervention program with refugees at the Center for Refugee Services (CRS) in San Antonio, Texas. The specific aims were: 1) To compare the pre and post RHS-15 survey and PW intervention scores, and 2) To identify internal and structural barriers affecting resettlement with a refugee woman's sewing group at the CRS.

Background: Refugees often suffer life-threatening circumstances prior to flight from their countries. During the resettlement process, they face internal and structural barriers that can affect transition to life in the United States. Studies have reported a higher prevalence of depression and post-traumatic stress disorder (PTSD) in this population. The CRS is an independent 501(c)3 nonprofit agency whose mission is to promote self-sufficiency and successful resettlement for refugees. The organization hosts a sewing group every week for women to create and sell their wares at an on-site market. These income-generating activities (IGA) are often referred to as cottage industries.

Methods: The RHS-15 consists of 15 questions, screens for common mental conditions in refugees, takes about 4 to 12 minutes to complete, and has been translated into eleven languages. Pathways to Wellness is an intervention that incorporates a support group model and consists of eight 90-minute sessions. The program is designed to help refugees recognize symptoms and understand stigma associated with mental health conditions in the United States. All participants were recruited in person from the woman's sewing group at the CRS. The purpose of the study was framed around greater good as it was important for the women to know that their input could help other refugees.

Results: Twelve women from six different countries regularly attended the PW sessions. Several of the women were proficient in English. Over seventy percent of the participants who took the surveys scored above threshold on the RHS-15 and required referrals. There were no significant differences in pre-post surveys results; however, the stories that emerged during the PW sessions were powerful. The women discussed the challenges of resettlement related to safe housing, cultural and social norms, stigma, and isolation. Finally, the social cohesion observed in the sessions suggests that participation in a cottage industry could be a protective factor against social isolation and depression.

Conclusion: The resettlement process can be difficult for refugees. Good mental health is important for their successful transition into life in the United States. Using culturally sensitive screening tools and interventions may decrease some of the stigma associated with mental health conditions and lead to improved health outcomes for refugees. Community organizations that provide resources such as income-generating opportunities, has the potential to decrease the multiple internal and structural barriers that refugees experience during the resettlement process.

Low Acuity Emergency Department Visits: Comparing Demographics and Patient Profiles for an Accountable Care Organization

Vicki Lynn Wagner, MSN, RN, FNP-BC, USA

Abstract

Frequent non-urgent emergency department (ED) visits have escalated despite legislation to enact routine affordable care for all Americans. It is already known that ED overcrowding often limits hospital functional capacity and can affect patient outcomes. Much of the ED crowding is due to unnecessary visits from patients who could have been evaluated in the primary care setting by their physician. The lower acuity patients often will wait longer for care depending on department census. Emergency departments domestic and international continue to investigate non-urgent emergency department visits seeking to understand the dynamics of this patient population. A large Midwestern Accountable Care Organization (ACO) has mimicked national trends with escalating non-urgent visits during weekdays when clinics are open. Policymakers concentrate on rising ED utilization as a direct reflection of community health and is regarded as a potential avoidable source of health care dollars. Our participating ACO has enrolled in a new care delivery model and payment structure of care through Centers for Medicare and Medicaid (CMS) that concentrates on aggressive patient care coordination. This model will be evaluated according to its ability to deliver better care to individuals, care coordination, better health for populations, and lower growth in expenditures.

Purpose: The purpose of my study was to characterize the non-urgent ED patients who have a physician assignment within the ACO and those who do not. Patients evaluated were treated and released from the ED during clinic hours Monday through Friday 8-4:30. Patient profiles provided an initial step into demand strategies of this group of patients and how to mitigate unnecessary visits.

Methods: My study was a twelve-month, retrospective review utilizing a descriptive comparative design. Information was collected from one inner city Level II trauma center. Yearly census averages 50-55,000 patients a year. Frequency and percentages of patient demographics including, gender, race, age, insurance status, and Zip Code were collected. Emergency Severity Index (ESI), marital status and discharge diagnoses were obtained to add richness to the data and further characterize the patient. A Chi-square analysis compared differences between the two variables, ACO vs. no ACO with a significance level set at 0.05.

Results: in process

Conclusion: in process

RSC PST 2 - Research Poster Session 2

Nursing as a Manifestation of Love

Marlienne Goldin, DCSc, MPA, BSN, AAS, RN, CCEP, CNML, USA

Abstract

Purpose: Over the past 35 years I have watched daily what I believe to be a demonstration of love of humanity in its' highest form. Watson, (1990) and Leininger, (1991), both describe caring as the essence of nursing. Nursing is directly related to caring for people, and it provides a perfect opportunity to practice the art of loving. What is it that drives nurses? I believe it is a love of humanity. Compassion, duty to act, caring, tenderness, and love, are all qualities associated with loving care that nurses provide. How do nurses describe what they offer their patients? If we believe that love is an essential ingredient in human existence, then demonstration of love in nursing practice is of critical importance. The relationship between the nurse and patient has many components, but the main one appears to be Agape, wanting what is best for the patient, for the patient's sake, not for the nurses' sake. The agape ethic transforms both the nurse and the patient being cared for. As the nurse finds out more about the patient he/she finds more about him/herself. Loving care is firmly rooted in relationship between the patient and the nurse. Nurses serve humanity, and the way they serve seems to me to be more than just caring.

Methods: This qualitative study used a hermeneutic phenomenological research design to attempt to understand and interpret the essence of how love is manifested in the day to day practice of nursing. The main data source was in depth conversations with the researcher and the participant. Using Moustakas' (1994) hermeneutic phenomenological model, Registered Nurses were interviewed until saturation was reached. The volunteer participants were obtained from two different critical care units, in a 500 bed hospital located in a southern city. All participants had been in practice a minimum of 2 years. The data is what both the study participants reported, and subsequently what the researcher reflected upon. The interpretive paradigm allows the researcher to look at the world through the perceptions and experiences of the study participants. In looking for the answers, the researcher who uses the interpretive paradigm uses the participants' experiences to build and translate her understanding from the collected data. The reflections on the experience helped all to understand the deeper meaning of the participants' experience. The researcher went back to the interviewee and asked more specific questions, to go deeper into the meaning of the experiences. The goal of this research study was to understand a human phenomenon, love in nursing, and the meaning this phenomenon had on experienced nurses in practice.

Results: After intense reflection the researcher interpreted the participants responses. Six themes appeared in the responses to the research question "How do you experience love in your day to day practice?" Spirituality, Unity of Being, Knowing, Touch as Communication, and Diversity were the main themes. Love was evident in all responses. Every nurse expressed gratitude to have chosen the profession of nursing.

Conclusion: This study reinforces the connection between love and nursing practice. The results of this study add to nursing's body of knowledge. Nurses experienced their profession as more than a job. Every nurse gave numerous examples of experiencing love in their day to day practice. This research study provides new information and insight about the existence of love of humanity in nursing practice. Not only does this study reinforce Caring Science, it surpasses it and takes it to a deeper level. It becomes more than a theory. It is a dynamic human motion, that touches soul and spirit of both the patient and the nurse. It needs to be included in all nursing curriculum.

Factors That Influence the Development of Cultural Competence in Undergraduate Nursing Students

Hsiu-chin Chen, PhD, EdD, RN, USA

Francine B. Jensen, MSN, ADN, BS (Zoology), RN, USA

Gary Measom, PhD, RN, USA

Sean Bennett, MS, RN, USA

Nyree Dawn Nichols, MS, RN, CEN, USA

Linda Wiggins, BSN, RN, USA

Adam Anderton, BSN, RN, USA

Abstract

Purpose: With increasing immigration and expanding globalization in the US, by 2050 minorities will represent half of the total population according to the United States Census Bureau 2010 data. As the US demographic patterns have shifted toward increasing diversity, it is imperative that health care providers be well prepared to provide culturally competent care to the patients. In recognition of the increasing diversity in consumers of health care, cultural competence in the delivery of nursing care provided by nursing education to effectively prepare nursing graduates to become more aware of culture-related nursing care throughout the nursing curricula is an expectation of accrediting bodies, such as the Accreditation Commission for Education in Nursing (ACEN). However, a considerable knowledge gap regarding how nursing students enact the concept of culturally competent care and the ability to envision effective ways of tailoring nursing education to integrate culture learning into curriculum still remain a challenge.

The purposes of this study were to assess the cultural competence level and to identify the essential factors that influence the development of cultural competence in undergraduate nursing students. The significance of this study is to provide evidence regarding student learning outcomes of cultural competence through curriculum across an academic semester and to map out the essential components influencing the development of cultural competence for nursing faculty members to develop cultural material for enhancing their teaching.

Methods: This correlational and predictive quantitative study recruited 169 undergraduate nursing students from a university by sending 200 email invitation letters to all nursing students for participation. Before collecting data, approval was granted by the university institutional review boards. Each student was fully aware of the objective of the study and participated voluntarily in this study. The IAPCC-SV[®] tool developed in 2007 by Campinha-Bacote based on *the Process of Cultural Competence in the Delivery of Healthcare Services Model* was used to collect the data of the level of cultural competence including the five subscales of cultural awareness, cultural desire, cultural knowledge, cultural skill, and cultural encounters among undergraduate nursing students. The participating students completed the demographic survey and the self-administered evaluation of cultural competence via the IAPCC-SV in a selected nursing course at the end of fall semester 2015. The IAPCC-SV[®] tool has 20 items and is a 4-point Likert type scale scoring from 4 = *strongly agree* to 1 = *strongly disagree*. All data using double entry were analyzed with the Statistical Package for the Social Science (SPSS) for Windows, version 22. Summary statistics were used to identify the demographic data and the level of cultural competence. Multiple regression was employed to determine what significant factors influencing the development of cultural competence in undergraduate nursing students. The significance level was set at .05.

Results: The 169 respondents consisted of 133 (80.1%) females and 33 (19.9%) males with three missing demographic data. The majority of students were White, non-Hispanic ($n = 151$, 91%), and had a healthcare related job ($n = 123$, 74.1%). About 59% ($n = 98$) of the students reported having continuing education or previous course work relevant to cultural competence, and 55.4% ($n = 92$) received education in cultural competence. The level of cultural competence among the participating students was 62.24 ($SD = 5.63$), which indicated a culturally competence level based on the Campinha-Bacote's (2007) definition. According to item means of each subscale of the IAPCC-SV, the participating students had lowest item mean score on the cultural knowledge ($M = 2.77$, $SD = .40$) and the highest item mean score on the cultural desire ($M = 3.46$, $SD = .40$). Seven variables were found to significantly correlate with the level of cultural competence, including experience interacting with who have different ethnic backgrounds, having continuing education relevant to cultural competence, and the five subscales. Multiple regression was used to analyze the seven variables using the stepwise solution for predicting the level of cultural

competence. The five subscales explained 98% of the variance in the level of cultural competence but the strongest influencing factor was the cultural encounters among participating undergraduate students (67.2% of the variance; Adjusted $R^2=.672$, $F=338.92$, $p<.001$).

Conclusion: Cultural encounter is demonstrated when the healthcare providers directly interact with patients from diverse backgrounds. It is suggested that educational interventions to facilitate the development of student cultural competence should engage students in caring for patients from diverse cultures and immerse students in lived experiences to increase cultural knowledge. In turn, improving culturally competent care among nursing students will lead to improved patient outcomes. Further research should focus on identifying cost-effective teaching and learning strategies to increase students' exposures to persons from other cultures.

RSC PST 2 - Research Poster Session 2

Identifying Teaching Strategies to Increase Cultural Competence Among Undergraduate Nursing Students

Hsiu-chin Chen, PhD, EdD, RN, USA

Abstract

Purpose: More identified racial and ethnic minorities have enriched cultural complexity in the US. The accreditation of nursing education has urged researchers to conduct evidence-based research to recognize factors such as societal biases and stereotyping or limited cultural sensitivity and competence contribute to health care inequities in order to develop strategies for increasing workforce diversity in health care providers. Given the need for decreasing the health disparity and preparing the nursing students with cultural competence, nursing faculty have focused on exploring the strategies to implement cultural diversity activities for the curriculum. While providing culturally competent nursing care starts with the preparedness of effective learning activities for students, faculty have struggled with what approaches can produce desired learning outcomes of multicultural activities within the education process. The purposes of this study were to identify the essential factors that can influence the development of cultural competence in undergraduate nursing students in order to develop effective teaching strategies. The significance of this study is to provide evidence regarding student learning outcomes of cultural competence through curriculum across an academic semester and to identify the essential components influencing student cultural competence for nursing faculty members to consider designing effective learning activities.

Methods: This comparative and predictive quantitative study was conducted in a university by sending 200 email invitation letters to all nursing students including ASN and BSN students for participation. Before collecting data, approval was granted by the university institutional review boards. Each student was fully aware of the objective of the study and participated voluntarily in this study. The IAPCC-SV[®] tool developed in 2007 by Campinha-Bacote consisting of five subscales of cultural awareness, cultural desire, cultural knowledge, cultural skill, and cultural encounters was used to collect data from undergraduate nursing students. In order to prevent "test bias," all nursing students were randomly assigned into either an experimental group or a comparison group. The experimental group completed the IAPCC-SV[®] at the beginning and the end of the semester, respectively; and the comparison group completed the self-administered evaluation of cultural competence via the IAPCC[®] only at the end of the semester in a selected nursing course in 2015. The IAPCC-SV[®] tool has 20 items and is a 4-point Likert type scale scoring from 4 = *strongly agree* to 1 = *strongly disagree*. All data using double entry were analyzed using the Statistical Package for the Social Science (SPSS) for Windows, version 22. Summary statistics were used to describe the demographic data and the level of cultural competence. Pearson *r* correlation and independent *t*-test were used to examine the associations between cultural competence and the variables relevant to students' cultural learning experience and the differences in cultural competence between pretest and posttest as well as between the experimental and comparison groups. Hierarchical multiple regression was employed to determine what significant factors influence the development of cultural competence in undergraduate nursing students. The *p* level was set at .05 for statistical testing.

Results: In total, 106 nursing students participating at the beginning of the semester consisted of 85 (80.2%) females and 21 (19.8%) males and 166 participants including 133 (80.1%) females and 33 (19.9%) males voluntarily participated in this study at the end of the semester. The majority of students were White, non-Hispanic, had a healthcare related job, had continuing education or previous course work relevant to cultural competence. The level of cultural competence among the participating students was 61.70 (*SD* = 5.80) at the beginning of the semester and 62.24 (*SD* = 5.63) for the end of the semester, which both indicated a culturally competence level based on the Campinha-Bacote's (2007) definition. The cultural competence level was increased from the beginning of the semester compared to the end of semester but was no statistically significant difference. The results also indicated no significant differences in cultural competence between the experimental and the comparison groups at the end of semester for all nursing students. Hierarchical multiple regression using the stepwise and enter solutions was computed to identify six significant predictors for cultural competence including experience interacting to people who have different ethnic backgrounds, having continuing education relevant to cultural competence, and the four subscales of cultural desire, cultural knowledge, cultural skill, and cultural encounters (Adjusted $R^2=.98$, $F=1353.05$, $p<.001$). The four subscales explained 78% of the

variance in the level of cultural competence and the strongest influencing factor was the cultural desire among participating undergraduate students (50.1% of the variance).

Conclusion: Cultural desire is the healthcare providers' aspiration and motivation to engage in the process of becoming culturally competent. Cultural encounter is demonstrated when the healthcare providers directly interact with patients from diverse backgrounds. It is suggested that faculty need to search opportunities to engage students in caring for patients with diverse cultures in clinical practice and to immerse students in the lived experiences to reflect their culturally competent care. In turn, students' desire to obtain cultural knowledge and skills may be triggered in a learning environment that is full of culturally diverse context. Future research may focus on testing learning strategies that can increase students' desire and exposures to persons with other cultures and identify what factors causing students' discomfort with people from diverse cultural background.

Rapid Response Team Sustainability Factors: Leadership, Funding, and Demonstrating Program Results

Deonni P. Stollendorf, PhD, RN, USA

Purpose

The purpose of this presentation is to describe differences in the organizational context between hospitals with high versus low RRT sustainability. Contextual differences that will be examined include leadership, funding, and demonstrating program effectiveness.

Target Audience

Hospital leaders, quality improvement personnel, and supervisors who are responsible for overseeing and evaluating RRT programs and associated outcomes in their local hospitals or nationally.

Abstract

Purpose:

The purpose of the study was to describe differences in the organizational context between hospitals with high versus low RRT. Contextual differences that were examined include leadership, funding, and demonstrating program effectiveness.

Methods: Study design and Measurement: A cross-sectional design using a survey methodology. Sustainability factors were measured using three sub-scales of the Program Sustainability Index (PSI) (Mancini & Marek, 2004). Thirteen items from the PSI were used to measure leadership competence ($\alpha = .81$, 5 items), demonstrating program results ($\alpha = .85$, 4 items), and strategic funding ($\alpha = .76$, 3 items). Item response options ranged from 1 = strongly disagree to 7 = strongly agree. Both individual item scores and composite sub-scale scores were evaluated for differences. RRT sustainability was measured using the Measurement Instrument for Sustainability of changed Work Practices (MISWP) (Slaghuis et al., 2011). Items were scored on a five point Likert scale (1=I don't agree at all to 5=I agree very much). A dichotomous dummy variable was generated to reflect high versus low sustainability. Two additional questions, "To what extent does the RRT project meet the needs of patients?" and, "How confident are you that the RRT project will be active in five years?" were included to examine for middle-range RRT program results. Response options were measured on a 4-point Likert scale (not at all, somewhat, moderately, and fully). Sample: All the hospitals in a southeastern state in the U.S. that participated in a 9-month statewide collaborative conducted in 2006 and 2007 with the goal to successfully establish, implement, measure, evaluate, and sustain RRTs in acute care hospitals in the state. Nurse leaders of possible participating hospitals received an initial email between July 2014 and November 2014 asking them to complete the on-line survey, administered via REDCap. Non-responder hospital leaders received a follow-up reminder in one week and a

Results:

Twenty-six hospitals participated in the study (Response Rate=46%). All hospitals offered 24/7 RRT coverage (n=26, 100%), had pre-determined RRT calling criteria (21, 81%), had an RRT order set (18, 69%), and had

Conclusion:

The study findings indicate that leadership and demonstrating program results are important factors to consider for RRT program sustainability. Sustaining interventions, like RRTs, requires a thoughtful process of having a clear program vision and mission, planning for sustainability and strategies for program survival, and have program evaluation plans in place. Surprisingly, in contrast to other studies, no statistically significant differences were observed for the variable "Funding". One of the possible reasons for this finding is that, unlike many other healthcare innovations/interventions, external funding was not available to adopt and implement these teams. Sustainability is important because of the investment cost surrounding the adoption and implementation of not only RRTs but many other healthcare innovations (e.g., electronic health records and TeamSTEPPS). Investment losses and opportunity costs result when hospitals fail to sustain innovations such as RRTs. Additional costs are also incurred when new processes must be adopted or a new innovation must be implemented when the previous one failed (Manfredi, Crittenden, Cho, Engler, & Warnecke, 2001; Young, 2006). This study adds to the body of literature on sustainability (Ament et al., 2012; Duckers, Wagner, Vos, & Groenewegen, 2011; King et al., 2013; Tricco et al., 2013) by demonstrating that leaders in healthcare settings play an important role in the sustainability of RRTs and likely other innovations/interventions. Similarly, developing evaluation plans prior to program implementation likely

increases an organizations potential for demonstrating results of RRT implementation. Leaders are likely the ones who initiates the development of evaluation plans to support their decision to adopt and implement these teams. Having evaluation plans in place increases the potential for program feedback to stakeholders and RRT users, thereby increasing the likelihood for program sustainability.

Complementary Medicine and Spirituality: Practices to Attain and Maintain Health Among Indian Immigrants

Rachel Abraham Joseph, PhD, RN, CCRN, USA

Samantha Anne Fernandes, MA, USA

Sarah Derstine, SN, USA

Micaela McSpadden, SN, BSN, USA

Abstract

Purpose: About five percent of immigrants to the United States are from India (Zong, Jie & Batalova, 2015). The use of complementary and alternative medicine (CAM) are quite common among Indians and upon migration to the U.S, they may continue to use CAM therapy for routine care, and access modern health care services for emergencies only (Rao, 2006). This can result in a lack of screening for certain diseases which may then delay diagnosis and treatment of that disease. The health seeking behaviors of Indian immigrants and their frequency of accessing preventative screening were not found in literature.

Methods: This cross-sectional descriptive study was initiated after obtaining the West Chester University (WCU) Institutional Review Board (IRB) approval. Participants are being recruited using snowball method (word of mouth). Twenty in person interviews are planned and data collection is near completion. Data on demographics, current health and lifestyle, prevalence of chronic illness, factors that affect access to health care as well as health beliefs and attitudes are collected.

Results: The findings from this pilot study will guide evidenced based practice for Indian immigrants. Knowledge about the patient/family preference will help nurse clinicians to provide optimum care to clientele of Indian origin. Prevalence of CAM therapy may alert nurses to verify drug interactions and resources can be provided to meet their spiritual need. It is also important to identify the role that spirituality has health care behaviors so that health care professionals are able to create effective therapeutic regimes when caring for these individuals. This will enhance patient experience, promote excellence in nursing, and increase patient/family satisfaction.

Conclusion: Insurance plays a major role in the kind of healthcare that the family access. Many Indian immigrant families may prefer natural and Ayurveda treatment options as compared to pharmaceuticals and are more likely to turn to CAM first before seeking medical treatment. The role of faith and spirituality plays a major role in the overall health and healing of an individual.

Clinical Decision-Making in Last Semester Senior Baccalaureate Nursing Students

Beth Phillips, PhD, RN, CNE, USA

Abstract

Purpose: Clinical decision making (CDM) is an integral part of what nurses do. Yet, nursing literature reveals concerns about the lack of preparation of new graduates to engage in effective clinical decision making (Benner, Sutphen, Leonard & Day, 2010). How students make clinical decisions has been of interest for many years (Baxter & Rideout, 2006). One of the challenges plaguing nursing education today regarding CDM is the interchangeable use of terms that gives rise to lack of conceptual clarity. It is not uncommon to encounter terms such as critical thinking, clinical reasoning, clinical judgment, and clinical decision making (Tanner, 2006; Benner, Sutphen, Leonard & Day, 2010) when describing how students make clinical decisions. These terms are interconnected but are not the same thing. How students are taught to make decisions may be a critical factor contributing to their inability to meet clinician expectations. What remains unclear is the way in which nursing students perceive they learn to make clinical decisions. The nature of the decisions they make, whether analytical or intuitive, remains unknown but such information is critical to guide development and implementation of educational interventions that enhance student clinical decision-making. This study was conducted to better understand 1) how senior nursing students learn to make clinical decisions and 2) the nature of students' decision making based on Hammond's (1996) Cognitive Continuum Theory (CCT), the conceptual underpinnings for this study. Relationships between clinical decision making and age, program type, previous degree/s, previous healthcare experience, or minority status were examined.

Methods: Nursing students in their final semester participated in this embedded mixed methods study. Following a pilot study, quantitative data were collected from 168 students at 11 schools in 4 states in the United States. Twenty-eight of these students also participated in focus groups (qualitative data). Two instruments were used: a demographic data form, and the Nurse Decision Making Instrument-Revised 2014 (NDMI). The NDMI, based on Hammond's (1996) CCT, is comprised of 24 items, and has 4 subscales reflective of decision making (Lauri & Salanter, 2002). Overall NDMI internal consistency for this study was 0.90.

Results: Six themes emerged from the focus group data: Partners in Learning, Finding One's Voice, Becoming Confident, Multiple Sources of Learning, Patient-Centered Care, and The Turning Point. These six themes were interrelated, leading to a core concept of Coalescing for Action. Nature of the decisions made: Three quarters of the participants scored in the quasi-rational range, indicating they were flexible making decisions. There were no statistically significant relationships between clinical decision making and the predictor variables.

Conclusion: Based on Hammond's CCT, the process of growing as a nursing student, through practice and experience requires time and systematic cognitive processing. As students recognized more cues, they were better positioned to make quicker decisions. Decision making is dependent on cognition, the cues recognized, and the task at hand. Curricular development and planning clinical experiences for students in regards to skills and complex patient care situations may greatly enhance decision making abilities. Limitations include a small sample size, homogeneous focus groups, and the inadvertent omission of gender on the demographic instrument. Longitudinal studies throughout nursing school and into practice may better inform clinical decision making abilities.

Bibliographic Review of Maternal Eating Practices and Their Relationship with the Weight of the Child

Diana Laura Hernández Briones, SN, SN, Mexico

Corina M. Alba-Alba, PhD, RN, Mexico

Abstract

Purpose: It is known that the mother is in charge of the feeding of the children in the families, but there are different Maternal Eating Practices which determine the quantity and quality of what the children eats so that could influence the weight of the child. The objective of this bibliographic review was to know the state of art related to Maternal Eating Practices and their relationship with the weight of the child, and also to know the Maternal Beliefs in relation with Eating Practices.

Methods: A bibliographic review was made in the databases: EBSCO host, Scielo & Redalyc with the MeSH keywords: Maternal Eating Practices, Child, Mothers and the boolean operators: "AND" & "NOT [Adolescents]" the research was made in Spanish and English, the year of articles was established between 2011-2016. Two hundred thirty-eight of articles was retrieved, then the lecture of titles allows to identify the most accurate articles for the topic of interest so 200 articles was chosen, after that, the abstracts of articles was read electing 150 articles. Finally the full text of 100 articles was read and analyzed to obtain the conclusions of this review.

Results: The bibliographic review included articles from Cuba, México, U.S.A. España, Perú & Argentina. It was found four Maternal Eating Practices Styles: Permissive, Authoritarian, Authoritative and Neglecting. The articles shown a relationship between Maternal Eating Practices and the weight of the child. Specifically the Eating Practices Styles Permissive and Authoritarian of the Mother shown a positive relationship with the weight of the child, in the other hand the Authoritative style it was related with a healthy weight of the child. Therefore it was found that factors: control are related with overweight, in the other hand the factors of discipline and limits can influence positive or negative in the weight of the child according in the strength of them. Related to Maternal Beliefs of Eating Practices it was found that these may influence either favorable or unfavorable in the decision on the food provided to the child and affect your weight.

Conclusion: The Authoritative Maternal Eating Practice Style and the factors: Adequate Limits and Discipline are related with a Healthy Weight of the Child. In the other hand, Maternal Beliefs like "the child has to finish the hole dish" could influence overweight in the Child.

Understanding the Role of Family Management in Ethnically Diverse Children With ADHD

Cynthia P. Paidipati, MSN, CRNP, PMH-NP/CNS-BC, USA

Bridgette Brawner, PhD, APRN, USA

Ricardo Eiraldi, PhD, USA

Connie M. Ulrich, PhD, RN, FAAN, USA

Jamil M. Lane, BSc, USA

Janet A. Deatrick, PhD, RN, FAAN, USA

Abstract

Purpose: Attention Deficit Hyperactivity Disorder (ADHD) is the most common neurodevelopmental condition of childhood with a prevalence rate of 5 to 11% in the United States (Centers for Disease Control and Prevention [CDC], 2015). Family, especially caregivers, are considered an important and integral aspect to the care, management, and well-being of children with ADHD (Bussing & Lall, 2010; Cunningham, 2007; Davis, Claudiu, Palinkas, Wong, & Leslie, 2012; DeMarle, Denk, & Ernsthausen, 2003; Dishion & Stormshak, 2007). The literature suggests that the behavioral management by families is a key determinant in treatment outcomes (Bussing & Gary, 2001). In fact, prior research has shown greater improvement in childhood ADHD outcomes with active family engagement and participatory collaboration between health care providers and family caregivers as compared to children without strong family involvement (Power, Soffer, Cassano, Tresco, & Mautone, 2011). In American societies, however, major health disparities exist in ADHD symptom recognition, diagnostic rates, treatment acceptability, and service use as a result of a myriad of socioecological influences, especially for children from diverse racial and ethnic backgrounds (Eiraldi, Mazzuca, Clarke, & Power, 2006). Despite this knowledge, there is a paucity of research on: 1.) how caregivers from ethnically diverse families view ADHD, and 2.) how their views influence the behavioral management of childhood ADHD and subsequent outcomes, including children's level of functional impairment. Using socio-ecological theory to underscore child, family, school, healthcare, and community level factors, the purpose of this study is to understand how ethnically diverse caregivers manage childhood ADHD in their everyday lives and how family management factors influence children's level of functional impairment.

Methods: Using an embedded concurrent nested design, the proposed research is a mixed methods study independently analyzing and then, integrating cross-sectional qualitative (n=50) and quantitative (n=50) data from ethnically diverse caregivers of children with ADHD. Participants are caregivers of children ages 5 to 12 years old with ADHD who live at least 50% of the time in the same household as their child. An eligible caregiver for this study is a biological or adoptive parent, legal guardian, grandparent, or family member, who views him or herself as assuming major responsibility for their child's care and lives in a primary residence within the city of interest. In this study, adequate representation of caregiver participants from different racial and ethnic backgrounds is ensured by using a stratified sampling plan using U.S. census data. Eligible and enrolled caregivers participate in a 60-90 minute in-person interview to complete surveys, including a demographic questionnaire, NICHQ Vanderbilt ADHD Assessment Scale, Family Management Measure (FaMM), and Impairment Rating Scale (IRS), and participate in a semi-structured interview with the lead investigator of the study. Guided by the Family Management Framework, caregiver interviews focus on key family management factors, such as the child's daily life, condition management ability, condition management effort, and view of condition impact, and the barriers and facilitators for each family management factor. This research is approved by the Institutional Review Board within the academic and health care institution in which the study takes place. Caregivers who complete the study receive a \$40 Visa gift card, binder of ADHD information and resources, and thank you card for their participation.

Results: After data collection and analysis is complete, the study findings will answer the following specific aims: 1) *Qualitative*: to explore how ethnically diverse caregivers manage ADHD in their everyday lives and understand the barriers and facilitators of family management; 2) *Quantitative*: to examine how child characteristics, family management factors, and caregiver and environmental characteristics influence children's level of functional impairment; and 3) *Mixed-Methods*: to integrate findings to explicate complementary themes and family management factors that influence the functional impairment of children with ADHD. Measurements are empirically validated and reliable instruments used in pediatric

research. Proposed analytic techniques are described including content analysis, descriptive and inferential statistics, and data integration.

Conclusion: By identifying the most salient family management factors that influence higher and lower levels of children's functional impairment, this study extends previous research on family management and ADHD in diverse populations and builds upon existing knowledge about cultural and family perspectives of children with ADHD. Within the conference theme of culturally-diverse health practices, this research provides transformative knowledge about how families understand and manage childhood ADHD within different cultural contexts and provides a launching point for future nursing research and implications for practice and policy. The knowledge gained from the study may lead into a program of research that aims to develop or adapt family-based interventions for culturally and ethnically diverse children with ADHD. Pediatric and mental health registered nurses and advanced practice nurses are at the forefront of implementing changes within nursing practice and nursing education regarding family and cultural perspectives, which may improve patient care outcomes for children with ADHD. Additionally, nurses are strong advocates for their patients, families, and communities, which can influence local, national, and international policy and decision-makers regarding the access, care, and services for childhood ADHD. Study limitations, methodological considerations, and final thoughts are addressed at the conclusion of this presentation.

Factors Influencing Retention Rates for RN to BSN Students

Audrey C. Tolouian, EdD, MSN, RN, USA

Melissa Wholeben, PhD, RN, USA

Abstract

Purpose: To coordinate existing data with data obtained from our study results to form a recommendation for change in areas of recruitment, maintenance and retention of students

Methods: A descriptive qualitative study using survey sent out via Qualtrics to online RN to BSN students who were graduating with less than 10 semester hours left to their degree completion.

Results: **Conscientiousness** has been consistently associated with academic success, (Conrad, 2006, Furnham, et al 2003).

Openness to Experience has also shown a positive relationship with post-secondary success (Rothstien, et al 1994). This trait has also been shown to be a factor in intelligence measures.

Extraversion has shown little if any factor toward academic success in the literature.

Neuroticism was found to be a negative factor in the study by (Furman and Chamorro-Premuzie (2003), showing possible negative effects of anxiety and stress.

Agreeableness has been shown in multiple studies that scientifically it has shown both positive and negative relationships toward post-secondary performance.

Conclusion: Career enhancement is ranked number one (1) for students in this study. This factor clearly indicates that opportunities for the nursing program to use this as a motivator and retention factor abound. Simple items like positive notes to key persons at the students place of employment (with the students approval) that may be placed in the students personnel file: notice of enrollment in the program; enthusiasm toward personal growth and study; health related projects worked on by the student; courses completed; significant achievement(s) by the student; progress toward completion of the program. Creating and 'Advisory Council' of local employer CEO's and/or CNO's to the on-line nursing program to bring greater awareness of the program and opportunities to students, as well as possible research opportunities for faculty.

Family involvement is a key factor in student retention. Some options to enhance this factor are; including key family members when possible in a portion of the interview process, to reinforce their importance and the importance of 'time and space' for the student and brief notes from faculty members or School Administration to the key family member(s) about the students' positive progress in the program.

Further research into the type of **gamer** personality will greatly assist in the understanding of the type student that will most readily adapt to on-line course work for an RN program.

Can Incident Report Learning Predict Incident Reporting Attitude and Satisfaction Among Nursing Home Staff?

Shu-Yuan Lin, PhD, RN, Taiwan

Abstract

Purpose: The purpose of this study is to evaluate the prediction of incident reporting learning to incident reporting attitude and incident reporting satisfaction among nursing staff and administrators in nursing homes.

Methods: This study was a cross-sectional survey conducted in nursing homes located in south Taiwan. Questionnaires were distributed to 146 full-time working nurses, nursing assistants and administrators, who had voluntarily participated and worked in 11 nursing homes. Data were collected by the scales of incident reporting attitude, incident reporting learning, and incident reporting satisfaction with 5-point Likert scale. Three scales of incident reporting attitude, incident reporting learning, and incident reporting satisfaction composed 9 questions, 25 questions and 10 questions in their order. All scales were newly developed for pursuing the study aim and tested for the content validity and reliability in this study. Content validity indexes of the scales of incident reporting attitude, incident reporting learning, and incident reporting satisfaction were 1.0, 0.96 and 0.92 separately. Coefficients of Cronbach's alpha of the scales of incident reporting attitude, incident reporting learning, and incident reporting satisfaction were .93, .93, and .91 in their order. The SPSS 19.0 version software was used for statistical analysis, and descriptive and inferential statistics such as mean, standard deviation, percentage, Pearson correlations and stepwise regression were adopted.

Results: The mean age was 40.7 (± 10.9) years old for all participants. The average year for current employment among participants was 5.2 (± 5.1) years. Nurses accounted for 45.2%, nursing assistants accounted for 43.2% and administrators accounted for 11.6% of all participants. The mean score of incident reporting attitude was 35.6 (± 4.9). Mean score for incident reporting learning was 98.2 (± 11.0), and mean score for incident reporting satisfaction was 36.9 (± 5.4). Pearson correlation results showed that moderate associations existed between incident reporting attitude, incident reporting learning, and incident reporting satisfaction ($r=0.43-0.65$). Results of stepwise regression showed incident reporting learning is the significant predictor for both incident reporting attitude and satisfaction. It explained 38.9% and 31.3% of total variance to incident reporting attitude and satisfaction.

Conclusion: This preliminary study results could be a reference for championing incident reporting learning. Developing a continuing education program in nursing homes for nursing staff to enhance their motivations to learn from reporting incidents is strongly suggested. Furthermore, safety culture of nursing homes could transform from punishment to learn through improving peer learning from reporting incidents.

RSC PST 2 - Research Poster Session 2

Do Double Gloves Reduce the Risk of Intraoperative Blood Borne Infection?

Chia-Wen Chuang, MSN, RN, Taiwan

Abstract

Purpose: Surgical teams rely on surgical gloves as a barrier to protect themselves against blood-borne pathogenic infections during surgery, but the perforation of gloves increases the risk of exposure to blood borne pathogens for the surgical team during surgery. However, the practice of wearing double gloves varies according to surgical specialties. The study aimed to prove that double-gloving, comparing to single-gloving, determine the reduction of incidence of blood borne infection.

Methods: Data collected from June 1 to August 31 in 2016. A total of six operation rooms and 400 pairs of gloves were collected from the Colon and Rectum Surgery and Orthopedics. There were twenty participants included in the study, and they are first surgeon, second or assistant surgeon, and scrub staff. All the gloves used in the study were Ansell latex powdered sterile surgical gloves. Fluorescent testing was used to observe visible blood on the hands of surgical team members, and air-inflation testing was used to detect the number of perforation of innermost gloves.

Results: Glove perforations were detected in 11 of 141 single-gloving sets (7.8%), and 9 of 259 in the innermost gloves of double-gloving sets (3.47%). The most common site of perforation was in the left hand with 5 of 20 (25%). Single-gloving was used more prevalently to against blood borne infection of Colon and Rectum Surgery than the use of double-gloving of Orthopedics (16.9% vs. 2.7%). The perforations of innermost gloves were lowered after the intervention of double-gloving in Colon and Rectum Surgery (0.8%). We used fluorescent testing to check whether the hands of surgical team members contaminated with blood after remove gloves (0%).

Conclusion: This study proved that double-gloving, comparing to single-gloving, decreases effectively the risk of blood borne infection and the risk of exposure to blood borne pathogens. Until now, double-gloving has not been a common practice among the surgical team members. The results of the study can be extended in parallel to improve the quality of operation room. The use of double-gloving should be introduced as a routine practice.

Improving the Health of Populations Through an Academic-Community Partnership

Susan Grinslade, PhD, RN, PHN-CS, BC, USA
Loralee Sessanna, DNS, RN, AHN-BC, USA
Priti Bangia, MBA, MSc, USA
Penelope W. McDonald, PhD, MSN, BSN, RN, FNP-BC, USA
Alexander Salinas, USA
Jada Douglas, USA

Abstract

Purpose: According to the American Heart Association (AHA) (2016) heart disease is the leading cause of death among men and women. Major modifiable risk factors for cardiovascular disease include high blood pressure, high LDL cholesterol, stress, obesity, and smoking. In Buffalo and Western New York (WNY) region, a community assessment identified an existing and significant disparity in cardiovascular disease and stroke in the African-American (AA) population. The University at Buffalo School of Nursing (UB SON) initiated a community based interprofessional screening activity guided by the Million Hearts® curriculum developed by the Ohio State University. To facilitate implementation, an academic-community health coalition was formed with members included the UB SON, Millennium Collaborative Care (MCC), Greater Buffalo United Ministries (GRUM), as well as two student representatives from the Multicultural Student Nurse Association (MNSA). The initial aim of the academic-community health coalition was to improve health behaviors and outcomes of a targeted underserved, and disparate population in the Greater Buffalo and WNY region. The current goal of the Health Coalition is to “empower the community to achieve the highest level of health and wellness through engagement with the community, healthcare professionals and community service organizations.” Inherent in the goal is the underlying intent to ensure that community-based health promotion interventions were evidence-based, spiritually and culturally appropriate, focus on improving the health of vulnerable populations, and eliminating health disparities.

Methods: The Million Hearts® curriculum was integrated into two junior level health promotion courses in the SON. The community-based Million Hearts® Screenings were completed as partial fulfillment of requisite service-learning hours for the SON. An invitation was extended to the University at Buffalo Schools of Exercise and Nutrition Science, Pharmacy and Medicine. Students from these schools completed the Million Hearts® curriculum and participated in the interprofessional health screening events as a course requirement or as volunteers.

Prior to beginning the community screenings, representatives from the SON and MCC met with the governing board of GRUM to develop the foundation for an engaged and trusting academic-community partnership. In spring 2016, Million Hearts® interventions were implemented in seven community churches with permission of the pastor and/or representatives of the health ministry. Churches were responsible for providing a place for the screening to take place, distributed information about the planned screening through community leaflets, and publicizing the upcoming event at church activities, including the Sunday service before the screening. Additionally, the church’s health ministry agreed to provide ongoing follow-up if a parishioner’s screening results warranted it. MCC was responsible for coordinating activities through the local American Heart Association Chapter, obtaining health resources for smoking cessation, providing individuals to screen participants for health activation measures, signing individuals (and families) up for health insurance, and securing appointments with primary care physicians if needed.

Students were provided with an in-depth lecture on cultural sensitivity provided by a community representative of the New York Area Health Education System (AHEC). A pre and post cultural competency assessment was completed before lecture and at the end of the semester after community based screenings. Health screenings for cardiovascular disease risk factors including high blood pressure, smoking, and weight as BMI were conducted by health science students. Nutrition science students provided comprehensive, individualized nutrition and diet information aimed at promoting heart

health. Medical students targeted activities for children and young adults and provided health education on the heart using animal models of the heart and interactive on-line education for young children. Exercise science students assisted with screening activities, answered questions about exercise, and recommended strategies to increase exercise in daily living activities. Pharmacy students provided guidance and education on currently prescribed medications.

Results: Through November 2016, the academic-community health coalition provided 11 community-based Million Heart Screenings at eight churches, two community events including one sponsored by the American Diabetes Association, and one inner-city charter school.

Data from the screening events demonstrate that participants are predominantly female, African-American, and between 51-80 years of age. One-quarter report smoking, and over 65% had a BMI between 25 – 39.9. 25% were identified as having Stage 1 hypertension while 8% were identified as having Stage II hypertension. On three occasions, screening results required an immediate intervention such as securing a primary care evaluation within 24 hours or follow-up with a church's health ministry.

After six months, Pastor Douglas, Director of the GRUM stated, "We are making progress. But we need to keep going. We need to eliminate health disparities, we need doctors and hospitals to treat people equally and inspire them to value their health and make better choices."

Conclusion: A program evaluation is being conducted. Focus groups comprised of participating faculty and students participated in guided discussions to determine how effective this activity was in promoting their understanding of population health, health promotion, culture awareness, and health disparities. Audio transcripts will be transcribed and a qualitative content analysis will be conducted. The results will be used for quality improvement.

Through MCC, the academic-community partnership was honored with the P2 Collaborative of Western New York's "Spotlight on Population Health (SOPHi) Award for Chronic Disease Prevention. Receipt of this award provides further evidence that when academia and community organizations work together, health can be improved and health disparities reduced.

RSC PST 2 - Research Poster Session 2

Do Educational Experiences With Culture Diversity Make a Difference in Patient Care?

Alicia Huckstadt, PhD, APRN, FNP-BC, FAANP, USA

A

bstract

Purpose: The purpose of this abstract is to share development and preliminary results of an educational project designed to explore if tailored didactic education and clinical experiences in underserved areas would result in positive nurse practitioner learner outcomes.

Methods: The background literature provides the framework for this project.

Improving the quality of care to diverse populations is an important national and international concern for nursing and the total health care system. Numerous reports reveal that health care disparities and inequalities continue to persist globally. In the United States, health disparities have significant economic impacts estimated in trillions of dollars. Schoeni, Dow, Miller, and Pamuk (2011) suggest eliminating health disparities for people with less than a college education in the US would have a \$1.02 trillion economic value. Beyond the financial considerations, eliminating health disparities builds health equity to allow all people access to better health care and healthier lives.

Nurses have historically been providers of care to all people. However, nursing students are often ill prepared to provide care to diverse patients. Arielli (2013) described how culturally diverse settings challenge students in emotional ways including frustration, conflict, and others. McClimens (2014) also found that nursing students expressed difficulties and challenges in meeting patient needs and concluded that students would benefit from preparatory education and training in culturally diverse settings. Recognizing how patients' cultural diversity impacts patients' health are important learning opportunities for advanced practice nurses.

Determining the best method to deliver cultural diversity education to health care workers has yet to be determined. Cultural diversity is extremely complex with numerous underlying facets. Thornton et al. (2016) stressed that social determinants, the conditions in which people live, work, play, worship, learn, are part of cultural diversity and are paramount in decreasing health disparities. Poverty; lack of access to health care facilities, education, employment; neighborhood conditions; exposure to violence; and other determinants are increasingly recognized to impact healthcare. Dankwa-Mullan and Perez-Stable (2016) emphasize that health disparities are a "place-based issue" where changing the conditions could make differences in health outcomes. Stone et al. (2013) described the development and testing of two training modules on cultural diversity for health care workers in England and Wales. Following testing, the researchers concluded the use of such modules was feasible and an effective way to improve participants' knowledge and understanding of cultural diversity. However, the best way in translating knowledge and understanding into practice remains unknown. It is reported that service learning, typically an experiential education opportunity that places health professional students in communities to learn social, economic, political contexts of health can be a positive vehicle for reducing health disparities (Sabo et al., 2015). In a service learning study, Rasmor, Kooienga, Brown, and Probst (2014) found in a small sample of nurse practitioner students who participated in an immersion experience with clinical practice settings such as free clinics with uninsured and non-documented immigrant patients, revealed that students challenged their own beliefs and attitudes regarding vulnerable populations, gained insight into care of these patients, and expressed intent to volunteer at these settings. These authors recommended further study beyond focus groups used in their small sample size study. It is not known if this learning experience extended beyond students' expressing intent to volunteer at these settings.

This study includes thirty-two advanced practice nursing students who are participating in the project. Interventions included an online learning module designed to increase cultural competent patient-centered care, working with interpreters, assessing populations, and planning services; a three-hour credit course analyzing major social determinants that affect health and their consequences; and two

semesters of clinical experiences in selected underserved areas. Outcomes that are being measured include students' knowledge of culturally diverse populations, faculty evaluations of students' performance, students' commitment to work in underserved areas, and employment in underserved areas after graduation.

Results: Preliminary qualitative data have revealed students' awareness of different cultures, knowledge that health has many different meanings to different individuals, importance of taking an extra few minutes to listen to patient's stories provides a much better picture of their health and concerns and helps patients and their families engage in the best possible treatment and outcomes. Both qualitative and quantitative data are being analyzed and results will be presented.

Conclusion: The findings of this study is important to advanced nurse practitioners and their culturally diverse patients.

Deliberate Practice: An Online Method to Develop Students' Interprofessional Critical Incident Reporting Skill

Jen-Huei (Vicky) Yeh, BSN, RN, USA
Gwen Sherwood, PhD, RN, FAAN, ANEF, USA

Abstract

Ineffective interprofessional communication contributes to treatment delays and can result in serious patient harms (The Joint Commission, 2015). Communication skills are a part of every nursing curriculum; however, opportunities for students to practice communication with providers of another profession to achieve proficiency are limited (Bartges, 2012; Guhde, 2014). Practice opportunities are compounded by competing priorities and time constraints in teaching essential hands-on nursing skills. Students are rarely provided opportunities to engage in critical conversations with providers in their clinical learning experiences even though evidence indicates ineffective communication increases safety risks, particularly for new graduates transitioning into the workforce. The theoretical framework of deliberate practice (DP) has been used to effectively provide health affairs students intentional, repetitive practice to develop psychomotor skills (McGaghie, Issenberg, Cohen, Barsuk, & Wayne, 2011; Oermann, et al., 2011). This study used an innovative approach in applying DP online to help students develop proficiency in reporting a patient critical incident to a provider.

Purpose: As a part of a pilot experimental study, the purposes of this study were to 1) design the online DP sessions based on the theoretical framework of deliberate practice and 2) explore the feasibility of using these sessions to develop pre-licensure nursing students' communication proficiency in giving a verbal report on a patient critical incident to a provider.

Methods: The online DP sessions used audio recorded clinical stories produced by StoryCare®, Eefform, LLC to simulate clinical encounters. Five stories that included a patient critical incident which required the primary nurse (the student) to report to a provider were selected and developed into five stand-alone practice sessions. Based on the four key components of DP, each practice session was composed of four sequential steps to be completed by students: 1) perform initial practice: record a verbal report to a provider using SBAR (Situation, Background, Assessment, Recommendation), a standardized communication tool (Kaiser Permanente), 2) receive immediate feedback: compare own performance with a standard SBAR checklist (Foronda et al., 2015), 3) self-reflect on the performance: appraise own performance by answering four self-reflection questions, and 4) repeat practice: record a refined SBAR report. Each session had a 45-minute time limit and were offered through an online educational platform used by the University to support its academic programs.

To explore the feasibility of using online DP sessions to develop pre-licensure nursing students' interprofessional critical incident reporting proficiency, following IRB approval, senior pre-licensure nursing students from one University were recruited by email to participate in this study. Over a two-week period, each student completed two online DP sessions. At the end of the second week, students were invited to participate in a one-hour focus group to provide feedback on the acceptability, clarity, and potential burden of completing the practice sessions. Ways to improve the DP sessions were also discussed in the focus group.

Results: Seven senior pre-licensure nursing students participated in the testing of the online DP sessions and five attended the focus group discussion. Students described the sessions to be well-formatted and beneficial in improving their critical incident reporting skill. They further identified the sessions as valuable practice opportunities that were time efficient and convenient; and they recommended offering them to all BSN students. To improve the DP sessions, the students recommended making the online experience more realistic, such as to provide an electronic chart-like patient profile. Although no technical difficulty was reported during the two-week study period, one student's verbal reports did not record. To address this issue, students recommended offering a recording tutorial prior to completing the first DP session.

Four major themes were identified in the focus group discussion: 1) Lack of opportunity to practice interprofessional critical communication: students collectively expressed having limited opportunity to practice interprofessional communication and that they had never reported a critical incident. 2) Difference between knowing and being able to do: by having to give a verbal report, students realized giving a focused report was more difficult than they had anticipated. One student stated part of the learning experience will be lost if they did not need to verbalize the report. 3) Wanting to practice interprofessional communication early in the program: students described feeling apprehensive about reporting to a provider as a shortcoming for most new graduates and that students would really benefit from start practicing this skill before their first clinical rotation. 4) Realness of the experience was important: students thought the audio recorded stories provided valuable reality, but real-world experience was most valued.

Conclusion: Student feedback indicated that the online DP session provided a well accepted approach for pre-licensure nursing students to practice reporting a patient critical incident in a safe environment without jeopardizing current class time. While the sample size was small, participating students affirmed the need to create deliberate practice opportunities and that pre-licensure students were motivated to improve their interprofessional communication skills. The DP sessions were then modified accordingly to use in future studies. Results from these studies provide guidelines for developing an education methodology to enable pre-licensure nursing students develop critical communication reporting skills that can have a direct impact on patient outcomes.

RSC PST 2 - Research Poster Session 2

"Hope" for People With Motor Neurone Disease in Japan

Masako Nagase, PhD, RN, PHN, Japan

Abstract

Purpose: In this study, we present materials to examine the "hope" harbored by patients with intractable neurological diseases. This study is part of research on the nature of the care system focused on end-of-life care for patients with intractable neurological diseases in Japan.

Methods: We conducted an interdisciplinary study using academic papers from various fields including nursing, psychology, and philosophy.

Results: Since the 1950s, "hope" has mainly been defined in the context of social science and there have been various attempts at measuring it. However, exploring a unified view of the concept of "hope" is a difficult task. Nekolaichuk writes in her discussion on the nature of "hope" that hope is categorized into seven themes on which it is based: universality, dimensionality, certainty, temporality, predictability, value, and reality.

In the discussion of universality, Nekolaichuk writes how differences can be seen in philosophical standpoints, such as how we perceive "hope" as an ultimate, universal concept, and how we perceive "hope" as a socially constructed concept. The positivism of the former standpoint explores the objective reality and develops a detailed description and unified framework for the concept, whereas the social constructionism of the latter standpoint attempts to understand the various significances formed by multiple people.

The discussion of dimensionality explores whether "hope" is perceived as a one-dimensional or multi-dimensional concept. If the conceptual framework is reliable (certainty), measurement, i.e. observation, should be possible. Snyder and Herth each developed hope indices, but from completely different standpoints. Snyder expands on the one-dimensional theory of Stotland who emphasized goal achievement, and defines "hope" as being composed of cognitive components that recognize pathways and agency. Herth, on the other hand, conceptualizes "hope" in a multi-dimensional framework composed of temporality and future, positive readiness and expectancy, and interconnectedness. However, the experience of "hope" is composed of both visible and invisible elements, which means that while both measuring tools are capable of measuring reliable elements, they do not succeed in understanding the internal, uncertain experience of "hope."

Studies of "hope" have been conducted in various subjects including elderly people, terminal patients, suicidal patients, caregivers and patients with chronic diseases. These studies have revealed that relationships with significant others and a strong connection with transcendental beings such as God and Buddha influence "hope." Existential problems also have a deep connection with "hope." Affirming one's value, feeling happy about one's own existence, sensing the significance and development of life, and other ways of thinking all strengthen "hope." Meanwhile, events that reduce "hope" include threatening perceptions, distress, conflict, sense of loss, and sense of despair.

From the standpoint of the Cognitive Metaphor Theory of linguistics, "hope" is a concept understood through expressions rich in temporal and spatial changes and signifies "a current feeling of happiness towards the good future." Meanwhile, the similar concept of "desire" signifies "the possibility that a good future will occur" and encapsulates prospects and expectations for the future. Both words are based on the assumption of "a good future." However, in terms of prognoses for intractable neurological diseases, it is difficult for patients to have "a good future" or "bright prospects." The "hope" held by patients with intractable neurological diseases is therefore thought to include context-dependent elements.

Conclusion: Some argue that "hope" is defined in two ways: one that is synonymous with expectation and another that is separate from expectation. "Hope" does not merely signify optimism for the future, but

is also based on concepts such as vitality and unconditional love. "Hope" is therefore not limited to clear achievement of goals for the future; it is based on the assumption of trust in an undetermined future.

Meanwhile, in exploring the concept of "hope" in end-of-life care based, the concept of "hope" in cancer and nursing literature is internal and therefore invisible in situations based on the premise of death, and is perceived as having a so-called metaphysical nature. This involves seeking healing and survival, or seeking something separate from healing, while expecting healing to be difficult and anticipating death.

So, what is "hope" to patients with intractable neurological diseases? What are the consequences of supporting patients in finding and maintaining "hope"? To answer these questions, we need to clarify the "hope" held by patients with different conditions including motor neuron disease, multiple sclerosis and Parkinson's disease.

Prescription Drug Spending and Medication Adherence in a National Heart Failure Sample

Blake Tyler McGee, MPH, BSN, BSFS, RN, USA

Abstract

Purpose: Nurse scientists can and should contribute more to health policy analysis. Many nurses have experience caring for persons with heart failure (HF), which is the most common cause of hospitalization among older adults in the U.S. and accounts for \$32 billion in health care expenditures annually in this country (Heidenreich et al., 2011). Survival depends on adherence to a complex daily regimen of prescription medications and dietary restrictions in the context of declining physical and cognitive function. When HF patients do not adhere to prescribed regimens, they frequently require costly acute care for complications such as fluid overload and impaired gas exchange.

A primary reason for non-adherence to chronic disease treatment in the U.S. is the cost of prescription drugs, even when part of the cost is borne by third-party payers. Numerous studies have shown that persons with higher point-of-care cost-sharing requirements (e.g. copayments and deductibles) are less likely to fill the prescriptions they need to manage their illness. Emerging evidence also links medication cost-sharing to increased downstream health care utilization and costs. However, only one published study in the past 11 years has investigated this issue in persons with HF, and results from nationally representative samples are lacking.

The current study, therefore, uses data from the national Medicare Current Beneficiary Survey (MCBS) to examine the relationship between medication cost-sharing and adherence in HF. The principal study aim is to examine the association between average out-of-pocket spending on common HF medications in Medicare "Part D" prescription drug plans and the adequacy of drug supply obtained by Part D enrollees with HF. Ethics approval for this study was obtained from the Emory University Institutional Review Board with a waiver of additional informed consent documentation.

Methods: This study consists of secondary analysis of 2010-12 cost and use data from the MCBS, a rotating panel survey of a nationally representative sample of beneficiaries of Medicare, the federal U.S. health insurance program for adults over age 65 or with a qualifying disability. The MCBS comprises in-depth questionnaires of personal health and financial information, administered three times yearly for four years and supplemented with medical bills, receipts and other personal records. Questionnaire responses are linked to administrative and claims data from the Centers for Medicare & Medicaid Services, the government agency that administers the Medicare program.

Since there are over 700 types of Part D plans and the MCBS does not include data on cost-sharing requirements for specific plans or drugs, the mean 30-day out-of-pocket payment by the beneficiary for each HF drug served as a proxy for cost-sharing. Adherence was approximated by the medication possession ratio (MPR), which is computed by dividing the total days supplied for all but the last refill by the number of days between the first and last refills. The result can range from 0 (perfectly non-adherent) to 1 (perfectly adherent). Excess days supplied were discarded, and the MPR was truncated at 1.0, consistent with the literature.

For this study, only two drug classes were considered: beta-blockers and angiotensin antagonists, the latter comprising angiotensin-converting enzyme (ACE) inhibitors and angiotensin receptor blockers (ARBs). This is because most patients with clinically diagnosed HF should be prescribed an agent from each of these two classes (Caboral-Stevens, 2014), and it is unlikely that a prescriber would discontinue a class altogether after initiation. Therefore, a low MPR for the entire class is a reasonable reflection of poor patient adherence rather than prescriber discontinuation. Because some patients do switch from an ACE inhibitor to an ARB, and these two types of agents are rarely prescribed together, the angiotensin antagonist class combines them.

Results: The study sample comprises 912 MCBS participants who were continuously enrolled in Part D coverage and met the case definition for heart failure, i.e. at least one inpatient or two outpatient/practitioner Medicare claims were filed with a principal or secondary diagnosis corresponding to HF, during the reference year (DiMartino, Shea, Hernandez, & Curtis, 2010). Of these, 58.9% are female, 13.5% are African-American or black, and 7.05% are of Hispanic or Latino background.

Preliminary results consist of univariate and bivariate analysis of key study variables. Non-parametric correlation analysis is indicated due to the skewed distribution of cost data. The mean out-of-pocket payment for a 30-day supply of a beta-blocker in this population was \$3.68 (SD = 7.06). The MPR for beta-blockers was significantly and inversely correlated with mean out-of-pocket expenditure ($r_s = -.075$, $p = .045$). The mean out-of-pocket payment for a 30-day supply of angiotensin antagonists was \$7.21 (SD = 15.11). The MPR for angiotensin antagonists was also significantly and inversely correlated with out-of-pocket spending on those drugs ($r_s = -.101$, $p = .010$).

Results of multivariate analysis are forthcoming. Covariates such as race and ethnicity, gender, age, education, income, marital status and self-reported health status will be examined for potential confounding effects. Similarly, a sub-analysis will examine these relationships separately among respondents who are co-eligible for the Medicaid program (primarily for low-income persons) or receive the Part D low-income subsidy versus those who do not.

Conclusion: The preliminary results of this study suggest an inverse correlation between out-of-pocket spending on prescription drugs and treatment adherence for heart failure among Medicare Part D enrollees. Despite participation in plans that provide some prescription drug coverage, this nationally representative sample may have faced financial barriers that inhibit optimal therapy to prevent heart failure complications. This finding is all the more notable given the burden that heart failure imposes on the U.S. health care system in terms of resource use.

Upon completion of multivariate analysis, this study will provide policymakers, insurers and consumers with nationally valid evidence about the potential of targeted cost-sharing relief to improve adherence for the nation's most expensive cardiovascular disorder. The findings may inform ongoing discussions about the design of health care benefits for other costly chronic disorders, as well. They also can support nurses from the boardroom to the bedside in providing optimal patient education and advocacy.

RSC PST 2 - Research Poster Session 2

The Effects of Tai Chi Exercise on Cardiovascular Functions: A Meta-Analysis

Hsiao-Ping Shih, MSN, RN, Taiwan
Yueh-Yen Fang, PhD, RN, Taiwan

Abstract

Purpose: According to the World Health Organization (WHO), the prevalence of cardiovascular diseases (CVDs) continues to rise, and will be accounted for 23.6 million global deaths by 2030. Physical activity plays an important role on cardiac rehabilitation. Prior studies had suggested that exercise-based cardiac rehabilitation had contributed to a reduction of 20% mortality in patients with coronary artery disease. Tai Chi, a traditional Chinese conditioning exercise, is well recognized by its effect on relaxation. Many studies had investigated its effect on cardiovascular functions, however, there was a lack of direct measure on heart functions and the study results were inconsistent across studies. To validate the effect of Tai Chi on cardiovascular functions, we reviewed current literature related to Tai Chi and its effect on direct measures of cardiac functions.

Methods: We searched two Chinese databases (CEPS, and the Chinese Thesis/Dissertation database) and four English databases (CINAHL, Medline, PubMed, and the Cochrane Central Register of Controlled Trials). The search was up to August, 2016. Only studies that investigated the effect of Tai Chi on stroke volume and cardiac output were included. Evaluations of study quality were conducted by the 2011 Oxford Centre for Evidence Based Medicine Levels of Evidence, and the Cochrane Collaboration's tool for assessing risk of bias. Meta-analyses were performed by the random effect model.

Results: 719 citations were reviewed. Most related studies only measured heart rate and blood pressure, only 4 studies measured stroke volume and cardiac output. These studies all encountered high risk of bias in allocation concealment, blinding of participants and personnel, and blinding of outcome assessment. The results of meta-analyses showed Tai Chi did not bring positive effect to systolic and diastolic blood pressure, heart rate, stroke Volume, and cardiac output.

Conclusion: Unlike other reviews, this study evaluate cardiac output and stroke volume to measure cardiac function more accurately. Findings of this study did not support Tai Chi as an effective method for improving cardiac functions. This result might indicate higher quality study to be conducted in the future.

Cultural Competence Among Nursing Students in Three Countries: A Cross-Sectional Study

Jonas Preposi Cruz, PhD, MAN, BSN, RN, Saudi Arabia

Paolo C. Colet, PhD, MAN, BSN, RN, RM, Saudi Arabia

Abstract

Purpose: The entire world is experiencing the highest human mobility recorded in history as indicated by the steady rise of global migration. Globalization and emigration increases cultural diversity and multiethnicity, which also enriches the cultural diversity in healthcare facilities (Perng & Watson, 2012). Moreover, migrants are often subjected to discrimination, violence and exploitation, which have a great impact to their physical and mental health. Because of this, nurses should be properly trained to provide culturally competent care that is current and responsive to the increasing challenges in the healthcare settings associated with the complexity, volume, speed, diversity and disparity among patients, in order to ensure the realization of every patient's fundamental right to health, regardless of their cultural and religious backgrounds (Cruz, Estacio, Bagtang & Colet, 2016). Thus, this study investigated the cultural competence of nursing students in three countries. It also compared the cultural competence of the students from the three countries and examined the significant predictors of their cultural competence.

Methods: A convenience sample of 723 Bachelor of Science in nursing students from India ($n=265$), Philippines ($n=258$) and Saudi Arabia ($n=200$) was surveyed in this descriptive, cross-sectional study. India and the Philippines have become the leading exporters of nurses to different parts of the globe. Saudi Arabia, on the other hand, has high numbers of migrants and has health care workforce that depends heavily on expatriates. Participants were recruited from nursing schools from each country where the authors have access. Data collection was conducted from January to March 2016. The Cultural Capacity Scale English (Perng & Watson, 2012) and Arabic (Cruz, Colet, Bashtawi, Mesde & Cruz, 2016) versions were used to gather data. A demographic and cultural-related variables information sheet was attached in the questionnaire. Descriptive statistics were used to fully describe the demographic characteristics and cultural-related experiences of the students. Mean (M) and standard deviation (SD) were calculated for cultural competence. ANOVA was used for comparison of cultural competence between countries, with Tukey HSD test for post hoc analyses. Pearson product moment correlation, ANOVA (with Tukey HSD test) and t -test for two independent samples were used to examine the relationship between the demographic and cultural-related variables and the cultural competence, as appropriate. Multiple regression analysis was conducted to identify the significant predictors of cultural competence. 95% confidence intervals were also calculated and reported. All statistical analyses were performed at 0.05 level of significance.

Results: The mean age of the respondents was 20.05 ± 2.19 years. Majority were females (75.8%), had not participated in diversity training (62.2%), had not taken care of culturally diverse patients (59.5%) and were not living in culturally diverse environment (68.2%). Contrarily, majority had experienced taking care of patients with special needs (68.0%).

The overall cultural competence mean score was 66.07 ($SD = 15.19$). Individually, Indian students had a cultural competence mean score of 64.68 ($SD = 17.28$), while Filipino and Saudi students had 68.63 ($SD = 12.18$) and 64.62 ($SD = 15.37$), respectively. Indian students reported highest competence in teaching and guiding others about planning nursing interventions for diverse clients ($M = 3.46$, $SD = 1.11$), while Filipino and Saudi students reported highest competence in understanding the beliefs of different cultural groups ($M = 3.61$, $SD = 0.88$) and in using examples to illustrate communication skills with diverse clients ($M = 3.45$, $SD = 1.08$), respectively. On the other hand, familiarity in health- or illness-related cultural knowledge or theory received the lowest mean from the Indian ($M = 2.86$, $SD = 1.17$) and Saudi ($M = 3.01$, $SD = 0.99$) students, while competence in comparing the health or illness beliefs ($M = 3.31$, $SD = 0.79$) and identifying the care needs of clients with diverse cultural backgrounds ($M = 3.31$, $SD = 0.77$)

received the lowest score from the Filipino students. Overall, Filipino students reported higher cultural competence than students from India and KSA ($F(2, 720) = 5.75, p = 0.003$). Significant differences were also identified in the individual scale-items when students were grouped by country of residence.

Bivariate analyses revealed significant relationship between the demographic characteristics and the cultural competence of the respondents. There was a weak positive correlation between the age and the cultural competence of the students ($r = 0.18, p < 0.001$). Furthermore, the cultural competence significantly vary between academic year level of the students ($F(2, 720) = 37.31, p < .001$). Tukey HSD test revealed students in the fourth year ($M = 72.23, SD = 12.20$) of the BSN program had significantly higher cultural competence than students in the third year ($M = 62.97, SD = 16.68, p < 0.001$) and second year ($M = 62.17, SD = 14.46, p < .001$). On the other hand, analyses have shown that cultural-related variables were significantly associated with the cultural competence of the respondents. Specifically, students who had attended diversity training in the last 12 months ($M = 71.50, SD = 16.86$) had significantly higher cultural competence than those who had not attended ($M = 62.78, SD = 13.04, t = -7.32, p < .001$). Students who had experienced providing care to patients from other race or ethnic group in the past 12 months ($M = 75.06, SD = 11.17$) had likewise higher cultural competence than students who did not have similar experience ($M = 59.95, SD = 14.51, t = -15.80, p < .001$). Moreover, students living in an environment with people with diverse race/ ethnicity ($M = 74.77, SD = 12.74$) were culturally more competent than students who were not living in a culturally diverse environment ($M = 62.02, SD = 14.53, t = -11.97, p < .001$). Finally, those students who had taken care of patients belonging to special population groups in the past 12 months ($M = 68.01, SD = 15.23$) reported higher cultural competence than those without similar experience ($M = 61.94, SD = 14.278, t = -5.10, p < .001$).

A multiple regression analysis was conducted to identify the significant predictors of cultural competence among the students in this study. The multiple regression analysis revealed country of residence, gender, academic level, experience of taking care of diverse patients and living in culturally diverse environment as significant predictors of the students' cultural competence ($F(10, 712) = 41.36, p < .001$), accounting for approximately 35.9% of the total variance of cultural competence ($R^2 = 0.367$; Adjusted $R^2 = 0.359$). Specifically, being a student from the Philippines and India increased the cultural competence by 6.84 (95% CI = 4.23-9.45, $p < .001$) and 5.88 (95% CI = 2.97-8.79, $p < .001$), respectively, than being students from Saudi Arabia. Being male student increased the cultural competence by 2.33 (95% CI = 0.04-4.63, $p = .046$) than being female students. Furthermore, being in the fourth year of the BSN program increased the cultural competence by 5.23 (95% CI = 2.43-8.02, $p < .001$) than being in the second year. Lastly, having experienced providing care for a patient from other race or ethnic group in the past 12 months and living in an environment with people with diverse race/ ethnicity increased the cultural competence by 13.61 (95% CI = 11.39-15.84, $p < .001$) and 6.25 (95% CI = 3.95-8.56, $p < .001$), respectively, than those students who did not have similar experiences.

Conclusion: The findings suggest that the cultural competence of the nursing students from the three countries had varying levels. This implies that appropriate interventions must be planned and implemented to address the specific needs of students from each country. The significant factors that were identified in this study should also be taken into consideration in planning educational intervention to ensure the development of cultural competence among the students. Moreover, assessment of cultural competence development among students should also be done regularly to monitor their progress. Lastly, cultural diversity and cultural competence should be incorporated in both classroom and clinical courses of the students throughout the nursing program to ensure a continuous development of their cultural competence.

RSC PST 2 - Research Poster Session 2

Understanding School Nurses' Diabetes Education and Transitional Care for Students With Type 1 Diabetes

Mee Kyung Lee, MSN, BSN, RN, PNP, USA

Abstract

Purpose: The purpose of this study was to gain a better understanding of school nurses' current practice and their perspectives about diabetes education and transitional care for students with type 1 diabetes in K-12 school settings. *Transitional care* is defined as "the purposeful, planned movement of adolescents and young adults with chronic physical and medical conditions from child-centered to adult-oriented health-care systems (Blum et al., 1993, p. 570)". This concept has been applied for youth with type 1 diabetes to emphasize successful transitions from childhood to adulthood in terms of care continuity related to changing healthcare systems. Since there are differences between pediatric care and adult care, having independent diabetes self-management responsibilities is an important element of successful transitions in youth with type 1 diabetes. Similarly, the term *transition planning*, which refers to "a coordinated set of activities to assist students with chronic health conditions" (Baszler et al., 2015, p. 125), has been used to discuss nurses' roles in providing care for children with special health needs. These roles include being knowledgeable about applicable laws; maintaining care competence; communicating with healthcare providers, school staff, and families; and being involved in policy development for managing children with chronic health diseases. In the context of school nursing, transitions can refer to changes in children's locations in school systems, such as transferring from one school to another, and entering a new school system. Providing care during any transitional events of students with type 1 diabetes can be time-consuming work for school nurses who coordinate and support diabetes management and education in collaboration with stakeholders, such as parents, teachers, and school staff. However, students with type 1 diabetes may benefit from school nurses' support in any of the forms of transition they face. There is little information about transitional care provided by school nurses for students with type 1 diabetes.

Methods: A convenience sample of 115 school nurses who have taken care of students with type 1 diabetes in public school districts in the State of Washington, U.S. were recruited for a study that was designed to explore the roles of school nurses in diabetes education. A subset of 20 individuals was selected to participate in follow-up interviews. Measures included online surveys. Demographic information was collected, and the Diabetes Education and Transitional Care Questions (Cronbach alpha = .72) were two measures employed. Data was collected by using the REDCap system. Descriptive statistics, and Pearson correlations were used for data analysis.

Results: Participants were highly homogeneous: predominantly female (97 %), non-Hispanic (95 %), White (90 %) RNs (94 %). The majority of participants (79%) were between ages 35 and 64 years. Commonly provided diabetes education in school were carbohydrate counting, hypoglycemia management, nutrition guidance (e.g. healthy eating, snacks, and food choices), and hyperglycemia management. The three educational content topics prioritized by school nurses were hypoglycemia management, carbohydrate counting, and emergency protocols. Sixty-one percent of school nurses did not use any standardized forms to evaluate the effectiveness of their diabetes education for students. Thirty-two percent of participants used the individualized health plan as an evaluation form for diabetes education. Sixty-eight percent of school nurses have provided transitional care. This transitional care focused on transferring students between schools (36 %), communicating with next school nurses (31 %), and supporting independence (23 %). There was no significant relationship between diabetes education and provision of transitional care ($p > .05$).

Conclusion: School nurses provided diabetes education to students with type 1 to cope with hypoglycemic or hyperglycemic situations and to manage insulin related to food intake, but diabetes education provided by school nurses was not related to transitional care provided by them. This indicates that school nurses may be taking care of students with type 1 diabetes in episodic situations, rather than supporting long-term education related to transition. Although some school nurses provided care for

transitions of students with diabetes, this care was more closely related to exchange of information between school nurses, rather than developing students' capabilities for diabetes self-management. Communication is essential between school nurses to know the current needs and abilities of students in diabetes management. However, ideally transitional care in schools does not only mean transferring students' information but also involves preparing students to be independent. School nurses can facilitate the improvement of students' diabetes self-management behaviors using a long-term educational plan to prepare for transitions as an additional part of an individualized health plan for daily diabetes management. This would be beneficial because the four most commonly provided educational topics in schools are ultimately aimed towards students gaining autonomy in diabetes management. Therefore, providing appropriate transitional care in school settings can help students with type 1 diabetes have successful transitions from one school to another, as well as to become independent in diabetes management.

Experience of Dutch Post-Doctoral Nurses of Leadership and Career Development: A Qualitative Explorative Study

Wedela de Lange, MSc, RN, Netherlands

Anne Mien Regelink, MSc, RN, Netherlands

Irina Uitewaal-Poslawsky, PhD, RN, Netherlands

Thóra Hafsteinsdóttir, PhD, MSc, BSc, RN, Netherlands

Abstract

Purpose: Currently challenges in health care call for leadership to rebuild the nursing workforce and implement new models of care. Therefore, it is highly important to strengthen the research capacity of nursing faculties by investing in leadership and career development of post-doctoral nurses (1,2). However, research on the experiences of post-doctoral nurses is lacking (3). The purpose of this study is to explore Dutch post-doctoral nurses' experiences with their leadership and career development in research functions.

Methods: A general qualitative design was used, in which the experiences of post-doctoral nurses were explored by conducting open, in-depth interviews (4). The data were analyzed with a thematic analysis approach containing six steps familiarizing with the data, generating initial codes, searching for themes, reviewing themes, defining and naming themes and producing the report (5).

Results: Twelve interviews were conducted with postdoctoral nurses working in research. Participants, eight women and four men, ranging in age from 30 to 65 years, worked in different research functions in the Netherlands. The thematic analysis of the interviews led to five themes: Scientific World; Professional Identity; Balance in Life; Appreciation, Collaboration, and Support; and Career Development and Leadership. Post-doctoral nurses have multiple functions, sometimes with conflicting demands between research and patient care or education. Support, collaboration, appreciation, identifying as a nurse, maintaining balance and leadership behavior are important preconditions for post-doctoral nurses to develop a successful career. On the other hand, the absence of these conditions was hindering post-doctoral nurses in the development of their career.

Conclusion: Post-doctoral nurses experience successful and challenging aspects as described in their career development. They use leadership behavior to balance these aspects in their own way. Leadership behavior was found to be highly important in their career development, in order to become a successful postdoctoral researcher. This study demonstrates that the scientific world can be a tough environment where leadership behavior, support, collaboration, nursing professional identity, and good balance in life is needed. Future research is recommended to gain insight into the actual academic development of nursing science in the Netherlands. The creation and development of more advanced academic functions for postdoctoral nurses in all arenas of nursing, including clinical practice, education and research is strongly recommended.

Correlation Between Presence of Biomarkers Associated With Sarcopenia and Quality of Life in the Elderly

Sandra Cecilia Esparza-Gonzalez, PhD, RN, Mexico
María de los Angeles Villarreal-Reyna, PhD, RN, Mexico
Maria Magdalena Delabra-Salinas, MSN, RN, Mexico
Pedro Enrique Trujillo-Hernandez, MSN, RN, Mexico
Deysi Hernandez, MSN, Mexico

Abstract

Background: Sarcopenia is the loss of mass and function of age-related skeletal muscle. It is now recognized as a clinical problem for the elderly and research in the area is expanding exponentially. (Sayer et al., 2013). Sarcopenia in elderly is often correlated with physical impairment and disability – with potentially severe clinical consequences including loss of mobility, osteoporosis, increased fracture risk, dyslipidemia, insulin resistance modifying quality of life (Cruz-Jentoft et al., 2010; Coin et al., 2013)

Studies have shown that the ACTN3 R577X polymorphism is the only structural gene for which a clear effect of genotype on muscle phenotypes has been demonstrated, especially for athletic women, there is controversy as to which allele (R or X) plays a potential role "Favorable "in the elderly. The variation of MSTN K153R is arguably the strongest candidate to explain the variance among muscle phenotypes in the elderly, but further research with large cohorts is still needed because of the very low population frequently of the 'unfavorable' 153R allele. (Garatachea & Lucía, 2011).

Recent studies show that a genetic approach, such as genotyping of codon 72 p53 polymorphism, associated with assessment of body composition is highly desirable, to prevent and control the risk of loss of muscle mass or reduction of ASMMI (skeletal muscle mass index Appendicular) in the female population. (Di Renzo et al., 2016).

Also genetic, serum markers have also been associated with sarcopenia including IL-6, TNF and vitamin D. Recent data indicate a pivotal role of this protein in the processes of muscle repair and hypertrophy following exercise-induced damage. Also vitamin D deficiency can cause myopathy of varying severity, and clinical studies have indicated that vitamin D status is positively associated with muscle strength and physical.

Purpose: Correlate the presence of serum and genetic markers associated with sarcopenia with quality of life in the elderly

Methods: In this study the population evaluated will be over 65 years of the city of Saltillo, Coahuila, during the months of January to December of 2017, the population will be chosen in a random manner. The study design is descriptive correlational. Participants will be fully informed about the nature, purpose, procedures, and risks of the study to obtain their consent.

The variables used will be biomarkers associate with sarcopenia and quality of life.

Blood samples will be taken from each participant to assess vitamin D deficiency and adequacy, as well as existing polymorphisms and their association with the diagnosis of sarcopenia, as well as anthropometric measurements, physical performance assessment (SPPB) tests, activities (Barthel and Lawton), body bio-impedancemetry, double indirect method because it is calculated by formula from water and total body fat, the muscular strength will be measured with a hand dynamometer (hand Grip), as well as DNA of nutritional risk and the MNA (Mini Nutritional Assessment) for the evaluation of nutritional status.

Results: A description of the results and findings will be made in comparison to studies performed.

Conclusion: Although there are certain complications associated with aging, among which Sarcopenia is found, besides being the result of multiple variables, which makes complex its pathophysiology, diagnosis, prevention and treatment complex. For this reason, it is important to investigate new options to contribute to diagnostic and prevention purposes that may help improve the quality of life of the elderly.

The association between the polymorphisms found and the use of biomarkers in the diagnosis of sarcopenia in the adult population of the city of Saltillo, Coahuila, Mexico will be discussed based on available scientific evidence and its implications for improving the quality of life in the elderly.

Creating a Culture of Health With a Clinical Trial to Promote Physical Activity

Leanne L. Lefler, PhD, APRN-BC, ACNS, FAHA, USA
Sara Jones, PhD, APRN, RN, PMHNP-BC, USA

Abstract

Purpose: The *Culture of Health* initiative endorsed throughout the United States (U.S.) by the *Future of Nursing: Campaign for Action* proposes that health is greatly influenced by complex social factors, such as individual and community perceptions and values, physical environments, socio-economic status, opportunities, access, and equity. Yet, few health promoting interventions consider these key contributors to health. Rates of participation in physical activity (PA) remain low in the U.S., especially in older and marginalized population groups, although evidence is undisputed that death and disability could be drastically reduced by PA. Strategies to change behaviors and attitudes to increase regular PA as an action to improve and promote health in our nation remain elusive.

The purpose of this research was to identify strategies that older and diverse women used while changing their behaviors to incorporate regular PA into their daily lives.

Methods: We performed a process evaluation of the Lifestyle Physical Activity for Older Women (LPAW) clinical trial using a descriptive, phenomenological qualitative design. We used the Culture of Health framework to consider the breadth of factors that may influence participation in regular physical activity. Using maximum variation sampling, we interviewed 20 older women about their experiences while participating in the LPAW clinical trial. Data were analyzed using narrative content analysis with constant comparison technique. Techniques to improve rigor were employed.

Results: Eight African American, 11 white women with 1 Native American from the control and intervention arms of the trial were interviewed. Participants had a mean age of 68 years (range 60-94), 40% had a history of cardiovascular disease, 85% were hypertensive, and 35% suffered from diabetes type II. Socio-economic status was low as 45% had annual incomes of less than \$30K and 50% had only a high school education.

Five central themes described how the older women changed their mindset, behavior and attitude about PA, which resulted in regular PA continuing even after trial completion. Results indicated that: 1) Sensed Benefits, 2) Motivation, and 3) Self-efficacy were central to success, while a reduction in 4) Barriers to PA were essential before regular participation in PA could occur. The last theme was described as a "life-changing awareness" of the significance of PA to health. This theme indicated that PA had become a shared value among these older women, an outcome directly related to the Culture of Health framework. An explanatory model, grounded and developed from the data, describes salient factors that these women used to engage in PA.

Conclusion: This study suggests key strategies to include in interventions to promote regular PA as a shared value among older and diverse women. Making regular PA a shared value of health is an action promoted by the Culture of Health initiative that will improve population health and well-being.

Nursing Leadership: Influence in Moral Courage

Georgia A. Dinndorf-Hogenson, PhD, RN, CNOR, USA

Abstract

Purpose: The purpose of this descriptive study is to understand how and which factors influence the perioperative nurses' moral courage in the operating room.

Methods: A mail questionnaire was randomly distributed to western United States perioperative registered nurses yielding a 30 % response rate ($N = 146$).

Results: Fear of reprisal and retaliation were positively correlated with moral distress ($p = .000$). Significant negative correlations occurred between fear of reprisal and retaliation and (a) peer support ($p = .000$), (b) the institutions response to ethical concerns ($p = .003$), (c) institution punishment of reporters ($p = .015$), (d) level of moral courage exhibited when not in the best interest of the patient ($p = .037$), and (e) level of moral courage in speaking up when risks are known ($p = .038$). The level of moral courage needed to overcome being silent showed positive correlations with (a) frequency of immediate reporting of ethical issues to administration ($p = .000$), (b) questioning a provider when not in the best interest of the patient ($p = .000$), and (c) frequency of speaking up regarding ethical issues ($p = .000$). Sufficient performance of the MCQN Likert-type scale showed contrast of scale scores to reflect variance; Cronbach's alpha measured 0.86.

Conclusion: Findings indicate the moral courage model performance was robust. Perioperative nurses reported high moral courage in situational threats to patient safety. Significant findings clustered influencing factors of fear, previous experience, peer support, and institutional culture. Supportive nursing management and administration promote perioperative nurses' exhibition of moral courage. Themes emerged in qualitative data: (a) nurse leaders who exhibited moral courage and supportive of moral courage increased staff nurses' speaking up with moral courage; (b) Nurses reported non-supportive nurse leaders created moral distress, job dissatisfaction, nurses leaving the job or profession, and fear of reprisal and retaliation. Future research is indicated for supportive nursing management and policy creation promoting moral courage. Nurse educators should support moral courage throughout the curriculum building a sturdy foundation for the novice nurse.

Use of Biomarkers for the Evaluation of a Psychoeducational Program in Mexican Informal Caregivers

Nadía Jasso, RN, Mexico

María de los Angeles Villarreal-Reyna, PhD, RN, Mexico

Jesus Acevedo-Alemán, PhD, Mexico

Maria Magdalena Delabra-Salinas, MSN, RN, Mexico

Abstract

Purpose: Evaluate, through biomarkers the effect of a psychoeducational program addressed for nursing guide to improve the emotional health in mexicans informal caregivers of older adults with dementia.

Methods: Quasi-experimental design with repeated measurements and two different groups: the experimental group will participate in a psychoeducational program which consist in 12 sessions of two hours per session in which will develop abilities for the solution of problems for care and self-care in the informal caregivers participants; the control group will receive conferences about chronic illness and healthy life style. The central hypothesis in this project is that the informal caregivers participants in the experimental group will reduce significantly his level of stress, anxiety and depression in comparison to the participants of a control group, rated through the use of biomarkers.

The sample size will be calculated using ANOVA for repeated measurements with three levels (level of trustfulness 95%, potency =0.90) for the interaction time per group, and a size of the large effect. We will use the nQuery Advisor 7.0 software. The variables result that will be measured before, during, after and folow-up about the experimental condition through validated instruments will be associated to the profiles of genetic expression in cortisol levels in saliva and serotonin in blood. Additionally will be identify the presence of polymorphism associated at this study variables. The data will be processed on the SPSS V24 database. The study will be through the semester August - September 2017.

Results: The variables result will be analyzed using ANOVA of repeated measurements and the post-hoc analysis to determine the differences between the groups and the effect size.

Conclusion: Will be discussed the use of biomarkers in the evaluation about the effect of the interventions in nursing in relations with the health condition that affect the quality of life of the mexican informal caregivers of older adults with dementia. In addition how nursing could be benefit with the use of biomarkers like an objective tool that promote the information about the mechanism that could promote the emotional health in informal caregivers.

Cognitive Concepts Predicting Medication Adherence and Asthma Control in Inner-City Adolescents

Hyekyun Rhee, PhD, RN, FAAN, USA

Annette Grape, PhD, LCSW, USA

Donald Harrington, MS, MBA, USA

Laurene Tumiel-Berhalter, PhD, USA

Elizabeth Sloand, PhD, RN, PNP-BC, FAAN, USA

Mona Wicks, PhD, RN, FAAN, USA

Abstract

Purpose: Asthma is the most common chronic health condition in adolescents. Poor adherence to treatment is often attributable to high asthma-related morbidity in inner-city adolescents. According to Social Cognitive Theory (SCT), individuals' behavior (e.g., medication adherence) is influenced by cognitive factors such as outcome expectancy, self-efficacy and the perceptions of personal/environmental impediments. Adolescents with higher self-efficacy are more likely to adhere to their asthma treatment.¹⁻⁵ Outcome expectancy is also associated with adherence to desired behaviors, resulting in better health outcomes.⁶⁻⁸ Yet, little is known about the extent to which outcome expectancy and perceptions of impediments affect medication adherence and asthma control in adolescents with asthma. Furthermore, the relationships among the three cognitive concepts of SCT remain to be examined. The aims of this study were: (1) to examine the relationships between the three cognitive factors; and (2) to determine the extent to which three cognitive factors (self-efficacy, outcome expectancy and impediment perception) predict medication adherence and asthma control in inner-city adolescents.

Methods: Subject eligibility criteria included (1) age between 12-20 years; (2) diagnosed asthma that has required health service use (preventive or acute) within 12 months prior to enrollment; (3) persistent asthma; (4) no other chronic medical conditions requiring daily medication; (5) primary residence located in inner cities; and (6) ability to understand spoken and written English. Participants were recruited from Buffalo NY (n=123), Baltimore MD (n=100), and Memphis TN (n=66). Modified asthma expectancy scale measures the cognitive constructs of SCT.⁹ The scale consists of three subscales, outcome expectancy ($\alpha=.76$), self-efficacy ($\alpha=.69$) and impediment perception ($\alpha=.70$). For medication adherence, Horne's Medication adherence report scale (MARS, $\alpha=.76$),¹⁰ was used in combination with the self-reported number of days preventive medication were used in the past 4 weeks. To assess asthma control, four impairment-based criteria (symptoms, nocturnal awakening, activity limitations and rescue inhaler use) were measured on a 4-point scale. Pearson correlations were computed to examine the relationships among the three cognitive concepts. Multiple regression analyses were conducted to examine the extent to which the cognitive factors predicted adolescents' medication adherence and asthma control. The regression models included sociodemographic factors (gender, age and household income) and age at the first asthma diagnosis as covariates.

Results: Of 289 inner-city adolescents (mean age=14.591.92) who participated in the study, 51% were female, most (>83%) were black, and 71% had public health insurance. The majority reported either not well controlled (51%) or very poorly controlled asthma (35%), and 71% (n=204) were on at least one preventive medication. The most common reason for not taking preventive medication was forgetfulness (42%) followed by "don't need it" (36%). Self-efficacy was positively associated with outcome expectancy ($r=0.52$, $p<.001$) and negatively with impediment perception ($r=-0.18$, $p=.002$). No significant relationship was found between outcome expectancy and impediment perception. In regression models where each cognitive factor was considered separately, after controlling for covariates, medication adherence scale was predicted by impediment perception ($B=-0.427$, $p=.004$), and actual number of adherence days in the past month was predicted by outcome expectancy ($B=0.185$, $p=.027$) and self-efficacy ($B=0.178$, $p=.03$). Symptom control was also predicted by self-efficacy ($B=-0.031$, $p=.017$) and impediment perception ($B=-0.024$, $p=.022$). In a full model where all three cognitive factors were considered simultaneously along with the covariates, self-efficacy and outcome expectancy were no longer significant predictors of

medication adherence or asthma control. However, impediment perception remained a significant predictor of medication adherence ($B=0.08$, $p=.006$), suggesting that as impediments increase adherence decreases. Medication adherence was higher in males ($B=1.32$, $p=.013$), and the number of preventive medication uses in the past month was greater in those from higher household income ($B=0.13$, $p=.042$) and lower in those whose asthma was diagnosed later in life ($B=-0.08$, $p=.003$). Symptom control was greater in those who were older ($B=-0.02$, $p=.04$), who were from higher income families ($B=-0.03$, $p=.004$), and whose asthma was diagnosed later in life ($B=-0.01$, $p=.021$).

Conclusion: Three cognitive factors including outcome expectancy, self-efficacy and impediment perceptions are associated with each other and influence medication adherence and/or symptom control in adolescents with asthma. The relationships, to some extent, appear to be accounted for by sociodemographic factors and age at diagnosis, suggesting the importance of understanding cognitive factors in the context of the circumstantial factors. These findings support the SCT's major assertion that individuals' behaviors are influenced by cognitive factors and their complex interplay with other inter- and intra-personnel factors. This study underscores the need for tailored interventions taking into account individuals' gender, age and SES as well as chronicity of asthma, which can modify cognitive factors to promote medication adherence and asthma outcomes in inner-city adolescents.

Partner Communication for HIV Prevention Among Refugee Hispanic Women in South Florida

Rosina Cianelli, PhD, MPH, RN, FAAN, IBCLC, USA

Natalia Villegas, PhD, MSN, RN, IBCLC, USA

Brian E. McCabe, PhD, USA

Lila de Tantillo, BSN, RN, PhDc, USA

Nilda (Nena) Peragallo Montano, DrPH, RN, FAAN, USA

Abstract

Purpose: The number of refugees increased in recent years due to factors worldwide, including violence, wars, political strife, and natural disasters. Refugees who are Hispanic women (RHW) in South Florida are a vulnerable population at risk of acquiring HIV infection. Although studies have shown a relationship between partner communication for HIV prevention and behavior changes, none have studied RHW. **The purpose** of this study was to assess whether predictors suggested by the literature (age, years living in the US, having insurance, self-esteem, number of partners, having a stable relationship with a male partner) are related to partner communication for HIV prevention among RHW in Florida.

Methods: The study is a secondary analysis that uses baseline data from a randomized controlled experimental study, SEPA. A total of 99 refugees Hispanic women from South Florida, 18-50 years of age, participated in the study. Adapted from Catania, a 10 item scale was used to elicit information about the women's main or primary partner. Items assessed were conversations with male partners about condoms and HIV/AIDS, health, negotiating efforts, and HIV/AIDS concerns during the past 3 months. The scale has an internal consistency of $\alpha = .82$.

Results: The mean age of participants was 33.79 (SD = 8.93), with a mean number of years of education of 15.12 (SD = 3.59). The majority of the participants (69 %) reported living with their partners, and the average of lifetime sexual partners was $M = 4.21$ (SD = 5.51). The mean score for communication with partner about HIV 3.31 (SD = 3.25, range 0–10). The largest group of women (32 %) reported no communication with their partners about HIV, more than half of the participants scored 2 points or higher on this scale, and only 25 % scored at 6 or above (on a 10-point scale). We used logistic regression analysis in SPSS 21 with communication with the partner about HIV as the outcome. As predictors we included age, years living in the US, having insurance, self-esteem, number of partners, having a stable relationship with a male partner. Having more than one partner was positively related to partner communication $B = 1.523$, $SE = .684$, $p = .026$, OR 4.585 and having a formal relationship with a male partner was negative related to partner communication. $B = -1.262$, $SE = .0443$, $p = .004$, OR.283

Conclusion: This study contributed to the expansion of knowledge about Hispanic refugee women in the U.S. The perspectives of women who have undergone the refugee experience can provide valuable insight regarding the role of partner communication for HIV prevention among a unique segment of the Hispanic immigrant population. It is also noteworthy that women in this study had very low communication with partners about HIV. It should be considered that the cultural context in which Hispanic women live may underscore the importance of promoting communication strategies for HIV prevention. Culturally competent sexual health education interventions in this population may impact self-efficacy for HIV prevention.

Time Perspectives and Health Behaviors of Adults With Hypertension: A Feasibility Study

Stephanie E. Kitch, BSN, RN, USA

Abstract

Purpose: Hypertension is a considerable population health problem. Nearly a third of American adults have hypertension; the prevalence of hypertension is also growing among young adults (Mozaffarian et al., 2015). Furthermore, almost half of adults with hypertension do not have the condition well-controlled (Nwankwo, Yoon, Burt, & Gu, 2013). Uncontrolled hypertension can lead to serious future health events, such as heart attack, stroke, organ damage, and even death (American Heart Association, 2016). Yet, hypertension is often preventable or manageable with the adoption of healthy behaviors (Centers for Disease Control and Prevention, 2015; James et al., 2014). Despite the importance of a healthy lifestyle, people often resist making necessary lifestyle changes, especially young adults (Carter & Kelly, 2013). One potentially important factor in health behavior is time perspective, or how people incorporate the past, present, and future into daily life (Zimbardo & Boyd, 1999). Past, present, and future time perspectives may influence health behaviors in varying ways, and time perspectives may be different for individuals of different ages (Guthrie, Lessl, & Ward, 2013; Sansbury, Dasgupta, Guthrie, & Ward, 2014). However, additional research is needed to examine time perspectives and health behaviors within the context of hypertension. Therefore, the purpose of this study was to examine time perspectives and health behaviors in adults with hypertension, and explore feasibility of selected recruitment methods for a larger study.

Methods: This study implemented a cross-sectional, descriptive correlational design. Time perspectives were measured using the Zimbardo Time Perspective Inventory (ZTPI), which captures past (negative and positive), present (fatalistic and hedonistic) and future perspective subscales (Zimbardo & Boyd, 1999). Hypertension-specific time perspectives were measured using the Hypertension Temporal Orientation (HTO) scale (Brown & Segal, 1997). Health-promoting behaviors (health responsibility, physical activity, nutrition, spiritual growth, interpersonal relations, and stress management subscales) were measured with the Health-Promoting Lifestyle Profile II (HPLP-II; Walker, Sechrist, & Pender, 1995). Each of these measurements uses a Likert scale format, and each subscale is reported as a mean. Recruitment efforts incorporated the use of flyers at local high traffic public spaces, businesses, and clinics, a display table at a local community event, and the use of a referral system. Participants who completed the survey were given the option to refer a young hypertensive adult (18-35 years old) using a referral card with a unique ID. If the referral card was returned, the original participant was entered in a gift card raffle. Participants completed a paper survey. To address missing data, mean substitution was used if a participant was missing only one item from any subscale. Data were analyzed using descriptive statistics. Additionally, correlations were used to examine the association among age, each mean time perspective subscale scores, and mean health-promoting behavior subscale scores.

Results: Fifty surveys were administered. Only four participants opted to take a referral card; two were returned. The local community event yielded the largest number of participants (n = 29). Three surveys were missing multiple data points in one or more subscales; thus, the final sample consisted of 47. Of these, 34 (72.3%) were women, 26 (55.3%) were Caucasian, 15 (31.9%) African American, and 6 (12.7%) Hispanic, Asian or other races. Ages ranged between 22 and 72 years. Categorized by generation, twelve (25.5%) were between 18 and 35; 16 (34%) between 36 and 51, 17 (36.2%) between 52-70, and the remainder were 71+ (n = 2, 4.3%) A total of 25 (0.4%) data points were calculated using mean substitution. Ranging from 1-5, mean (SD) ZTPI scores were 2.652 (0.712) for past negative, 3.865 (0.573) for past positive, 2.214 (0.623) present fatalistic, 3.227 (0.587) present hedonistic, and 3.834 (0.497) for future. Preliminary data analyses revealed several significant correlations. Negative correlations were found between a past negative perspective and nutrition ($r = -.357, p = .014$), interpersonal relations ($r = -.314, p = .031$), and total health-promoting lifestyle ($r = -.309, p = .034$). Past positive perspective significantly positively correlated with spiritual growth ($r = .343, p = .018$). Present hedonistic was positively correlated to spiritual growth ($r = .319, p = .029$), stress management ($r = .321,$

p = .028), and total health-promoting lifestyle (r = .288, p = .05). Higher present fatalistic perspectives negatively correlated with health responsibility (r = -.332, p = .022), spiritual growth (r = -.401, p = .005), interpersonal relations (r = -.391, p = .007), and total health-promoting lifestyle (r = -.356, p = .014). Higher future perspectives correlated with spiritual growth and interpersonal relations (r = .403, p = .005; r = .353, p = .015, respectively). However, neither present nor future time perspective correlated with physical activity or nutrition, which was an unexpected finding. The HTO measure did not significantly correlate to any health-promoting behaviors. Age did not significantly correlate to any time perspective. Additional data analysis is ongoing.

Conclusion: Recruitment at events within the local community appeared to be the most successful approach, although the referral process yielded very few prospective participants. Recruitment strategies yielded adults of all ages. However, there was no significant correlation between age and mean time perspective scores with preliminary data analysis. In this sample, mean past positive and future time perspective scores were the highest. A number of significant relationships between various time perspectives and health-promoting behaviors emerged. However, unexpected nonsignificant relationships were also identified. A future study may require a larger sample size to detect additional significant relationships among age, time perspectives, and/or health-promoting behaviors while controlling for other variables. As indicated in preliminary analyses, individual time perspectives influence different health-promoting behaviors, and in differing directions. Thus, incorporating an individual's past, present, and future perspective may provide a well-rounded approach to identifying underlying behavioral influences. Gaining a better understanding of the relationship between time perspectives and health-promoting behaviors will guide nurse researchers in the design of tailored, individualized interventional strategies to encourage health-promoting behaviors. Individual interventional strategies can be implemented to better prevent or manage hypertension, and to reduce the long-term negative health outcomes associated with uncontrolled hypertension.

1991-2015 Trends of Adolescent Smoked First Whole Cigarette Before Age 13 in the U.S.

Yu-ku Chen, BSN, RN, USA

Yu-han Zheng, BSN, RN, USA

Jiunn-Jye Sheu, PhD, MSPH, MCHES, USA

Abstract

Background: The Youth Risk Behavior Survey (YRBS) has been established to monitor tobacco use trends among adolescents. Most reports had reported adolescent's current smoking prevalence trends by either sex, race/ethnicity, or grade separately. This study took a more holistic view and identified the disparity by sex-grade-race/ethnicity specific rate trends of a first whole cigarette smoked before age 13.

Problem: The longitudinal prevalence trends of a first whole cigarette smoked before age 13 stratified by more than 2 demographic variables have not been extensively investigated. The published studies are either of lack of national sampling representation, small in sample size, cross-sectional design, or reported prevalence trends by only one or two demographic variables from participant's grade, gender, or race/ethnicity.

Purpose: This study described the 24 years longitudinal prevalence trends of a first whole cigarette smoked before age 13, compared them in the specific grades, genders, and major races/ethnicities, and suggested nursing intervention.

Methods: The Centers for Disease Control and Prevention (CDC) established this biennial Youth Risk Behavior Surveillance System (YRBSS) in 1991 to display health-risk behaviors amongst youth at national, state, and local levels. The YRBSS surveys adolescents in grades levels 9-12 from sampled schools across the United States. Therefore this offers the maximum representative data for youth health risk behaviors. The CDC designed YRBSS to see the health-risk behaviors among high school students. This assesses whether these behaviors increase, decrease, or stay the same over time. YRBSS focuses only on youth health-risk behaviors.

Results: The trends in adolescent's smoking a whole cigarette before the age of 13 changed by each grade progression. Across 24 years, males of Hispanic in grades 9th and 12th and African Americans in the 9th grade had higher proportions of smoking a whole cigarette before the age of 13. There was not a clear distinction among male and female White 9th-12th graders, Hispanics grades 10th and 11th, and African Americans 10th, 11th and 12th.

Conclusion: Resources that are distributed and policies established should be made based on scientific evidence with sufficient stratification. Especially when public health budgets and resources are limited, priorities should be given to the higher risk groups identified by such analysis.

Characteristics of Nurse Directors That Contribute to High Registered Nurse Satisfaction Scores

Debra A. Burke, DNP, MBA, RN, NEA-BC, USA

Abstract

Purpose: Attracting and retaining Registered Nurses (RN) is essential to ensure excellence in patient care delivery. Research studies have identified many factors that contribute to job satisfaction and impact RN retention. A supportive practice environment, strong nurse manager support, and an emphasis on quality all impact nurse satisfaction (Kelly, McHugh & Aiken, 2011; Smith, Hood, Waldman & Smith, 2005). Additionally, good communication, respect and feeling cared for have been identified as positive attributes of Nurse Directors (NDs) that RNs value (Feather, Ebright, Bakas, 2015).

Many satisfaction surveys are quantitative and provide clinical areas with scores, but the details behind those scores are missing. Despite what is known about RN satisfaction, there is a lack of research exploring perspectives of both the RNs and the NDs in settings where job satisfaction is reportedly positive.

The purpose of this study was to explore Registered Nurse and Nurse Director perceptions of positive ND characteristics that contribute to high work environment satisfaction scores.

Of note, at the study hospital, nurse director is synonymous with the term nurse manager.

Methods: This was a qualitative study, utilizing one-on-one interviews with NDs (n=9) and RNs (n=9). Interview questions utilized an appreciative inquiry framework intended to identify strengths, best practices and successes of NDs.

Thirty three units were invited to participate from a variety of clinical areas, all of which scored higher than benchmark on the Practice Environment Scale of the Nursing Work Index (PES-NWI) quantitative survey in the component of "Nurse Manager ability, leadership and support of nurses" in an acute care hospital (Lake, 2002).

Qualitative content analysis of transcribed audiotapes was conducted. Two reviewers identified themes within each ND and RN group. Across case analysis was also conducted to identify congruency between groups.

Results: Four themes describing leadership were identified within the Registered Nurse sample; empowerment, visibility, role modeling, and passion for excellence. Within the Nurse Director group, four themes were also identified; empowerment, visibility, role modeling and authentic presence.

Characteristics identified describe transformational leadership styles of Nurse Directors. Characteristics identified support previous studies about qualities of exemplary leaders; however there is strong correlation between the views of the RNs and NDs in this study; which is different from other studies.

Conclusion: Although leadership characteristics may vary by Nurse Director, RN and ND participants in this study cohort identified similar themes representative of leadership attributes and behaviors that contribute to RN satisfaction.

This study enhances our understanding of the quantitative scores on the PES-NWI survey and is critically important to our need to understand what contributes to RN satisfaction. Findings suggest ways NDs may effectively influence RN satisfaction. The consensus between RNs and NDs in this study suggests strong alignment.

Findings have the potential to guide nurse executives in hiring prospective ND candidates by ensuring they identify characteristics important to RNs. These results may help inform leadership development programs for existing and future NDs.

Barriers and Facilitators to Timely Epinephrine Administration for Anaphylaxis in Schools: A Systematic Review

Emily Christensen, BA, RN, USA

Susi Miller, MLIS, AHIP, USA

Victoria von Sadovszky, PhD, RN, FAAN, USA

Abstract

Purpose: Anaphylaxis affects 2% of the United States population and the incidence is increasing the US, UK, and Australia (Koplin, Marcin, & Allen, 2011; Lieberman et al, 2006). Rates of anaphylaxis are highest in children between the ages of 0 and 19 years, with between 10%-18% cases of all pediatric anaphylaxis occurring in schools (Song, Worm, & Lieberman, 2014). In children not previously diagnosed with anaphylaxis, 24% of first time anaphylaxis occurred at school (Dinakar, 2012). In 32 cases of fatal anaphylaxis in the school setting, 28% of those were due do a delay in the administration of epinephrine (Sicherer & Mahr, 2010). At present there is some research examining issues with availability and use of epinephrine in the United States population (Song, 2014) and no research examining systems that expedite administration. The purpose of this systematic review is to examine the scientific literature for research on epinephrine administration in the American school system.

Methods: Following the guidelines of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA, 2015), two reviewers performed independent literature searches in PubMed, CINAHL, Psychinfo, OVID and ERIC. The Keywords searched were “anaphylaxis”, “school” and “epinephrine” with additional searches on “barriers” and “facilitators”. Limits for the search included: 1) peer-reviewed publications, systematic reviews and meta-analyses; 2) published within the past 10 years; 3) pediatric population. Seventy-eight abstracts were selected and two researchers are evaluating the associated articles for inclusion in the systematic review and agreement on abstracts will provide interrater reliability. Articles will then be reviewed by the study authors. Articles will be analyzed for epidemiology, demographics, and epinephrine use in schools.

Results: This review is currently in progress and we anticipate the findings to be completed by March 2017.

Conclusion: Anaphylaxis is a severe and unpredictable life-threatening allergic reaction that is fairly common in developed nations (Koplin, 2011; Lieberman, 2006). Anaphylaxis frequently occurs in the school setting, however there is scant research regarding facilitators and barriers of rapid epinephrine administration. A systematic review is needed to direct future research as well as current practice regarding epinephrine administration at school.

1991-2015 Longitudinal Prevalence Trends of Suicide Ideation Among High School Students in the U.S.

Yu-han Zheng, BSN, RN, USA

Yu-ku Chen, BSN, RN, USA

Jiunn-Jye Sheu, PhD, MSPH, MCHES, USA

Abstract

Purpose: This study is aimed to describe the trends of suicide ideation during a 24-year time span from 1991-2015 among nationally representative high school students and to stratify those high school students by gender, grade, and ethnicity/race.

Methods: The Centers for Disease Control and Prevention has a Division of Adolescent and School Health, and they created a Youth Risk Behavior Surveillance System. The Youth Risk Behavior System has a survey that is published once every two years, and the surveys have been conducted since 1991. These surveys are used to watch health risk behaviors in young people, and they are at the state, local, and national levels. YRBSS scientifically samples high schools in the United States in order to collect data. This is said to be among the most representative data for young people. YRBSS is used to see what the prevalence of health risk behaviors is in young people. It helps to see whether the rates increase, decrease, or stay the same. In addition to that, YRBSS can be used to see if certain health-risk behaviors occur at the same time. YRBSS does not look at what causes health risk behaviors. In addition to providing state, local, and national data, YRBSS can be used to look at and provide data for subpopulations of young people. Furthermore, YRBSS helps with monitoring the progress in reaching national objects for the years 2000, 2010, and 2020.

The Youth Risk Behavior Surveillance System produces a Youth Risk Behavior Survey. Youth Risk Behavior Surveys are used to look at six different categories of behaviors that can cause problems such as disabilities and death. The categories of behaviors are measured in the United States. The behaviors that are measured are: 1) behaviors that increase the risk of violence and unintentional injuries; 2) using tobacco; 3) using alcohol and other drugs; 4) being sexually active and getting STD's or getting pregnant; 5) eating unhealthy foods; and 6) level of physical activity, which shows the amount of overweight/obese people and the amount of people who have asthma.

Results: All three figures have the same trends in regard to gender; however, there are no generalizable trends when looking at the suicidal ideation rates between grade and race/ethnicity. White females had a declining amount of suicidal thoughts across grade level between the years 1991-1993. During those same years, there was a peak for White females for all of the grades except for twelfth grade where it declined from 1991-1997 for twelfth grade. Another trend is that for White females, there was a decreasing trend from 2001-2003. Each one of the grade levels for Hispanic or Latino have different peaks in different years. Furthermore, there is an inconsistent decrease in the prevalence of suicidal ideation for females within the African American race/ethnicity for all of the high school grade levels between the years 1991-1993.

Conclusion: In conclusion, the current literature reported insufficient about adolescent longitudinal trends in suicide ideation with limited stratification by grade over the year, and did not find much information from CDC either. Such understanding help to know each groups results.

Parental Perceived Barriers and Facilitators to HPV Vaccination: A Literature Review

Lisa N. Mansfield, MSN, BSN, RN, USA

Abstract

Purpose: The human papillomavirus (HPV) is the most common sexually transmitted infection among men and women in the United States (U.S.), and is associated with 90% of cervical and anal cancers and 70% of vaginal, vulvar, penile and oral cancers. Nearly 38,800 new cases of HPV-associated cancers emerge each year in the U.S. Individuals aged 15-24 comprise roughly 50% of these newly diagnosed cases. The Advisory Committee on Immunization Practices (ACIP) recommends the three-dose vaccine, Gardasil, for administration in adolescent beginning at ages 11 and 12 to prevent infection from HPV. While HPV vaccine initiation rates (i.e., receive 1 dose) have steadily increased within the last seven years to 60% among adolescent girls and 42% among adolescent boys, completion rates (i.e., receive 3 doses) remain significantly low at 39.7% and 21.6% among adolescent girls and boys respectively. Therefore, the purpose of this literature review is to examine parental barriers and facilitators that contribute to low rates of HPV vaccination initiation and completion among adolescents in the United States.

Methods: To identify relevant literature on parental barriers and facilitators to HPV vaccination, several databases (PubMed, CINAHL, ProQuest Central, and PsychINFO) were searched in September and October of 2016 using the following keywords: "HPV vaccination," "adolescents," "facilitators," and "barriers." Inclusion criteria were: English language; participants that were parents of adolescents ages 9-17 who had received at least one dose of the vaccine, completed vaccination requirements, or were unvaccinated, and; publication since 2006, as the HPV vaccine was approved for administration in 2006. Studies conducted outside the United States were excluded. Additionally, intervention-based studies were excluded to insure focus on understanding the barriers and facilitators to vaccination rather than increasing vaccination.

Results: The initial search returned 1365 articles and 38 were retained for this review. Most of the studies used quantitative methodology using cross-sectional, survey designs (n = 27). Convenience, purposive, and probability sampling methods were used across all studies. Parents' ages ranged from 30 to ≥ 50 years and the average adolescent's age ranged from 11 to 17 years. Three major themes emerged for parental perceived barriers: vaccine concerns, age of vaccine administration, and adolescent sexual activity. Four themes emerged for parent perceived facilitators: provider recommendation, attitudes towards HPV and vaccination, HPV knowledge, and awareness and perceived risk for HPV.

Conclusion: Many of the studies in this review were limited by design and/or instrumentation choice. For example, cross-sectional designs preclude understanding of how parental perceptions may change over time, and how perceptions ultimately affect vaccination rates. Longitudinal designs would be well-suited to understanding how and whether perceptions are related to outcomes. Additionally, since parents' perceived barriers and facilitators to HPV vaccination varied between different racial and ethnic groups, future work should focus on the unique experiences of groups traditionally underrepresented in research, with the recognition that variation exists within these groups that also warrants investigation. Finally, only three studies noted that parents included their children in the decision-making process for HPV vaccination. Future work may consider exploring whether family members' experiences and vaccination rates differ based on whether or not children were participants in their health care decision making.

Strategies to Engage Lower-SES, Working-Age Adults in Health Research: Results From the SMART Life Study

Lindsey N. Horrell, BSN, RN, USA

Shawn M. Kneipp, PhD, MS, BSN, ANP-BC, APHN-BC, FAANP, USA

Cecilia M. Gonzales, BA, USA

Mary Grace Flaherty, PhD, MS, MLS, USA

Matthew Lee Smith, PhD, MPH, CHES, FAAHB, USA

Ziya Gizlice, PhD, MS, USA

Abstract

Purpose: The Chronic Disease Self-management Program (CDSMP) is a six-week, community-based education intervention that has been associated with positive health outcomes, improved healthcare utilization, and decreased healthcare costs among participants managing at least one chronic condition (Ory et al., 2015; Lorig et al., 1999). While these results have been observed among a wide age-range of adult participants (Ory et al., 2014), this course has been primarily implemented among older, white, female populations of higher socioeconomic status (SES). As a result, marketing materials for this program often display messages and images that overwhelmingly reflect the motivations and characteristics of this aging population. This presents considerable challenges to researchers currently trying to engage younger, lower-SES adults, who face rapidly rising rates and disproportionate adverse outcomes related to chronic conditions, in the CDSMP. The purpose of this presentation is to discuss the development, dissemination, and evaluation of recruitment materials utilized by the SMART Life Study, which is an ongoing RCT at the University of North Carolina at Chapel Hill that studies the effect of the CDSMP on work productivity, health, and healthcare utilization among working-aged, lower-wage earning adults.

Methods: To develop recruitment materials for the SMART Life Study, the project team convened an advisory panel of community members that reflected the study's target population according to key demographic and socioeconomic characteristics. This panel informed the development of all recruitment materials and methods through an approximately 6-month iterative process.

Results: Following the suggestions of the advisory panel members, SMART Life recruitment materials largely incorporate messages reflecting themes of enhanced financial and employment stability and increased ability to spend time with and provide for family members. The materials also contain hopeful messages of "better health" and "decreased stress" rather than loss-framed messages. While recruitment is ongoing, these advertisements have engaged the interest of approximately 1,055 adults who have completed the study registration form. Among those engaged, approximately 85% are female, 43% identify with a minority racial status, and 5% identify as Hispanic. Additionally, the mean age of respondents is currently 48.2 years old, and 49% report living in homes in which the annual household income is less than \$60,000.

Conclusion: The results of this process indicate that developing targeted recruitment materials is an effective approach to engaging the interest of working-age, lower-SES adults in studies of the CDSMP. Incorporating the advertisement cue and strategy preferences discussed during this presentation could enable future nurse leaders to further engage this group in similar health promotion/disease prevention programs. In doing so, we may finally begin to curb the disparities in health outcomes that continually plague this population across the globe.

RSC PST 2 - Research Poster Session 2

Process Evaluation of the Implementation of Cancer Treatment Summaries for Cancer Survivors in England

Desiree Tait, DNSc, RN, NMC, United Kingdom

Sharon Waight, MSc, RN, NMC, United Kingdom

Janet M. E. Scammell, DNSci, MSc (Nsg), BA (SocSci), DipNEd, RGN, SCM, RNT, England

Abstract

Purpose: The purpose of this study is to examine the factors that influence the implementation of cancer treatment summaries and cancer survivors' experiences of receiving them. The percentage of people living beyond cancer continues to increase due to improved prevention strategies and early treatment interventions (Independent Cancer Task Force, 2015; American Cancer Society, 2014). The use of an integrated package of care including care plans, treatment summaries and follow up care has been proposed to support a reduction in side effects following treatment and early detection of returning disease (National Cancer Survivorship Initiative Recovery Package, 2014).

Methods: Six hospitals took part in the study during 2015 and 2016. A mixed method approach was used and included a survey of lead cancer nurses in the sample hospitals to determine the progress made towards the implementation of treatment summaries and factors that influenced their progress. The second approach included the use of interviews and focus groups to describe cancer survivors' experiences of receiving a treatment summary. Ethical approval was obtained from the participating university and permission to gain access for data collection was collected from all participating sites. Data were analysed using SPSS and qualitative data analysed using thematic analysis. **Results** have been presented to the participating hospitals and strategic boards

Results: Data were collected in the first six months of project implementation. Results indicated that in the sample group 49% of colorectal patients and 62% of breast cancer patients received a treatment summary after completing a treatment episode. Factors that affected the implementation process included human resources, availability and accessibility of information technology, information about patient selection and documentation, education, multidisciplinary involvement, leadership champions, and feedback from staff and patients. For cancer survivors, not all could remember having a treatment summary, they felt overwhelmed by the amount of information received. Those who did remember found them helpful and provided them with information that they could share with their family and friends. The participants interviewed did not experience any integration between secondary and primary care services following their treatment.

Conclusion: The percentage of patients receiving treatment summaries compares favourably with implementation data published internationally from USA and UK (Jabson, 2015; Rechis et al, 2014). The factors identified as influencing the implementation of treatment summaries were similar to those experienced by nurses implementing service improvement plans (Jun et al, 2016; Rajasekhar et al, 2016). For the cancer survivors, the experience of receiving a treatment summary felt like receiving a piece of a puzzle that would eventually help them to understand the picture. The individuality of each survivor and their coping strategies emerged as the interviews and focus groups progressed and highlighted that some survivors will be willing to engage in follow up services while other will not, preferring to develop their own coping strategies.

RSC PST 2 - Research Poster Session 2

Does Oral Health Predict Cognitive Decline Among Older Adults? The Health and Retirement Study

Shaoqing Ge, MPH, BSN, RN, USA

Hanzhang Xu, BSN, RN, USA

Wei Zhang, PhD, MS, USA

Bei Wu, PhD, FGSA, USA

Abstract

Purpose: Oral health is an important component of health. Poor oral health has been shown to be an indicator of lower quality of life (Thomson, 2014), and has also been shown to be associated with multiple health conditions, such as diabetes (Leite, Marlow, & Fernandes, 2013), heart disease (Vos et al., 2013), and depression (Hybels et al., 2016). Increasing evidence from longitudinal studies have shown some level of associations between oral health and the cognitive outcomes, although the evidence is still weak (Wu, Fillenbaum, Plassman, & Guo, 2016). Previous studies were limited in that (1) most of them used binary measures of cognitive function by “with/without dementia”, instead of examining the change of cognitive function over time; (2) previous studies often examined one oral health indicator, such as periodontitis, or tooth loss; (3) there is racial disparities in oral health (Wu, Liang, Plassman, Remle, & Luo, 2012), and the rate of decline in cognitive function may differ across different groups (Gupta et al., 2016; Schwartz et al., 2004). However, there is a lack of understanding of the potential differences in the associations between oral health and cognitive decline over time across racial groups.

The aims of this study are to (1) examine the associations between oral health and cognitive decline over time among non-hispanic white older adults; (2) examine the associations between oral health and cognitive decline over time among the African American older adults; and (3) compare the racial difference in the associations between oral health and cognitive decline over time.

Methods: The sample included 781 non-Hispanic white, and 110 African American community-dwelling older adults 65 years and above who (1) enrolled in the 2008 wave, and (2) were followed up in 2010 and 2012 from the Health and Retirement Study, and (3) completed both cognitive measure and the 2008 oral health module. We constructed three indicators of oral health: edentulism (yes/no), overall mouth conditions (range: 1-5), and self-rated oral health (range: 1-5). Cognitive function was measured by the HRS/AHEAD cognitive battery in each wave (Ofstedal et al., 2002). Weighted descriptive and growth curve analyses were performed. Controlled variables included sociodemographic (gender, marital status), socioeconomics (education, household income), and health factors (depression, number of medical conditions, number of physical difficulties).

Results: All the results presented below are based on the fully adjusted models. The results on edentulism showed that there were no significant difference in level of cognitive function at baseline between edentulous and non-edentulous older adults from either non-Hispanic White or African American. African American older adults who were edentulous in 2008 had a faster rate of cognitive decline as they grew older ($\beta = -0.337, p < .05$), compared to those who were not edentulous in 2008. However, this faster decline rate was not seen in their white counterparts ($\beta = -0.024, p > .05$). For overall mouth condition, non-Hispanic whites who had worse overall mouth condition in 2008 had significantly worse cognitive function at baseline ($\beta = -0.889, p < .05$) compared to those who had better overall mouth condition. However, this difference was not found among African American older adults ($\beta = 0.522, p > .05$). For self-rated oral health, there were no significant differences in neither level of baseline cognitive function nor the rate in cognitive decline, regardless of race ($p > .05$).

Conclusion: This study suggests that community-dwelling African American older adults with worse oral health have faster deterioration of cognitive function over time. Non-Hispanic white and African American older adults showed different patterns in the associations between oral health and cognitive function. This study provides a preliminary knowledge base that oral health can be a modifiable risk factor for cognitive

decline. This study highlights the importance of developing early intervention strategies to protect and promote oral health as for the purpose of decelerate cognitive decline.

"Smoke Another One": The Experiences of South African Family Members Caring for Cancer Patients

Lize Maree, DCur, RN, ANSA, South Africa

Dineo Moshima, South Africa

Modiehi Ngubeni, South Africa

Lethukuthula Zondi, South Africa

Abstract

Purpose: The purpose of our study was to provide a descriptive summary of the experiences of the family care givers of cancer patients using the public health care system in South Africa.

Methods: We used a qualitative descriptive design and conducted unstructured interviews with 20 purposive selected participants, 10 men and 10 women, who were between the ages 20 and 65 (average 42.1; SD±12.3), identified as primary family care giver by cancer patients treated at the specific hospital. One opening question "Please tell me what it is like for you to live with a family member with cancer?" was asked. Probes and prompting questions were used to clarify issues and enhance an in-depth description of the participants' experiences. Field notes were also taken. Data gathering and analysis occurred concurrently until data saturation was achieved. The interviews were transcribed verbatim immediately after the interview and the field notes were inserted at relevant points. Qualitative content analyses analysed the data.

Results: Three themes arose from the data: responses towards a cancer diagnosis; taking the role of the care giver and living a changed life with a changed person. Learning their loved one was diagnosed with cancer was a shock to most of the participants. However, there were those for whom cancer was yet another diagnosis as their family member was sick for as long as they could remember. Not all the participants knew what cancer was and some waited for it to go away. Most participants wanted to be strong when learning about the cancer diagnosis, but some experienced anger and stress about the situation they found themselves in. Participants were overwhelmed with the care responsibilities which had a negative influence on their work and family life. The additional responsibilities resulted in unplanned financial expenditure and merely getting and accompanying the sick person to hospital was a major challenge. Some participants felt emotionally broken and alone in this journey and experienced the rest of their family as uncaring. Not only had the lives the participants knew changed, but the person in their care also changed. Participants had to put their own lives on hold and make sacrifices involving their children, work, possible relationships and their normal activities to care for the sick person who in many instances became a person they did not know. Most of the participants used religious practices to cope with their situation, however, some used other coping mechanisms like recreation and even smoking.

Conclusion: Caring for a family member with cancer was not easy. Cancer was not known to all and created fear and uncertainty about the present and future. Participants had to sacrifice their normal lives and had to live with person changed by the cancer and its treatment. The burden of care had a negative influence on the emotional well-being of the care givers and those with a small or no income could not cope with the additional financial burden.

Exploring the Experiences of Three Management Strategies in Auditory Hallucinations in Chronic Schizophrenic Patients

Chao-Hsin Chen, MSN, RN, United Kingdom

Abstract

Purpose: The purpose of this study is to clarify the experience of auditory hallucination symptoms in chronic schizophrenia patients who using auditory hallucination management strategies. Therefore, this study uses three management strategies including listening music, concentrating and talking to someone in order to understand the experience of the patients.

Methods: This is a cross-sectional study and using group therapy to understand the experience of employing auditory hallucination management strategies in patients. A total of 13 chronic schizophrenia patients who with auditory hallucination from a psychiatric hospital in the Northern Taiwan were included in the study. In addition, the group of 8 to 12 patients who met once a week, each time is 50 to 60 minutes and a total is 12 times.

Results: Content analysis of the interview scripts showed two main themes: (1) the experience of auditory hallucination symptoms from the past to present, including content: vocal and non-vocal voice, timing: stress, isolation, doing nothing and mood, identification: doubtfulness and verification and coping strategies: engagement and extrication; (2) the effect of management strategies, which include prerequisite: medication adherence and fitness, appropriation: involvement, diversification and preoccupation and after auditory hallucination appeared and difficulty factor: limitations. In accordance with the contents and the types of auditory hallucination symptoms, which divided into the small themes to discuss and analysis. More than half of patients believe that the hallucination management strategies used in life can reduce the effect of auditory hallucination symptoms and improve the quality of life.

Conclusion: According to the results, were recommended that chronic schizophrenia patients who have auditory hallucination symptoms can use auditory hallucination management strategies to enhance the skill of symptom management and rehabilitation motivation. Therefore, this study can be used as a reference for clinical nursing programs to increase the knowledge and understanding of patients who have auditory hallucination symptoms. Furthermore, it can assist patients with chronic schizophrenia in reducing the effect of auditory hallucination symptoms and promoting patients' quality of life.

Augmenting Sickle Cell Anemia/Sickle Cell Disease Genetic Knowledge Through Simulation: A Descriptive Pilot Study

Leighsa Sharoff, EdD, RN, NPP, AHN-BC, USA

Abstract

Purpose: Genetic/genomic knowledge has radically changed the way health care is provided. Augmenting this newly required competency into constrained nursing curricula is a challenge. Simulation provides such an opportunity. This post-test pilot descriptive study explored the genetic component of a simulation scenario addressing sickle cell anemia/sickle cell disease exploring students' and nurse educators' perceived genetic knowledge. The genetic knowledge of Sickle Cell Anemia/Sickle Cell Disease [SCA/SCD] of pre-licensure baccalaureate undergraduate nursing students, and nurse educators, in a diverse urban nursing school was explored. Thirty-one junior (pediatric simulated scenario; 26 females/4 males) and thirty-one senior (adult medical/surgical simulated scenario; 29 females/2 males) nursing students and eight clinical simulation facilitators (1 male/7 females) were randomly selected to receive the simulation experience with the SCD genetic component. A sickle cell anemia/sickle cell disease case scenario (SCA/SCD; aka Mr. Tony Wallace) was developed with the aim of enhancing students' experience with genetic knowledge, patient education and care. Junior grade level students, who were scheduled for a pediatric simulation experience, received the simulated patient case of a 3 year old, including appropriate age-related changes in medications, doses and laboratory data. Senior grade level students, who were scheduled for a medical-surgical simulation experience, received the same simulated patient case but the patient was now 24 years old, and included appropriate age-related changes in medications, doses and laboratory data.

Methods: A descriptive, post-test design was employed to evaluate the self-perceptions of genetic knowledge among nursing students and simulation facilitators following a genetic-based simulation experience. A six question survey examined students' genetic knowledge after their simulation experience, exploring the understanding of the genetic component (SCA/SCD); ability to provide the patient and family with information about SCA/SCD; level of understanding of SCA/SCD appropriate to provide effective and efficient nursing care with appropriate nursing interventions; critical thinking skills about providing genetic information to a patient; clinical judgment about providing genetic information to a patient and asked if this scenario enhanced their overall ability to integrate genetics into their knowledge base of nursing and nursing care. Participants could respond to each question by noting "Strongly agree", "Agree", "Disagree" or "Strongly Disagree". Participants were asked to respond to "How can this simulation integrating genetics be improved to further enhance your overall knowledge?" Data were coded and entered into an SPSS database. Descriptive statistics including frequencies and percentages were utilized for demographic while contingency table analysis was used to summarize the categorical perception data. Per question response rate was 100%. Qualitative data was summarized by the most common themes.

Results: Majority of students (88.6%; mean=1.42) agreed that their understanding of the genetic component of SCA/SCD improved after the simulation; their ability to provide the patient and family with information pertaining to SCA/SCD was satisfactory after the simulation (n=49; mean=1.47); level of understanding of SCA/SCD was appropriate to provide effective and efficient nursing care with appropriate nursing interventions (n=53; mean=1.47); majority agreed that their critical thinking skills (mean=1.42) and clinical judgment (mean=1.45) about providing genetic information improved with this simulation and this scenario enhanced their overall ability to integrate genetics into their knowledge base and nursing care. Comparatively, there was minimal differences noted between junior (pediatric clinical) and senior (adult clinical) to each survey question. All faculty felt that this scenario enhanced their overall ability to integrate genetics into their knowledge base and nursing care.

Conclusions: These pilot findings support integrating a genetic component into simulation to further enhance the genetic knowledge of both students and facilitators. It is imperative that nursing curricula stay abreast of current mandated competencies. Including a genetic component during a simulation

experience enhances students' and nurse educators' perception of their genetic knowledge base. This evaluation revealed that including a genetic aspect to a simulation experience was not only feasible but was viewed positively by both students and educators. All participants agreed that their genetic knowledge improved after the simulation. With millennial nursing students, it is necessary for nurse educators to provide a variety of learning strategies, engaging students intellectually as well as motivationally. Simulation offers a creative and innovative learning strategy to enhance the genetic knowledge of nursing students. With new knowledge come new responsibilities reflected by the new required competencies. Implementing these competencies into a heavily burdened curriculum requires nurse educators to establish new integrative teaching formats. Simulation prepares students for real-world experiences and as we enter the genetic/genomic era, simulation has an obvious role in expanding and developing these competencies, in a safe and friendly learner-centered environment. By integrating genetics into a simulation, the facilitators' genetic literacy knowledge base will improve, thus furthering their confidence and ability to assist students to meet these new competencies.

Evaluation of Community-Based Program on Health Indicators in Food Insecure Population

Mark Wilkinson, MSN, RN, USA

Abstract

Purpose: The purpose of this project is to improve the health outcomes of a food insecure population through health interventions of health screenings, health education, dietary education, and increased physical activity.

Methods: The intervention of health screenings of weight, BMI, diastolic/systolic blood pressure, and blood glucose readings in conjunction with health education and increased physical activity will be initiated within a food insecure population.

Results: The research is ongoing.

Conclusion: The research is ongoing

Food insecurity is defined as not having enough quantity or quality of food for all household members to have an active, healthy lifestyle. Food insecurity is a risk factor for diabetes, obesity, and hypertension. 1 in 6 Americans are food insecure. Hispanic and African American poverty stricken adults are at a greater risk than non-Hispanic Whites. Food banks and pantries that were intended to be a temporary resource have become the primary food source for many in poverty. Food from food banks is often high in carbohydrates, salts, and processed foods. There is a need to address the health disparities in food insecure adults. Feeding America is a program initiated for food banks to address the health disparities of the people they serve. The Action family program is a community based effort to meet the need of food bank dependent population. Research has shown Community and faith-based programs aimed at increasing physical activity, screenings for health risks, and health education can have positive results in reducing the health disparities of the food insecure population. Pender's health promotion model (HPM) can be used to empower this population to make healthy lifestyle changes. HPM is rooted in the expectancy value theory that presents the idea that individuals engage or participate in activities to achieve goals they believe to be possible.

RSC PST 2 - Research Poster Session 2

Measuring High-Fidelity Simulation Instruction: Its Effects to Knowledge, Skills, and Attitudes Toward Patient Safety

Sasha Alexis Rarang, PhD, MSN, RN, CCM, USA

Abstract

Nursing practice requires measures that promote patient safety. Gregory, Guse, Dick, and Russell (2007) stated that in today's healthcare environment, patient safety serves as a crucial factor in determining quality of patient care through decreasing patient care errors. The integration of high-fidelity simulation (HFS) in the undergraduate nursing curriculum had required evidence that supported the acquisition of learning outcomes which includes KSAs towards patient safety (Howard, Ross, Mitchell, & Nelson, 2010). Therefore, a need of validating scenario-based HFS as a learning pedagogy towards patient safety was needed (Robertson, 2011).

Purpose: The purpose of this quasi-experimental non-equivalent control pretest-posttest study was to determine if there was a statistically significant difference in the posttest scores of knowledge, skills, and attitudes towards patient safety among the beginning nursing students in a private accelerated baccalaureate nursing program in the Western United States.

Methods: The study used a quasi-experimental nonequivalent control posttest design using beginning nursing students as samples through convenience sampling method with a the total sample of 156 subjects that were randomly assigned to both control and treatment groups.

Results: The data analyzed were scores from the H-PEPSS survey posttest (Ginsburg, Castel, Tregunno, & Norton, P. G., 2012) questions corresponding to six patient safety categories. Descriptive statistics and independent t-test for analysis of mean difference was used. In all three categories, statistically significant difference was found legitimizing the efficacy of scenario-based HFPS as a teaching pedagogy (Gates et al, 2011). It is recommended that a broader study that utilizes faculty observed performance towards acquisition of KSAs of patient safety be used rather than students' perspective (Blum & Parcels, 2010). Conduct a longitudinal study in determining knowledge and skills retention and transferability in both the simulation and clinical settings as well as using a broader demographic of nursing student population.

Conclusion: It is recommended by this study to conduct a broader study that may include the use of faculty observed performance that focuses more on student's acquisition of KSAs towards patient safety rather than sole students' perspective (Blum & Parcels, 2010). Conduct a longitudinal study determining knowledge and skills retention and transferability combining faculty and student evaluations relevant to patient safety in both the simulation and clinical settings as well as using a broader demographic of nursing student population, including students from traditional baccalaureate and associate degree nursing programs. The results of this study add to the existing literature in providing evidence that scenario-based HFS is an effective teaching methodology towards acquisition of KSAs of patient safety, understanding of its important in the undergraduate nursing curriculum in meeting certain learning objectives and justify its use as an alternative teaching methodology for clinical experience.

The Relationship Between Student Engagement and Outcomes for Online MSN Students

Patricia A. Riccio, PhD, MSN, BSN, RN, USA

Joanne Farley Serembus, EdD, RN, CCRN, CNE, USA

Abstract

Purpose: This study sought to examine the relationship between student engagement and student outcomes for online MSN students.

One of the many challenges with nursing education in the online setting is to obtain a scientific measure of how nursing students optimize their learning. The basis for this research is to evaluate student engagement and subsequent learning outcomes from two core courses in the online Master of Science in Nursing (MSN) program at Drexel University- a **Research Methods and Biostatistics** course and a **Health Policy and Politics** core course. One key essential outcome for graduate students is the ability to integrate new learning experiences with vital critical thinking skills which is a focus of these online courses.

While faculty design these courses to apply critical thinking, students vary in their ability to engage in the online environment. Online learning can be isolating for students leading to attrition. Minimal instructor interaction and lack of course information are some of the most common reasons for attrition (Hannum, Irvin, Lei, & Farmer, 2008). Reducing attrition rates among online education programs is a major concern and impacts the success of higher education institutions. Engagement serves as a foundation to successful student retention initiatives. The more engaged a student is, the more likely he or she will remain enrolled in a particular course or in the institution as a whole (Lundberg & Sheridan, 2015).

Alexander Astin (1975;1985; 1988; 1993) conducted the seminal work in what he termed student involvement. He defined student involvement as the amount of physical or psychological activity or student energy devoted to the academic experience. This construct evolved over time to the term engagement (Kuh, 2003). Student engagement is viewed as the level of interest students show towards the subject matter being taught; their interaction with the content, instructor, and peers along with their motivation to learn and progress through the course. Student engagement pertains to the time and physical energy that students expend on activities in their academic experience. Building community by engaging learners in their learning tasks is one of the first necessary steps toward successful online learning (Cooke, 2016). So in essence, the theory of involvement (engagement), according to Astin (1975; 1985; 1993), described students as highly involved if: 1) they interacted with faculty more, 2) participated actively with fellow students on a more frequent basis, and 3) devoted more time to studying. Likewise, according to Astin (1985) those students who neglected studying, had less frequent interactions with faculty and with fellow students were considered to be on the opposite end of high levels of involvement.

Cochran, Campbell, Baker, & Leeds (2014) found that students make decisions such as withdrawal based on the engagement they feel in the online environment. Students satisfied with their online education named a number of factors: faculty activity in discussion boards, faculty e-mailed announcements and prompt response to their questions, along with overall faculty availability via e-mail and phone, faculty respect for students, Videos and audio recaps of the lessons and assignments helping to improve their understanding of course material. (Price, Whitlatch, Maier, & Bundi, 2016). Faculty need to identify strategies to engage, motivate, and support students in online courses.

Analysis of data related to student engagement can be obtained from the learning management system (LMS). Collecting and analyzing such data is known as the field of learning analytics. Oblinger (2012, p. 11) defines learning analytics as focusing on “students and their learning behaviors, gathering data from course management and student information systems in order to improve student success”. Using learning analytics has the potential to enable faculty to increase their understanding of their students’

learning needs and to influence student learning and progression. This would benefit students as well as, the institution's retention and success rate (de Freitas, 2015; Slade & Prinsloo, 2013).

Methods: A secondary analysis of Blackboard Learn Course Analytics was conducted using quantitative analyses. The sample for this study included 300-geographically diverse online students who completed two online graduate Nursing courses: 1) A **Research Methods and Biostatistics** course and 2) a **Health Policy and Politics** course during the 2015-2016 academic years. To maintain confidentiality of all data from the faculty researchers, an honest broker was used to abstract all data using "course analytics" from files stored in Blackboard Learn. This included all identifiers located in all of the data files in course analytics. Specifically, the variables included in this examination included: course access, total minutes, total interactions and total submissions- all completed identifiers within course analytics in Blackboard Learn. Demographic data were stored in Blackboard Learn but de-identified as well. Abstracted data were managed and organized within Blackboard Learn and once identifiers were excluded from these data, they were downloaded directly into an analysis program.

Results: Using descriptive statistics, demographic data were analyzed using frequency and percentage distributions to describe the sample. Two way AVOVA and multivariant regression analyses were used to examine the relationships between the **input** variables present prior to entering the courses at Drexel University (GPA and Selectivity) with **engagement** (total course access and total minutes, total interactions and total submissions) occurring while students were in the course, with **outcomes** in the course- grades- which were obtained at the end of the course.

Preliminary results from the **Research Methods and Biostatistics** and the **Health Policy and Politics** courses described quite similar results. Those students who received a higher grade in these courses, spent fewer amounts of time in the course, had fewer course accesses and fewer interactions with fellow students and faculty.

Conclusions: These findings are consistent with Astin's seminal work on student involvement (engagement). Given the continued growth in online learning, reports of high attrition, and an overall interest in seeing students succeed, the investigators set forth to better understand student traits and characteristics most successful in the online environment. Faculty play a vital role in student engagement, retention, and long-term program sustainability.

KATTS Framework and Kaplan Resources Remain Effective for NCLEX-RN® Success After 2013 Passing Standard Increase

Maria Flores-Harris, DNP, RN, CNE, USA

Abstract

Purpose: The purpose of the study was to identify the predictive value of Kaplan NCLEX-RN® Prep resources on first-time NCLEX-RN® examination test takers after the increase in the passing standard in 2013. Consequently, five independent variables were examined, Diagnostic Exam scores, Readiness Exam Scores, Question Trainer 6 and 7 scores, and QBank scores, to determine their predictive value of the independent variable, NCLEX-RN® examination success. Logistic regression analysis was used to examine predictors of first-time success on the NCLEX-RN® examination after the increase in the passing standard on April 1, 2013.

First-time NCLEX-RN® examination pass rates are considered the key quality indicator of nursing programs. Nursing graduates must pass the NCLEX-RN® licensure examination to practice as registered nurses in the United States. Nurses make up the largest portion of health care providers in the country and are vital to the adequate and proper delivery of healthcare in the United States. In April of 2013 the passing standard for the NCLEX-RN® examination was increased. It was the largest one-time increase on record. In 2014 the lowest national pass rate on record was reported at 81.8 percent.

Nursing programs must deliver quality strategies that assist graduates with passing the licensure examination. This quantitative study examined retrospective student data gathered by a test prep company. The data included the scores on several tests and predictive examinations. The scores for tests named Question Trainer 6, Question Trainer 7, QBank, Diagnostic test, and Readiness test were examined utilizing logistic regression to determine each test scores predictive value on passing the NCLEX-RN® examination.

The Knowledge Base, Anxiety control, Test-Taking Skills (KATTS) framework was the theoretical framework for this study. This framework focuses on three components for NCLEX-RN® examination success – an adequate knowledge base, anxiety control, and effective test-taking strategies. All three components are equally needed for success and are found within the Kaplan resources.

Kaplan has several NCLEX-RN® predictor exams – the Diagnostic examination, the Readiness test, and the Secure Predictor One examination– that provide evaluation of students' strengths and weaknesses based on the NCLEX-RN® test plan. The generated report for these exams identifies students' knowledge deficits according to the NCLEX-RN® examination test plan. Based on this evaluation, students are guided to the Kaplan NCLEX-RN® Content Review Guide and Content Review videos, categorized by the NCLEX-RN® examination test plan, to increase their knowledge base.

Active anxiety control, the second component of the KATTS framework, includes eliminating the fear of the unknown by exposing students to NCLEX®-like conditions before they take the examination. Kaplan's predictor exams provide a similar testing environment to the NCLEX-RN® examination. The Kaplan Strategy video provides information about the NCLEX® process and the exam itself to lessen students' fear of the unknown on test day.

Effective test-taking skills, the final component of the KATTS framework, involves practicing NCLEX®-style questions, understanding rationales for correct and incorrect answers, and question drills. Kaplan provides nearly 2500 NCLEX®-style questions for practice and remediation, including the variables in this study, Question Trainer 6 and 7 and the QBank. Kaplan's four-day prep course consists of one half day of learning critical thinking test taking strategies, two and one-half days of question drills and a final day of practicing the learned strategies. The Kaplan course and resources address all three of the components of the KATTS framework.

Methods: A quantitative, non-experimental, logistic regression design was utilized for this study. The study variable analyzed was NCLEX-RN® examination outcome which is defined as either pass or fail; therefore, it is dichotomous. The variables applied for this study were scores on the Kaplan Q-Bank questions, scores on the Question Trainer Tests, and scores on two predictor exams, the Diagnostic examination and the Readiness test. This study measured the predictive relationship between the scores on the specific Kaplan NCLEX-RN® prep resources and success on the NCLEX-RN® examination. There was no manipulation of subjects or variables. A retrospective review of student data gathered by Kaplan from April 2013 to December 2014 was analyzed for this study. The information was accessed electronically via the Kaplan Integrated Testing system platform and exported to an Excel® spreadsheet.

Data from the retrospective spreadsheet was analyzed using the Statistical Package for the Social Sciences (SPSS), version 22, and included predictions utilizing logistic regression.

Results: Logistic regression analysis showed that the Diagnostic exam, Readiness exam, and QT 7 are predictive of NCLEX-RN® examination success. The QBank and Question Trainer 6 are not as strong predictors when compared to the other resources. The Diagnostic and QT 7 have Significance values of 0.00 and, therefore, are major factors in the passing of NCLEX® examination. The Diagnostic, Readiness and QT 7 all have positive B values indicating that an increase in these scores results in an increase in the probability of passing NCLEX® examination.

The study findings support the use of the Kaplan Diagnostic exam, Readiness exam, and QT 7 as predictive of success on the NCLEX-RN® examination. The QBank and QT 6 were predictive when examined alone but not in conjunction with the other resources. The Diagnostic exam and QT 7 were the most significant predictors of NCLEX® success, followed by the Readiness exam.

Conclusion: The KATTS framework, a test success framework, consists of a sound knowledge base, active anxiety control and test taking strategies. The Kaplan resources map to areas of the KATTS framework. Results of the study show that addressing the areas of the KATTS framework continues to result in NCLEX® success even after the increase in the passing standard of the examination. The results of the study also provide support that the Kaplan resources continue to be predictive of NCLEX® success even after the increase in the passing standard of the examination. Though the creation of many of the Kaplan NCLEX® Prep resources predates the computer-adaptive exam, these results demonstrate that creation of new preparation resources and strategies are not necessary for students to be successful on the computer-adaptive examination. Many of the strategies and resources already in place, the KATTS framework approach and the Kaplan resources, continue to be effective when utilized.

Mothering From the Inside Out: A Mentalization-Based Intervention for Mothers Enrolled in Mental Health Services

Monica Roosa Ordway, PhD, APRN, IBCLC, USA

Lourdes De Las Heras Kuhn, MS, USA

Thomas McMahon, PhD, USA

Nancy E. Suchman, PhD, USA

Abstract

Purpose: A cornerstone of parenting is managing dyadic psychological distress. However, among those struggling with mental illness, the dynamic and fluctuating nature of adult psychopathology complicates the parent-child relationship and challenges mental health clinicians due to the paucity of evidenced based mental health programs focused on parenting. The process of mental health intervention adaptation and implementation with vulnerable populations is not well described in the literature. We worked as a community-partnered team to adapt and pilot an empirically-supported intervention program for mothers of infants and toddlers in an outpatient mental health clinic that primarily serves a low income community. The conceptual frameworks of mentalization theory and parental reflective functioning (RF) provide a foundation for understanding the mental states (thoughts, emotions, intentions) underlying one's own and another's behavior that can help a parent break the viscous cycle of psychological distress and dysregulated relationships. We suggest that there are potential benefits of developing and evaluating interventions for parents with mental illness that target parental RF. To date, however, there have been no reported efforts to pilot such interventions with parents who struggle with mental illness. Considering the demonstrated efficacy in two randomized clinical trials with mothers enrolled in treatment for substance abuse, the aim of this study was to examine the preliminary feasibility, acceptability and efficacy of adapting *Mothering from the Inside Out (MIO)* for use at an urban community mental health clinic. The adapted MIO intervention is delivered by an interdisciplinary group of clinicians (nurses, social workers, psychologists) and involves 12-weekly, 1-hour individual therapy sessions focused on helping mothers make sense of their child's and their own emotional experience within the parent-child relationship. In this study, we were interested in: 1. determining whether community-based clinicians could deliver MIO with sustained fidelity, 2. examining the preliminary feasibility, acceptability and efficacy of MIO when delivered by clinicians in a community mental health center, and 3. replicating prior tests of the proposed treatment mechanisms identified in the two RCTs.

Methods: This trial was conducted on site in a satellite clinic of a large, urban community mental health center that serves children, adolescents, young adults and adults. The clinic is located adjacent to a small northeastern city where many clients are exposed to urban problems (e.g., crime, poverty, minimal affordable housing) typically identified with larger cities. Interested mothers who were enrolled in outpatient services themselves or who had a biological child enrolled in outpatient services at the treatment center were eligible for treatment if they were caring for a child between birth and 84 months of age. All mothers who consented received 12 sessions of a manualized mentalization-based intervention called *Mothering from the Inside Out (MIO)* that was originally designed for mothers enrolled in treatment for drug addiction. Mother-child dyads were eligible to participate if the mother was English speaking and caring for a child between birth and 84 months of age (the target child in the study) and either the mother or target child was enrolled in the outpatient mental health treatment program where the study was conducted. Treatment attendance and alliance served as measures of feasibility and acceptability, respectively. Maternal outcomes included reflective functioning, parenting stress and psychiatric distress. Mother-child interaction outcomes included maternal sensitivity, child involvement and dyadic reciprocity. Seventeen mothers caring for a child between birth and 84 months of age consented to participate and completed an initial intake evaluation and baseline assessments. Treatment fidelity was measured using a scale developed for the randomized trial involving substance using mothers. Treatment attendance and alliance served as measures of feasibility and acceptability, respectively. Treatment outcomes included maternal reflective functioning, psychiatric and parenting stress, and mother-child interaction quality.

Results: Our findings indicated that MIO was feasible and acceptable when delivered in the community-based setting and that all maternal indices improved. As shown in Table 1, mean RF score showed a moderate increase from baseline to post-treatment ($d = .34$). Potential RF also showed a moderate increase from baseline to post-treatment ($d = .35$). Child-focused RF showed a large increase ($d = .64$) whereas self-focused RF showed no increase ($d = .04$) from baseline to post-treatment. At the end of 12 sessions, mothers had also reported their experience of parenting and psychiatric stress had fallen to ranges that were considered within normal limits ($T < 60$ on the Brief Symptom Inventory; $d = -.41$). Similarly, findings for the group mean for depression were also found and the magnitude of this change from baseline to post-treatment corresponded to a medium effect ($d = -.58$). Support was found for the proposed mechanisms of change: Therapist fidelity to the unique MIO treatment components predicted improvement in maternal RF ($r = .53, p = .03$) which, in turn, was associated with improvement in quality of mother-child interactions ($r = .43, p = .08$). With regard to implementation, key lessons from this implementation include: 1. The importance of formative work to build community relationships; 2. The importance of designing plans for training and reflective supervision that fit within the flow of the clinic and can tolerate disruptions; 3. Use of an interdisciplinary approach is feasible with the development of a plan for communication and the support of a trained reflective clinical supervisor.

Table 1. Effect size (d) for treatment outcome differences from baseline to 12 weeks

	Baseline	12 weeks	d
Maternal Reflective Functioning			
Mean RF	2.85 (.58)	3.11 (.60)	.34
Potential RF	4.12 (.86)	4.53 (.80)	.35
Child-focused RF	2.91 (.51)	3.42 (.64)	.64
Self-focused RF	2.81 (.72)	2.85 (.72)	.04
Parenting Stress			
Personal Distress	30.35 (9.73)	26.71 (10.74)	.25
Dysfunctional Interaction	21.06 (5.58)	21.00 (8.09)	.01
Difficult Child	30.59 (8.57)	27.82 (8.12)	.23
Psychiatric Symptoms			
Global Psychiatric Distress (BSI; T Score)	62.35 (10.01)	55.94 (11.9)	-.41
Depression (BDI)	16.88 (9.26)	10.06 (7.39)	-.58
Mother-Child Interaction			
Maternal Sensitivity	3.39 (.75)	3.41 (.72)	.02
Child Involvement	3.28 (.87)	3.34 (.78)	.05
Dyadic Reciprocity	3.28 (1.06)	3.27 (1.06)	-.01

Conclusion: These findings add to a growing body of evidence showing the validity of this treatment model for improving mother-child relationships in high risk dyads where psychoeducational instruction and behavioral coaching have proven insufficient. These findings suggest that a mentalization-based parenting therapy for mothers involved with mental health services may enhance the effects of the mental health services that target their psychiatric symptoms. The key lessons from the implementation advance the scientific knowledge available to healthcare managers and researchers who are looking to adapt mental health clinical interventions for a vulnerable population.

Access to Healthcare for Transgendered People

Hatice Kaya, PhD, RN, Turkey
Yeliz Culha, RN, Turkey
Nuray Turan, PhD, RN, Turkey
Gulsun Ozdemir Aydin, MSc, RN, Turkey
Aysel Ozsaban, MSc, RN, Turkey

Abstract

Purpose: Transgendered people are more vulnerable and at risk in terms of certain diseases. These people are more hesitant on health protection and cannot benefit from health care services for various reasons.

Methods: In this article, the relevant literature and research findings on transgendered people's attitudes to protect their health and the responsibilities of the nurses in this regard were examined and discussed, and application-oriented suggestions were offered.

Results: The concept of transgenderism was firstly addressed in the Diagnostic and Statistical Manual DSM III under the heading of psychosexual disorder. transgenderism is person's rejection of anatomic gender and desire to have the primary and secondary sex characteristics of the opposite sex. The incidence of male and female transsexualism is not completely known in the world and in our country. According to the World Professional Association for Transgender Health (WPATH), the ratio of female transgenders has been stated between 1/30.400 and 1/200.000, and the ratio of male transgenders has been stated between 1/11.900 and 1/45.000. Transgendered people have a transition period to physical appearance or gender expression specific to the gender they perceive. Hormone replacement therapy or surgical operation is widely used in this period. There are risks associated with hormone therapy such as venous thromboembolism, cardiovascular disorders, diabetes mellitus, cancer and osteoporosis. Transgendered people are at increased risk for HIV, sexual violence and mental health problems, depression, anxiety and suicide. In these people, risky health behaviors such as smoking, alcohol and substance abuse also increase the incidence of these diseases. To understand the health risks of transgendered people is important and ensures the effective provision of health care. However, it was seen that there was a strong relationship between access to health care services of these people experiencing stigma and othering in the society and its consequences. In the study carried out by Yılmaz and Göçmen (2015) with lesbian, gay and transgendered people, 7.6 percent of the people who participated in the study stated that they did not receive treatment and delayed their treatment for the fear that they would be exposed to discrimination. Nurses have an important position in the protection and development of the health of this group and in increasing the quality of care they receive.

Conclusion: Nurses should raise these people's awareness on hormone usage, the ways of protection from sexually transmitted diseases, the importance of early diagnosis in the prevention of cancer, the prevention of risky behaviors such as smoking, alcohol and substance use, and the ways of protection from depression by taking part in awareness-raising trainings related to the health of transgendered people. Nurses should help to improve the quality of life of the people by making them feel that they are away from prejudice during the entire care process.

RSC PST 2 - Research Poster Session 2

An Evidence-Based Nursing Framework to Improve the Hepatitis C Care Continuum in HIV Co-Infection

Laura E. Starbird, MS, RN, APHN-BC, USA

Jason E. Farley, PhD, MPH, ANP-BC, AACRN, FAAN, USA

Abstract

Purpose: The purpose of this presentation is to a) describe the development of an evidence-based nurse case management intervention to increase uptake of HCV care in an HIV primary care setting using the revised Criteria for Reporting the Development and Evaluation of Complex Interventions in Healthcare (CReDECI 2) (Möhler et al., 2015); and b) illustrate a conceptual framework for a theory-based nurse case management intervention to improve the HCV care continuum among people living with HIV.

Over 185 million people have been infected with hepatitis C virus (HCV) globally (World Health Organization, 2014). HCV is the most common cause of non-AIDS related death among people living with HIV (Centers for Disease Control and Prevention [CDC], 2014). One quarter of people living with HIV are co-infected with HCV, which accelerates the progression to end stage liver disease and hepatocellular carcinoma (CDC, 2014; Lo Re et al., 2014). HCV can be cured with a single daily pill in just 12 weeks (Thomas, 2014); however, in the United States only 1 in 5 people with chronic HCV are linked to HCV care and fewer than 10% have ever initiated treatment (Cachay et al., 2014; Yehia et al., 2014). Barriers to engagement in HCV care include low knowledge and perceived threat of HCV, and HIV-HCV drug-drug interactions, which will exist for up to 88% of people with HIV/HCV co-infection in the setting of new HCV treatments (Patel et al., 2015). In this era of effective all-oral HCV treatment, linking patients to specialty HCV services is essential to maximize the lifesaving potential of available therapies and cure HCV. Evidence-based interventions to increase knowledge about HCV, its perceived threat, and available treatments are needed to improve the HCV care continuum and increase uptake of curative therapies among people co-infected with HIV/HCV.

Methods: We developed a multifaceted intervention comprised of nurse-initiated referral, strengths-based education, patient navigation, and coordinated drug-drug interaction prevention. Andersen's Behavioral Model of Health Services Use (1995) was applied to inform the intervention components. According to Andersen, a person's use of health services is a function of predisposing factors, enabling resources, and perceived and actual need for care. Perceived need can be changed through education; the greater the perceived and actual need, the more likely one is to use services. Andersen also suggests that enabling resources can be influenced by interventions at the system, provider, and patient level. The more enabling resources one has, the greater the likelihood of healthcare utilization. Enabling resources for the uptake of HCV care can include patient navigation, appointment reminders, and support for drug-drug interaction prevention. A literature review guided by the Andersen Model was conducted to examine successful engagement in care intervention components in similar populations. The concepts of the Andersen Model were then used to adapt these evidence-based components into a brief nurse case management intervention specifically for the HIV/HCV co-infected population in an HIV primary care setting.

Results: Examination of the Andersen Model and current literature resulted in three outcomes: 1) A brief nurse case management intervention to improve engagement in HCV care that can be administered in HIV primary care was developed. The intervention components include nurse-initiated referral to HCV care, strengths-based education, patient navigation, appointment reminders, and coordinated drug-drug interaction prevention; 2) The relationships between Andersen's concepts and the intervention components were illustrated in a conceptual framework. This framework indicates the pathway to which the HCV care continuum, specifically linkage to care and treatment initiation, can be improved; and 3) A randomized controlled trial was designed based on the conceptual framework to test the hypothesis that a nurse case management intervention will improve the HCV care continuum for patients co-infected with HIV by increasing perceived need and maximizing enabling resources.

Conclusion: We are at a defining moment for HCV care. All-oral treatments are available that provide us with the opportunity to cure HCV in nearly all patients with few side effects in 12 weeks. While necessary, these exciting new advances are not sufficient to solve the problem of the poor HCV care continuum. Without knowing how to get people to the point of starting HCV treatment, even the best medications can have no impact on HCV-related morbidity and mortality. Interventions that increase perceived need and maximize enabling resources have the potential to improve the HCV care cascade for people co-infected with HIV. This framework describes the first evidence-based, theory-driven nurse case management model to improve the care continuum within this new era of HCV in a real-world HIV primary care setting. The intervention described may ensure that the most effective linkage to care and treatment approach is integrated into care of this population across the care continuum. Studies to test the effect of this intervention in different settings are needed.

Nursing Students' Technological Equipment Usage Status and Individual Innovation Levels

Hatice Kaya, PhD, RN, Turkey

Nuray Turan, PhD, RN, Turkey

Hanife Durgun, MSc, RN, Turkey

Turkinaz Asti, PhD, RN, Turkey

Abstract

Purpose: This research was carried out to determine nursing students' technological equipment-usage status and individual innovation levels, and the relationship between them.

Methods: All nursing students studying in the Nursing Department of a Faculty of Health Sciences in Istanbul in the 2015-2016 academic year constituted the population of the research which was designed in the descriptive-cross-sectional type, and 165 nursing students who agreed to participate in the study constituted the sample group. Informed consent was obtained from the institution and the students before starting the research. The data were collected by interviewing face-to-face using Structured Question Form, Technological Equipment Usage Scale and Individual Innovation Scale. In the evaluation of the data, Student t test, Mann Whitney U test and Pearson Correlation Analysis were used in addition to descriptive statistical methods (mean, standard deviation, frequency).

Results: It was determined that the age average of the students was 20.92 ± 1.63 years, 93.3% of them were female, 98.2% of them were single, 47.3% of them had 2 siblings, the incomes of 87.3% of them covered their expenses, 94.5% of them had health insurance, 92.1% of them did not work in any job, 80% of them lived with their family, and 89.7% of them spent most of their lives in the Marmara Region. It was found that 85.5% of the students were members of at least one social networking site, 83% of them used social networking sites every day, and they spent an average of 2.32 ± 1.89 hours on these sites. When their technological equipment usage statuses were examined, it was determined that 95.8% of the students mostly preferred smart phones among technological equipments, they spent an average of 4.72 ± 2.93 hours per day on smart phone, the number of controlling smart phone was an average of 26.02 ± 23.38 times in a day, 61.2% of them preferred Android system on smart phone operating system, and 80.6% of them preferred WIFI 4.5G connection. In the Technological Equipment Usage Scale, it was determined that the point average of the Technological Equipment Usage sub-dimension was 50.44 ± 14.51 , Social Media sub-dimension was 27.86 ± 10.09 , The Place of Technology in Life sub-dimension was 27.53 ± 7.68 , Educational Use sub-dimension was 29.32 ± 7.19 , and the Communication sub-dimension was 16.01 ± 5.20 . It was found that the total point average of the Technological Equipment Usage Scale was 135.15 ± 27.09 , and the point average of the Individual Innovation Scale was 61.02 ± 8.89 . In the sub-dimensions of the Technological Equipment Usage Scale, a statistically negative relationship was found between the total points of the Technological Equipment Usage sub-dimension and the Individual Innovation Scale ($p < 0.05$), a statistically positive relationship was found between the total points of the Place of Technology in Life sub-dimension and Individual Innovation Scale ($p < 0.05$), a statistically positive relationship was found between the total points of the Educational Use sub-dimension and Individual Innovation Scale ($p < 0.05$), and a statistically significant negative relationship was found between the total points of the Communication sub-dimension and Individual Innovation Scale ($p < 0.05$).

According to individual characteristics, when the points of the Technological Equipment Usage Scale and the Individual Innovation Scale were compared, a statistically significant difference was found in terms of the number of siblings and the Educational Use sub-dimension points ($p < 0.05$). It was determined that the Communication sub-dimension points of the students working in any job were statistically significantly higher compared to nonworking students ($p < 0.05$).

Conclusion: While students' technological equipment usages are at medium-level, their individual innovations are at the level of questioning. It is very important for nursing students to be innovative, to initiate and sustain innovation within the context of the use of technological equipments and their

contemporary roles and responsibilities. In this context, awareness should be created in the process of nursing education.

RSC PST 2 - Research Poster Session 2

The Experience of Adult Daughters Living With Mother's Breast Cancer

Ting-Chun Chen, BSN, RN, Taiwan

Su-Ying Fang, PhD, RN, Taiwan

Abstract

Background: Breast cancer tends to be genetic and is more likely to be inherited by daughters than sons. When mothers suffer from cancer, daughters are usually the ones who take the role of the caregiver. In addition to their own concern of the risk of getting cancer themselves and worrying about their mother's health, the combination of undertaking the role of the caregiver may be even more threatening the psychological health of adult daughters. Previous studies showed that mothers getting breast cancer will affect the psychological health of their daughters, but does not reveal the impact of adult daughters facing their mothers after cancer therapy, nor the experiences of living in the shadow of the risk of getting cancer themselves. Understanding the aforementioned issues and phenomenon helps in providing more appropriate intervention from a daughter's perspective to meet the needs of women with high risks of breast cancer.

Purpose: To understand the experiences of adult daughters living with mothers' breast cancer.

Methods: This study adopts the phenomenological qualitative research method to understand the experience of adult daughters whose mother suffered with breast cancer in southern Taiwan. Semi-structural interviews are used to conduct in-depth interviews with adult daughters of women with breast cancer. Text data analysis is conducted by using the seven step analysis method proposed by Colaizzi (1978). The number of interviews and amount of data are stopped when data reached saturation.

Results: A total of six adult daughters interviewed in this study. After the interview transcription has been translated for text analysis, 4 themes were emerged: 1) triple fear from self, mother and my daughter, 2) multiple roles on me at the same time, 3) changed communication and relationship with my mothers, and 4) desire for more medical care support.

Conclusion: This study found that adult daughters of women with breast cancer usually undertook the role of the caregiver for their mothers, which corresponds with the psychological stress of daughters shown in previous literatures. These daughters not only perceived threat to their own lives due to their mothers' sickness, but also experienced fear and concern of the high risk of suffering from breast cancer themselves. Additionally, they also concerned how to discuss disease-related information with their next generation under the risk of genetic inheritance etc. This study provide some implications that psychological support, disease-related information and appropriate communication and interaction support with their mother can be provided to improve their physical and psychological health.

Common Care Challenges From Female Spouse of the COPD Patient: Content Analysis

Hsiu-Hui Lei, MS, RN, Taiwan

Tien-Hui He, MS, RN, Taiwan

Abstract

Purpose: Due to the irreversible and progressive development, patients may come across problems such as different disabled body parts with inconsistent progress, as well as recurrent attacks, etc., which lead the female spouse of the patient to overwhelming pressure and torment. The purpose of this study is to offer references to common problems for female spouse of the patient through content analysis.

Methods: 40 female spouses of the patients from the chest out-patient department and the COPD home care unit of a medical center in southern Taiwan were interviewed, based on their care burden. Content analysis was used to set the profile and to analyze.

Results: 40 female spouses of the patients had the average age of 62.3 years old. The average years of caring was 4.6 years. 25% of the subjects had jobs and 92.5% of the subjects had religious beliefs. 65% of them had chronic diseases, and 32.5% had one chronic disease. The perceived health status of most of the subjects (50%) was neither good nor bad, and only 7.5% of them perceived bad health status. The average age of the patients was 72.8 years old and averagely affected with COPD for 7.1 years. 17.5% of the patients used oxygen. 52.5% were not admitted within the past year and 47.5% were admitted within the past year, and among them, 24.5% of them were admitted once. 72.5% has chronic diseases and 35% of them had two chronic diseases.

The COPD burdens that are common to the female spouses in order are listed as the following: 1. They concern about the condition of the patients (70%) 2. They do not know how to cope with emergent conditions (62.5%) 3. They are afraid that they can't afford the medical expense (50%) 4. They feel alone and out of help(25%).

Conclusion: It's crucial for the spouses that nursing staff can find out their torment and evaluate the situation so that the staff can solve the care challenges of the female spouses. Some advice was suggested: emergent service should be offered promptly, and so do the mental and social support. These assistances can relieve the care burden of the female spouse, and help them to get a better quality of life in the meanwhile.

Walking Pre-Heart Transplant Patients With Percutaneously Placed Axillary-Subclavian Intra-Aortic Balloon Pump

Frederick R. Macapagal, BSN, RN, CCRN,, USA

Emma G. McClellan, MSN, RN, CCRN, NEA-BC, USA

Lisa Marie Green, BSN, RN, CCRN, USA

Carolyn Bridges, MPT, CLT, CKTP, USA

Abstract

Purpose: Heart failure is a chronic, debilitating disease that often progresses to end stage quickly when severe left ventricular dysfunction leads to alteration in organ perfusion even at rest. Approximately 500,000 people are diagnosed as having heart failure each year. Heart transplantation is the definitive treatment for patients with end-stage heart failure. The intraaortic balloon pump (IABP) is a treatment for end-stage heart failure patients not responsive to pharmacological therapy while they await heart transplantation. Traditional femoral artery placement of an IABP requires bedrest with its associated complications. An innovative approach for a percutaneously placed axillary-subclavian intraaortic balloon pump (PAIABP) developed by cardiologists in our hospital enables patients to be mobilized while awaiting transplant. We aimed to determine if PAIABP therapy enables pre-heart transplant patients to safely mobilize and create new nursing protocols for safe patient care management.

Methods: This was a retrospective study of pre-heart-transplant PAIABP patients in the Coronary Intensive Care Unit (CICU) from 2007 to 2013 (n=45; 35 men, 10 women). Data are presented as mean (standard deviation) for continuous variables and number (percentage) for categorical variables. All analyses were performed with STATA version 13 (StataCorp, College Station, TX).

Results: Patients were mobilized at 1.39 (\pm 1.41) days after PAIABP insertion. The number of times mobilized per day was 1.79 (\pm 2). PAIABP pre-transplant duration was 21.11 (\pm 25.40) days. Six patients died before receiving a heart transplant, unrelated to the PAIABP. Thirty-seven patients (82%) received a heart transplant. Two deteriorating PAIABP patients had a left ventricular assist device (LVAD) inserted and were later transplanted. PAIABP patients were 100% mobile when medically stable. Complication rates were as follows: bleeding from insertion site, 4%; ischemic complications, 7%; IABP-related infection, 2%.

Conclusion: Pre-heart-transplant patients receiving PAIABP therapy can be safely and effectively mobilized. New nursing care protocols were developed for this procedure to take care of this patient population.

RSC PST 2 - Research Poster Session 2

Maternal Peripartum Antibiotic Usage and Depressive Symptoms at One-Month Postpartum

Jordan R. Murphy, BSN, RN, USA

Elizabeth J. Corwin, PhD, RN, FAAN, USA

Abstract

Purpose: The gut-brain-axis is a bidirectional signaling pathway between the gut microbiome and stress response systems of the brain including the hypothalamus, and is increasingly being studied for its role in affecting mood. Antibiotic exposure can contribute to a dysbiotic, or abnormal gut microbiome, by altering the microbial composition, and this is suggested as a mechanism for the increased risk of depressive symptoms in non-pregnant, non-postpartum persons. The immunological, metabolic, and endocrine changes that occur during pregnancy influence the overall functioning of the gut microbiome and represent a potentially robust pathway for exploring the effect of antibiotic-induced gut dysbiosis as a contributing factor in the development of postpartum depression (PPD).

Our lack of knowledge regarding the relationship between gut dysbiosis related to the perinatal use of antibiotics and the subsequent development of depressive symptoms postpartum is especially important given conservative estimates that greater than 40% of women are administered antibiotics during the perinatal period for treatment of a known infection or prophylactically to prevent an infection. While antibiotic use decreases the risk of infection in both mothers and infants, scientists have yet to consider the potentially negative consequences of antibiotic exposure during that time. Thus, we sought to determine the relationship between antibiotic use during the perinatal period and through the first 14 days postpartum and depressive symptoms at 1-month postpartum, the time identified in the DSM-V as diagnostic of PPD.

Methods: A secondary data analysis was conducted on 125 women from a prospective pregnancy cohort. Pregnant women in the third trimester were enrolled into the study and provided demographic characteristics and health history. Each woman completed questionnaires including the Edinburgh Postnatal Depression Scale (EPDS) at that time, and 1- and 2-weeks and 1-, 3-, and 6- months postpartum. Research coordinators completed a chart review to obtain clinical measures including hours in labor, premature rupture of membranes (PROM), perineal tear, and mode of delivery.

Results: A linear regression model was used to explore the relationship between antibiotic use and postpartum depressive symptoms within our cohort. Antibiotic exposure is independently predictive of 1-month postpartum depressive symptoms while controlling for age, depression history, and perineal injury ($p=.038$, $t=2.101$, CI (.080-2.750)), with the overall model explaining 11% of the variance within our cohort ($p=.013$, $F= 3.343$).

Conclusion: We have demonstrated a need for additional studies to investigate more thoroughly the relationship between the gut microbiome, antibiotic usage, and risk for postpartum depressive symptoms. Future work in this area of research will provide new evidence and considerations for modifying clinical practice guidelines for the use of antibiotics during the peripartum period.

Exploring Milieu of Sexual Preference, Sexual Orientation, and Sexual Risk Behavior Among HIV+ Latino Males

Jane Champion, PhD, DNP, MA, MSN, AH-PMH-CNS, FNP, FAAN, FAANP, USA

Abstract

Purpose: Disclosure of HIV status to friends and family was cited as one of the most significant stressors of living with HIV among Latino men. Thus, lack of communication regarding sexual orientation and HIV serostatus may perpetuate stigma and shame regarding same sex relationships among HIV+ Latino men.

The purpose of this presentation is to describe sexual preference, HIV disclosure behavior, sexual risk behavior and substance use among Latino HIV + males to facilitate additional understanding of relationships between these behaviors that perpetuate stigma and shame regarding same sex relationships among HIV+ Latino men.

These findings will be utilized for modification of sexual health promotion interventions in primary care-based settings.

Methods: This presentation includes an analysis of study entry data including individuals, male or female, older than 18 years of age, including all ethnicities, previously diagnosed with HIV/AIDS and enrolled in a HIV interventional trial for persons who were not current receiving medical treatment.

Eligible participants were identified through individual chart reviews of persons who were HIV seropositive and not currently receiving any treatment in a metropolitan health district in the Southwestern United States.

Eligibility criteria for this secondary data analysis included HIV positive serostatus, Latino ethnicity, male and 18 years of age or older.

Institutional Review Board approval was obtained from both the University and Metropolitan Health District settings. Informed consent was obtained prior to study enrollment.

Each participant completed a semi-structured questionnaire following study enrollment. This questionnaire was adapted specifically for this study and contained questions utilized to assess demographics, sexual preference, HIV disclosure behavior, sexual risk behavior and substance use.

The questionnaire was initially developed through extensive ethnographic work for use among individuals experiencing high risk sexual behavior and at risk for STI/HIV.

Descriptive statistical methods: As in all research, the importance of selecting predictors on the basis of a well-justified, theoretical model cannot be overemphasized. This study utilized a process for selection of a set of variables to assess for associations based on a theoretical framework (AIDS Risk Reduction Model).

A diverse number of variables identified through this model were found via bivariate analyses to be associated and are presented in the manuscript. Although there are many benefits in using multivariate procedures, problems are encountered such as increased ambiguity in interpretation of results.

Because this study included a diverse set of theoretically based independent variables intended to provide evidence for the design and modification of cognitive behavioral interventions, multiple regression analysis was not considered an optimal analytic strategy to achieve the study purpose.

Results: 93 HIV+ Latino males who had ever had sex with males or females.

Self-identified sexual preference included straight (heterosexual) (41.9%), gay (43.0%) and bisexual (15.1%) preferences.

Age range was 21-57 years (39.56 mean, SD 8.472). The majority (62.2%) had never been married (gay 97.4%, bisexual 53.8%, straight 28.9%, $p=.000$); 11.1% were currently married with the remainder divorced, widowed or separated; 34.5% were currently living alone.

Most straight men had children (68.4%) compared to bisexual (38.5%) or gay (5.4%) men ($p=.000$). Only 15.6% of men were currently employed full/part-time (gay 25.6%, bisexual 15.4%, straight 5.6%, $p=.048$).

Majority of men (71.6%) reported total combined household income of less than \$750/month; 43.5% reported having being unable to pay bills while 18.5% were homeless and 13% were arrested during past 3 months.

All participants who indicated they were straight reportedly had sex with women in the past while 43.6% of those identifying as gay and 91.7% of those identifying as bisexual reportedly had sex with women in the past ($p=.000$).

All participants who self-identified as gay or bisexual reported sex with men while among straight men, 13.9% reported having sex with men.

Sexual behavior as reported by participants was high.

Sexual behaviors including anal, sex with men, group sex, sex with men and women together, sex for drug, sex in bathhouses, and use of sex toys was reported more often by gay or bisexual men.

Sex with a prostitute and sex with women was reported more often by straight as compared to gay or bisexual men.

Almost all participants had previously used condoms however significantly more bisexual or gay than straight men.

Overall fewer men reported current condom use (33.3%) with no significant differences by sexual preference.

Gay men reported they had "barebacked" and "doubled condoms for protection significantly more often than bisexual or straight men.

Gay and bisexual men reported less disclosure of HIV + status if using condoms.

Most men (56.7%) reported alcohol use the past 3 months with an average weekly intake of 10.03 drinks (19.01 SD).

More straight (44.7%) than bisexual (35.7%) or gay (25.0%) men believed they had a drug or alcohol problem in past 3 months.

High levels of substance use were identified overall: marijuana (87.4%), crack/cocaine (71.9%), IV drugs (40.4%), methadone/heroin (37.1%), downers (27.0%), methamphetamines (21.3%) and ecstasy (16.9%).

Men often reported sharing needles (35.6%) and sex with an IV drug user (44.9%).

Significantly more marijuana, methadone and IV drug use including sharing of needles and sex with partners who use needles was found among straight men.

Significantly more methamphetamine, ecstasy and use of downers were found among gay men.

Gay men reported more HIV testing prior to learning HIV status (35.0%) compared to bisexual (21.4%) or heterosexual (10.5%), ($p=.036$). They also more frequently had HIV testing because they wanted to know for health (17.5%) as compared to straight (5.3%) or bisexual (0%) ($p=.046$). They also reported highest frequency of disclosure of HIV status to family (94.7%) as compared to straight (80.0%) or bisexual (76.9%) men ($p=.197$).

In contrast, men who were straight and never had sex with men compared to MSM/MSMW less frequently had HIV testing prior to learning of their HIV status (6.5% vs.33.9%, $p=.004$) and less frequently had notified family members of their HIV status (75.9% vs. 92.7%, $p=.054$).

Differences were found concerning perceptions about how the men had contracted HIV.

Almost all gay men (91.9%) believed they contracted HIV through sex compared to bisexual (66.7%) or straight (48.3%).

Straight men more often perceived acquisition of HIV via IV drug use (44.8%) as compared to bisexual (16.7%) or gay (2.7%) men.

Bisexual men reported sex and IV drug use as the source of HIV infection more frequently (16.7%) than either straight (6.9%) or gay (5.4%) men ($p=.000$).

Among straight men who had never ever had sex with men versus MSM/MSMW, 50.0% believed they had contracted HIV through IV drug use as compared to 7.8% of MSM/MSMW ($p=.05$).

Gay men more often reported that they got HIV from having sex with a gay partner (17.9%) as compared to straight (2.6%) or bisexual (0%), ($p=.029$). They also reported they got HIV from unprotected sex with a HIV positive partner (28.2%) as compared to straight (10.5%) or bisexual (7.7%)($p=.074$). They also reported more often that they got HIV from unprotected sex with more than one partner (28.2%) as compared to straight (13.2%) or bisexual (23.1%) ($p=.226$).

Straight men reported more often that they got HIV from sharing needles (23.7%) as compared to gay (7.7%) or bisexual (15.4%) ($p=.154$).

Men who never had sex with men reported more frequently than MSM/MSMW that they believed they had gotten HIV from sharing needles (25.8% vs. 10.7%, $p=.067$).

Gay men more frequently reported having sex with only HIV positive partners (35.9%) as compared to straight (8.9%) or bisexual (7.7%)($p=.042$). They also more frequently reported having told a partner that they had HIV (67.5%) versus straight (57.9%) or bisexual (50.0%) men ($p=.435$).

There was agreement that it was important to tell partner you are HIV positive even if you use condoms all of the time (straight 73.9%, gay 79.5%, bisexual 76.9%, $p=.114$)

A current partner was reported by 40% of the men overall however more bisexual (46.2%) or straight (43.2%) than gay (35.0%), ($p=.419$).

Overall, 83.8% were currently having sex with this partner (bisexual 100%, gay 86.7%, straight 76.5%, $p=.421$). 89.2% of partners knew about HIV status of the men (bisexual 100%, gay 93.3%, straight 82.4% $p=.428$).

Of those who had current partners, 52.8% of current partners have HIV; however significantly more gay (73.3%) or bisexual (60.0%) than straight (31.3%) ($p=.055$) men had partners who are HIV positive.

Conclusion: HIV testing, disclosure and sexual behaviors of ethnic minority men suggest that addressing sexual risk behavior and underlying reasons for not receiving HIV testing or disclosing HIV+ status - unique to differing populations - would increase the efficacy of sexual health interventions.

Descriptive behaviors and underlying perspectives reported in this study suggest that public health interventions for HIV+ Latino men who self-identify as heterosexual should explicitly identify substance use, needle sharing, and unprotected sex with current partners as behaviors placing both oneself and partners at high risk for contracting HIV.

The diversity of sexual behavior among gay, straight, and bisexual HIV+ Latino men in this study ultimately suggests clinicians cannot rely on simplistic conceptions of sexual orientation in assessment of their self-care needs. Care in presentation and discussion of self-identified sexual behavior and orientation as sexual behavior is indicated as it does not determine sexual orientation - and vice versa.

Healthy Siblings of Children Living With Chronic Diseases: A Systematic Review

Victoria von Sadovszky, PhD, RN, FAAN, USA

Susi Miller, MLIS, AHIP, USA

Emily Christensen, BA, RN, USA

Bonnie Jennings, PhD, RN, FAAN, USA

Abstract

Purpose: Approximately 26% of children in the United States live with a chronic disease or condition and this number is rising, especially among children experiencing social or economic disparities (Price, Khubchandani, McKinney, & Braun, 2013; Spencer, Blackburn, & Read, 2015). Unpleasant symptoms, lower quality of life, and missed school are a few of the experiences for children living with chronic diseases or conditions (Varni, Limbers, & Burwinkle, 2007). Most models of care delivery and research have centered on the health and welfare of the child with the chronic disease or condition. What is not clear, however, are the physical and psychosocial effects of healthy siblings who are in a family with a sibling who has a chronic disease or condition and what interventions are needed, if any, for this group. Few investigators have examined the healthy siblings in the family unit. To date, most of the research on healthy siblings has been about the perceptions and experiences around end of life and bereavement after a death (Gaab, Owens, & MacLeod, 2014; Wallin, Steineck, Nyberg, & Kreicbergs, 2016). The purpose of this systematic review, therefore, is to examine the scientific literature in regard to these physical and psychosocial effects on the healthy siblings.

Methods: Using Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA, 2015) guidelines, a literature search was performed in CINAHL, OVID Medline, and PsychInfo. Keywords used were: "sibling burden", "healthy sibling", "sibling survivor", "sibling guilt", "neurotypical sibling", "surviving sibling", and "chronic disease". Limits for the search included: 1) peer-reviewed research reports, systematic review, or meta-analyses; 2) published within the past 10 years; and a 3) pediatric population. To date, a total of 137 abstracts were found. Two researchers are examining the abstracts for inclusion in the review. Interrater reliability will be obtained for level of agreement for inclusion abstracts. Associated articles will be retrieved and reviewed by the study authors. Articles that qualify for this systematic review will be analyzed for demographic information, type of chronic disease/condition of the affected sibling, and associated physical or psychosocial effects/consequences experienced by the healthy sibling(s) within the family unit.

Results: The review is currently in progress. We anticipate the review will be completed by April 2017.

Conclusion: Recommendations will be made for future research and, if applicable, clinical practice to promote healthy outcomes for siblings living with children who have chronic diseases or conditions.

New Male Contraception: College Students' Attitudes and Perceived Behaviors Related to Non-Hormonal Injectable Gel

Kirstin A. Buck, BA, RN, USA

Jessica L. Stadick, MS, RN, PHN, USA

Abstract

Purpose: At present, people assigned male at birth have extremely limited means by which to control their reproductive health. While medical advancements have yielded numerous modern contraceptives, nurses still have few modalities to recommend for male patients (Kanakis & Goulis, 2015; Davidson, London, & Ladewig, 2016). Hence, men, who represent over half the world's population, experience stunted reproductive autonomy (Campo-Engelstein, 2011), the physical and economic burdens of pregnancy prevention are disproportionately relegated to women (Guttmacher Institute, 2011), and opportunities to expand the valuable individual and societal outcomes of family planning are missed (Waller, Bolick, Lissner, Premanandan, & Gamerman, 2016; Davidson et al., 2016). Although some posit that gender norms around birth control would impede male involvement (Brown, 2015), further investigation is warranted given that international studies have suggested that men are willing to assume increased contraceptive responsibility (Kanakis & Goulis, 2015) and that women would trust male partners to use contraception (Campo-Engelstein, 2013). Concerns have also been raised about the impact alternative male contraception could have on sexually transmitted infection (STI) rates by potentially lowering the usage of protective barrier methods (i.e., condoms, dams, gloves) as seen with female hormonal methods (Smith et al., 2012; Brown, 2015; Milhausen et al., 2013). To date, researchers have primarily tested male hormonal approaches which have been inconsistently effective (Oduwole & Huhtaniemi, 2014), associated with undesirable side effects (Kanakis & Goulis, 2015), and have prompted pharmaceutical companies to prioritize more lucrative investments (Campo-Engelstein, 2011). In response to this global sexual health deficit, development of a promising new form of long-acting and reversible contraception for males has emerged: non-hormonal injectable gel (NHIG). NHIG is bilaterally injected into each vas deferens and different polymer types work to degrade or obstruct the passage of spermatozoa while allowing the ejaculation of other seminal fluid that contains either functionally disabled sperm or no sperm at all (Kanakis & Goulis, 2015; Waller et al., 2016). With a characteristic period of sexual vulnerability accompanying the transition from adolescence to adulthood (Milhausen et al., 2013; Cheney et al., 2014), members of this demographic would be prime recipients of such innovative contraception; yet there is a dearth of research on how the NHIG option will be received within this subgroup.

The purpose of this study was to explore young adults' perceptions regarding NHIG while addressing the following question. In undergraduate college students, is there a difference between attitudes and perceived behaviors related to NHIG contraception amongst potential users (i.e., people with testicles) compared to non-users (i.e., people lacking testicles and/or who do not intend to have partnerships that could lead to pregnancy)?

Methods: A questionnaire for data collection was designed and modelled after relevant sections from the American College Health Association's (2015) National College Health Assessment IIc (ACHA-NCHA IIc). Question generation was informed by a literature review and a theoretical framework that extended the theory of planned behavior (TPB). Focus was given to the constructs of control beliefs, intentions, and moral norms in relation to sexual interactions (Turchik & Gidycz, 2012). Eight variables were measured pertaining to NHIG: (a) eligibility for use, (b) likelihood of use or encouraged use, (c) factors influencing use, (d) behaviors across different sex acts (i.e., vaginal, anal, and oral sex), (e) concurrent use of multiple contraceptives, (f) attitudes toward contraceptive responsibility, (g) attitudes towards contraceptive trust, and (h) previous knowledge of the NHIG method. Demographic information was obtained as well. Logic pathways were set up to direct respondents to appropriate questions based on previous answers. Surveys were distributed via an online platform (SurveyMonkey®) to the student body at a small, Midwestern, liberal arts college. Respondents self-selected to participate and students 18 years or older, of all genders, sexes, and sexual orientations were invited to submit.

Results: The sample ($N = 474$) was 67.6% female, 84.6% heterosexual, and 89.2% white with ages ranging from 18 to 24 years old. There were fewer potential users ($n = 133$, 34.2%) than non-users ($n = 254$, 65.3%). Preliminary results revealed that a greater portion of potential users reported that it would be unlikely ($n = 58$, 43.61%) for them to use NHIG, whereas non-users were more likely ($n = 128$, 51.41%) to encourage its use. Over a quarter of respondents in both user groups replied to the likelihood of use question neutrally. For users and non-users alike, low cost, reversibility, and infrequent administration were the top three options indicated as factors that would increase the likelihood of NHIG use. High cost was the most frequently selected deterrent, uncertainty arising from the newness of the new product was second, and the third diverged respectively between administration route or lack of STI protection for users and non-users. In the context of hypothetical NHIG use, users and non-users at risk for pregnancy were most likely to incorporate protective barrier methods during vaginal intercourse, followed by progressive decreases for anal and oral intercourse. Users were less likely than non-users to intend to utilize protective barrier methods or hormonal methods simultaneously with NHIG. The majority of respondents ($n = 374$, 95.9%) agreed or strongly agreed that all sexual partners should be equally responsible for contraception and that both men and women could be trusted to use contraceptives. However, more trusted women ($n = 303$, 79.4%) than men ($n = 221$, 56.8%). Additional statistical tests are scheduled to be completed to further analyze the results.

Conclusion: As NHIG contraceptives enter the pharmaceutical marketplace, it will be vital for nurses to be knowledgeable about the products and the behavioral implications they may bring. For young adults in the foundational stage of forging lifelong sexual practices, nursing will play a critical role in anticipating patients' needs and providing education that will enable fully informed decisions about NHIG. Nurses must serve as advocates to eliminate financial barriers to contraception and proactively promote the simultaneous use of protective barrier methods with NHIG for STI prevention. Guiding male patients in the safe and effective use of NHIG will have the potential to benefit both men and women, thus advancing the Global Health Initiative's (2012) principle of gender equality in the realm of reproductive health.

Psychometric Evaluation of the Patient Health Questionnaire-9 Depression Scale in the Korean Population

Eun-Hyun Lee, PhD, RN, Korea, Republic of (South)
Seung Hei Moon, MSN, RN, Korea, Republic of (South)
Jung Hee Cheio, MPH, RN, Korea, Republic of (South)
Eun Suk Park, MPH, RN, Korea, Republic of (South)
Myung Sun Cho, MPH, RM, Korea, Republic of (South)
Jin Sil Han, MPH, RN, Korea, Republic of (South)
Soon Young Kim, MPH, RN, Korea, Republic of (South)

Abstract

Purpose: The Patient Health Questionnaire-9 is a short self-administered instrument consisting of nine items asking the presence of depressive symptoms. The purpose of this study was to assess the psychometric properties of the Korean version of the Patient Health Questionnaire-9 (PHQ-9-K).

Methods: The original English version of the instrument was translated into Korean using a forward and backward translation technique. A total of 324 participants were recruited from seven community health centers (n= 275) and two community mental health centers (n= 49) in South Korea. The participants were asked to complete a package of questionnaires: the PHQ-9-K, the Korean version of the Generalized Anxiety Disorder-7 (GAD-7-K), the Korean version of the Perceived Stress Scale-10 (PSS-10-K). The structural validity of the PHQ-9-K was tested using confirmatory factor analysis (CFA). The convergent validity was assessed with the GAD-7-K and PSS-10-K using the Pearson's correlations. The known-groups validity was evaluated by the mean difference between two groups (the group recruited from mental health centers who were diagnosed with depression vs. the group recruited from community health centers without the diagnosis with depression) using a *t*-test. Internal consistency reliability of the PHQ-9-K was assessed using Cronbach's alpha.

Results: One-dimensional structural model of the PHQ-9-K fitted the data well: the ratio of χ^2 to the number of degrees of freedom (CMIN/DF) = 3.52; standardized root mean square residual (SRMR) = .03; goodness-of-fit index (GFI) = .94; normed fit index (NFI) = .96; comparative fit index (CFI) = .97; root mean square error of approximation (RMSEA) = .08. As hypothesized, the PHQ-9-K was highly correlated with the GAD-7-K ($r = .91, p < .001$) and PSS-10-K ($r = .76, p < .001$), implying satisfied convergent validity. The PHQ-9-K was significantly higher for participants with depression disorder than for the non-depression participants ($t = 8.74, p < .001, d = 48.66$). The finding supported the known-groups validity of the PHQ-9-K was satisfied. The Cronbach's alpha of the PHQ-9-K scales was .94, indicating excellent internal consistency reliability.

Conclusion: The study provided the excellent psychometric properties of the K-PHQ-9. Therefore, the K-PHQ-9 appears to be suitable for use in both clinical research and clinical practice. For further study, it is recommended to test the test-retest reliability of the instrument.

The Grieving Mr. Mom: Exploring Life After Maternal Death

Donald Johnston, PhD, MHS, RN, RRT, USA

Abstract

Purpose: In 2015, over 300,000 women lost their lives due to pregnancy related complications worldwide. That is over 800 women per day. These deaths are a tragic loss for the surviving child and the father, as well as the extended family. What is currently known about the phenomenon of maternal death is primarily in the form of statistical data. While the problem has been analyzed in quantitatively, no qualitative exploration of the phenomenon currently exists in U.S. literature. Findings from this qualitative case study will provide a valuable window into the lifeworld of fathers and guardians, as well as implications for health care practitioners. This study sought to uncover a previously unexplored aspect of maternal death, the stories of children and families left behind. By replacing numbers with stories, we sought to personalize the problem, raise awareness, and identify needs. The study sought to answer the following questions: What happens to the children left behind after maternal death? What is the impact on the surviving family and on the community as a whole?

Methods: The lead researcher conducted a series of in-depth, semi-structured interviews with fathers and family members following maternal deaths. Interview guides were used only to initiate conversation, with probing, clarifying questions growing out of subsequent dialogue as it emerged, in order to elicit as much detail as possible. All interviews were transcribed verbatim and analyzed using interpretive phenomenological analysis.

Results: Using interpretive phenomenological analysis, we explore in depth fathers' experiences during the weeks and months following the death of the infants' mothers, including infant hospitalization, legal battles, and the struggle to adjust to life as a widowed father. Common themes were identified among participants, including *relentless absence*, *regrets*, *guardianship*, *filling her shoes*, and *seeking support*. This study highlights critical needs for support, as well as how those needs are met, or in some cases left unmet.

Conclusion: It is imperative that health care practitioners treating women during pregnancy make every effort to include fathers throughout the pregnancy, educate fathers as to the mother's high risk health concerns, and be prepared to provide local sources of support in the event of maternal death. Practitioners should also be aware that support needs continue to be high throughout the infant's first year of life. Extended family and friends may be involved in the infant's health care in order to help fill the maternal role.

The Maternal Opioid Morbidity Study (MOMS)

Lisa M. Cleveland, PhD, RN, PNP-BC, IBCLC, NTMNC, USA
Frank Puga, PhD, USA

Abstract

Purpose: Overdose by “ingestion of drugs” is the second leading cause of maternal mortality in the state of Texas. *Maternal mortality* is defined by the Centers for Disease Control and Prevention as a death occurring during pregnancy or within the first 365 days following the end of a pregnancy. Maternal overdose death in Texas is second only to maternal deaths caused by a cardiac event. Case records (including postmortem toxicology and police reports) indicate that most of these deaths involved the use of licit or illicit prescription opioids. This is consistent with the nationwide increase in prescription overdose deaths, a major public health crisis. While these statistics are concerning, little is known about the context of maternal overdose death. The purpose of this two-year, exploratory study is to provide insight into the contextual factors that surround maternal opioid overdose deaths.

Methods: Qualitative data collection will begin in January of 2017. We will recruit women who have experienced an opioid use relapse and/or overdose, during the maternal period, from gender specific substance use disorders treatment programs. We will also recruit family members, friends and the significant others of women who have died of a maternal overdose. We will first conduct focus groups and individual interviews to guide the development of our interview guide. Following this, we will pilot test our interview guide with our population of interest. Year one data collection for this project will be complete by the end of August 2017. Our plan is to incorporate feedback from participants to hone our interview guide and possibly add survey and biological data collection during year two of this study.

Results: To analyze the qualitative data from year one of this project, we will use thematic analysis. Two experienced qualitative researchers will first analyze the data independent of each other. Following this, we will discuss emerging themes until a consensus is reached. These themes will be incorporated into our interview guide to ensure the collection of rich qualitative and quantitative data in year two of this project.

Conclusion: Having a better understanding of the context and circumstances surrounding maternal overdose could help predict overdose death and contribute to the development of targeted interventions to prevent deaths in this vulnerable population of women.

RSC PST 2 - Research Poster Session 2

Facilitation of Self-Leadership in Nurse Educators

Vhothusa Edward Matahela, MCur (NsgEd), RN, RM, RNE, South Africa

Gisela H. Van Rensburg, DLittetPhil, MACur, BACur (Hons), BACur, RN, RM, RCN, RPN, RNE, RNM, RON, South Africa

Abstract

Purpose: Self-leadership is a process through which people influence themselves to achieve self-direction and self-motivation necessary to behave and perform in desirable ways (Houghton & Neck, 2002:672; Manz in Politis, 2006:204).

Nurse educators are coordinators of programmes, disciplines, subjects and projects in the institutions and are recognized as very strong role models who can easily foster the leadership development of student nurses (Halstead, 2013:4). However, leadership experts such as Neck and Manz (2007:2) indicate that one cannot be expected to lead others effectively if they are unable to lead 'the self' effectively. The challenges that nurse educators meet during teaching and learning require nurse educators who are creative, innovative, resilient and self-leaders. Individuals with self-leadership have high degrees of internal motivation, that is, they have the internal drive to expect more of themselves and persist through difficulties until they achieve their goals (Watson, 2006:460). Although nurse educators are expected to be role models and leaders who promote the professional development of student nurses and peers, there are instances where they fail to display the expected self-leadership attributes. The question that arose therefore was:

What can be done to facilitate self-leadership within nurse educators in nursing education institutions?

The purpose of the study is to understand the self-leadership within nurse educators in order to develop guidelines that could facilitate nurse educator self-leadership

Methods: The study employed an exploratory, descriptive sequential mixed-method design to answer the above question. The study has three (3) phases. Phase 1 consists of two sub-phases. This oral presentation reports on Phase 1, sub-phase 2, the qualitative phase that explores and describes the perceptions of nurse educators with regard to their self-leadership and how this can be facilitated in a nursing education institution.

The population for the qualitative phase was nurse educators teaching at a selected private nursing school, a public nursing college and a university in the Gauteng Province in South Africa. Focus group interviews were held with participants using a semi-structured interview guide. The questions guiding the semi-structured interviews were:

- *Can you please describe how you perceive your self-leadership?*
- *What are the self-leadership activities that you engage in as a nurse educator?*
- *How can the self-leadership in nurse educators be facilitated in a nursing education institution?*

Data obtained from the semi-structured focus group interviews was analysed by the researcher and an independent co-coder using Tesch's protocol (Creswell, 2014:186).

Results: The themes that emerged from the qualitative phase were related to benefits of self-leadership practices, obstacles of self-leadership and factors that facilitate self-leadership within a nursing education context.

Conclusion: The data obtained in this sub-phase will be integrated into the quantitative phase to eventually address the research questions of the study.

RSC PST 2 - Research Poster Session 2

Reactive Depression's Relationship to Rehospitalization in Heart Failure Patients

Mary Renee Walters, PhD, RN, CCRN, FNP-BC, USA

Abstract

Purpose: To explore the effect of reactive depression on all-cause rehospitalization and all-cause mortality in NYHA Class III and IV patients during the 12 month following an index hospitalization for HF exacerbation. The study aims were: (a) describe the effect of depression, (b) explain the variance of depression, and (c) determine the moderator effect of depression on patient preparedness to manage complex HF home care all-cause rehospitalization and/or all-cause mortality in HF patients.

Methods: A Secondary Data Analysis of data obtained from a longitudinal study. Descriptive statistics, logistic regression, and multiple linear regression analyses with and without interaction effects were performed to address the study purpose and aims. Wagner's Chronic Care Model provided the theoretical framework that guided the study. Instruments included in this study: demographic sheet, the Center for Epidemiological Studies Depression Scale (CES-D), and the Dartmouth Primary Care Cooperative Information Project Chart System (measure social support), Income Adequacy rating scale, Preparedness for HF Home Care, and a medical record review for determining the comorbidities index score.

Results: Logistic regression, multiple regression, and moderator analysis were conducted to address the research questions. These analyses demonstrated that depression consistently has a significant relationship to rehospitalization. Depression as measured by CES-D score greater or equal than 16 has a significant relationship with all-cause rehospitalization $p=.09$ and all-cause rehospitalization and mortality $p=.09$. In this study, depression did not demonstrate a relationship with mortality alone. In addition, depression did not have an interaction effect between preparedness and all-cause rehospitalization and/or mortality.

Conclusion: A significant relationship was identified between depression and all cause readmission. The relationship between depression and the composite variable (all cause readmission and mortality) was also significant due to all cause readmission alone. This further supports the strength of the relationship between depression and rehospitalization. Screening for depression should be part of heart failure management. Management of depression may decrease rehospitalization in HF patients.

Community Resiliency Model Training to Improve Mental Well-Being

Linda Grabbe, PhD, PMHNP-BC, FNP-BC, USA

Jordan R. Murphy, BSN, RN, USA

Sarah San Fratello, BSN, RN, USA

Ann Craven, CHC, USA

Abstract

Purpose: Emotion regulation skills afford better coping in the face of stress and trauma and therefore may improve resiliency. The Community Resiliency Model (CRM) is an easily-taught set of somatic mindfulness skills to increase resiliency in any population (Miller-Karas, 2015). The basic three CRM skills are tracking, resourcing, and grounding. These sensory-motor awareness skills serve to re-equilibrate the nervous system when persons are “bumped” out of their “Resiliency Zone” by excessive sympathetic or parasympathetic discharge. Symptoms which result from stress and trauma are seen as normal biologic responses and the CRM skills are also biologic, grounded in the body (van der Kolk, 2015). The impact of CRM training for diverse populations will be presented.

Methods: CRM trainings are 3-4 hours in length and consist of didactic instruction, demonstration, and practice. A pre-/post-test design is planned for 1) hospital nurses and 2) homeless or incarcerated women and youth. There will be a control group for the nurse intervention. Paired samples T-tests will be presented. Established measures of mental wellness are being used to examine response to the CRM intervention. Surveys on the acceptability and usefulness of CRM skills will be described. Use of the free CRM app, "ichill" by participants will be described.

Results: Measures of anger, depression, and anxiety from incarcerated and homeless youth in response to the resiliency training will be presented. Preliminary results indicate reduced anger among incarcerated young women. Findings on well-being, resiliency, and secondary traumatic stress for the nurses will be presented. Heart rate variability as a measure of autonomic flexibility is being considered for future studies with first responders in particular.

Conclusion: Resiliency training to withstand stress and trauma can be taught in a brief group format for diverse populations. The Community Resiliency Model is a simple set of mental wellness skills which nurses can incorporate into their toolkit. Nurses may use the skills for mental wellness self-care and share with family, friends, and patients.

RSC PST 2 - Research Poster Session 2

Factors Associated With Hospitalized Preterm Infants' Sleep/Wake Patterns

Hsiang-Yun Lan, PhC, RN, Taiwan

Abstract

Purpose: Around 15 million infants (about 1 in 10 infants) worldwide are born preterm (gestation < 37 weeks) every year. Sleep plays a key role in preterm infant brain development. However, factors influencing preterm infants' sleep remain controversial. Current knowledge of preterm infants' sleep/wake patterns is limited by short measurement periods and the extent to which these patterns are related to infants' characteristics in the context of routine NICU caregiving with constant light and noise levels. Understanding factors associated with preterm infants' sleep can assist clinicians and researchers to identify preterm infants at high risk for sleep issues, which have been linked to potential developmental concerns. Thus, the purposes of this Actiwatch-based study were to (1) investigate sleep/wake patterns (sleep efficiency, total sleep time, average duration of sleep/wake bouts, percentage of sleep time, and frequency of sleep/wake bouts) for 3 consecutive days in preterm infants with different PMA, and (2) explore how these infants' sleep/wake patterns are associated with their characteristics under current routine NICU caregiving and environmental conditions (i.e., constant light and noise levels).

Methods: In this prospective repeated-measures study, sleep patterns and circadian rhythm were measured by using Actiwatch for 3 continuous days in infants with gestational age of 28-36.4 weeks in a neonatal intensive care unit and hospital nursery. Data on postmenstrual age, body weight, gender, chronological age, and illness severity were collected from medical records.

Results: For the study sample of 30 preterm infants, better sleep/wake patterns were associated with male gender, younger postmenstrual and chronological age, lower body weight, and less illness severity. Preterm infants' total sleep time ($B=41.828$, $P<0.01$) and percentage of sleep time ($B=3.711$, $P<0.01$) were significantly longer at night than during the day.

Conclusion: Overall our study findings suggest that preterm infants' sleep/wake patterns are better if they are male, have younger PMA and chronological age, less body weight, and less severe disease. Preterm infants' total sleep time and percentage of sleep time were significantly longer at night than during the day. Clinicians could use these findings to provide individualized support and protection to maintain the integrity and quality of preterm infants' sleep. For instance, clinicians could provide preterm infants a combination of non-nutritive sucking, oral sucrose, and facilitated tucking during intrusive procedures to minimize stress/pain and protect their sleep integrity. Moreover, clinicians can help preterm infants develop their circadian rhythm through interventions, such as modulating infants' states, to optimize the NICU environment and protect their sleep, thus improving their neurological development.

Effect of Communication Technology Usage on Sleep and Physical Activity Level in Nursing Students

Yeliz Culha, RN, Turkey

Hatice Kaya, PhD, RN, Turkey

Turkinaz Asti, PhD, RN, Turkey

Nuray Turan, PhD, RN, Turkey

Gulsun Ozdemir Aydin, MSc, RN, Turkey

Abstract

Purpose: Electric and magnetic fields (EMA) have an important place in the life of all living things in the natural structure of the world. At the same time, with the development of technology, the use of human-based EMA tools has become an integral part of human life, bringing together many problems. Today, communication technologies that are widely used among university students are widely used among nursing students. Nursing students who are studying in the field of health and who will serve patient individual after graduation constitute a special group among the university students. It is important for technological tools to be aware of their effects on the negative effects of sleep and movement, which are important elements in the developmental period, and to raise awareness and take appropriate precautions. The present study was conducted in order to examine effect of communication technology usage on sleep and physical activity level in nursing students.

Methods: This descriptive and cross-sectional study was carried out with 215 nursing students in the Nursing Department of a Faculty of Health Sciences in Istanbul in the 2016-2017 academic year. 215 nursing students who agreed to participate in the study constituted the sample group. Approval of the institution and informed consent was obtained from patients before the start of the study. The data were collected by interviewing face-to-face using "Structured Question Form", "Pittsburgh Sleep Quality Index (PSQI)" and "International Physical Activity Inventory (IPAQ short form)". Data obtained by using data collection forms with validity of the research data gathered were analyzed in the program of SPSS 21.00 (Statistical Package for the Social Sciences). Data analysis was performed with frequency, percentage, arithmetic mean, standard deviation, median, minimum, maximum, Mann-Whitney U, Kruskal Wallis, Bonferroni Adjusted Mann-Whitney Spearman's rho correlation tests were used.

Results: The data of the study were collected. The results are analyzed and interpreted.

Conclusion: Results of the research will be presented at the congress.

Effect of Handwashing Poster and Voice Message on Handwashing Behaviors

SeungKyo Chaung, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: The purpose of this study is to test the effectiveness of the use of intervention strategies of handwashing poster and voice message to improve the handwashing behaviors in college students.

Methods: The study was conducted in September 2016 at S university in J city, South Korea. 300 students who used restrooms were divided into three groups of 100(m: 50, F: 50); non-intervention group, poster group, and voice message group. The subjects were observed in different restrooms of different buildings to avoid testing duplicated subjects. The research focused on whether the students washed hands using soap for at least 20 seconds (as called handwashing compliance), performed the six-step technique of washing hands, and the duration of handwashing. The data were analyzed using SPSS 20.

Results: 17.3% of male students and 34.7% of female students washed hands using soap for over 20 seconds. The result showed a significant difference between gender ($\chi^2=11.7$, $p=.001$). Handwashing compliance of male students was not significantly different among three groups; poster group (24%), voice message group (18%) and non-intervention group (10%) ($\chi^2=3.44$, $p=.1791$), but it was different in female students, respectively voice message group 50%, poster group 32%, and non-intervention group 22% ($\chi^2=8.899$, $p=.012$). Only 1 female student (2.4%) from the voice message group practiced six-step handwashing technique, whereas no male students completed six-step hand washing. 40% of male students in the poster group performed three steps or more hand washing, 25.6% in the voice message group, and 20.6% in the non-intervention group, but there was no significant difference ($\chi^2=3.45$, $p=.175$). 63.4% of female students in the voice message group, 36.4% in the poster group, and 33.3% in non-intervention group performed three or more hand washing procedures, and there was a significant difference ($\chi^2=9.09$, $p=.011$). The interaction of gender and intervention strategies was significant in the time spent handwashing ($F=4.76$, $p=.009$). Female students who heard a voice message washed their hands the longest (15.9±10.2 seconds), and non-intervention male group washed their hands the shortest (5.6±6.12 seconds).

Conclusion: There was a difference in the handwashing behavior according to the intervention strategy in each gender. Voice message strategy was effective for female students while the effect of poster for male student was not significant. Therefore, it is necessary to use an effective handwashing promotion strategy for each subject rather than a uniform method.

RSC PST 3 - Research Poster Session 3

Developing and Validating a Tool to Improve Self-Management of Antineoplastic Therapy at Home

Annamaria Bagnasco, PhD, MSN, RN, Italy

Abstract

Purpose: To develop and validate an educational tool consisting of a deck of cards for lung cancer patients to educate them to autonomously and safely manage their biological antineoplastic oral therapy at home. This process could increase patients' self-confidence and adherence to treatment.

Methods: We started from the definition of 'self-management' coined by Corbin & Strauss (1988): 'Self-management aims at helping patients to maintain a wellness in their foreground perspective' (Lorig & Holman 2003, p. 1). Therefore, self-management is based on the perception patients have about problems linked to their conditions. This led us to choose a method based on the theory of problem-based learning, such as the Barrows Cards (Barrows & Tamblyn, 1977), and applied it to patients with the purpose of improving self-management through therapeutic education.

The Barrows Cards were originally used to test decision-making skills and critical thinking in medical students. This method—also known as the 'Portable Patient Problem Pack' or simply P4 System—uses a situational card that describes a complex problem and learners can choose from a deck of at least 15 cards each of which describes a possible solution to that problem with the support of a picture. The setting was the Oncology Day Hospital of our Teaching Hospital. The participants were 14 adult lung cancer patients taking antineoplastic oral therapy at home.

The instrument development and validation process included the following steps: 1) A review of the literature to retrieve scientific evidence to support the purpose of our study; 2) Obtaining support and advice from cancer experts; 3) Checking the nursing records of the 14 patients under treatment; 4) Using a short questionnaire, feedback from patients on the clarity of the statement provided on each card and on the appropriateness of the picture that illustrates the statement was obtained.

Results: At the end of this study, all of the 14 patients were very satisfied with the deck of 15 cards, plus a situational card initially developed with the support of our cancer experts. Through the active participation of patients, we ensured that the cards were actually appropriate for the purpose of educating them to safely self-manage their biological antineoplastic oral therapy at home. This qualitative process enabled to validate the cards initially developed by our experts.

Conclusion: Despite the great number benefits provided by new antineoplastic drugs, there are still some important issues linked to the incorrect management of oral antineoplastic therapy when patients are at home. The most common issue was found to be the lack of adherence to therapy, which reduces the effectiveness of therapeutic treatment. Therapeutic patient education performed by nurses based on a validated structured model such as the Barrows Cards, can significantly promote adherence to treatment and in achieving better health outcomes also in vulnerable populations, such as cancer patients.

Who Decides?: Analysis of Decision-Makers in the Adoption of Virtual Patients for Nursing Education

A. J. Kleinheksel, PhD, CHSE, USA

Francisco Jimenez, PhD, MA, MA, USA

Abstract

Purpose: As faculty implement more simulations into their nursing curricula, it is important to understand who is being empowered to make the decision to adopt these technologies. This study analyzed data collected as part of the Virtual Patient Adoption and Integration in Nursing (VPAIN) survey distributed in 2015, in order to identify the characteristics of those empowered in the decision-making process to adopt computer-based, interactive, and asynchronous virtual patient simulations for their courses (Kleinheksel, 2015).

Methods: Participants: This study analyzed self-reported demographic data provided by nursing faculty who participated in the 2015 Virtual Patient Adoption and Integration in Nursing (VPAIN) survey, which was designed to identify and measure the factors related to technology adoption and integration by nursing faculty who use computer-based, interactive, asynchronous virtual patient simulations.

Instrument: The final version of the VPAIN survey instrument included four sample eligibility items, ten demographic items, seventy-one adoption items, and twenty-one integration items.

Procedure: The final version of the VPAIN survey instrument was open to participants February 23, 2015 through March 30, 2015. The population of nurse educators using virtual patient simulations was identified through convenience and snowball sampling.

Analysis: The researchers conducted a multiple logistic regression analysis to predict decision-makers in the adoption of virtual patient simulations ("Were you part of the decision-making process to adopt the virtual patient you use in your course? 1 = Yes, 0 = No) using the following predictors: institution type, teaching in a Licensed Practical/Vocational Nursing program (LPN/LVN), teaching in a Bachelor of Science in Nursing program (BSN), teaching in an RN-to-BSN program, teaching in a Master of Science in Nursing program (MSN), teaching in a Doctor of Nursing Program (DNP), current faculty status, years teaching in a nursing program, course delivered face-to-face, course delivered web-enhanced, course delivered fully online, course length being traditional semester, course length being accelerated semester, number of semesters faculty used a virtual patient program, and who currently pays for the virtual patient program. A full model was fit with all the previously detailed predictors, as existing literature identified them as being potentially relevant to best predict the likelihood of being empowered to make the decision to adopt a virtual patient simulation. The multiple logistic regression model was fit using maximum-likelihood estimation (Agresti, 1996). AIC and deviance D values were used as model comparison indices between a constant only (baseline) and full models. The models were fit using the glm function of the package stats in R (R Core Team, 2015).

Results: The baseline model had an AIC value of 372 and a deviance D value of 370.01. The full model including all predictors had an AIC value of 339.42 and a deviance D value of 259.42, which indicated better model fit in comparison to the baseline model. Table 1 shows that teaching in an RN-to-BSN program (log odds = 1.015), teaching in a Master of Science in Nursing program (MSN) (log odds = -1.250), and teaching in a Bachelor of Science in Nursing program (BSN) (log odds = -1.427) were significantly associated with being a decision-maker, controlling for all other variables in the model ($p < .05$). Regarding faculty status, holding a positions as a Clinical Assistant Professor (log odds = 2.004), Instructor (log odds = 1.893), Assistant Professor (log odds = 2.246), or Associate Professor (log odds = 1.277) were significantly associated with being a decision-maker, controlling for all other variables in the model ($p < .05$). Years of teaching experience also had a significant effect. Model results showed that the more experience the faculty had, the higher the odds of being a decision-maker (log odds ranging from 2.228 for 2 and 4 years to 4.376 for between 21 and 25 years). In addition, compared to having used the

virtual patient program for one semester, faculty who had been using it for three semesters (log odds = 1.296), four semesters (log odds = 1.412) or more than four semesters (log odds = 1.391) were more likely to be a decision-maker in adopting. Institution type, course delivery method, course length, and who currently pays for the virtual patient program were not significantly associated to being involved in the decision-making process.

Conclusion: With the increased number of pedagogical innovations available to educators, it is important for faculty and administrators to understand who is being empowered to make the decision to implement a given technology. In the case of virtual patient simulations, the institution type at which a faculty taught, the delivery method of their course, and funding source do not affect a faculty's decision-making status. However, RN-BSN, MSN, and BSN faculty, faculty with more experience, and Clinical Assistant Professors, Instructors, Assistant Professors, and Associate Professors are more likely to have the authority to decide to adopt virtual patient simulations.

Technological Solutions to Foster Communication in Multisite, Longitudinal Studies

Julia A. Greenawalt, PhD, RNC-OB, CHSE, USA
Margory A. Molloy, DNP, RN, CNE, CHSE, USA

Abstract

Purpose: A call noted in the literature has been for more rigorous multisite studies to be executed to drive nursing and healthcare (Mariani and Doolen, 2016). Many obstacles and challenges need to be surmounted to successfully implement a multisite study. This presentation will share some lessons learned and how technology and social media were used to successfully navigate many of the challenges inherent in multicenter research work.

Methods: Multisite studies require close collaboration between all involved, most notable during the preparation and implementation phases. However, time, scheduling, and distance are common challenges of a successful study. This presentation shares with the audience an innovative use of a web-based tool for maintaining open lines of communication used during one multisite study. Solutions and “work arounds” from a ten site national study in the USA will be presented. Strategies for maintaining open lines of communication implemented by the principle investigators allowed for a large sample size with broad generalizability in this multisite study. A free, publically accessible web-based tool will be discussed and how the use of this tool fostered collaboration, communication and cohesiveness for the research team.

Results: The tool is mobile, user-friendly and web-based and allowed team members to send updates and share resources in a timely manner. Video meetings could be conducted with the project team and viewed synchronously or asynchronously from a computer or mobile device. These online meetings provided a means to stay in touch without the need for travel or expense while still benefiting from a live, engaging, and immersive environment. Obstacles such as time and distance were eliminated to allow for successful study implementation.

Conclusion: Evaluating various new technologies for project planning and managing multisite studies can provide future study teams with the tools needed to foster a team commitment to the completion of a successful multisite study to advance the science of healthcare. Lessons learned about multicenter research collaboration, albeit national or global will be explored in this interactive presentation. Other emerging technological applications will be shared that are simple, secure and have reliable messaging and video capabilities which may be applied in the same fashion to foster equal or better results. Further research is warranted to trial these emerging technologies to advance the science of healthcare.

The Effectiveness of Using High-Fidelity Simulation Team Training on Advanced Cardiac Life Support

Lichien Yang, MSN, RN, Taiwan

Abstract

Purpose: The medical developments increasingly complex, many medical practices staff needs through different areas in order to jointly completed, the occurrence of most medical blunders, poor communication and a lack of teamwork is the main reason. In Taiwan, the first aid care quality is very valued, in order to allow physicians, nurse in emergency care that can demonstrate teamwork and advanced cardiac life support capabilities, we aid based on AHA 2015 ACLS guideline processes and hospital medical staff recovery practices, incorporating the spirit of TRM training. Through a systematic way to teach a team how to effectively communicate and collaborate, expect to reduce clinical errors, enhance the advanced cardiac life support (ACLS) knowledge, teamwork, and overall satisfaction, to protect patient safety. The purpose of this study is to evaluate whether the using High-Fidelity Simulation Team Training would produce greater improvement in advanced cardiac life support (ACLS) knowledge, teamwork, and overall satisfaction with the training method.

Methods: This is an interventional study, conducted 18 group of 108 people (54 resident physicians and 54 nurse) for team training from February 2015 to October 2016. The SIM-Man (patient simulator) are Used to training and teaching, and designed a clinical situation. The process according AHA 2015 ACLS guideline included teamwork spirit and made a checklist. ACLS qualified professional teachers to assess the effectiveness of training for each group, and questionnaires. In SPSS for Windows statistic package software was used to process the data analysis.

Results: The use of high-virtual team training compared with the traditional training. There were significant intergroup differences for enhancement class satisfaction ($p < 0.05$), individual professional ability ($p < 0.05$), teamwork spirit ($p < 0.05$) and practical work efficiency ($p < 0.05$).

Conclusion: We recommended that successful implementation of a training program should meet the demands of trainees. Such interventions may include incorporation of the Team Resource Management model, utilization of High-Fidelity Simulation Team Training, scheduled integrated team-based drills, and unscheduled hands-on practice and tests. The results of this study could serve as a reference for the improvement of future ACLS training courses.

Effective Design Characteristics of Virtual Simulation in Nursing

Hyunsook Shin, PhD, RN, CPNP-PC, Korea, Republic of (South)

Hyojin Kim, MSN, RN, Korea, Republic of (South)

Da Hae Rim, MSN, RN, Korea, Republic of (South)

Sojeong Park, BA, RN, Korea, Republic of (South)

Abstract

Purpose: An educational strategy has to be advanced as technology evolves. Virtual nursing simulation is one of the attempts for a transition of the nursing education method. This study is to develop a template with design characteristics for virtual simulation, to build a sample scenario of virtual simulation using the developed template and with using the developed template, to test the validity of the virtual simulation using the developed scenario in a multi-user virtual environment.

Methods: A methodological study was conducted through three phases. The first process was developing a virtual simulation template based on the findings of literature review and focus interviews with clinical nurses and experts to identify essential components of characteristics of virtual simulation design. The second phase of the study was to build a sample of virtual simulation using the developed template. Testing the validity of the sample virtual simulation was the final development process.

Results: Effective virtual simulation template with design characteristics was developed. The developed template consisted of three domains, which were educational outlines, design characteristics of virtual simulation, and case presentation. The components of the design characteristics in the template were affordance, interaction between a computer and a participant, participant representation, strategies for user interface design, the type of virtual simulation, simulation framework and the overall theoretical framework. The developed sample scenario was a pediatric case representing common pediatric patient situation using a platform in multi-user virtual environments. The sample of virtual simulation established its validity through expert content validity and face validity with clinical nurses.

Conclusions: Virtual simulation scenarios for nursing education should be developed based on the effective design characteristics of virtual simulation. The findings of this study showed the design characteristics of the developed template could allow nurse educators to build more structured virtual simulation strategies for nursing education. Further study focused on evaluating the effectiveness of the virtual simulation is warranted.

Elevating Caring Qualities of Emergent Myocardial Infarction Patients Through Systematic Information

Shu Lien Hsu, BSN, RN, Taiwan

Abstract

Purpose: Heart disease remains the second leading cause of death in Taiwan. Medical treatment constantly makes great amount of progress and the time of patient treatment and care is against the clock. Therefore, the time we fight for patients from they sent to ER until medical team members complete the performance of door-to-balloon time in this hospital is critical. According to references, make door-to-balloon time less or no more than 90 minutes could lower down the death rate the the likelihood and amount of cardiac muscle damage.

Methods: Through the design of systematic information, triage nurses are able to utilize the program to page doctors, registered nurses and ECG medical technologists (regularly on duty) so that these team members can arrive at ER in no time. Next, they set up primary PTCA to remind the staff of cardiac catheterization room to look into patients' history and other information, and then take the elevator for emergency use to get the patients to the room immediately.

Results: Due to the set up of systematic information, data can be sent to the team member at once. Since it began to implement from January to April in 2013, the number of patients who took PTCA within ninety minutes has risen to 82.27%. Furthermore, the system brought different medical team members worked together so that we can make the time get patients from ER to cardiac catheterization room 3-5 minutes shorter resulted from completing ECG study, medication treatment, and preoperative preparation in 30 minutes.

Conclusion: The completion of PCTA surgery within 90 minutes can achieve more than 80% in the hospital indicates that myocardial infarction patients can effectively decrease death rate and complications under the collaboration among multiple team work, simplified information system and door-to-balloon time. Therefore, the timely medical treatment and teamwork intervention on the survival of patients is helpful.

Refugee Health Education: "Learn to Succeed. Together We Build Our Community."

Maria Theresa P. Panizales, MSN, RN, USA

Abstract

Purpose: The purpose of the project is to develop and implement a comprehensive culture sensitive health education program to address the resettled refugees identified health needs as a result of lack or cessation of support after the refugee resettlement program ends. The health needs were identified through a community needs assessment conducted in Fall 2015.

Methods: The program is a quality improvement project using a qualitative design guided by Avedis Donabedian's quality framework that encompasses structure, process and outcome, and the use of Deming's Plan-Do-Study-Act cycle methodology for continuous process and program improvement.

The project is a collaborative community-based training program with stakeholders involved as resource, and subject matter expert from their respective organizations. The number of community trainers vary depending on date and time availability, the DNP student assumes teaching the course where necessary. The total number of participants are 15, male and female, aged 18 and above, and post resettlement program support. There were participants that does not meet the criteria and would like to attend, this was allowed. The refugee participants are from different ethnic background within the target community, mostly Somali and Congolese.

The program is a 2-hours weekly session to resettled refugees at Providence, Rhode Island ZIP Code 02907. The curriculum is divided into three: (1) health education, (2) community immersion, and (3) case management. Health education will include topics selected from the community needs assessment such as simple illnesses and management, first aid, nutrition, preventive health care, etc. while community immersion activity involves marketing (grocery/market visit as feasible) and socio-cultural "Thanksgiving Dinner" event. Case management is the provision of resource handbook and health insurance road map or guide.

Participant experiences, and composite measures based on the curriculum and program goals and objectives were collected using survey tools for knowledge, skills and general program. The tools were developed by the DNP student based on the community needs assessment to assess if the needs were met. This will be analyzed and utilized to drive improvement of the program. Participants complete pre and post knowledge and skills survey to identify strengths and weakness of the curriculum, teaching methodology and program structure. Refugee community leaders were engaged actively, so skills can be gained in program management and teaching.

The program survey tool will collect quantitative data to determine program efficiency based on the program goals and objectives. Qualitative data will include collecting feedback from participants and random anecdotal reports during meetings with community stakeholders, program staffs, community health advisory board and trainers.

Results: A cursory analysis of the pre-health education program survey reveals knowledge and skills gap in basic health care, and navigation of government health services.

Conclusion: The health education program is expected to be completed by Dec 17th. There will be two more classes after Dec 3rd.

RSC PST 3 - Research Poster Session 3

Nurse Practitioner Knowledge, Attitudes, and Practices Regarding Lung Cancer Screening in the United States

Karen Kane McDonnell, PhD, MSN, RN, OCN, USA
Amy C. Dievendorf, DNP, APRN, FNP-BC, USA
Jan M. Eberth, PhD, USA
Erica Sercy, MSPH, MSPH, USA
Deborah Warden, MSN, RN, CNL, CPAN, USA
Lauren Blew, USA

Abstract

Purpose: Lung cancer is a leading cause of cancer morbidity and mortality among men and women in the United States. Lung cancer is usually diagnosed during its most advanced stage, resulting in a dismal 17% five-year survival rate (Siegel, Miller, & Jemal, 2016). However, recent results from the National Lung Screening Trial (NLST) indicate the potential to detect lung cancer at earlier stages, thereby decreasing mortality. Low-dose computed tomography (LDCT) for lung cancer screening has been shown to reduce lung cancer-related mortality by 20% (Bach et al., 2012). Based on this new evidence and the development of practice guidelines, the United States' Centers for Medicare & Medicaid Services (CMS) added lung cancer screening as a benefit for patients at risk for lung cancer, requiring counseling and a shared decision-making visit with a care provider and annual screening with LDCT (CMS, 2015). While lung cancer screening can save lives, very little is known about how it is perceived by primary care providers, and how those perceptions are translated into the practice setting. The required shared decision-making process between care providers and patients is also largely unexplored (Volk & Foxhall, 2015; Ersek et al., 2016; National Academy of Science, Engineering, and Medicine, 2016). This study is part of a larger survey including several types of primary care providers. The purpose of this study, now underway, is to examine knowledge, attitudes, and practices regarding lung cancer screening among nurse practitioners who work with high-risk patients in primary care settings.

Methods: A mixed methods design was used. A conceptual framework of barriers to screening guideline adherence, developed by Cabana et al. (2012), guided the development of the survey and data interpretation. The pre-tested paper survey was distributed to a random national sample of 3,000 nurse practitioners (NPs) self-identified as working in a primary care setting in the United States. A sequential explanatory method will use the quantitative survey data to inform development of questions for a qualitative interview. Audio-recorded interviews will be conducted over the telephone and transcribed by a professional service. Descriptive statistics will be the primary analysis approach. All quantitative analyses will be conducted using SAS®Procedures. Population-based estimates will be based on weighted calculations of completed survey responses. Weights will be applied to ensure that the sample is representative of age, gender, and geographic differences. Comparisons of primary care NPs' knowledge, attitudes, or screening practices across sub-groups (e.g., practice setting, age range, gender, and race/ethnicity) will be made using Pearson's chi-squared tests or t-tests, with associated tests of statistical significance. Standard multivariate linear and logistic regression will be used to analyze relationships between knowledge about and attitudes toward screening (independent variables) and screening practices (dependent variable). Thematic analysis processes outlined by Braun, Clarke and Terry (2015) will be used to analyze and identify common themes among the transcribed qualitative interviews.

Results: Study findings will be used to inform the development and testing of educational interventions targeting identified knowledge gaps among NPs caring for high-risk patients in primary care settings, as well as, clinical interventions to facilitate shared decision-making relating to lung cancer screening. The results will provide researchers in other areas of lung cancer screening research with baseline data to develop and test patient-, provider- and systems-level interventions to increase awareness of and reduce barriers to lung cancer screening in clinical practice.

Conclusion: This is the first study to examine knowledge, attitudes, and practices regarding lung cancer screening of nurse practitioners who work in primary care settings. Results of this study will be used to support this research team's efforts to secure additional funding to further develop this important program of research.

RSC PST 3 - Research Poster Session 3

Prevalence of Metabolic Syndrome and Its Components Among Korean Cancer Survivors

Ji-su Kim, PhD, RN, Korea, Republic of (South)

Kyunghee Kim, PhD, RN, Korea, Republic of (South)

Insil Jang, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: The 5-year survival rate of Korean cancer patients is continuously improving, and more than half of cancer patients are known to survive for more than 5 years. Recently, the cause of death in cancer survivors is often attributable to cardiovascular diseases resulting from factors related to metabolic syndrome rather than cancer relapse; therefore, the management of metabolic syndrome and its components is important to improve cancer survivorship. However, large variations in the prevalence of metabolic syndrome in cancer survivors have been reported depending on the study, and there is no guideline for management of metabolic syndrome in cancer patients yet. Furthermore, the number of studies on cancer survivors in Asian countries, including South Korea, is insufficient. This study aimed to identify differences in the prevalence of metabolic syndrome and its components depending on the cancer type, gender, and age group in Korean cancer survivors.

Methods: Data from the 2008–2012 Korean National Health and Nutrition Examination Survey (KNHANES)—a cross-sectional and nationally representative survey undertaken by the Korea Center for Disease Control and Prevention (KCDC)—were used. The KNHANES has a stratified multistage probability sampling design comprising health interviews, health behavior and nutrition survey, and health examination study. The SAS version 9.3 survey procedure (SAS Institute Inc., Cary NC, USA) used a complex sample design based on the survey data analysis; this provided sampling weights and nationally representative estimates. Differences in the ratios between the metabolic syndrome and its components by cancer type, gender, and age group were analyzed using chi-square tests.

Results: The results of the study are as follows. 1) Regarding the general characteristics of cancer survivors, 62.5% were female, the mean age was 57.7, 77.5% were urban residents, and 34.7% were elementary school graduates. As for economic status, 25.8% fell under the 2nd lowest quartile, and 44.4% were currently economically active. Among the cancer survivors, 7.4% were current smokers, 36.8% drank alcohol more than once a month, and 20.7% exercised regularly. Regarding cancer-related characteristics of cancer survivors, the mean age upon cancer diagnosis was 50.1, and 35.3% were currently undergoing treatment. In terms of the type of cancer diagnosed, gastric cancer accounted for 19.6%; thyroid cancer, 18.5%; cervical cancer, 13.8%; breast cancer, 12.40%; colorectal cancer, 10.3%; liver cancer, 2.77%; and lung cancer, 2.21%. 2) Based on the diagnostic criteria of the American Heart Association/National Heart, Lung, and Blood Institute Scientific Statement, the prevalence of metabolic syndrome was 46.9% in cervical cancer, 43.9% in colorectal cancer, 38.6% in lung cancer, and 35.9% in breast cancer. 3) Regarding gender, the prevalence of metabolic syndrome in female cancer survivors was 38.3%, which was significantly higher than that in male cancer survivors (30.4%) ($p = 0.022$). In the components of metabolic syndrome, there were differences depending on gender in waist circumference, low HDL-cholesterol, and high blood sugar. The rates of waist circumference obesity and high blood sugar were higher in female cancer survivors, while the rate of low HDL-cholesterol was higher in male cancer survivors. 4) In terms of age, the prevalence of metabolic syndrome was higher as age increased, and the difference was statistically significant ($p < .001$): 18.4% in the young adult group (20-39 years), 27.9% in the middle age group (40-59 years), and 46.1% in the old age group (60 years and older). In the components of metabolic syndrome, high triglyceride, low HDL-cholesterol, and high blood sugar differed depending on the age group; as age increased, the rates of high triglyceride, low HDL-cholesterol, and high blood sugar became higher.

Conclusion: In summary, the prevalence of metabolic syndrome in cancer survivors was approximately 10 to 20% higher than that in healthy Koreans. Particularly, the prevalence of metabolic syndrome was higher in female cancers, including cervical cancer and breast cancer, and in colorectal cancer.

Moreover, the prevalence of metabolic syndrome was higher in females and in the old age group. Therefore, management of metabolic syndrome should be actively carried out for groups with a high prevalence of metabolic syndrome, and consideration should be given to components with a high risk of onset for each group when developing programs for metabolic syndrome in cancer survivors.

This study was supported by the National Research Foundation of Korea (NRF) funding grant (NRF-2015R1C1A1A02036408).

Delaying the Second Pregnancy Among Teen Mothers: An Innovative Community Collaboration

Ainat Koren, PhD, RN, USA

Annette McDonough, PhD, CNS, USA

Abstract

Purpose: Nearly one in five births to teens, ages fifteen to nineteen, are repeat births. Most (Eighty six percent) are second births. (MMWR, 2013). Teen pregnancies and births have a negative effect on the physical, psychological, and social wellbeing of all teen mothers and their offspring (Martinez & Abma, 2015). Teenage mothers who have a rapid second birth have substantially poorer socioeconomic and familial outcomes than do those who delay subsequent childbearing. The likelihood that a teen mother will finish high school, break the cycle of welfare dependency, and rise above her social standing, all diminish rapidly with the arrival of each succeeding infant. Early intervention programs for teen parents and their babies during pregnancy significantly reduced the rate of second pregnancies for high-risk mothers (Klerman,2004). Further, initiation of home visits (as a part of the program) prior to the birth of the infant was associated with a lower rate of subsequent childbearing. Parenting teens' access to contraceptive services, in and of itself, does not decrease subsequent birth rates during adolescence. These rates are reduced, however, when access is combined with defined educational goals and support provided by schools and programs. The program goals were:

1. to delay a second pregnancy among first-time adolescent mothers,
2. to encourage consistent and correct contraceptive use
3. to assist the young mothers with continuing their education and graduating from high school or equivalency programs, and
4. to support positive motherhood.

The program consisted of two components: bi-monthly group meeting for support and content delivery, and ongoing, individual support provided by a role model case manager.

This poster will share an innovative and sustainable community collaboration to develop a comprehensive support model for pregnant and parenting teen mothers in a city in Northern Massachusetts with disproportionately high teen birth rates.

Methods: Program evaluation consisted process and outcome evaluations. Team meeting were documented to track the process of program development. Collaboration strategies, challenges and solutions in program implementation were summarized. Individual interviews were conducted with the participating teen mothers and the program staff.

Results: Nine organization from the community collaborated to develop and execute the program. The organization included the state university, community health center, local hospital, women and children (WIC), two high schools, and 4 non profits in the area that serves high risk families and children. Process evaluation identified that program sustainability is essential to the survival of a program. Sustainability has been defined as the capacity to maintain program services at a level that will provide ongoing prevention and treatment for a health problem. Non profit housed the case management project to overcome the challenge of low budget and legal implications. Teen groups were held at the high schools to increase participation. Outreach and collaborations were established with organizations with competing services in the community.

Conclusion: In today's reality where funding is sparse, community organization collaboration is essential. This program is unique by incorporating the case management under existing non-profit organizations. In addition the groups were provided where the teen mothers were, namely the high school.

Factors of Metabolic Syndrome and Quality of Life Among Korean Postmenopausal Women

Young Man Kim, MSN, RN, Korea, Republic of (South)
Yerin Cha, BSN, RN, Korea, Republic of (South)

Abstract

Purpose: This study aimed to identify factors affecting metabolic syndrome and investigate association between metabolic syndrome and health-related quality of life (HRQOL) among Korean postmenopausal women.

Methods: This study was performed using data from the Korea National Health and Nutrition Examination Survey (KNHANES) from 2010 to 2014. The KNHANES is a complex, stratified, multistage, probability cluster survey and also the sample data represents the Republic of Korea. Included number of postmenopausal women was 7,123, and the weighted sample size was 6,530,873. General characteristics, clinical characteristics, HRQOL, and five components of metabolic syndrome including triglyceride level, high density lipoprotein level, hypertension, diabetes, and abdominal obesity were evaluated and correlated with variables of sample at individual and contextual level. After applying sampling weights, the data was analyzed with chi-square test, logistic regression, Poisson regression, and Tobit regression. The used statistical programs were SPSS 23 and STATA 13.

Results: The mean age of sample was 62 and self-reported menopause age was 48. The increase in prevalence of metabolic syndrome according to increase of the postmenopausal age was statistically significant (p for trend $< .001$). The beginning point of the rapid change in slope was with the 50-54 age-group. And Body Mass Index (BMI), education level, employment status, house income and time lapse of postmenopause were statistically significant in both logistic regression and Poisson regression model. As the number of metabolic syndrome components increased, HRQOL among postmenopausal women was decreased ($\beta = -0.025$, $p < .001$). Of five components, factors had a great effect on the HRQOL are high blood pressure ($\beta = -0.067$, $p < .001$) and abdominal obesity ($\beta = -0.047$, $p = .003$).

Conclusion: Metabolic syndrome affect the HRQOL and weight control is the key factor in preventing metabolic syndrome among Korean postmenopausal women. Since the vulnerable groups' socioeconomic status was low, intervention programs should be done at community or national level, considering the critical time point.

Psychosocial Predictors of Emotional Eating in Lebanese Young Males

Rita Doumit, PhD, MPH, BSN, RN, Lebanon

Abstract

Purpose: It was previously believed that DE primarily affects women and the vast majority of DE research focused on females. However, recent studies have suggested that DE symptomatology (emotional, restrained and emotional eating) may be underestimated in the male population. Indeed, over the last decade, it was revealed that a substantial number of men suffer from DE and ED (Eating Disorders) (Striegel et al., 2012; Strother et al., 2012), and that up to 25% of all individuals with ED are males (Hudson et al., 2007). Moreover, a recent review paper revealed that 42-45% of individuals engaging in binge eating were males; as were 28-100% of individuals who regularly purged. Laxative abuse among genders was nearly even, and fasting for weight loss was endorsed by nearly 40% of the males (Mond, Mitchison & Hay, 2014). This is the first study to investigate psychosocial predictors of DE in a sample of Middle-Eastern males, thus findings will provide prevalence data about DE behaviors in this context. The present study examined depression as a potential mediator of the relationships between body image dissatisfaction, strategies to change muscle and weight, media pressure, and DE in male young adults. Based on findings from the literature, it was hypothesized that: BID will be indirectly associated with DE through depression (Hypothesis 1); Strategies to change muscle and weight will be indirectly associated with DE through depression. (Hypothesis 2); Media influence (MI) will be indirectly associated with depression and DE (Hypothesis 3).

Methods: This is a cross-sectional design study. After obtaining the ethical approval of the university IRB, which is constituted in accordance with the US Code of Federal Regulation (45CFR 46.107, 21CFR 56.107), and Good Clinical Practice ICH (Section 3), a convenient sample of 260 male undergraduates aged between 17 and 33 was asked to participate voluntarily in the study and completed a self-reported questionnaire. Confidentiality and anonymity were ensured. Data was collected during class time and testing sessions lasted around 35 minutes. Each student received a survey pack with an informed consent.

Results: Path analyses indicated that media pressure and strategies to decrease body weight had direct positive effects on depression ($\beta = .85$ and $.18$, respectively), which in turn predicted emotional eating. Media pressure had a direct positive effect on emotional eating ($\beta = .57$), whereas strategies to decrease body weight did not exhibit a direct effect on emotional eating ($\beta = -.16$ with 95% CI $-.47 - .15$). The link between media pressure, strategies to decrease body weight and emotional eating was partially mediated by depression. The full model provided an acceptable fit to the data: CFI = .99, TLI = .99 and RMSEA = .01 with PCLOSE of .45.

Conclusion: To our knowledge, the present study is the first to explore the psychosocial predictors of DE in a sample of Middle-Eastern males and to explore the mediating effect of depression on DE. Our results will assist in the development of prevention and intervention programs targeting the roots of DE, and ultimately eating disorders. Specifically, nurses could assess psychopathology indicators, and in particular depressive symptoms in males, once they detect that strategies to lose weight are being applied, as a preventive measure against distorted eating. Clinically, it is important to pay attention to behaviors among males that aim at becoming thinner through a change of eating patterns, food choice, and exercise. Such behaviors are indicative of worry and concern about losing weight, which can lead to negative feelings (especially if the behaviors are ineffective, or the individual has the intention but is unable to consistently apply those strategies to decrease weight). Those feelings can, in turn, result in emotional eating, which is ultimately a risk factor for eating disorders (Fairburn, Cooper, Doll, & Davies, 2005). In addition, findings from this study bring attention to the impact of media and importance of restructuring the perceptions of an "ideal" male figure that directly impacts males' emotional functioning, which reflects in emotional eating patterns. These findings have special relevance for the Lebanese context. The region is in need of centralized efforts towards providing holistic health care to males at risk of developing DE habits. A multidisciplinary approach is needed, whereby psychologists, public health

and nursing professionals, as well as nutritionists can join efforts to detect, assess, and treat DE behaviors.

Factors Associated With Postpartum Depression Among Women Who Conceived With Infertility Treatment

Chuan-Chen Li, MS, RN, Taiwan
Li-Yin Chien, ScD, RN, Taiwan

Abstract

Purpose: Around 15% of all couples of childbearing age in Taiwan have infertility. About 7~20% of women have depressive symptoms during infertility treatment, and the psychological pressure might remain high when they become mothers. Postpartum mood disorder of mothers will lower the ability of taking care of themselves and the baby, thus affect the health of the mother and the baby. Most of previous researches on infertile women focused on psychosocial problems during infertility treatment, few focused on examining the effect of different infertility treatments on postpartum depression.

Methods: This study was a cross-sectional survey performed from November 2014 through May 2015. The study participants were 180 women who conceived with infertility treatment and were within 6 months postpartum at a medical center in Taipei, Taiwan. Data were collected by telephone interviews and chart review using a structured questionnaire. The study variables included socio-demographics, personal and family history of depression, women and infant health history, breastfeeding, pressure change, social support, history of infertility, and infertility treatment. The dependent variable is postpartum depression within 6 months after delivery as measured by the Edinburgh Postnatal Depression Scale with a cutoff score of 10.

Results: The prevalence of postpartum depression within 6 months after delivery is estimated at 34.4% among the study women. The binary logistic regression revealed that breastfeeding (OR=0.347, 95% CI=0.123~0.980), social support (OR=0.901, 95% CI=0.853~0.952), and baby gender in line with expectations (OR=0.177, 95% CI=0.060~0.523) were negatively associated with postpartum depression. Perceived postpartum pressure higher than before infertility treatment (OR=4.403, 95% CI=1.512~12.822), duration since infertility diagnosis longer than 3 years (OR=5.158, 95% CI=1.825~14.577), maternal age older than 35 years old (OR=8.313, 95% CI=2.642~26.155), pregnancy via IVF (OR=5.738, 95% CI=1.420~23.189), and experiencing three or more different courses of infertility treatment (OR=8.671, 95% CI=2.382~31.567) were associated with a higher risk for postpartum depression. These eight variables explained 50.6% of variances for postpartum depression.

Conclusion: Women who conceived with infertility treatment in Taiwan had a high prevalence of postpartum depression. Longer duration since infertility diagnosis, older maternal age, conception via invasive treatment, and multiple courses of infertility treatment were associated with an increased risk for postpartum depression. Policies regarding infertility treatment should incorporate mental health counseling and prevention of postpartum depression. Health care professionals should enhance pregnancy- and labor-related health education for women who conceived through infertility treatment and offer them more support and help after delivery.

Drug Costs vs. Charges: You Can. Should You?

Vincent F. Maher, JD, MSN, RN, CRNA, USA

George V. Priovolos, PhD, CPA, USA

Barbara M. Cohen, PhD, JD, MS, MEd, BSN, RN, USA

Elisabeth J. Maher, MSN, PMHNP-BC, USA

Abstract

Purpose: Pharmaceutical manufacturer Mylan increased the cost of Epi-Pens by 400 percent. The new list price for a two-pack of EpiPens is just above \$600 which charge was just over \$100 when Mylan acquired the product in 2007. The company's CEO, Heather Bresch, whose salary was \$2.4 million in 2007 also raised her salary to 18 million dollars per year. Her acts recapitulate those of former Turing Pharmaceuticals CEO Martin Shkreli who imposed drug charge increases from \$13.50 to \$750 a pill for the price of Daraprim, a medication used by HIV patients, and also of his recommended increases in executive compensation by Turing following his departure. Mental health outpatient drug costs have risen roughly 20% a year in each of the past 5 years for which national data are available (1996-2001). Antipsychotic drugs billed to Medicare have risen 71% in recent years.

Methods: Analysis is based on media and pharmaceutical industry sources and social media response to these actions.

Results: There seems to be a default setting in most people's psyches that cost and charge are supposed to resemble some unspoken reasonable relationship to one another and are not to enter the realm of beyond the pale or even of obscenity. Most would agree that the one producing a product is entitled to a profit. How much profit and its reasonableness are two entirely different issues and not infrequently evade norms on many number of levels. Choice differentials are utilized by consumers pertaining to transportation, housing, education medication and recreation: first class and economy seats will get you to the same place as will a Rolls Royce or a Vespa. Generic versus brand name ibuprofen will provide analgesia. Consumers make a choice. The process of research, price setting and charges practices are typical in the pharmaceutical industry. When speaking of life saving medications however, such differentials are rendered moot and necessarily, many would argue, become the object of public policy scrutiny. Specifically, one needs a particular medication when one needs it or one dies. There isn't an alternative for those who need products like Epi-Pens, Daraprim or Naloxone.

Conclusion: This paper will examine contemporary cost versus charge as applied to commonly used medications and to those that are life-saving and with limited markets, the funding of pharmaceutical research, the impact of direct to consumer advertising, the issue of executive compensation, the realities that legislators around the world have engaged in to remove the immediate charges of emergency medications from the individual to the public realm and product branding issues faced by the manufacturer. The authors will propose recommendations for Nursing and public health advocacy in this regard and will invite discussion by participants.

Proper Mobilization of Elderly People With Hip Fracture

Pedro Enrique Trujillo-Hernandez, MSN, RN, Mexico

Sandra Cecilia Esparza-Gonzalez, PhD, RN, Mexico

María de los Angeles Villarreal-Reyna, PhD, RN, Mexico

Raul Adrian Castillo-Vargas, MSN, RN, Mexico

Abstract

Background: The proximal fracture of the femur or hip fracture is one of the major health problems of the elderly people. It includes an increase in morbidity, mortality, functional impairment, costs and increases the degree of dependence and institutionalization of these patients in a year of fracture. There are studies that estimate that, worldwide, the incidence of hip fracture will exceed 6 million in the year 2050. Some authors have already used the term epidemic to qualify this increased incidence in proximal fracture of the femur. Overall hospital mortality is 5%, ranging from 2% to 8%. Reaching 30% of patients at 12 months of fracture. And sin was reduced during a long second half of the last century. Its cost attributed to our environment is high. In the United States of America, it stands at about \$ 20 trillion, a fact that does not oblige to prioritize not only preventive measures but also the most efficient rehabilitation alternatives.

Rehabilitation must begin from the moment of admission. It is important that the patient and the family know the chosen therapeutic plan, along with the recommendations for the post-hospital discharge. Many patients with hip fractures have to remain with disabilities and it is important that they receive the necessary explanations to restore their state of mind. Therefore, early mobilization reduces the percentage of complications due to conditioning syndrome, respiratory complications, pressure ulcers, the risk of deep venous thrombosis and delirium, to which elderly patients are very susceptible.

The main postoperative goal in early rehabilitation, beginning with the mobilization and multidisciplinary rehabilitation, according to indications of the Traumatology and Rehabilitation services in general, must first, if the general conditions of the patient permit, in the first 24-48 hours. The intervention, since the osteosynthesis through the fixations of the nail plate and the arthroplasty allow the load in the joint practically 24 hours after the surgery (always after the radiological control), although the use of prosthesis endomedulares usually delay the full charge until the third day. Despite advances in patient care and surgical techniques, very often, although the operation is successful in terms of healing fractures, the patient is unable to reach the level of function and independence before.

Since most adults who suffer from this type of fracture end the rehabilitation in their home where they are cared for mostly by relatives or primary caregivers who receive little or no training for care and mobilization by health personnel. Of opportunity that if they did not attend can cause the older adult to recover their basic functions, causes immobility syndrome, fear of wandering, pain and worse case a displacement of the prosthesis and a new recidivism of the elderly people. The hospital where it should be reprogrammed for a new surgery, involving a new expenditure in the health sector, a new type of bed in the hospital, which can be assigned to another patient in need.

Purpose: Develop a standardized protocol aimed at primary caregivers of elderly people with hip fracture for proper mobilization and rehabilitation exercises to achieve a successful recovery of the functions prior to the traumatic event.

With this proposal of intervention is intended to put in place a standardized protocol for the care of elderly people with hip fracture, creating a Guide to Practice to guide the primary caregivers about how they must perform the mobilization and rehabilitation exercises to prevent hospital readmissions by displacement of prostheses or falls that the older adult were to be as a result of poor mobilization.

This project is aimed mainly at the primary caregivers who are under the charge of older adults with hip fracture so that they have the scientific basis about how to perform a successful mobilization and

rehabilitation exercises. As well as to all staff in the area of health to learn more about this topic and to be able to better orient the time of hospital discharge both the older adult as the carer.

In terms of the benefits it has provided for the realization of this proposal range from: health institutions, patients and nursing staff which are:

For the institutions, the anticipated savings in health care costs by recurrences hospitalers by displacement and falls to the older adult with hip fracture, and thus these resources could be used in the care of other patients with multiple diseases chronic degenerative diseases, in improving the infrastructure of the health care clinics or in the purchase of better medical equipment or medicines.

For the nursing personnel, since with this protocol may be a further step in the professionalization and social recognition, and hospitable to improve the care of elderly people and avoid repercussions unnecessary for the health of this group of people. And with regard to the workload would be reflected as such interventions previously made by the staff to the elderly people that reincidió can be used in other patients and improve the attention and the quality of the nursing care.

For patients, because with a correct mobilization and appropriate exercises can recover their basic functions of daily life and thus avoid the functional dependence and psychological alterations by the process that is taking, so too could be reflected in less spending money for the purchase of medications or support teams.

Methods: The present proposal is based on the model of transitional care. So also this research lies within the paradigm of critical-purposeful, even in the health field, where its actions should be eminently human, flexible and we identify potentials that are constantly changing and is justified because it allows us to deal with the various situations that will be present in the normal development of research which makes the problem more manageable.

Results: will be compared. Descriptive statistics, means comparison and correlation analysis will be used.

Conclusion: It will be analyzed based on the results, if the correct mobilization of an elderly people with hip fracture, based on a standardized protocol allows the reinsertion of the elderly people to their activities prior to the event, taking into account the scientific evidence available in the advanced nursing practice and its implications on positive health outcomes in Mexican elderly.

The Correlation of Patients with Spinal Cord Injury and Psychiatric Disorders

Chinghui Chuang, MSN, RN, Taiwan

Abstract

Purpose: Psychiatric disorders often occur concomitantly with spinal cord injury. However, the relationship between psychiatric disorders and spinal cord injury (SCI) remains unclear.

The study was to investigate the correlation between psychiatric disorders and SCI.

Methods: During the 10-year study period, 71253 patients spinal cord injury were enrolled for analysis. The study was to conduct a retrospective cohort study to assess whether psychiatric disorders were an independent risk factor of SCI. Newly diagnosed SCI outpatients (N=71253) during the years 2000-2009 by the Taiwan National Health Research Institute. We categorized psychiatric disorders into four main disorders, including depression disorders, schizophrenia, anxiety disorders, and major depressive disorder recurrent episode. The prevalence of each psychiatric disorder before and after SCI was estimated respectively. McNemar's test was performed to compare the paired prevalence of each disorder before and after SCI.

Results: There was significantly higher prevalence after SCI than before SCI in depression disorders (12.1% vs. 9.2%, $P < 0.0001$), schizophrenia (1.4% vs. 1.1%, $P < 0.02$). It was significantly lower prevalence after SCI than before SCI in anxiety disorders (3.8% vs. 6.0%, $P < 0.0001$), and major depressive disorder recurrent episode (0.2% vs. 0.6%, $P < 0.001$). Among the subgroups of cognitive disorders, the prevalence of schizophrenia and other psychotic disorders was significantly elevated after SCI (2.1% vs. 1.4%, $P = 0.001$). Among the subgroups of mood disorders, the prevalence of Unspecified schizophrenia was elevated after SCI (1.4% vs. 1.1%, $P < 0.02$).

Conclusion: The prevalence of schizophrenia and depression disorders, and other psychotic disorders otherwise specified tended to increase after SCI. Our current study is a population-based study with a large, nationally cohort sample. The study showed that psychiatric disorders in patients may be associated with the development of spinal cord injury, and that this risk was more predominant in young patients. The comorbidities of chronic kidney disease, hyperlipidemia, this may have had an impact among spinal cord injury patients

Injury Factors and Medical Conditions of Motorcycle Riders Were Analyzed By Trauma Database in Taiwan

Pei-Ling Lee, MSN, RN, Taiwan

Chao-Wen Chen, MSN, Taiwan

Wen-Hui Hsiao, BSN, RN, Taiwan

Abstract

Purpose: According to the Taiwan Ministry of Health and Welfare announced in 2015, the accident death for the death of the Taiwanese ranked the fifth, and the average number of years lost in traffic accidents was 25.1 years. However, according to the Taiwan National Police Agency, from 2010 to 2015, the motorcycle of traffic accident in Kaohsiung City, the incidence was 18.7%, higher than the average.

Methods: To analyze the trauma registration database of one level I trauma center in Kaohsiung City, southern Taiwan. The cases were the motorcycle riders taking emergency medical treatment and hospitalization from 2010 to 2015.

Results: There were 5,819 cases. Males were 55.7% and females were 44.3%. The youngest was 11 years old, and the oldest was 98 years old. The mean was 42.7 years old. The way into the hospital by ambulance is 62.5%, by transferred from others is 24.4%. The 1st triage degree is 5.2%, the 2nd is 46.5%, and the 3rd is 46.4%. Occurrence time has two peaks, AM7-10 and PM5-6. Occurrence time is different from weekday and weekend. The top three of the incidence of blunting object are cars (38.7%), motorcycle (27.3%), and loss of control (24.8%). The deadly blunting objects were trucks (4.3%) and pedestrians (2.0%). The injury severity score (ISS) 1-8 score was 54.5%, 9-15 score was 30.2%, more than 16 score was 15.3%. ISS > 16 score mortality rate was 27.9%. The 97.5% was discharged and 1.6% was dead. The region of injured body were extremities > head/neck > chest. However, the major death factor was head/neck of AIS 4 or 5 score (57.8%). Among the deaths, patients with no helmets were 69.9%, and some with positive alcoholic reactions were 59.1%.

Conclusion: The result shows that wearing helmets and no drunk driving should promote for road safety. For the patients with head injury caused by traffic accidents should be further observed to promote the medical quality.

Teeth for Two: Oral Health in Pregnancy and Early Childhood

Erin Hartnett, DNP, CPNP, APRN-BC, USA
Judith Haber, PhD, APRN, BC, FAAN, USA

Abstract

Purpose: During pregnancy, changes occur in the oral cavity that may lead to oral disease. Poor oral health during pregnancy is associated with negative outcomes for mothers and their children. The purpose of this pilot project was to develop a standardized oral health curriculum to prepare Nurse Family Partnership (NFP) nurses to integrate oral health in home visits to high-risk, first time pregnant women and their children.

Methods: The NYU College of Nursing Oral Health Nursing Education and Practice (OHNEP) Program trained NFP nurses in Miami, Florida about oral health during pregnancy and early childhood using Cavity Free Kids (CFK), an evidence-based toolkit for integrating oral health into home visits. NFP nurses used the CFK oral health toolkit during home visits with first-time pregnant women and first-time mothers of children ages 0-2. Nurses and clients completed surveys (baseline, 30 and 90 days) to measure changes in oral health knowledge and practices. The nurse survey was self-administered through a web-based survey, and the client survey telephone-administered by trained interviewers. For the client data, changes across the three points in time were tested for statistical significance using a paired sample t-test.

Results: Following the intervention, there was an increase in the number of nurses including oral health content in their home visits. There was also a statistically significant increase in the number of clients reporting that they have received oral health education and referral.

Conclusion: Including oral health in NFP home visit curriculum is an effective way to positively influence the oral health self-care and child care practices of high risk pregnant women and children. NFP nurses meet with each first-time mom in 64 planned home visits until the child reaches two years of age, when the majority of primary teeth should have erupted. They are well suited to provide the parental education needed to reduce the number of dental caries children experience in their primary teeth. The main barrier to this is finding a place to include oral health in an already jam-packed curriculum. Increased awareness of the burden of oral disease in the United States and greater funding are needed to ensure that oral health becomes a standard component of the home visiting framework.

RSC PST 3 - Research Poster Session 3

Investigating Physical Activity and Exercise Motivation in Women With Systemic Lupus Erythematosus

Mei-Ling Wu, MSN, RN, Taiwan
Jen-Chen Tsai, PhD, RN, Taiwan

Abstract

Purpose: Physical inactivity lifestyles are common among systemic lupus erythematosus (SLE) populations. The purpose of this study was to investigate SLE women's level of physical activity and the type of motivation that is related to the amount of physical activity in order to design effective ways to improve physical activity.

Methods: This cross-sectional correlational study collected data from a medical center in Taiwan from August 2015 and July 2016. The study comprised 124 women with SLE who did not have physical limitations or psychiatric disorders, or other diseases that would prevent physical activity. All participants wore a pedometer for 7 days to monitor the level of physical activity and completed the demographic inventory and the modified Behavioral Regulation in Exercise Questionnaire (BREQ-2). Descriptive statistics and Pearson correlation were used to identify the levels of physical activity and the relationships between demographic variables, motivation and physical activity. Multiple regression analyses were further used to find predictive variables of physical activity.

Results: On average, the mean age and disease duration of participants was 43.5 ± 11.0 and 11.1 ± 7.7 years. The demographic data showed that 83 (67%) had a job, 87 (70%) were married, and 59 (48%) had a university or graduate education. Pedometer-determined physical activity classified by zone approach revealed that 47 (37.9%) were sedentary (<5000 steps/day), 46 (37.1%) were low active (5000-7499 steps/day), 21 (16.9%) were somewhat active (7500-9999 steps/day), 7 (5.6%) were active ($\geq 10,000$ -12,499 steps/day) and 3 (2%) were highly active ($\geq 12,500$ steps/day). Identified regulation and intrinsic regulation were significant correlate to both daily step ($r=0.25$; $r=0.3$, respectively) and moderate or vigorous intensity physical activity (MVPA) ($r=0.29$; $r=0.26$, respectively). None of demographic variables was correlated with exercise motivation and physical activity. Daily steps were only predicted by intrinsic regulation which explained 9% of the total variance. Moreover, MVPA was predicted by identified regulation which explained 8% of the total variance.

Conclusion: Results offered a feature of SLE population's low physical activity. To promote active life styles, exercise counseling could focus on how to elicit SLE women's intrinsic motivation and emphasize benefits of exercise to health.

RSC PST 3 - Research Poster Session 3

Factors Associated With Implementation of Early Goal-Directed Therapy in Septic Patients

Shu-Fen Lu, MSN, RN, Taiwan

Abstract

Background: Sepsis is a systemic inflammatory response that cause by infection and it is a continuously process. Sepsis common occur in critically ill patients. Surviving sepsis campaign guidelines in 2012 and 2008 have highlighted the importance of "initial resuscitation- six golden hours", which is the time point sepsis care bundle shall start. Before/ after sepsis care bundle started, we will compare the length of stayed in ICU, the days of hospitalization and mortality rate in patients with severe sepsis or septic shock.

Purpose: This study aims to explore the implementation of early goal directed against sepsis patient prognostic factors of treatment analysis.

Methods: The design of study was retrospective cohort study. We enrolled participants in the forty-two beds Medical & surgical intensive care unit of northern Taiwan. The inclusion criteria were the adult patients who admitted to the ICU from 2012 to 2014, and diagnosis of sepsis. The exclusion criteria were non-sepsis patients. The study tool is checklist of EGDT. Statistics analysis Statist using descriptive statistics presented participants basic information, t-test and chi-square test conducted observations, the outcomes by the logistic regression and survival analysis.

Results: This study recruited 838 patients of severe sepsis patients, including the implementation of early goal-directed therapy for the 687 patients implementation rate of 82%, which reached a total of 581 cases, 84.6% achievement rate. The impact of sepsis patients outcomes of disease severity, types of fluid and goal-directed therapy completion rates.

Conclusion: Achieved goal-directed therapy, the recovery of the initial intravenous infusion type and severity of illness related factors affecting the prognosis of patients with sepsis, it is recommended to enhance the implementation of health care compliance monitor of early goal-directed therapy. This study provides intensive medical care in performing clinical reference basis. This study provides critical care staffs to perform clinical reference basis.

Implication: Nurses play a critical role in the process of EGDT recognition, diagnosis, and treatment of sepsis. The SSC guidelines provide updated evidence-based practice recommendations that help to promote best practices for patient care. Critical care nurses' knowledge of the new guideline recommendations can help to ensure that patients with sepsis receive therapies that are based on the latest scientific evidence.

RSC PST 3 - Research Poster Session 3

Self-Reported Parenting Stress and Salivary Cortisol Following Mindfulness-Based Stress Reduction Intervention

Lisa R. Roberts, DrPH, MSN, RN, FNP-BC, CHES, USA

G. Griffin Boostrom, BA, USA

Salem Omar Dehom, MPH, USA

Cameron L. Neece, PhD, USA

Abstract

Purpose: To examine the correlation of self-reported stress and salivary cortisol, a stress biomarker.

Parents of children with developmental delays (DD) experience higher levels of stress than parents of typically developing children. Roughly one- to two-thirds of parents of children with DD experience clinical levels of parental stress (Davis & Carter, 2008). Children with DD have significantly more behavior problems, experience more emotional difficulties, and are more likely to have clinical levels of behavior problems than typically developing children (Emerson & Einfeld, 2010). Parenting stress and child behavior problems appear to have an interdependent, reciprocal relationship (Neece, Green, & Baker, 2012; Woodman, Mawdsley, & Hauser-Cram, 2015). This relationship, parenting stress and child behavior problems, appears to be responsible for the risks associated with the DD, rather than the delay itself (Herring et al., 2006).

Families of children with DD are susceptible to a range of comorbidities and associated risks including higher levels of parent stress associated with parental depression, more marital conflict, poorer parental physical health, higher child anxiety, poorer child social competence, poorer child emotional regulation, and increased likelihood of a child Attention Deficit Hyperactivity Disorder (ADHD) diagnosis. Additionally, the elevated levels of behavior problems associated with DD puts children at risk for developing future mental disorders such as ADHD and Oppositional Defiance Disorder (Anthony, Bormberg, Gil, & Schanberg, 2011; Baker, Neece, Fenning, Crnic, & Blacher, 2010; Eisenhower, Baker, & Blacher, 2009; Mathis & Bierman, 2015).

One way to intervene to reduce these risks is through mindfulness-based stress reduction (MBSR) with parents of children with DD. MBSR is an empirically based eight-week long training program designed to reduce stress through a series of standardized meditation practices (Kabat-Zinn, 1990). MBSR has been found to be feasible for parents of children with DD (Roberts & Neece, 2015), and has proven effective across multiple outcome measures. After the MBSR intervention, parents of children with DD report significantly less stress, greater practice and experience of mindfulness, increased parenting and life satisfaction, greater self-compassion and well-being, more social interactions with their children, better sleep, and lower levels of depression and anxiety (Bazzano et al., 2015; Dykens, Fisher, Taylor, Lambert, & Miodrag, 2014; Neece 2013; Singh et al., 2007; van der Oord, Bögels, & Peijnenburg, 2012). While children do not receive a direct intervention, children's outcomes after parents' completion of the MBSR training included significantly reduce behavior problems and increased social skills (Neece, 2014, Singh et al., 2007, van der Oord et al., 2012).

While these self-report and observational improvements are promising, the question arises if biologic measures can further validate these results. Cortisol levels and changes in cortisol levels over the first hour after awakening for the day are sensitive to anticipated demands of the day (Hibel, Mercado, & Trumbell, 2012). Among healthy adults salivary cortisol levels increase by 50 to >100% (Kudielka, Gierens, Hellhammer, Wüst, & Schlotz, 2012). However, this normal physiological response to awakening is significantly altered in individuals experiencing chronic stress (Chida & Steptoe, 2009), and provides a strong biological basis for measuring stress (Chida & Steptoe, 2009; Kudielka et al., 2012). Few studies have examined cortisol in conjunction with MBSR interventions (Dykens, Fisher, Taylor, Lambert, & Miodrag, 2014; Ruiz-Robledillo, Sariñana-González, Pérez-Blasco, González-Bono, & Moya-Albiol, 2015). We therefore set out to explore the association of self-report findings and cortisol response biomarkers to determine the physiological impact of the MBSR intervention on parenting stress.

Methods: We utilized a randomized, wait-list controlled design with baseline, pre-posttests and six-month follow-up assessments. Participants voluntarily chose to participate in salivary cortisol sample collections ($N=53$), and were part of a larger MBSR study involving parents of children with DD between the ages of 2.5 to 5 years. Measures included basic demographics, and Perceived Stress Scale (PSS) at baseline. Measures at pre-post and 6 months follow-up included Parenting Daily Hassles, Life Stressors subscale (PDH-LS), Self-rated stress at the time of saliva collection, and salivary cortisol measured as area under the curve ground (AUCg).

Results: There were no demographic differences between groups, therefore, results are reported for the combined groups. The majority of the parents participating were mothers (90.6%), married (79.2%), had more than a high school education (69.8%) and about half (50.9%) had a family income of less than \$50,000/year. At baseline the mean PSS score was 23.74 (SD 4.53).

Changes over time for PDH-LS, self-reported stress at the time of saliva collection, and AUCg were analyzed using repeated measures ANOVA, a mixed model procedure and Least Squares Means for missing data. Parenting daily hassles reported in terms of how often child and family hassles occurred were significantly reduced ($p = .012$), and though the intensity of the hassles trended in the desired it did not reach statistical significance. Self-reported stress was decreased at posttest and remained lower at follow-up but did not reach statistical significance. AUCg was reduced at each time point and highly significant ($p < .001$).

Conclusion: At baseline participants' mean PSS score indicates a high perception of stress (Cohen & Janicki-Deverts, 2012). After completion of the MBSR intervention, parents of children with DD reported significantly less parenting stress in terms of how often they experienced child and family hassles. They also reported reduced intensity of these hassles and reduced general stress. Parents' perceptions of reduced stress was validated physiologically in the significantly reduced AUCg. These biologic stress response reduction results were found both at immediate post-treatment, with sustained results on general stress at 6-months follow-up and continued further reductions of stress by all other measures. Results indicate that MBSR is effective for reducing parenting stress and general stress among parents of children with DD, reinforced by objective biophysiological data. Of note, biologic markers were even stronger than self-report which are more susceptible to mood changes. The reduction in parenting and general stress through MBSR is promising for this group of highly stressed parents of children with DD, decreasing the likelihood of child behavior complications as well as a myriad of parental comorbidities and poor mental health sequelae.

RSC PST 3 - Research Poster Session 3

A Grounded Theory Investigation Into Depression in Freshman College Students

Theresa A. Kessler, PhD, RN, ACNS-BC, CNE, USA

Abstract

Purpose: Freshman students may find adjusting to college a stressful experience. The stressors students face during this time of transition require the use of previously developed coping mechanisms, as well as the development of new strategies to effectively adjust to university life. Because adapting to these life changes may be challenging, freshmen college students are at risk of developing depressive symptomology. In a survey of 74, 438 college students in the US, 30.3% reported feeling so depressed it was difficult to function, and 42.0% reported feeling hopeless (ACHA, 2015). Consequences of unrecognized or untreated depression in adolescents can be significant. These consequences may include high-risk behaviors, poor academic performance, sleep disturbances, physical health problems, and suicidal ideation (Reeves & Riddle, 2014).

Based on the significance of this problem, the purpose of the study was to gain knowledge about the experience of living with depression as a freshman college student. The majority of the studies addressing adjustment to college have used quantitative data collection methodologies, thus, missing the richness of social processes surrounding this experience. By using grounded theory and no predetermined questions, students could freely discuss their experiences of living with depression as a college freshman.

Methods: Participants were recruited through scripted class announcements and flyers placed across campus which described the desire to learn about depression and adjusting to the first year of college. After providing informed consent, each participant completed an interview with the primary investigator. Each interview began with the same question: *What is the experience of your freshman year in college?* Every interview was audio recorded, transcribed verbatim, and reviewed by the primary investigator for accuracy. Using grounded theory, the research team analyzed each interview using constant comparative methodology. Data collection continued until saturation was achieved.

Results: A convenience sample of 12 sophomore-level college students from a Midwestern, private, faith-based university in the US participated. The sample consisted of 11 females and one male, with an average age of 19.92 years. Nine participants were Caucasian, two were Hispanic, and one was African American.

Following analysis of the data, four major themes related to living with depression as a college freshman emerged. These themes include expression of stress, changes in eating habits, sleep issues, and procrastination/putting things off. Descriptive examples of each of the themes were found throughout the interview data. These themes reflected the participants' perceptions of their freshman year in college. The descriptors suggested the emotional, social, physical, and behavioral responses to what is perceived as depression. Through individual reflections, students also described how these themes were connected to form the process of living with depression their freshman year.

Conclusion: With a greater understanding of the experience of living with depression as a freshman college student, nurses and other mental health professionals will have additional evidence to guide their professional practices. The results of this study may provide additional insight into prevention strategies to help college students move successfully through the freshmen experience.

Difficulties Associated With the Support for Autism Spectrum Disorders (ASD)

Yasuko Koyano, PhD, RN, PHN, Japan
Hiromi Watanabe, MSN, RN, PHN, Japan

Abstract

Purpose: The objective of this study was to identify the difficulties experienced by staff members providing autism spectrum support services in psychiatry day-hospitals and community institutions for persons with psychiatric disabilities.

Methods: A self-administered questionnaire survey was conducted of staff members of WAM NET-listed day-hospitals and community institutions for persons with disabilities in Japan. The questionnaire contained items to determine the experiences, difficulties, views, and other related issues to autism spectrum support services.

Results: A self-administered mail-based questionnaire survey was conducted with 1561 workers involved in support for adolescents and adults without intellectual disabilities at 1561 institutions for disability aid and psychiatry day- hospitals. The response rate was 17.9%. A total of 251 responses to the questionnaires were collected and the data was analyzed.

The percentage of staff who had participated in specialized training programs was 72.4%, and 92.2% of the support to persons with ASD. The difficulties were related to the behavioral characteristics of the care receivers (48.9%), coordination among care users (25.1%), support development (24.9%), and responses of the family and from the workplace (15.1%). In addition, 89.4% of the staff predicted that the support for persons with developmental disorders in psychiatry day-hospitals would increase in the future.

In order to improve communication with users, the staff provided with some devices: to emphasize important information (55.5%), to give users concrete instructions(36%), to allow them to visualize their schedule (28.1%), and to utilize memos (19.1%), pictures, and photographs (15.8%). Of the respondents, 98.6% felt the need for support to the staff, and the types of support that many of the respondents wished for were case studies (39.3%) and study meetings to allow them to acquire medical knowledge (31.7%).

Conclusion: Currently, staff providing support to subjects with Autistic Spectrum Disorders have access to other persons that can give them support and that they can consult with, and are therefore able to participate positively in training programs, however, they still face some difficulties. For psychiatry day-hospitals and community facilities where increase in the numbers of adolescents and adults having ASD without intellectual disabilities are expected, a better understanding of persons with ASD by the staff providing care and improvements in concrete support skills may be necessary.

Postpartum Contraceptive Use Among Adolescent Mothers in Thailand

Punpilai Sriarporn, PhD, RN, Thailand
Rudee Pungbangkadee, PhD, RN, Thailand
Saowanee Liamtirat, MNS, RN, Thailand
Patchaneeya Chiengta, MNS, RN, Thailand
Prueksalada Khiaokham, MNS, RN, Thailand
Idchayar Monsaeng, MNS, RN, Thailand

Abstract

Introduction: In Thailand, an average of 355 women under the age of 20 give birth every day, 10 of whom are less than 15 years old (Public Health Statistics, 2012; Bureau of Reproductive Health, Department of Health, 2013). In 2012, 11.7% of mothers aged 15-19, or 6.4 per 1,000, gave birth more than once or were pregnant for a second time before they reached the age of 20. According to the Ministry of Public Health, over the nine-year period between 2004 and 2012, repeat birth rates among 15-19 year olds increased from 4.9 per 1,000 adolescents, peaked at 6.4, then subsequently decreased to 6.2 in 2012-2013. Repeated pregnancy in postpartum adolescents is a crisis that affects their physical and psychosocial well-being. The consequences of repeat pregnancy are significant for adolescents and society. Repeat adolescent pregnancy implies a failure in reproductive health services, especially in terms of advising adolescent mothers to start using birth control immediately after giving birth. Previous studies have found several factors associated with repeat pregnancy among adolescents. These include inconsistent contraceptive use, lower educational achievement, and an unsupportive family member. Use of highly effective contraception in the postpartum period can reduce the risk of rapid repeat pregnancy among sexually active mothers. Research on adolescents' postpartum contraceptive use has been limited to adolescents living in Northern Thailand. Little is known about the use of contraceptives, knowledge and attitudes toward contraceptive methods and the factors that influence contraceptive use among Thai adolescent mothers.

Purpose: The purpose of this exploratory study was to use qualitative methods to better understand contraceptive use among Thai adolescent mothers. In-depth interviews were used to understand the factors influencing adolescent mothers' postpartum contraceptive use. Qualitative research is well-suited to explore complex phenomenon like contraceptive use because it provides rich contextualized data and can capture important variations among individuals. In-depth individual interviews in particular can illuminate participants' perspectives and experiences as well as the social context that shapes them. Because adolescents' contraceptive use before pregnancy is strongly associated with their use afterward, this study focuses on learning more about contraceptive use before pregnancy.

Methods: Participants - The participants were 26 adolescent mothers in intermediate postpartum hospitalization. Data were collected at four hospitals in Northern Thailand, during June to November 2015. The sample size was determined by data saturation as is appropriate for qualitative research. All participants and their parents provided written informed consent. This study was approved by the Chiang Mai University Faculty of Nursing Research Ethics Committee.

Procedures - The research instruments included a semi-structured interview guide, which explored a broad range of contraceptive use before pregnancy and after birth, including contraceptive use, knowledge about contraceptive, attitudes and intentions toward contraceptive use after birth. Interviews were conducted privately in a separate room, and participants were encouraged to speak freely about their opinions. Interviews lasted approximately 30 to 45 minutes.

Data analysis - Interviews were recorded using a digital audio recorder and the co-facilitator took notes. Audio files were transcribed verbatim by the investigative team immediately after interview completion. Data were categorized using content analysis. Emergent themes were identified. Descriptive statistics were used to characterize the participants.

Results: The median age of participants was 17 (range 15-19); the mean age was 17.27. All (100%) participants were primigravid. Twenty-four participants (92.31%) used contraception at the time of conception, whereas, two participants (7.69%) did not use any contraception. Twenty participants (76.92%) reported that the pregnancy was unplanned.

The five contraceptive methods used included condoms, birth control pills, contraceptive injections, external ejaculation, and emergency contraceptive pills. The majority of participants reported that a lack of knowledge and misinformation about sex, reproductive health, and contraceptive methods contributed to adolescent pregnancy. Some participants did not know how to take birth control pills and inconsistently used other forms of contraception. Reasons given included forgetting to use contraception or that condoms reduce pleasure for the male. Some participants believed that external ejaculation prevented pregnancy. Participants noted that they often lacked adult supervision because of their parents' work situations, leaving them on their own without productive activities. Other factors such as the media, alcohol, and stigma of abortion were contributing factors to adolescent pregnancy. Participants reported that convenience, perceived effectiveness, familiarity, and side effects were the primary reasons for selecting or changing a method of contraception postpartum and recommended several methods of promoting contraceptive use among adolescents.

Conclusion: The findings from this study indicate that patterns of contraceptive use among adolescent mothers place them at high risk of rapid repeat pregnancy. Understanding adolescent mothers' contraceptive use and the influencing factors is important for developing effective program for interventions.

Experience of Being a Young Adult Who Abstains From Alcohol Consumption

Luz Patricia Diaz Heredia, PhD, MSN, RN, Colombia

Abstract

Purpose: This work sought to understand the meaning of the experience of being a young adult who abstains from consuming alcohol.

The phenomenon of alcohol consumption in the young adult population in the world, Latin America, and Colombia has evolved in recent years and is currently a social, public health, political, and economic problem that affects youth and society (1).

Non-consumption as the result of therapeutic processes has been described and its components indicated in individuals who have had alcohol addiction problems, but little is known on the factors that mediate non-consumption in those who have never done it (2). Understanding the significance of the experience of not consuming alcohol within a society that promotes consumption is important because it will permit promoting healthy lifestyles in young adults (3). Youth is a period in life when higher degrees of consumption and addiction are established or when healthy behaviors are structured (4). Nursing, by being a practical discipline with orientation and social commitment, can contribute to knowledge in the area of addictions by recognizing these components seen from the potentiality of the people under their care. This study sought to understand the meaning of the experience of being a young adult who does not consume alcohol in a university setting

Methods: This was a qualitative research with phenomenological approach conducted from an interpretative perspective (Van Manen), used to collect qualitative data through the application of an in-depth interview. To the moment, three informants have been interviewed, who were intentionally invited because they were members of a university community. The interviews were recorded and these lasted between 40 minutes and one hour. The informed consent was signed, maintaining the ethical principles of research with human beings.

Van Manen indicates that the method is aimed at: 1) concentrating on a phenomenon that is truly of interest and which is committed with the world; 2) researching the experience on the way it is undertaken and not on how it is conceptualized; 3) reflecting on the essential aspects that characterize the phenomenon; 4) describing the phenomenon through the art of writing and rewriting; 5) maintaining a solid pedagogical relation with the phenomenon and aimed at it; and 6) balancing the context of the research, always considering the parts and the whole (5).

Results: The analysis performed permitted identifying two large themes: *recognition of the importance of caring for the body*; in this sense, the body is conceived as a good that must be protected and not damaged with alcohol. It is recognized that alcohol is harmful to physical and spiritual health, affects the person's performance, making them carry out actions that no good to them or to society. It is noted that not consuming helps with self-care and promotes wellness.

"How am I going to damage my body? I conceive that body and soul must be in harmony and try to eat well, avoid consuming things that harm me; if one has the integral conception of spirituality, one avoids excess". (e1, p1 r 17)

"My character is quite strong; I say I don't do it and don't because I have high self-esteem". (e 3, p 4 , r 17)

"Suddenly you note what is caused by excessive consumption, like accidents, abuse, how some men are transformed and you see some women being hurt by men when they are drunk. I experienced it myself and got very violent. And I don't feel secure when I drink". (e 3, p 3, r 18)

“Because if there are no drinks in the party, the party is bad because I don’t always need to feel drunk to get disinhibited, because I feel okay with myself and can be spontaneous without drinking”. (e1, p 4, r 11)

“I feel I enjoy the party or reunion if I am sober”. (e 3, p 2,r 16)

The other theme is *feel well with themselves when they are responsible for their actions*, they have the opportunity of acting freely and being responsible and aware of themselves. Alcohol can be considered a buffer to stressful situations, but when it is not consumed one is completely capable and one has power over issues of life, in addition to enjoying more. One has clarity and the possibility to make decisions without pressure and subsequent feelings of guilt.

“...it has to do with the theme of responsibility because it becomes sort of a way to atone guilt in alcohol, which makes no sense that even legally, that is, when you decide to start drinking; that is where your decision is and when you must assume all the consequences. It even seemed interesting to me that people drank as if engaging in the exercise of drinking, in other words, I make decision to drink with all the consequences this brings, whether good, bad and whatever, but it is not so, it is like a thing of inertia”. (e2, p6, r20)

Conclusion: This partial result permits evidencing that significance constructed is in line with the value individuals have of their own being, of their capacity to control situations, and of their responsibility with themselves and with life.

Further information must be collected to more completely understand the meaning.

The Effect of the Program "Don't Bite Your Nails, Cut Them" Behavior of Biting

Kamer Gur, PhD, Turkey
Saime Erol, PhD, Turkey
Nur Incir, RN, Turkey

Abstract

Purpose: The purpose of this study is to show the effect of the program "Don't Bite Your Nails, Cut Them" in changing the nail biting behavior.

Methods: The population of the study, conducted with pretest/posttest quasi-experimental design, consisted of 299 students who were studying in the first and fourth grades of a primary school located in Istanbul in 2015 (N=1083), had nail biting (n=339), and were voluntary to participate in the study, and whose parents gave consent. The data of the study was collected by using the questionnaire of descriptive information and independent variables, "schedule for follow-up of the nail biting behavior", and the photographs of hands.

Process of the Program "Don't Bite Your Nails, Cut Them";

- **First Stage;** the students and teachers were informed about the purpose and the process of the program. The students' nails were assessed in the classroom and those with nail biting behavior were determined. These students and their parents were invited for participation in the program.
- **Second Stage;** The data collection forms were applied on the students and their parents. The schedule for follow-up of the nail biting behavior was delivered to them and the photographs of their hands were taken.
- **Third Stage;** A training on nail biting behavior was provided to the students and their parents and brochures were delivered.
- **Fourth Stage;** The changes in the nurse students' nails were compared by examining a former photograph taken once a week and counselling was provided by making assessment according to schedule for follow-up of the nail biting behavior.
- **Fifth Stage:** The posttest was applied.
- **Impressions;** After the posttest, the students were followed up with the schedule for follow-up of the nail biting behavior and photographs three times. The successful students were given certificates.
The data of the study were evaluated by using descriptive statistics (numbers, percentages) and Mc-Nemar Test.

Results: When the pretest and the third follow-up were compared as a result of the program "Don't Bite Your Nails, Cut Them", it was observed that those not biting their nails today increased from 32.1% to 78.2% and those cutting their nails increased from 0.66 to 81.9% ($p < 0.001$). Those picking and removing their nails decreased from 66.2% to %22.4, and those picking and biting their nails decreased from 61.2% to 7.6%, and those picking and removing only their cuticle decreased from 64.8% to 14.7% in a statistically significant manner ($p < 0.001$).

Conclusion: The program "Don't Bite Your Nails, Cut Them" had a positive effect in decreasing the nail biting of students. It can be recommended for the school nurses to implement the program.

RSC PST 3 - Research Poster Session 3

Nursing Students' Attitudes Toward Complementary and Alternative Therapies for Stress Relief

Elizabeth V. Kinchen, PhD, RN, AHN-BC, USA

Victoria W. Loerzel, PhD, RN, OCN, USA

Abstract

Student nurses' experience of stress while enrolled in educational programs is well-documented in the global literature (Cleary, Horsfall, Baines & Happell, 2012; Fornes-Vive, Garcia-Banda, Frias-Navarro & Rosales-Viladrich, 2016; Galbraith, Brown & Clifton, 2014; Graham, Lindo, Bryan & Weaver, 2016; Suresh, Matthews & Coyne, 2012); however, strategies to alleviate, manage, and cope with education-related stressors have not been fully explored.

Stressors to which nursing students are particularly vulnerable can have significant effects on ability to navigate educational and clinical environments, often contributing to 'burnout', dissatisfaction, and attrition in the profession (Asuero, Queralto, Pujol-Ribera, Berenguera, Rodriguez-Blanco & Epstein, 2014). In addition, the demands of didactic and clinical education leave little time for faculty to directly teach students self-care strategies.

Interventional strategies used by students to alleviate educational stress may take the form of pharmaceutical, psychological, or behavioral therapies. Yet there is a growing body of knowledge regarding the use of complementary and alternative modalities (CAM) for stress-related challenges in nursing programs (Escuriex & Labbe, 2011; Galbraith & Brown, 2011). Mindfulness programs, particularly meditation and yoga, are garnering interest as alternatives to established interventions, especially pharmaceutical preparations, which are costly and potentially problematic in clinical and educational environments.

Purpose: This study reports secondary analysis of qualitative data from a larger study exploring the use of, and attitudes toward, yoga and CAM on stress and quality of life in nursing students.

Methods: A convenience sample (n=80) of undergraduate nursing students in a southeastern U.S. university was invited to complete study surveys via email. Inclusion criteria included being age 18 or older, able to speak and read English, and in nursing classes at the time of study start date. Baseline data were collected using an investigator-developed instrument to explore participants' experience with, and attitudes toward, yoga and complementary practices as stress-relieving therapies. Demographic data obtained from participants included age, gender, and race/ethnicity. Content analysis was used to analyze data.

Results: Data reveal that nursing students are open to the use of complementary therapies, that they employ a variety of such therapies to relieve, manage and cope with stress, and that they perceive CAM to have a positive impact on personal health. Themes identified in the data regarding CAM impact include self-empowerment, relaxation and restoration, mind/body/spirit/emotion, and alternative/complement to traditional medicine.

Conclusion: Student nurses experience a variety of stressors in nursing programs, and use a variety of strategies to relieve, manage and cope with stress. Data support the importance of CAM in dealing with educational stressors, and highlight the need for further research on individual CAM therapies in student nurse populations.

The Effect of Safe-Movement and Walking Program on Reducing the Fear of Falling in Elderly

Gulcan Kar, PhD, RN, Turkey
Saime Erol, PhD, Turkey

Abstract

Purpose: The aim of this study is to determine the effects of “Safe Movement and Walking Program” on reducing the fear of falling in elderly individuals living in a nursing home.

Methods: The study was carried out in a nursing home in İstanbul between November 2012 and April 2013 in a quasi-experimental research design with the pretest and posttest groups. The population of the study consists of 73 individuals who were volunteers for the research, aged 65 and above, having mental scores higher than 24 and were able to move themselves or with the help of walking aids. Those participants were randomly assigned to experimental (n=37) and control (n=36) groups. Elderly Information Form, Tinetti Falls Efficacy Scale (FES), Elderly Falls Behavioral (FaB) Scale and Tinetti Balance and Gait Assessment Form (BGAF) were used as a data collection instrument. Data was collected by the researchers and volunteer participants were educated using the methods of face to face interview and observation before and just after the application of the program and 3 months later. The content of “Safe Movement and Walking Program” was prepared in order to reduce the individuals’ fear of falling and make them able to take their own precautions within the literature studies. The topics such as “Falling”, “the Fear of Falling”, “Safe Movement”, “Physical Activities and Walking” were provided to the participants in groups of 8-10 in a six-week schedule. Verbal lecture, barcoveision, catechism, sample case, observation, interview and demonstration methods were used in the education program and an educative booklet was also provided for each participant after the program. Student 1 and Mann-Whitney U test were used in the evaluation of the obtained data. The analysis of variance was used in repeated measures and Bonferroni test was used within group comparisons.

Results: The “Fear of Falling” scores showed no difference between the experimental and control groups in either pretest or posttest, as well as the follow-up observations. Scale scores remained the same in the control group ($p>0.05$) whereas it increased in the experimental group which is statistically significant. The average scores of Tinetti Falls Efficacy Scale showed no difference between the experimental and control groups in all of the three measurements ($p>0.05$). A statistically significant difference in experimental group in the pretest, posttest as well as the follow-up observations ($p<0.05$). The total score of Elderly Falls Behavioral (FaB) Scale and the sub scale scores of Cognitive Accommodation, Activity, Avoidance, Awareness, Practicability, Level Change, Catching up Phone Calls and Carefulness were measured higher ($p<0.05$) than the scores of the control group for the mentioned topics above. The levels of the sub scale scores of the elderly individuals about taking a walk tirelessly for 30 minutes and starting regular walking in last 6 months were measured higher ($p>0.05$) than the scores of the control group.

Conclusion: The program showed no efficacy in reducing the fear of falling whereas it is found helpful in the affairs such as taking a walk for 30 minutes each day, avoidance of falling, foreseeing the dangers in falling and planning. In order to reduce the fear of falling, it can be proposed that thorough interviews can be carried out, awareness raising applications can be done and coping strategies about fear can be taught to the elderly.

The Association of Health Literacy, Understanding of Health Information, and Food Choice in Female Caregivers

Sukhee Ahn, PhD, RN, WHNP, Korea, Republic of (South)

Jiwon Oh, MSN, RN, Korea, Republic of (South)

Jisoon Kim, MSN, RN, Korea, Republic of (South)

Seyeon Park, MSN, RN, Korea, Republic of (South)

Hyeji Yoo, BSN, RN, Korea, Republic of (South)

Abstract

Purpose: Female caregivers play an important role to take care of their family health and food choice when one of family members is sick. Caregivers with inadequate health literacy skills have been shown to have poorer understanding of anticipatory guidance such as healthy food choice. Little is known about the relationships among health literacy, understanding of health information, and food choice in female caregivers at hospitals. This study was to explore the relationships among health literacy, understanding of health information, and food choice in female caregivers of adult patients in Korea.

Methods: Using a cross-sectional survey design, 217 female caregivers were recruited from 5 hospitals via convenience sampling. Health literacy was measured by 6 items of Newest Vital Sign (NVS). Understanding health information was measured by 8 items of Mandarin health literacy scale (Lee S-YD, Tsai T-I, Tsai Y-W, 2013) from National Health Research Institutes. Food choice was measured by 12 items based on USDA Diet and health knowledge survey.

Results: Mean age of female caregivers were 44.52 years old (SD=12.25) and 46% graduated college and above, and most of them (68%) were wife. Level of health literacy was 3.62(SD=2.09) ranged from 0 to 6 indicating inadequate level. Correction rates for NVS items to measure health literacy was wide ranged from 26% to 80%. Level of understanding health information was about 3 point out of 5 indicating greater need for further explanation. They believed to have strong relationships between illness and food nutrients such as calories, trans-fat, cholesterol, and sodium. However, only 31% of women read food label. Women's better health literacy and greater perceived benefit of healthy diet pattern were associated with better food choice.

Conclusion: Female caregivers reported inadequate health literacy but they believed illness and food nutrients were highly related. Health literacy and healthy food choice were related. Health education and counseling for female caregivers may help promoting women and their family health.

Fact-Finding Survey of Defecation Behavior in Young Japanese Adults

Megumi Katayama, PhD, RN/PHN, Japan

Yoko Aso, PhD, RN/PHN, Japan

Aki Ibe, PhD, RN/PHN, Japan

Osamu Katayama, PhD, Japan

Hiroko Matsuzawa, MSN, RN, Japan

Abstract

Purpose: Defecation is an act that is essential to maintaining biological activity and is a basic physiological need in humans. Spending one's daily life without discomfort or hindrance to defecation is also associated with quality of life. Several past surveys of defecation have focused on constipation and fecal incontinence, and many surveys have focused on the presence or absence and causes of constipation. However, the postures that individuals adopt when independently performing defecation behavior, and behaviors that have been devised to facilitate defecation remain unclear. The purpose of this survey was to clarify the state of defecation behavior and coping behavior for constipation in young adults

Methods: Survey subjects - A total of 300 healthy university students at a nursing faculty.

Survey period - December 2015

Survey method - We created a proprietary self-administered questionnaire in which subjects could fill out information on their experience of constipation, posture during defecation, behavior during defecation and other facts. The questionnaires were distributed to subjects at once and recovered using a collection box in which subjects voluntarily submitted their questionnaires. To avoid coercion of subjects during distribution and recovery of the questionnaires, an investigator with no connection to the allocation process of students' academic credits was assigned to distribution and recovery.

Survey details - Survey items included age, sex, pattern of defecation frequency, the Constipation Assessment Scale (CAS), use of constipation prophylaxis, methods of coping with constipation, use of laxatives, style of toilet, ease of defecation based on the style of toilet, time required for one defecation, fatigue after one defecation, defecation posture, and means of facilitating defecation.

Analysis method - 1) Percentages were tallied up for age, sex, use of constipation prophylaxis, use of laxatives, defecation style, and ease of defecation based on defecation style. 2) Subjects were divided into two groups based on the pattern of defecation frequency: a constipation group who "did not defecate for 3 days or more" and a normal group comprising all other subjects. Subjects were also divided into two groups based on the CAS: a constipation group who scored at least 5 points and a normal group who scored less than 5 points. The CAS incorporates a subjective sense of constipation, which was considered in line with the purpose of this survey. To evaluate fatigue after defecation, subjects were asked to indicate on a visual analog scale (VAS) how fatigued they felt. A VAS score of 0 denoted "Almost no change," a score of 50 denoted "Mild sense of muscle fatigue," and a score of 100 denoted "Either general muscle fatigue, malaise, shortness of breath or other sensation." Those who scored below 50 were allocated to a "low fatigue group" while those who scored over 50 were allocated to a "strong fatigue group." For defecation posture, subjects were divided into three groups: an "upright 90° posture group," "forward leaning group" and "belly-to-thighs group." For defecation time, subjects were divided into 5 groups: a "1-2 minutes group," "3-5 minute group," "6-9 minute group," "10-15 minute group" and "15 minutes or more group." These groups were used to test for statistical differences by using chi-square tests. As "means of facilitating defecation" and "methods of coping with constipation" were open-ended questions, their content was categorized to examine trends.

A *p* value of less than 0.05 was considered to indicate a significant difference in statistical processing, which was done using the statistical software SPSS Ver. 23.

Results: Of the 300 questionnaires that were distributed, 258 were recovered (recovery rate: 86%). The subjects were 30 men and 227 women: the ratio of men and women was 12% and 88%, respectively. The mean age of subjects was 20.5 ± 1.42 years.

The defecation frequency was daily in 51%, every 2 days in 24%, every 3 days in 19% and every 3 days or more in 6% of subjects. CAS scores were 5 points or below in 75% and 6 points or more in 25%. Constipation prophylaxis was used by 47% and not used by 53%. Coping methods were used during constipation by 51% and not used by 49%. Laxatives were used by 10% and not used by 90%. Among those who answered that they used coping methods, 85% described specific methods. Of these methods, laxatives were used by 10%. The style of toilet used was a Japanese-style toilet in 1% and a Western-style toilet in 99%. In response to "ease of defecation based on the style of toilet," 14% responded with a Japanese-style toilet and 86% responded with a Western-style toilet. Defecation time was "1–2 minutes" in 31%, "3–5 minutes" in 40%, "6–9 minutes" in 15%, "10–15 minutes" in 11%, and "15 minutes or more" in 3%. The fatigue score was 50 or below in 86% and over 50 in 14%. The defecation posture adopted was "90°" in 19%, "forward leaning" in 76% and "belly-to-thighs" in 5%.

Significant statistical differences were seen between CAS score and coping methods during constipation ($p < 0.01$), CAS score and use of medication ($p < 0.01$), CAS score and defecation time ($p < 0.05$), CAS score and defecation posture ($p < 0.01$), fatigue and defecation time ($p < 0.01$), and defecation posture and fatigue ($p < 0.05$).

Means of preventing constipation were often described as associated with diet, such as "eating vegetables," "eating yogurt" and "consuming plenty of fluids." Subjects also described conscious defecation behavior, such as "immediately going to the toilet upon feeling the urge to defecate" and physical maintenance including "jogging" and "getting a massage." Methods of coping with constipation were mostly the same, but included methods such as "taking laxatives" and "applying heat."

Means of facilitating defecation during constipation included moving the body such as "crossing legs," "raising heels," "pressing on the tailbone," "twisting the stomach" and "making a fist," but also included physical methods, such as "holding onto handrails," "placing feet on a low platform," "stimulating the anus with a washing machine," and "pushing against the wall with the feet."

Conclusion: CAS scores of at least 5 points in 25% of subjects revealed that a quarter of the students surveyed felt that they were constipated. We also found that many students employed some kind of coping method when they felt constipated. Some subjects relieved constipation by taking oral laxatives, which were used by 10% of all subjects. Those with higher CAS scores tended to be more likely to use laxatives. While laxatives were used as a coping method by 10% of subjects, the remaining 90% used other methods. This revealed that the majority of subjects coped with constipation by means other than medication. The fact that the subjects of this survey were young adult students studying nursing who had knowledge of medications and strong awareness of health may have influenced the results.

As for defecation postures, the majority of subjects adopted a forward leaning posture, which is consistent with a posture considered to morphologically facilitate defecation. This fact-finding survey investigated the postures that people naturally adopt to facilitate defecation and revealed that people adopt a logical posture.

In this survey of healthy adults, 86% of subjects experienced "mild fatigue from defecation," indicating that many subjects felt fatigued after defecating. However, results may differ in elderly people with diminished muscle strength required for defecation and in patients undergoing treatment for heart disease or cerebrovascular disease that restrict actions such as straining during defecation. We intend to continue investigating defecation behavior in such subjects.

RSC PST 3 - Research Poster Session 3

Uncovering Issues Most Important to Parents After Their Child's Suicide Attempt: A Comparison Study

Kari Lynne Hickey, PhD, RN, USA

Jeanette Rossetti, EdD, RN, USA

Jan Strom, PhD, MPH, RN, USA

Kendal Klein, BSN, RN, USA

Abstract

Purpose: The purpose of this presentation is to compare two studies that surveyed adolescent mental health experts practicing in a suburban and rural setting on their perspectives as to what matters most to parents after their child has made a non-lethal suicide attempt.

Methods: A Delphi technique was utilized with an interdisciplinary panel of adolescent mental health experts in a suburban and a rural mental health setting. Inclusion criteria for the expert panel were over the age of 18 and clinically worked with adolescents who have made a non-lethal suicide attempt and their families. First round questions asked the panelists to provide their opinions as to what matters most for parents whose child has made a non-lethal suicide attempt, what are the needs of parents whose child has made a non-lethal suicide attempt, and what are the current treatment interventions for parents whose child has made a non-lethal suicide attempt.

Using the constant comparative method, two researchers analyzed the data for emerging themes. The themes from each questions were then returned to the participants in a second survey. They were asked to rank the importance of each theme on a 5 point Likert scale (1, very important; 2, quite important; 3- neither important or unimportant; 4- quite unimportant; 5- very unimportant).

Results: 31 total participants from a suburban setting and 18 from the rural setting completed both rounds of the surveys. Professional titles of participants included registered nurse, clinical therapist, social worker, behavioral health associate, and advanced practice nurse.

Both groups indicated that keeping their child safe, understanding what caused the attempt, and how to access support was very important for parents after a non-lethal suicide attempt. Both groups also thought the most important need for parents is education on how to prevent another attempt. In regards to treatment interventions, both groups noted therapy (individual and family) and support groups; however, the rural providers emphasized the Screening, Assessment, and Support Services (SASS). From comparing these two groups of adolescent mental health providers, it was clear that rural providers highlighted the use of SASS as part of the treatment team. Rural providers also consistently cited the need for accessible resources and support. The provider mix of both groups included substantially fewer registered nurses in the rural group.

Conclusion: It is clear from the opinions of the adolescent mental health practitioners that safety of their child is a priority concern of parents after their child has made a non-lethal suicide attempt. This finding may indicate that professionals working with these parents must address the safety concerns before continuing with other therapeutic interventions. Data from both the studies will inform a qualitative research study utilizing focus groups with parents of adolescents who have made a non-lethal suicide attempt to uncover what issues are most important to them.

An Emergency Department Nurse-Led Educational Intervention of Bystander Hands-Only Cardiopulmonary Resuscitation in the Homeless Community

Caroline Warren, BSN, RN, CHES, USA

Diana Lyn Baptiste, DNP, MSN, RN, USA

Abstract

Purpose: An estimated 360,000 out-of-hospital cardiac arrests (OCHAs) occur each year in the United States. Individuals living in low socioeconomic neighborhoods and members of the homeless population are at a higher risk for death due to cardiovascular complications. Homeless individuals experience cardiovascular deaths at a higher rate due to inequities related to a lack of access to preventative and routine health care. According to the U.S Department of Housing and Urban Development, there are 7,856 individuals who are without homes in Maryland. Of the individuals experiencing homelessness in Maryland, 22% are considered habitually homeless and demonstrate a high burden of disease including chronic health problems, substance abuse, and mental illness. Cardiovascular disease and related complications are the leading cause of death in the state of Maryland, stimulating concern for the how healthcare professionals manage this problem among the homeless who are disproportionately affected.

The aim of this community-based health education project was to evaluate the feasibility of the implementation of an emergency nurse-led bystander cardiopulmonary resuscitation (CPR) education program for homeless adults in Baltimore. The goal of our education program was to address individual and community health needs by providing instruction of best practice with hands-only CPR to homeless individuals in a transitional setting. We conducted a pilot evaluation of the implementation of hands-only bystander CPR education sessions in the East Baltimore Homeless Community aimed at developing strategies for future sustainable emergency nurse-led programming.

Methods: We conducted a pilot evaluation of the implementation of hands-only bystander CPR education sessions in a homeless shelter aimed at developing strategies for future sustainable emergency nurse-led programming. The setting for this study was a low barrier emergency shelter located in Baltimore, Maryland that offers services to more than 275 adults. This shelter is managed by Catholic Charities of Baltimore and sponsored by the city of Baltimore. Residents of the shelter are encouraged to attend classes like this bystander CPR education session by the on-site counseling staff and are incentivized for their attendance through the shelter's self-sufficiency development programming. The class size was limited to 10 participants so they each could have their own CPR manikin. Our Institutional Review Board deemed this study as non-human subject research and exempt from review.

Instruction was provided by volunteer registered nurses who practice in the adult emergency department in a Level One urban academic medical center that sees 70,000 patients annually. Instructional methods were based on the program American Heart Association's (AHA) Hands-Only CPR curriculum. Hands-only CPR is to be implemented when a teen or adult collapses in an everyday setting and then a trained bystander can initiate the two basic steps which includes starting compression-only CPR (i.e. no mouth-to-mouth breaths are administered). The education program delivered to participants was based on teaching two basic steps to responding to a cardiac arrest, 1) call 911, and 2) "push hard and fast at the center of the chest." Nurses first demonstrated hands-only methods on manikins and provided real-life scenarios in which OCHAs can occur. A focus of this program was to gain the participant's trust of emergency services with the instruction given by emergency nurses who could advocate to create a culture of health and promote a change to increase community safety.

Results: A total of 52 people were trained over seven sessions with the emergency nurse volunteer instructors. Each session lasted for 30 minutes, with a total of 10 volunteer impact hours. Our highest attendance was during the code blue alert months October through March. A total of 32 participants attended during code blue months while 20 attended during non-code blue months. A 64% difference in attendance was apparent. Attendance was lower during the warmer months, when residents were typically less likely to participate in community-based education programs at the shelter.

Conclusion: The AHA Hands-Only CPR curriculum is simple to teach and designed for populations with varying levels of health literacy. The straightforwardness of the hands-only course allows for the educators to specifically target people who live in low-income neighborhoods and communities with an increased risk to die from cardiac arrest. Attendance to this program in-house at the shelter was voluntary, but there was some internal motivation for attendance. We discovered that while many residents were interested in attending the session, the timing often created a scheduling conflict with their other required programs. Through this experience, we learned that it is important to consider the time of the day so that residents can attend other required programs and obligations to shelter rules. Further investigation is necessary to explore learning outcomes, knowledge and attitudes among the participants receiving the hands-only bystander CPR education.

Helping Relationships Intervention Enhances Health-Promoting Lifestyle and Quality of Life

Miaofen Yen, PhD, RN, FAAN, Taiwan
Shu-Mei Chao, MSN, MS, RN, Taiwan

Abstract

Purpose: This study examined the effects of a targeted helping relationships strategies improved quality of life, health-promoting lifestyle behaviors, renal protection knowledge, and physical indicators of patients with early CKD. Helping relationships from significant others, including understanding, caring and coach to assist people to act and maintain health promotion, which is a positive behavior to prevent disease or solve health problems for increasing health and approach to wellness. The trans-theoretical model (TTM) has become increasingly influential as a framework for understanding health-related behavior and directing efforts in health promotion. Whether helping relationships from significant others of TTM are effectively associated with the processes of healthy lifestyle modification among patients with CKD is still unknown, and this study addresses this gap in the literature.

Methods: A repeated-measures design randomized 120 CKD patients from two southern Taiwan outpatient nephrology clinics into control and intervention groups. Data were collected four times over a year from July 2015 to September 2016. The generalized estimating equation (GEE) model was used to determine whether outcome variables (physical indicators, renal protection knowledge, healthy promoting lifestyle, and quality of life) were different across time in patients in the experimental and control groups. Measurements at baseline and at 3, 6, 9, and 12 months included World Health Organization Quality of Life Questionnaire, the Health Promoting Lifestyle Profile—II Chinese version (HPLP-II) questionnaire, the Renal Protection Knowledge (RPK) Checklist, and physical indicators.

Results: The attrition rates were similar between the two groups. Reasons for failure to follow up included refusal to participate, missing the clinic appointment, lack of time, and death. The participant retention rate was 87.5%. The majority of the subjects were male 72 (72.4%), married 86 (81.9%), 52 participants in experiment group, and 53 participants in control group. The mean age was 62.99 ($SD = 13.06$) years old with more than half reporting a junior high school education. Over half were employed 59 (56.2%). From stage 1 to stage 4 of CKD were 4 (2.9%), 8 (5.8%), 62 (44.6%), and 31(25.3%) participants, respectively. At baseline, CKD patients in both groups showed no significant difference in physical indicators, such as body mass index, waist circumference, hip circumference, waist-hip ratio, systolic blood pressure, diastolic blood pressure, BUN, creatinine, HbA1C and Modification of Diet in Renal Disease(MDRD), except comorbidity index. The baseline values different were adjusted as a covariance-comorbidity index and helping relationships from significant others for these variables in the GEE model. The results of hip circumference ($p = .027$) indicated the experimental had significant changes comparing control groups. The results of body mass index ($p = .000$), systolic blood pressure ($p = .002$), diastolic blood pressure ($p = .000$) revealed significant changes between the two groups over 12 months. The intervention group demonstrated significant improvement with regard to improve trend of renal function protection knowledge ($p = .000$), renal function protection ($p = .000$), diet with CKD ($p = .000$), use of Chinese herbs ($p = .000$), overall health-promoting lifestyle ($p = .003$), health responsibility ($p = .001$), physical activity ($p = .000$), and overall quality of life ($p = .000$), physical domain ($p = .000$), psychological domain ($p = .000$), social domain ($p = .000$) as well environmental domain ($p = .000$) indicated the experimental had significant changes comparing control groups over 12 months. The interventions of helping relationships from significant others among patients with CKD promotes improve health status, adherence health behaviors and increase quality of life.

Conclusion: The interventions of helping relationships for patients with CKD increased renal protection knowledge, act and maintained health-promoting lifestyle as well improved health status and quality of life. Individualized plan about health-promoting lifestyle according to assessment of helping relationships from significant others should include partners, families, peers and medical staff to assist and accompany with people for learning, performing and maintaining disease-related knowledge as well health promoting

lifestyles. Educate nurse students or medical staff to assess and implement strategies of helping relationships from significant others for improving individual's health-promoting lifestyle and quality of life.

Physical Activity Habits and Its Relationship to the Weight of Children

Ana Luisa Rivera Villanueva, Mexico
Sandra Patricia Gutierrez Castro, Mexico
Antonia Linares Valdez, Mexico
Karla Mestizo Hernandez, Mexico
Corina M. Alba-Alba, PhD, RN, Mexico

Abstract

Purpose: The objective of this study was to identify the state of art in reference to the relationship between Physical Activity Habits and Weight.

Methods: A systematic research in the databases: EBSCO, SCIELO, MEDLINE, GOOGLE SCHOLAR, DIALNET was made with the next keywords: Physical Activity Habits, Children, Body Mass Index, and the boolean operators "and" & "not [Adolescents]". A total of 5214 articles published in the last 5 years was retrieved; then 450 relevant titles were chosen, the irrelevant abstracts were rejected and finally 150 articles in English and Spanish were chosen were considered relevant to the knowledge of the subject.

Results: The 150 articles selected were from; Mexico, Brazil, Chile, Colombia, Peru, Venezuela, United States of America, London, Australia, Lithuania, Portugal, Canada, Marruecos, France, United Kingdom, Argentina, Cuba, Spain and Germany.

A correlation between Physical activity habits and Body Mass Index in children were identified. It was observed that there are still limitations in research, which address different approaches in the variables and in their measurements, so the construction of more diverse knowledge is not so deep. It is visible that has not yet been able to implement or execute a comprehensive solution for promoting Physical Activity Habits in Children. And therefore becomes important to develop research to provide relevant information and incorporate new knowledge for nursing and other professions contributing to the solution.

Conclusion: Physical activity is related to the child's BMI, however more research is needed to deepen and corroborate the results. A correlation between Physical activity habits and Body Mass Index in children were identified. It was observed that there are still limitations in research, which address different approaches in the variables and in their measurements, so the construction of more diverse knowledge is not so deep. It is visible that has not yet been able to implement or execute a comprehensive solution for promoting Physical Activity Habits in Children. And therefore becomes important to develop research to provide relevant information and incorporate new knowledge for nursing and other professions contributing to the solution.

Public Health, the Environment, and Nursing Practice: Health Promotion in a Toxic World

Hacah U. Boros, MSN, RN, USA

Abstract

Purpose: Nurses are at the forefront of community and preventative health as educators and practitioners. It is imperative that they provide comprehensive, quality care as it relates to environmental health issues; acknowledging advances in research that are exposing the correlation between chemicals and our body burden. The incidence of many serious diseases and disorders are on the rise and understanding the link to environmental exposures is critical. There is growing consensus among the scientific and medical community that exposure to toxic chemicals in our every day environment including those found in building products, plastics, personal care products and household cleaners, are linked to the rise of many of these diseases. The President's Cancer Panel Report (2010) noted the link between chemicals and cancer has actually been significantly underestimated, as over 80,000 chemicals in commerce have been largely unregulated and untested. The Panel wrote: "the American people—even before they are born—are bombarded continually with myriad combinations of these dangerous exposures...that needlessly increase health care costs, cripple our Nation's productivity, and devastate American lives." [1] Through review of research there is a knowledge gap within nursing as it relates to this body of knowledge; which impacts nursing care and population health.

Methods: Surveys are being created for distribution to nursing schools and hospitals, within the state of Connecticut (USA), that will assess for the need for inclusion of curriculum, annual education and continuing education offerings to assess for environmental health issues, and the nurse's role in assessment and care. An educational webinar is also being offered to provide information on environmental health issues and related nursing interventions, with a pre/post test to assess for competency.

Results: This project is in process, however based on current research it is apparent that there remains a needs gap. The gap shows enhanced education requirements to create competency and nursing leadership in public health.

Conclusion: Environmental factors often disproportionately affect vulnerable and underserved populations. Exposure to toxic, environmental chemicals during critical windows of development (even prenatally) are linked to adverse health outcomes that span a lifetime and also impact fertility and pregnancy. In addition to the health impacts of chemical exposure, the economic impacts are staggering. The NIH projects that cancer costs will reach at least \$158 billion by 2020. [2] Nurses are well suited to be leaders in protecting the public through environmental health education, evaluation, and research to incorporate this expanded view of environmental health. Therefore it is imperative that this knowledge be interwoven into nursing curriculum and offered as continuing education in all practice areas within nursing to improve competency.

RSC PST 3 - Research Poster Session 3

Talkin' Bout My Generation: Divergence of Academic Atmosphere Evaluations in Nursing Student and Faculty Cohorts

Kate Rocklein Kemplin, DNP, MSN, BNSc, RN, CCEMTP, USA

Emery Lee Dunn, USA

Emily Faith Benoit, USA

Caitlin Bosarge, USA

Laura Barry Williams, USA

Michael Semore, BS, USA

Abstract

Purpose: The purpose of this study was to ameliorate a large gap in the body of knowledge by quantifying perceived intergenerational differences between nursing students and faculty in comparative analysis of their measured perceptions of the academic nursing environment and related subscale constructs. The current global nursing shortage is due in large part to the lack of faculty available to teach nursing students (Flinkman, Isopahkala-Bouret, & Salanterä, 2013; Twigg & McCullough, 2014). Within schools of nursing (SON), the issue is further complicated by disparate expectations and perceptions between nursing faculty and students – often of extensively dissimilar generations. In this innovative study, we built on previous research (Rocklein, 2014; Payne, 2013; Payne & Glaspie, 2014) by capturing and quantifying - for the first known time - perceived faculty-student disconnects of the academic atmosphere within a large American doctoral-degree-granting school of nursing (SON). Despite exhaustive reviews of extant literature, we did not find evidence germane to divisions specifically between nursing faculty and students.

Methods: After obtaining institutional review board (IRB) approval, the Dundee Ready Educational Environment Measure (DREEM) - a psychometrically superb instrument (de Oliveira Filho, Vieira, & Schonhorst, 2005; Miles, Swift, & Leinster, 2012; O'Brian, Chan, & Cho, 2008; Rocklein, 2014; Roff, 2005; Zawawi & Elzubeir, 2012) - was administered to nursing faculty and student groups with subscale constructs measuring perceptions of learning, professors, the scholastic self, pedagogical atmosphere, and social elements. The DREEM instrument has been used worldwide in medical and clinical educational research to quantify effects of various compositional constructs of the educational environment such as curriculum, teaching, and student perceptions.

Results: Multivariate analyses found statistically significant differences ($p < .05$; .01; .005; .0005) between student and faculty perceptions and independence of observations within the instrument and all subscale analyses, with strong correlations ($r = .57 - .68$) within many participant responses and generational delineation. Though both groups rated the educational environment favorably, nursing faculty overall had more positive perceptions of the educational environment and their performance than students. Subscale analysis was most fruitful in determining the majority of group differences.

Conclusion: Distal implications from this study are ultimately improvement of nursing faculty knowledge of their effects on students and thereby enhanced communication, expectations, and retention. This rigorous investigation of the nursing educational environment specific to the dichotomy inherent between faculty and students is essential for understanding intergenerational differences and those effects in schools of nursing. By disseminating this study to an international audience, replication within more heterogeneous groups is possible, as is longitudinal investigation. As such, we recommend future research is directed to formally replicate this study with larger, divergent samples within diverse nursing programs to generate additional evidence and initiate changes based on reliable data and precise analyses. Additionally, this study is generalizable to the greater international nursing workforce, as intergenerational differences affect the entire profession.

The Effect of Cinnamon in Blood Glucose Level of Patients With Type II Diabetes Mellitus

Pearl Ed G. Cuevas, PhD, MAN, RN, Philippines
Rohanney Lucman, BSN, RN, Philippines

Abstract

Purpose: The study aims to determine the effects of cinnamon to the blood glucose level of patients with type 2 Diabetes Mellitus. Specifically, the study parameters are on the FBS, BMI, weight and waist circumference profile of the participants compared in terms of their pre-test and post-test results.

Methods: The researcher used a non-equivalent group design under Quasi-experimental research because it allowed control to the target population by means of randomization and it included a pretest and posttest for the experimental and comparison group.

The subjects of the study are from the community people in Mandaluyong City, Philippines who passed the inclusion criteria. The researchers invited both men and women, ages 40-59 years and with the diagnosis of type 2 Diabetes Mellitus.

Results: The experimental group lowered their FBS with the percentage of 73.3% also with the other parameters such as Waist circumference with a percentage of 73%, Weight with the percentage of 86.6% and BMI with the percentage of 86.6%. Most of the control group increased their FBS with the percentage of 66.67% and there were no changes with their other parameters.

Out of 15 respondents who experienced drinking cinnamon tea of 2 grams twice a day for 6 weeks, participants showed improvement in their BMI. There were evidences of weight loss, decrease in FBS result and reduced waist circumference. These results show that cinnamon reduces blood glucose levels among patients with type 2 Diabetes Mellitus in the experimental group.

Conclusion: This study showed that cinnamon affects the blood glucose level of the respondents. There is a decrease in their FBS as well as their weight and BMI.

Studies similar to the present study have shown improved insulin sensitivity and blood glucose control by taking as little as ½ teaspoon of cinnamon per day (Dolson, 2014). Likewise in the study of Polansky (2010), a noteworthy reduction in fasting plasma glucose, BMI and waist circumference were noticed at week 12 compared to baseline in the experimental group, but the changes were not major as compared to the control group. Wong (2015) added that after 40 days of taking cinnamon blood glucose was reduced by 18 to 29 percent.

Although conclusive for this study, the researchers suggest further experimental studies on the use of cinnamon employing a larger sample size and given intervention for a longer period of time.

Impacting Congenital Abnormalities and Infectious Complications During Pre-Conception Through Pregnancy: The Zika Prevention Program (ZPP)

Pamela Allyn Di Vito-Thomas, PhD, RN, CNE, USA

Abstract

Purpose: On February 1, 2016 the World Health Organization (WHO) declared a public health emergency of international concern related to the number of births with microcephaly and other neurological disorders affected by the Zika virus (Centers for Disease Control and Prevention (CDC), 2016). The infected mosquito (species *Aedes*) transmits the Zika virus as a primary infection; secondary transmission occurs during unprotected vaginal intercourse, unprotected anal intercourse, or fellatio (CDC, 2016). CDC resources indicated that men traveling to or residing in areas with active Zika virus have been found to carry the virus in their semen up to 62 days after symptoms subside. Notably, the virus will continue to spread over time, and it will be difficult to determine the effects of the virus. 80 % of persons affected may have no knowledge of caring the virus or demonstrate signs or symptoms of infection (Oster et al., 2016, Hurlburt, 2016). Also, the Zika virus can be passed from a pregnant woman to her fetus during pregnancy (Martinez 2016). Therefore, the **purpose** of this **evidence-based practice project** is to investigate the Zika Prevention Program (ZPP) compared to current guidelines in decreasing the rate of congenital abnormalities and infectious complications during pre-conception through pregnancy.

Methods: Population: Currently an extreme health issue exists during critical fetal development in an affected mother. **Intervention:** The Zika Prevention Program (ZPP) seeks to educate the public, and set up health policies for public awareness to decrease the number of birth defects. Health education and prevention can significantly decrease the transmission of the Zika virus. More interventions need to take place in order to decrease birth defects related to Zika virus. **Comparison:** Current educational programing.

Results: Outcome: Decreased rates of congenital abnormalities and infectious complications during pre-conception through pregnancy related to the Zika virus.

Conclusion: The Zika virus is a nationally notifiable disease and healthcare providers are directed to report cases to their local health department for reportable diseases. On-going research continues to determine the outcomes for maternal Zika virus infection, as there is no treatment or vaccine for Zika virus disease at this time.

Effects of Mindfulness on Outcomes in Cardiac Rehabilitation Participants: A Pilot Study

Stephanie L. Turrise, PhD, RN, BC, APRN, CNE, USA
Nasrin Falsafi, DnSc, RN, PMHCNS-BC, AHN-BC, USA
Richard S. Pond, PhD, USA

Abstract

Purpose: The purpose of this pilot study is to assess the effectiveness of a mindfulness intervention compared to a non-intervention, control group (treatment as usual) on physiological and psychosocial outcomes in a sample of cardiac rehabilitation participants.

Methods: This study utilizes a quasi-experimental, repeated-measures design with participants randomly assigned by cohort to one of two groups: a mindfulness practices (including self-compassion) intervention group or a wait-list control group (i.e. treatment as usual). Fifty participants (25 per group) are being recruited from two sites with a phase II cardiac rehabilitation program in Southeastern North Carolina. Participants in the mindfulness intervention group receive eight weeks of assigned interventions in a group by a doctorally prepared psychiatric clinical nurse specialist who is also board certified as an advanced holistic nurse. Participants are asked to practice their mindfulness intervention for 20 minutes each day. They also receive a book on mindfulness and an MP3 player with soft music and audio-guided meditations on mindfulness and self-compassion. Participants in the control group receive treatment as usual, which includes general information on stress management and deep breathing exercises. All participants are given a journal to document their daily home practice and any important event related to their daily life and emotional state. For both groups, outcome measures are collected at baseline, 4 weeks, 8 weeks, 12 weeks (i.e., 4 weeks post intervention completion) and 24 weeks (i.e., 3 months post intervention completion). Outcomes include anxiety measured by the State-Trait Anxiety Inventory short version (STAI), depression assessed with the Patient Health Questionnaire-9 (PHQ-9), anger measured with the State-Trait Anger Expression Inventory (STAXI), hostility assessed with the hostility subscale of the Positive Affect and Negative Affect expanded version (PANAS-X; Watson & Clark, 1994), stress measured with the Perceived Stress Scale (PSS), and health related quality of life measured by the MacNew Heart Disease Health Related Quality of Life questionnaire. Physiologic outcomes include body mass index and blood pressure. Rate of CR program completion will also be obtained.

Results: Pending completion of data collection and analysis.

Conclusion: Pending completion of data collection and analysis

Physical Activity and Cognitive Function Among Mild Cognitive Impairment Community-Dwelling Elderly Adults: The Transtheoretical Model

Tzu-Ting Huang, PhD, RN, Taiwan
Ying-Fang Huang, MSN, RN, Taiwan

Abstract

Background: Mild cognitive impairment (MCI) is a common clinical syndrome that identifies people at high risk of developing dementia, and the prevalence range from 7.7 to 51.7%. Although treatments for MCI are currently unavailable, preliminary evidence has identified potential neuro-protective effects of physical activity (PA), which may lead to improved outcomes. However, the design and delivery of an appropriate programme for people with MCI is challenging for having physical, psychological, cognitive, and social barriers.

Purpose: The purposes of this study are to develop and examine physical activity program, on primary outcomes (cognitive function & IADL), and secondary outcomes (physical fitness, QOL, social support and depression) among community-dwelling elderly adults with MCI.

Methods: We developed a PA stage-matched intervention (SMI) base on the Transtheoretical Model of Change (TMC), literature and our previous findings, then, 81 elderly adults with MCI were recruited in to a 2-group pretest-posttest randomized controlled trial for 6 months and a 6-month follow-up to examine its effectiveness among community-dwelling elderly with MCI. The 24-week SMI consist of three components: (a) the stage-matched counseling strategies base on main constructs derived from the TMC; (b) exercise behavior training: we provided a 24-week, 2 times group-based (8-12 participants with 2 instructors at community centers, 60' each) and one home-based (with the PA program VCD and manual to bring home, 30'); and (c) telephone counseling each week.

Results: After this 24-week PA SMI, the PA group participants showed significantly better MMSE than those in the comparison group ($t=2.585$, $p=.012$); however, Mixed model analysis showed significantly on group effect only ($F=8.846$; $p=.004$). Also, the PA participants demonstrated significantly better mobility (interaction effects $F=5.325$; $p=.024$).

Conclusion: A 24-week PA SMI could improve cognitive and mobility ability among MCI elderly adults. However, more participants and physical activity other non-pharmacological interventions (such as cognitive training) may boost the effects on cognitive function among MCI elderly.

Factors Associated with Non-Acceptance of Testing and Evaluation of Household Contacts Exposed to Tuberculosis

Elvy G. Barroso, MD, MSc, MS, MPH, RN, RN, USA

Abstract

Purpose: The WHO reports that the incidence of TB is approximately 9.0 million new cases globally each year and approximately 3.3 million cases are missed by health systems as either undiagnosed or not reported. A single index case can infect up to 10 to 15 contacts over the course of a year. Thus, complete and timely evaluation of all contacts exposed to TB is crucial for decreasing the transmission and incidence of TB. Several barriers to testing of contacts have been identified, however, no studies specifically address contacts' non-acceptance to TB testing and evaluation. Both nurses and non-nurse managers conduct contact investigations (CI), but it is not known if there are differences in adherence to TB testing and evaluation based on type of provider. The study will seek to determine factors associated with non-acceptance of TB testing and evaluations as well as compare testing adherence rates among household contacts managed by nurses versus non-nurse managers.

Pender's Health Promotion Model (HPM) will guide the examination of factors that prevent contacts from accepting TB testing and evaluation. The HPM stresses that an understanding of the major determinants of health informs the counseling of healthy behaviors. Uncovering the factors that determine a contact's behavior will likely lead to effective counseling of contacts exposed to TB.

Methods: A retrospective study of four years of data extracted from the New York City Department of Health and Mental Hygiene TB registry will be used to assess factors associated with household contact's non-acceptance of TB testing and evaluation. Data elements include demographics, contact information, reporting and assignment, clinical disposition, and case management provider type. Logistic regression will be used to assess the probability of not accepting TB testing and evaluation based on independent variables, and to assess differences between two independent variables: a nurse manager and a non-nurse manager with non-acceptance of TB testing and evaluation.

Results: On-going research.

Conclusion: Study findings will provide data to facilitate health departments to develop appropriate strategies to increase household contacts' acceptance of TB testing and evaluation.

Deployment-Related Needs of Children of Army Reserve Soldiers

Margaret C. Wilmoth, PhD, FAAN, USA
Alicia Gill Rossiter, DNP, FNP, PCPNP-BC, FAANP, USA
A. Suzanne Boyd, PhD, MSW, USA

Abstract

Purpose: The spouse of a deployed Army Reservist said that her 5 year old was the only child in his kindergarten class whose daddy was in the military. He would sit in a corner and cry during school yet refuse to talk to his daddy on Skype. Concerned for her child's health she reached out to the community for support and encountered many barriers. Not only did she have difficulty finding a child therapist to help her son, finding one with experience caring for the unique physical and psychological healthcare needs of military children was nonexistent. The school, while willing to help, lacked the knowledge and expertise to fully comprehend the impact of parental military service on children. Furthermore, the family did not live near an active duty military post, however even if they did, her spouse's reservist status would significantly limit services available to her child.

This is just one story from thousands of stories on the effect of a parent's deployment on Army Reserve children (ARC). Military children sacrifice when a parent volunteers to serve in the Armed Forces of the United States and face many of the same stressors as their Army Reserve (AR) parent—essentially military children serve too. Little is known about the impact of deployment on children of Army Reserve Soldiers. This project identifies gaps in the literature regarding deployment concerns of AR children and provides the first ever description of this population.

Methods: Systematic review of the literature on the physical and mental health needs of children of deployed Reserve Component (RC) Soldiers. Descriptive analysis of AR Child and Youth Services (CYS) Programmatic Needs Surveys utilized a convenience sample of parents attending a pre-deployment Yellow Ribbon Program.

Results: The systematic review of the literature is ongoing, but of the 10 studies reviewed to date, RC children comprised approximately 10% of the total sample and none had a sample limited to AR children. A convenience sample of 6,000 parents of children of AR Soldiers who completed the CYS Programmatic Needs Survey, with a majority of children in the age range of (4-16), noted that the greatest need of their child are school support services that include school transition, individual education plans, 504 accommodations, decline in grades due to deployment, and behavior concerns related to deployment. In addition, finding affordable and quality childcare within their local communities can be very challenging. This challenge is compounded if the child requires specialized childcare due to medical or behavior health requirements.

Conclusion: While military children as a whole are an understudied group, even less research is available regarding Army Reserve children specifically. Their needs differ from those of their active duty peers because of their geographic distribution, often making them the only military child in their school, church and other community organizations. Knowledge regarding these unique needs is critical to meeting the educational needs as well as the physical and psychological healthcare needs of this underserved population.

Army Reserve Component children face challenges that differ in many ways from their Active Component counterparts, such as reduced access to military-sensitive psychological support services, military-sensitive school support and peer group support for both parent and child/adolescent. Given the paucity of data on this population, no definitive conclusions can be drawn about the impact of deployment on their psychosocial development. More funding to support research in this population is essential.

The Antimicrobial Effects of Water-Soluble Essential Oils in the Nursing Practice

Yuka Saeki, PhD, RN, Japan

Kimiko Akamatsu, PhD, RN, Japan

Abstract

Purpose: Essential oils have been widely applied for a variety of purposes. Essential oils often have antimicrobial, antioxidant and anti-inflammatory properties¹⁻³. When essential oils are applied as spray in daily life with the intention of removing microorganisms, they have to be dissolved in alcohol at first followed by water. In this case, it can't be clear if antimicrobial effect could be caused by essential oils or alcohol. Therefore, this study was designed to clarify the antimicrobial effect of water-soluble essential oils dissolved with an *emulsifier* and investigate an application in nursing practice.

Methods: Antimicrobial effect was evaluated by measuring adenosine tri-phosphate (ATP) and adenosine mono-phosphate (AMP). ATP is a chemical substance that acts as an energy source for all living organisms on the planet. AMP is derived from ATP during the processing. The presence of ATP or AMP can be considered proof of the presence of a living organism. ATP + AMP were measured at cutting boards, overflows in the bathroom, and necks of yukata (Japanese night clothes), which had been used for nursing skill practice several times by nursing students. The tested area were wiped using the swab stick, which combines a reagent and self-contained swab device (LuciPac Pen, Kikkoman Co. Ltd. Tokyo), after which light is emitted as a result of chemical reaction between luciferase-luciferin-PPDK reagent and ATP and/or AMP. The level of luminescence was measured using the measuring instrument (Lumitester PD-20, Kikkoman, Tokyo), and the degree of cleanliness is determined based on the amount of ATP + AMP detected by it.

Water-soluble essential oils, tea-tree (*Melaleuca alternifolia*) and eucalyptus (*Eucalyptus globulus*) dissolved with an emulsifier were used in this study (Biken Co. Ltd. Tokyo). These water-soluble essential oils were diluted to 100 times with sterilized distilled water and used as spray. The liquid containing only emulsifier without essential oil was also diluted 100 times and used as a control (control). Samples were obtained by wiping up the surface of the sprayed sites to be tested as mentioned above using the swab stick at 30 minutes after the liquid with essential oil or without (control) was sprayed. A swab stick was moved up and down 10 times in a fixed sized area (4 cm x 4 cm) to wipe up. The site for spraying control liquid was about 5 cm apart from that for essential oils. The significance of difference between essential oil and control was evaluated by applying the Wilcoxon rank sum test and were considered statistical at $p < 0.05$.

Results: ATP + AMP in the necks of yukata showed 867 ± 1635.5 RLU (Relative Light Unit, $n=20$) for control, and 242.6 ± 381.1 RLU for tea-tree ($n=20$). For eucalyptus, ATP + AMP showed 163.1 ± 136.3 RLU ($n=14$) and 333.9 ± 199.6 RLU ($n=14$) for control. ATP + AMP for tea-tree or eucalyptus showed significant decreases to 39.0 ± 29.8 % or 49.2 ± 15.6 % compared with that for control (100%) in the necks of yukata, respectively. After spraying tea-tree, ATP + AMP significantly decreased to 36.5 ± 23.5 % in cutting boards ($n=7$) and 37.6 ± 23.8 % in overflows in the bathroom ($n=10$).

Conclusion: The spraying the liquid containing essential oils decreased ATP + AMP in the neck of yukata, the cutting board and the overflow in the bathroom in this study. These results indicate that essential oil must be available to prevent infection by spraying liquid containing essential oil to various things in daily life. In order to apply to nursing practice, further investigation about the antimicrobial effects of essential oils would be needed in clinical practice including nursing clothes, linen goods, and so on.

Factors of Risk Behaviors for Exposure to Endocrine Disruptors in Female College Students in Korea

SoMi Park, PhD, RN, Korea, Republic of (South)

ChaeWeon Chung, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: Environmental hormones are known to affect women's health, inducing endocrine imbalances and reproductive health issues. As college students live more independently, they consume more fast food, disposable products, and convenient household items, which exposes them to more environmental hormones. Protecting women's reproductive health is crucial for the succession of health to the next generation. This study examined the factors associated with risk behaviors for exposure to endocrine disruptors in female college students in Korea.

Methods: A cross-sectional correlative study was designed by using a questionnaire survey. The major variables were 1) the predisposing factors of 'interest in health concerns', 'concern about endocrine disruptors', 'perception of endocrine disruptors related to female reproductive health'; 2) the reinforcing factors of 'menstrual problems', 'self-appraisal of exposure to endocrine disruptors', 'need for information on endocrine disruptors'; and 3) the enabling factors of 'participation in pro-environmental activity', and 'pro-environmental lifestyle'. The outcome variable was 'risk behaviors for exposure to endocrine disruptors'. Data were collected from September to October in 2015. A total of 199 female college students in Korea voluntarily participated.

Results: Based on the PRECEDE conceptual framework of the study, the influences of the factors on risk behaviors for exposure to endocrine disruptors were analyzed by a hierarchical regression. In the first step, demographics explained 11.7% ($F=27.3$, $p<.001$) of the variance of the risk behaviors of exposure to endocrine disruptors. The second step showed an additional 20.1% variance ($F=23.1$, $p<.001$) by adding the predisposing factors. In the third step, reinforcing factors markedly increased the explained variance to 55.4% ($F=36.1$, $p<.001$), which added 24.7% more. Finally, by adding the enabling factors, 61.7% ($F=36.4$, $p<.001$) of the variance was explained.

Conclusion: Women with less sense of need for information about endocrine disruptors and a poor pro-environmental lifestyle engage in more risk behaviors for exposure to endocrine disruptors. Education should include practical information about environmental hormones and should focus on leading young women to a pro-environmental lifestyle.

Development of an Educational Program for Women's Health Related to Endocrine Disruptors

ChaeWeon Chung, PhD, RN, Korea, Republic of (South)
SoMi Park, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: The environment surrounding us makes changes in the patterns and prevalence of disease. Precocious puberty has become one clear health issue in Korea, showing a 4.4-fold increase in the past 5 years and threatening the reproductive health of young women. Behavior is habitual and guided by cognitive processes, and awareness and perception are essential for individuals to obtain information and to participate in optimal health behaviors. Therefore, it is necessary to provide proper education to the population of young women to help them maintain health behaviors throughout their lifespan. This study aims to develop an educational program to protect young women's health from environmental hormones, which has two specific objectives: 1) to identify knowledge and behavioral patterns of exposure to endocrine disruptors, and 2) to validate the program using an expert group.

Methods: Design: A methodological study was designed; the first phase will use three strategies: cross-sectional survey, individual interviews, and a literature review. During the second phase of the study, a preliminary program will be produced by integrating the data from the first phase. The third phase will contain validation of the program by experts.

Sample and Setting: First, a convenience sample of 600 young women will be recruited for the cross-sectional survey from middle and high schools and colleges in W city in 2016. Individual interviews will be completed with 30 participants from each school age group. The literature review will utilize databases including MEDLINE, PubMed, and CINAHL. For the validation phase, an expert panel will be composed of one Ob-Gyn specialist, one medical doctor in preventive medicine, and three nursing researchers.

Measurement: For the survey, a structured questionnaire will be prepared to measure knowledge about endocrine disruptors and behavioral patterns of exposure to endocrine disruptors. For the interview, key questions for facilitators to ask and barriers to minimize exposure to endocrine disruptors will be incorporated. An expert panel will examine the tentative program for validity and applicability.

Results: Results are anticipated early 2017 and will be presented at the Research Congress.

Conclusion: The conclusion will address each of the two objectives of this study.

"This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(NRF-2015R1D1A3A01017746)"

Bibliographic Review About Anthropometric Measurements in Mother-Child Dyads

Montserrat Morales Alducin, Mexico

Rubi Chantal Casco Ojeda, Mexico

Corina M. Alba-Alba, PhD, RN, Mexico

Abstract

Purpose: Anthropometric techniques are diverse and they do require skilled levels in order to be executed. It is important for the nursing workforce to know about the most practical anthropometric techniques to be applied at community or research interventions, especially when mother-child dyads are assessed to know the relationship between Body Mass Index of both. Anthropometric measurements of mother-child dyads are useful in clinics or research, as alterations can be detected on time for preventing health-related issues. Therefore, the objective of this research is to identify the most practical, reliable, and precise anthropometric indicators for mother-child dyads.

Methods: A systematic research at the Scielo, nursery index, EBSCO, and PubMed databases was carried out using the following keywords: anthropometric, child, mother, and Boolean operators ("AND", "OR", and "NOT"). Retrieving articles published in the last five years, a total of 277 articles were obtained. After that, 200 outstanding titles were chosen; then, the summaries without key information for the research were dismissed; consequently, the whole texts were read and 150 articles, either in English or Spanish, were chosen. Finally, 50 of the most accurate articles related to the information of the mother-child dyads' anthropometric measurements were selected for this literature review.

Results: 50 articles from Brazil, Spain, China, Colombia, Venezuela, and Cuba were retrieved. It was found out that the main anthropometric measurements used to evaluate children were weight, height, waist circumference, and BMI (according to OMS BMI calculator and classification for male and female children); and to evaluate the mother, they were BMI (according to weight/height² formula) and waist circumference. However, a few of them measure skinfold, hip-waist relationship and brachial folds for children and mothers, but these techniques need high trained and standardized skills.

On the other hand, it was found out that manual bio-impedance is not advisable as an interchangeable method for children and adolescents. The BMI and bioelectrical impedance are the ideal indicators to detect symptomless disorders. In fact, the price and special indications in procedures for bioelectrical impedance made this tool less convenient for practical purposes and, besides, enough articles investigating the convenience of every anthropometry technique were not found.

Conclusion: As yet, it has not been found enough information that points out the specific relationship of anthropometric registers among mother and child dyads. The BMI and waist circumference are considered the most practical anthropometric measurements in both child and mothers. Such measurements can be applied by nurses for clinical or research purposes. Finally, it was concluded that the anthropometric measurements must be individualized according to each clinical or research purpose.

RSC PST 3 - Research Poster Session 3

Effect of Health Belief Model-Based Osteoporosis and Fall Prevention Program on Early Old-Aged Women

Jiwon Oh, MSN, RN, Korea, Republic of (South)
Sukhee Ahn, PhD, RN, WHNP, Korea, Republic of (South)
Jisoon Kim, MSN, RN, Korea, Republic of (South)
Seyeon Park, MSN, RN, Korea, Republic of (South)
Rhayun Song, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: Osteoporosis is globally affecting the health of people, especially menopausal women. Decreased amount of estrogen during menopause causes loss of bone mass leading to bone fractures. International Osteoporosis Foundation (IOF) (2015) reports 1 in 3 menopausal women are at risk of osteoporotic fractures. One of the typical sites of osteoporotic fracture is at proximal femur and hip fracture is known to increase the risk of mortality rates by 10% to 20% (Miller, 2016; Buttaro, Trybulski, Bailey, & Sandberg-Cook, 2013). Fracture of the hip can be a burden both at an individual and social level because its treatment requires longer hospital stays than any other common chronic illnesses (IOF, 2015). Long hospital stays due to osteoporotic fractures are costly and can be prevented by early identification (Hopkins et al., 2016; Solomon et al., 2014). Due to asymptomatic feature of the disease until fracture develops, higher mortality rates by bone fractures, and great expense followed by its complication treatment, it is important to prevent osteoporosis and fall among population at the most risk group. The purpose of this study is to determine whether Health Belief Model (HBM)-based Osteoporosis and Fall Prevention Program has an impact on the level of osteoporotic/fall related knowledge, self-efficacy on physical activities and diet change, and preventive behaviors among women aged 65 to 74.

Methods: This untreated control group design with pretest and posttest study was performed within community settings for two months. Women who received HBM-based Osteoporosis and Fall Prevention Program (n=47) attended a total of 4 sessions of 1-hour long education and counseling once every two weeks. The remaining participants (n=47) in the control group received 1-hour osteoporosis education after posttest.

Results: Results showed statistically significant differences between control and intervention group on the level of osteoporosis and fall related knowledge ($t = -13.91, p < 0.001$; $t = -2.354, p = 0.021$), self-efficacy of osteoporotic physical activities ($t = 2.736, p = 0.008$), and osteoporosis and fall preventive behaviors ($t = 4.761, p < 0.001$; $t = 3.879, p < 0.001$).

Conclusion: Participants in the intervention group had significantly higher levels of knowledge, self-efficacy, and preventive behaviors after completing 4 sessions of the program. Therefore, the HBM-based Osteoporosis and Fall Prevention Program seems to have an outstanding effectiveness on osteoporosis and fall prevention among early old aged women. The result is meaningful in terms of the intervention program is basing on a theory. In addition, one-to-one counseling session included in the experimental intervention, but was not in the control intervention, may imply individualized care had been performed and had beneficial impact on increased level of knowledge, self-efficacy, and preventive behaviors. Also, the outcome suggests that the program may have the potential to reduce the cost resulting from long hospital stays by osteoporotic fractures.

RSC PST 3 - Research Poster Session 3

The Impact of Bar Code Medication Administration Technology on Faculty Supervision of Nursing Students

Eileen Creel, DNS, RN, USA

Ann Carruth, DNS, RN, USA

Abstract

Purpose: The purpose of this research was to identify current practices, policies, and processes impacting nurse faculty who supervise nursing students administering medications in the clinical setting using bar coded medication administration systems (BCMA). BCMA are one of the proposed solutions to medication administration errors. They have been reported to reduce medication errors by as much as 86% (Rivish & Modeda, 2010). Up to 50% of United States (U.S.) hospitals had implemented BCMA technology in 2011, with the goal of improving compliance with the Five Rights of medication administration (Hassink, Jansen, & Helmons, 2012). BCMA were intended to eliminate “workarounds” which contribute to medication errors. However, this has not been fully realized. Kelly, Harrington and Matos (2016) state that workarounds are most commonly developed as solutions to barriers in patient care delivery and are developed to account for a technology shortcoming.

Very little has been written about nurse faculty’s role related to nursing student supervision while administering medications using BCMA. One of the competencies of the Quality and Safety Education for Nurses (QSEN) project for safety is that student nurses obtain knowledge of safety-enhancing technologies, such as barcode medication administration systems (QSEN, 2014). Research on the impact of the changes related to supervision of nursing student medication administration by faculty in the clinical setting is limited. In some settings students are not provided with a unique log-in code for electronic health records or BCMA records. When faculty supervise student nurses’ administration of medications in these situations, the faculty code is used and faculty name is reflected as the person administering the medication in the record. Reid-Searl (2013) suggested that legal requirements surrounding nursing student medication administration are not being met. Nurse practice acts across the U.S. stipulate documentation of interventions to be within scope of practice as a registered nurse. The act of improperly documenting the person who gives medication potentially violates the standard of care and in essence falsifies the record (York, Cynthia. “Documentation of Medication Administration by Student Nurses During Clinical Experience.” Received by Ann Carruth, September 4, 2106 letter).

Methods: A descriptive cross sectional survey method was used to better understand the current use and policies used by nursing faculty supervising nursing students. Two hundred thirteen (N= 213) surveys were returned from an online invitation to a national sample of Dean’s of Schools of Nursing. Nurse faculty from 17 states returned surveys. These states represented all regions of the U.S.

Results: The findings revealed that most agencies do not give BCMA codes to student nurses to retrieve assigned patient medications, but (60%) were given codes to chart in the electronic health care record (EHR). However, nurse faculty (54%) said they or a nurse scanned their badge at the time of medication administration. The majority (74%) felt technology had increased patient safety, but 25% indicated it was inadequate for use with student nurses. Faculty (50%) indicated over-rides are frequently required due to technological issues, and 32% indicated a student had a medication error using a bar code system. The majority of agencies either had no policy about student administration of medication, or the faculty were unsure about an agency policy (55%). Additionally, the majority of the faculty 54% were over the age of 50 likely indicating they were not originally trained to give medications using this technology.

Conclusion: It is important that faculty and nurse preceptors who supervise nursing students in the skills of medication administration know and are able to recognize what constitutes workarounds. Faculty should receive clear policies and training in the use of all electronic health records and BCMA systems they use while supervising nursing students. This training should include hands on experience to the extent that the faculty feels comfortable enough with the system to avoid workarounds, which maybe longer if faculty are older and have used the technology for a shorter length of time. Kelly et al., (2016)

indicated ongoing evaluation and adjustments within a safety culture environment that is user–centric with input from front line users is a pro-active approach that can be used by organizations to address workarounds. Frontline users include nursing faculty and the nursing students they train and as such need to have input into these policies and processes.

These findings are relevant as technology usage continues to increase seemingly without consideration for the training of future nurses. Most hospitals do not have a separate policy for nursing student medication administration, which could help to address issues with student nurse use of BCMA. The use of the BCMA's and EHR systems has legal implications for supervision of nursing students by faculty. Future research into the impact of BCMA systems and EHRs on the safe and legal training of our future nursing workforce is needed to ensure protection for patients, students and faculty who teach them.

Food Insecurity, Early Childhood Feeding, and Weight Outcomes in Hispanic Children and Their Mothers

Elizabeth Reifsnider, PhD, RN, WHNP-BC, PHCNS-BC, FAANP, FAAN, USA

David McCormick, MD, ., USA

Michael Todd, PhD, ., USA

Lucy Reyna, BA, CCHW, USA

Irma Pecina, AA, USA

Maribell Guzman, USA

Lu Zheng, MHI, RN, USA

Abstract

Purpose: Early and rapid growth in infants is strongly associated with early development and persistence of obesity in young children. Obesity adversely affects the lives of nearly 17% of American children and youth aged 2–19, while 8.1% of infants and toddlers under 2 years of age have high weight-for-length. Obesity prevalence is consistently found to be highest among low-income, Hispanic, African American, and American Indian children and adolescents. Longitudinal studies show an association between early experience of childhood poverty and long-term obesity risk. As a result, disparities in early childhood obesity risk are tied to poorer health outcomes. Food insecurity is a household-level economic and social condition of limited or uncertain access to adequate food to promote health and especially for children, to promote healthy growth and development. Obtaining sufficient amounts of healthy food is a major struggle for many Americans. According to the most recent USDA report on food insecurity, an estimated 49 million individuals and 12.6 million US households are food insecure, while 16 million children face food insecurity. Children who are food insecure are more likely to visit emergency rooms and are more likely to have asthma, and food-insecure mothers and children are more likely to be overweight/obese.

Methods: Randomized clinical trial with rolling enrollment of 150, randomized to 75 intervention and 75 control mother/infant dyads. All Recruitment was done at WIC offices in Houston TX. Inclusion criteria for mom: Mexican descent, 18-40 years old, in 3rd trimester pregnancy, no chronic diseases, pregnancy or postpartum complications. Baby inclusion criteria: 38-42 weeks gestation, at least 2500 gm, discharged home with mom and no birth complications. The mothers needed to be able to receive home visits and planning to remain on WIC and in Houston. Home visits to all for measurements, done by community health worker (promotora) blinded to group assignment. Visits at Prenatal, then at 1 week to enroll infant and obtain birth history, then 1, 6, 12, 18, 24, 30 and 36 months of age. Intervention home visits by 2 promotoras to intervention group only. Visits at Prenatal, then 2 weeks, 2, 4, 6, 9, 12, 18, 24 months to deliver manualized intervention content that was personalized for each subject based on status and request. Measures included: anthropometrics for mom and baby, 24 hour diet history; breastfeeding history, Edinburgh Postpartum Depression Survey (EPDS) , Brief Infant Sleep Questionnaire (BISQ), Home Observation for Measurement of the Environment (HOME), Brief Acculturation Rating Scale for Mexican Americans (ARSMA), Mexican American Cultural Values Scale (MACVS), Demographics.

Results: The mean age of the mothers was 29.72 (SD = 5.87). More than 17% of households had an annual income under \$10,000, 62.7% had an income between \$10,000 and \$30,000, 18% had an income between \$30,000 and \$40,000, and 2% had an income over \$40,000. The average household had 5.2 people living in it (SD = 1.7). The mean number of children per family is 2.67 (SD = 1.57). Slightly more than 42% (n=64) of mothers were born in the US, 56.0% (n=84) were born in Mexico, and 1.3% (n=2) were born elsewhere. There is a high rate of food insecurity among the sample with 100% using WIC, 50% receiving SNAP (food stamps), 15% using food banks, 5% skipping meals due to no food, and 89% running out of money to buy food weekly/biweekly. Rates of cesarean delivery are high – up to 38%, with 8% having gestational diabetes, and a mean postpartum BMI of 33. Normal weight infants have a longer duration of breastfeeding than do overweight or obese children. Mother's weight was the most consistently linked to breastfeeding status across time points. Mothers who reported no breastfeeding at either assessment were consistently heavier than those reporting either exclusive breastfeeding or non-exclusive breastfeeding. The association between breastfeeding and weight was significantly more

pronounced at 6 months than at 1 month ($p = .014$). Mothers reporting no breastfeeding at either time point were the heaviest ($p = .017$). At one month, 23.9% of the mothers exclusively breastfed, 35.5% non-exclusively breastfed, and 40.6% did not breastfeed. At six months, 17.4% of the mothers exclusively breastfed, 17.4% non-exclusively breastfed, and 65.2% did not breastfeed.

Conclusion: Social issues frequently create a lot of stress in the families with interest in child feeding taking lesser importance than securing food for family. Prolonged breastfeeding in conjunction with counseling by promotoras *may* promote healthy weight status. Delivery status, C-section versus vaginal, did not appear to be associated with W/L status at most recent visit. In a subgroup of engaged mothers, targeted counseling appeared to reverse unhealthy weight gain trends. Further analysis needed to determine if the engagement is a result of the education provided only or if the positive outcome is a result of an effective working relationship established by the promotora with the families. Any breastfeeding at six months provided a significantly lower mean weight among the participants than did no breastfeeding. Early and sustained breastfeeding for at least six months may reduce the chance of women entering the next pregnancy with retained weight from the previous pregnancy. Although breastfeeding did not show a significant effect on the occurrence of postpartum depression, a trend to significance occurred at six months between mothers who continued to breastfeed and those who did not. We found the low level of depressive symptoms in our population surprising, given studies estimating that nearly 20% of US mothers experience a depressive episode in the first 3 months postpartum. During the early postpartum period, studies have found significantly increased rates of postpartum depression (21-53%) in the Mexican-American population. Several of these studies have indicated that symptoms of depression are associated with level of acculturation in Hispanic and specifically Mexican American mothers. It may be that as the majority of mothers in our sample were more acculturated to the Mexican culture than to the mainstream culture, their Mexican cultural value of *familia* (close family support) contributed to the low levels of depressive symptoms observed in this sample.

Use of Outside Services and Other Needs of Informal Caregivers of Adult Oncology Patients

Susan C. Cobb, PhD, RN-BC, USA

Abstract

Purpose: The care of oncology patients often involves the assistance of informal caregivers such as family members or friends. Data from the United States reveal that an estimated 40 million caregivers provide care to adults (aged 18+) with a disability or illness. Caregiver services were valued at \$470 billion per year in 2013 – up from \$375 billion in 2007. With the aging population expected to double between 2000 and 2030, the impact of caregiving on healthcare will likely continue to increase (Family Caregiver Alliance, 2016; Cobb, Etkins, Nelson, Egleston, Sweeney, 2016). The important role that informal caregivers play in providing optimal care to oncology patients has been recognized by the Oncology Nursing Society and has consistently been a part of ONS's Research Agenda since 2001 (Knobf, et al, 2015).

An initial study conducted by the PI of this study and her study team compared the reactions and experiences of informal caregivers of oncology patients to that of informal caregivers of patients with other chronic illnesses. One of the key findings of the initial study was that 78% of caregivers reported not using any outside services in providing care to patients in the home setting. A review of the literature revealed only a few research studies exploring caregiver use of outside services and potential barriers to use. In a study of informal caregivers of cancer patients 63% of the caregivers reported that they provided all of the care for the patient without assistance (vanRyn, et al., 2011). Green and Smith (2015) reported a systematic review related to barriers and facilitators for male carers (caregivers) in accessing formal and informal support. The findings from these studies reveal a gap in our knowledge of caregiver needs for home care support services, barriers to use of these services, how these needs change over time and how to best support caregivers in their role.

Another major finding of the initial study was that informal caregivers viewed offering emotional and psychological support to the patient as the most challenging caregiving activity. This finding was consistent with that of vanRyn et al. (2011) who found that while 71% of caregivers in their study felt "very" to "extremely" confident about providing physical care to the patient, they felt much less confident about care of the emotional needs of the patients (49% felt "very" to "extremely" confident). The burden to support patients emotionally and psychologically falls on caregivers who also are burdened with their own emotional and psychological coping needs. Further study of what caregiver needs are in regards to emotional burdens and how healthcare providers can help in this area is merited.

Most caregiving research to date has been static and focused on a specific point in time e.g. diagnosis or palliative care phases (Stamataki, et al, 2014). Few studies have addressed how caregiver experiences and needs change over the trajectory of the cancer experience (Given, Given & Sherwood, 2012). One of the participants in Cobb's original study remarked that caregiver *"emotions change day to day, even hour to hour"*. How caregiver needs and experiences may vary over time is an area of needed study

The purpose of this study is to explore the experiences and needs of informal caregivers of adult oncology patients. The primary aims of this study are to identify what information caregivers need and desire in relation to outside services to assist them in their role and to describe barriers to use of outside services by informal caregivers. Secondary aims are to explore experiences and needs of caregivers relative to providing emotional and psychological support to the care recipient (patient) and to describe how caregiver experiences and needs change over time

Methods: The methodology for this study is qualitative description using structured, open-ended individual interviews with informal caregivers. Data analysis will consist of review of interview transcripts and field notes with identification of themes and key comments. The investigator will search for themes that represent commonalities across participants' comments.

Results: Themes will be generated inductively from responses to interview questions and field notes. Recurring ideas and perspectives will be recorded as themes. Preliminary themes will be identified as the records are reviewed. Themes will be interrelated, by juxtaposing those with similar meanings. Suggestions from study participants regarding what could be done to help them be more effective and cope better in their caregiving role will be analyzed and compiled.

Conclusion: The findings from this study will provide nursing and social work staff with information on how to better support informal caregivers in their very important role in the care of oncology patients. The findings may also be used to inform planning and content of caregiver education for nursing and other staff, to better meet the needs of this population.

The Effect of Music Therapy on Hospitalized Psychiatric Patients

Tso Ying Lee, PhD, RN, Taiwan

Abstract

Purpose: In this study, we explored the effects of music therapy on hospitalized psychiatric patients' anxiety levels using the physiological measures of finger temperature and EEG and a psychological instrument. This study aimed to explore the effectiveness of music therapy in reducing anxiety in hospitalized psychiatric patients.

Methods: The authors used a randomized clinical trial design and randomly allocated the 24 enrolled participants to the experimental or the control group. Patients in the experimental group received music therapy in a therapy room at a set time for 30 min each morning for 11 days. The authors administered the Beck Anxiety Inventory (BAI) and measured skin temperature and brain waves to determine anxiety level before, during, and after music therapy.

Results: Experimental group participants had lower scores on the BAI than control participants, after the music therapy ($z=-2.0$, $p<0.05$) and at 1-week follow-up ($z=-2.2$, $p<0.05$), indicating that they were experiencing significantly less anxiety. The mean BAI anxiety score fell in the experimental group from 23.9 (SD=9.9) at baseline to 13.9 (SD=8.8), after music therapy, and 12.7. (SD=10.5) at follow-up. The experimental group demonstrated a significant elevation in the average alpha electroencephalographic (EEG) percentage (from 38.1% to 46.7%) and a reduction in the average beta EEG percentage (from 61.9% to 53.4%) after the music therapy. After adjusting for change in patient finger temperature on the first day, mean change in finger temperature did not differ significantly between the experimental and control groups.

Conclusion: Our findings support the effectiveness of music therapy in facilitating relaxation. This kind of music can mitigate sympathetic nervous system reaction, resulting in decreased muscle tone and lowered sympathetic activity. Listening to music can, not only convert a person's mood from nervous to calm, also arouse alpha waves in the brain, which are associated with relaxation. Future studies on music therapy should consider mechanisms such as the alpha wave hypothesis and finger temperature in order to advance the understanding of music's psychological and physiological effects.

Related Factors on Sexual Risk Behaviors Among Adolescent at Vocational School in Thailand

Prueksalada Khiaokham, MNS, RN, Thailand

Punpilai Sriarporn, PhD, RN, Thailand

Apsorn Konrad, PhD, RN, Thailand

Piyawan Nuntapong, MNS, RN, Thailand

Abstract

Introduction: Adolescents involve in many changes and these changes sometimes incongruent, contributing to teenagers' confusion, lack of confidence, and lack of restraint. These impacts may lead them to make wrong decisions in risky circumstances and engage in harmful manners, including sexual behaviors. There is a higher incidence of sexual behaviors among adolescents than other groups because the consequences of dynamic sexual development and the influence of dramatically increasing sexual hormones lead to high sexual drives and craving to know about sex. In Thailand, as society changes in terms of increasing nuclear families, parents appear to not have enough time to take care of their children like in the past. As a consequence, the children have direct risks for sexual behaviors.

Most adolescents lack of awareness and are unable to control themselves in terms of expressing appropriate behaviors with opposite genders. These issues lead to risky sexual behavior. In the developmental stage of adolescents, they crave to know about—and try to do—new things, but they do not realize that they are immature and lack of experiences and life skills. Therefore, due to being unaware of the consequences of having pre-marital sex, they might face many problems, such as unwanted pregnancy, seeking criminal abortion, unsafe abortion, and sexually transmitted diseases. The severity and rate of these impacts have been dramatically increasing amongst adolescents (Saifon Eakwarangkorn, 2012; Kungploy Aeiwittayasuporn, and Ornnicha Pomeanthip, 2011).

A study of the relationship between sexual education, self-control, and communication in the family regarding sexual risk behaviors in terms of being with opposite genders among vocational students is needed in order to gain more understanding and develop a program for providing education to adolescents, as well as for preventing sexual risk factors in terms of being suitable for vocational students' contexts in Northern Thailand.

Purpose: The purposes of this correlational research study will determine the relationship between knowledge in sex education, family communication, self-control and sexual risk behaviors and explore the predictability of knowledge in sex education, family communication, and self-control on sexual risk behaviors of adolescent vocational students.

Methods: The samples will be 328 adolescent students aged between 15-19 years old who are studying in vocational school in Thailand. Five assessment tools including one questionnaire and four measurement scales will be used for collecting data, as following: 1) demographic questionnaire, 2 knowledge in sex education scale 3) family communication scale 4) self- control scale and 5) sexual risk behaviors scale. Data will be analyzed by using descriptive statistics, Pearson' product-moment collected and multiple regression analysis.

Results: The expected results will be as follow; 1) Self- control, knowledge in sex education and family communication whether relationship with Sexual risk behaviors of adolescent students. 2) Self- control, knowledge in sex education and family communication whether predict sexual risk behaviors of adolescent students.

Conclusion: The result of this study will be beneficial for health professionals, educators and staff who have been working closely with vocational adolescent students. The results will help to know about basic information and to get more understandings. These data will be useful for planning health education in class and developing program for preventing risk behaviors in vocational school.

Behaviour Development of Early Detection of Breast Cancer Among University Students With Peer Education Model

Seher Yurt, PhD, RN, Turkey
Rabía Aksut, PhD, RN, Turkey
Hasibe Kadioglu, PhD, RN, Turkey

Abstract

Purpose: Breast cancer, with a rate of 40.7%, is one of the most common cancers among women. Lack of knowledge about this issue among women in developing countries causes late diagnosis of breast cancer and increase of cancer incidence.

Women can realize the 80-90 % of mass by breast self-examination (BSE). After a regular BSE, woman familiarizes her breast tissue and can recognize the changes easily. Furthermore, BSE is a costless, simple, reliable and effective method. Alongside the women over 40 among whom incidence of breast cancer has increased, it is highly important for young women to improve knowledge about BSE and do a regular BSE. One of the important steps to acquire sanitation behaviours and take sanitation responsibilities among young people is informing the young with health education.

The study aims to improve knowledge and early detection behaviours of breast cancer with peer education model among university students.

Methods: In the methodology part of the study, the method of pre-test, post-test and control group will be used among groups that are not randomized. The sample of the study will consist of all first grade students studying at Maltepe University in 2016-2017 fall term (n=2500). In the implementation phase of the study, peer education model for an hour will be applied which aims to give knowledge about breast cancer and BSE. As peer educators, 60 intern nurse students will take part.

The implementation of the project will be between from October to December 2016. For the evaluation of the effect of education, BSE scale developed according to Champion's health belief model will be used.

Results: The project is in process and will be concluded in December 2016. The findings of the study will be presented after the project finishes.

Conclusion: This findings of the study will be presented after the project finishes in January 2017.

Encouraging Healthy Coping, Self-Care Efficacy, and Agency in Nursing Students

Paula A. Barbel, PhD, RN, PNP, USA
Amanda Coyle, PhD, RN, FNP-BC, USA

Abstract

Purpose: To examine the effect of the Self-Care Education for Nursing Students (SCENS) program on self-care efficacy, coping, sleep, disordered eating and alcohol use among junior nursing students.

Methods: Undergraduate nursing students are fiercely driven students, but along with this drive to achieve comes a significant amount of stress and anxiety. Often these students develop unhealthy coping mechanisms such as alcohol use, disordered eating, and sleep disturbances (Barry & Piazza-Gardner, 2015; Carvalho Bos, et. al, 2013; Gaultney, 2010; Hershner & Chervin, 2014; Schaumberg, Anderson, Reilly & Anderson, 2014). Nursing students can lack healthy self-care and effective coping strategies while learning to care for others. Lack of appropriate self-care practices can lead to deviations in health status which can have detrimental effects on the physical and mental well-being of nursing students as well as their academic performance (Carvalho Bos, et. al, 2013; Hershner & Chervin, 2014; National Eating Disorders Association, 2015). It is therefore necessary to identify effective intervention programs that will improve self-care practices, healthy coping, and self-care efficacy which in turn leads to increased overall general health and well-being in these students.

The sample consisted of 70 junior nursing students beginning the traditional nursing program at a college in Upstate New York. The Self-Care Education for Nursing Students Program (SCENS) is a mandatory part of the nursing program and consists of three meetings with a graduate counseling student. These meetings took place in the first, eighth, and final week of classes. Meetings consisted of groups of approximately 25 students each. The first meeting focused on how healthy eating and sleeping aid in stress management and self-care. The second meeting covered use of drugs and alcohol and how they can hinder self-care and impair coping. The third meeting included healthy coping strategies. For each of the three meetings, students were directed to on-campus resources for help if needed. The study was explained to the nursing students and if a participant chose to participate, they signed a consent form and completed the questionnaires. There was no penalty for non-participation. The following instruments were utilized: AUDIT-Enhanced measured alcohol; the Exercise of Self-Care Agency Scale (ESCAS) measured self-care agency; the Coping Self-Efficacy Scale (CSES) measured coping self-efficacy; the Eating Disorder Diagnostic Screen (EDDS), questions 1 – 5 and 15 – 18, measured disordered eating, and; the Sleep Difficulty Index measured sleep difficulties. Data were analyzed using descriptive statistics and paired t-tests utilizing SPSS version 22.0.

Results: A final sample size of 65 students participated in the study. Participants were mostly Caucasian female students (75.9%, 88.9% respectively) with an average age of 20.8 years old. Most were never married and without a partner (59.3%) and half of the students were working. The vast majority were not caregivers (92.6%) and did not engage in volunteer activities (85.2%). Only 32.5% reported that they spent time each week on supporting their spiritual needs. Participants had a mean pre-program sleep difficulty score of 7.82 (SD 2.169) and a mean post-program score 8.46 (SD 2.187). However, 18.5% had scores from 11 to 13 indicating significant difficulty sleeping. Higher scores reflect greater difficulties with sleep. The majority of the students (62.9%) reported having suffering from sleeplessness from 1-2 times a month to more than once a week. Students also reported that the sleeplessness did affect their ability to work (66.1%) and most reported having difficulties falling asleep (75.8%) and having woken up in the night and not being able to go back to sleep.

The mean pre-program AUDIT-Enhanced score was 5.52 (SD 4.023) and the mean post-program score was 6.53 (SD 5.173). A score of 8 or greater indicates harmful or hazardous drinking. The majority of the students reported drinking alcohol (90.3%) with 66.1% reporting drinking between 1 to 4 drinks on the occasions that they were drinking, 25.4% drinking 5 or 6 drinks, 6.8% having 7 to 9 drinks and 1.7% 10 or more drinks. Approximately 64% reported having drank 5 or more drinks on one occasion at least

monthly, with 19.4% reported weekly. Several students (32.2%) reported feeling guilt or remorse after drinking and 35% reported being unable to remember what happened the night before because of drinking. Students 23% reported drinking alone (23%), while depressed (19.7%), when they felt nervous (27.9%) and reported drinking to forget their problems (23%).

The pre-program mean score for the questions 1-4 of the Eating Disorder Diagnostic Scale was 12.03 (SD 7.485) and the post-program mean score was 15.05 (SD 9.054). A significant percentage of students (79%) reported feeling slightly to extremely fat and 54.8% had a moderately to extreme fear of gaining weight (54.8%), with 16.1% reported extreme fear of gaining weight. Several students (48.5%) also reported that weight has influenced how they think of themselves, and 55.6% have reported consuming an unusually large amount of food on occasion in the past 6 months. However, none reported having made themselves vomit or use laxatives as a way to prevent weight gain although 11.2% did report fasting or skipping meals at least once a week to prevent weight gain and 19.4% report having exercised excessively to prevent weight gain.

The mean pre-program score for the Coping Self-Efficacy Scale was 178.06 (SD 35.01) and the mean post-program score was 176.15 (SD 39.79). The mean pre-program score for the Exercise of Self-Care Agency Scale was 154.50 (SD 13.826) and post-program score was 154.53 (SD 14.083). Higher scores reflect greater coping self-efficacy and exercise of self-care agency. There were no statistically significant differences in scores between the pre-program measures and the post-program measures.

Conclusion: Results of the study indicate that junior nursing students have self-reported difficulties with sleep including sleeplessness. Students also have significant issues with some disordered eating patterns related to body image perception and alcohol use, with a small percentage reporting binge drinking. This finding is consistent with the literature regarding alcohol use among nursing and health care students (Barry & Piazza-Gardner, 2015; Carvalho Bos, et. al, 2013). Students did have higher levels of perceived coping, self-care efficacy and exercise of self-care agency. Although there were no statistically significant differences in the pre and post program scores, the findings highlight the continued stressors faced by nursing students as they progress through the nursing program. These factors may contribute to unhealthy and ineffective coping strategies and ultimately affect academic performance and achievement. Further studies need to be conducted to develop effective programs to help address these issues for nursing students.

Factors Associated With Intermittent and Light Smoking Among Korean Adolescents

Jin Suk Ra, PhD, APN, NNP-BC, Korea, Republic of (South)
In Sook Park, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: Smoking in adolescence is a risk factor of lung cancer and death from cardio-cerebral vascular disease in adulthood; in the short term, it can also be associated with adolescents' poor psychological health such as depression or suicidal ideation. However, approximately one quarter of adolescents appear to underestimate the harm caused by smoking. In particular, adolescents who engage in intermittent (i.e., smoking on 1–29 days out of every 30) and light smoking (smoking less than 10 cigarettes per day) were more likely to consider that their smoking behaviors were not harmful to their health. Similarly, intermittent and light smokers were less often advised to quit smoking by health care providers than were heavy smokers, and showed more increased risk for cancer, cardiovascular disease, and respiratory symptoms than non-smokers. Most adolescent smokers, including those in the Republic of Korea, exhibited intermittent and light smoking. Thus, adolescents who are still intermittent and light smokers might be an important target group for school-based smoking cessation programs. To maximize the effect of these programs by tailoring them to their target group, the identification of factors associated with intermittent and light smoking among adolescents would be a first step. The purpose of this study is to identify the factors associated with intermittent and light smoking among Korean adolescents based on biopsychosocial model.

Methods: In this cross-sectional study, we employed secondary data from the 2015 Korea Youth Risk Behavior Web-Based Survey, and used the biopsychosocial model as a framework. The analysis was performed using the data of 31,038 high school students (both non-smokers and current smokers). We defined intermittent and light smoking as smoking for 1–29 days in a 30-day period and smoking less than 10 cigarettes per day. Logistic regression analysis using the complex samples procedure was applied to examine the factors associated with intermittent and light smoking among adolescents.

Results: Among all study participants, 11.7% were current smokers; of these current smokers, 42.2% were intermittent and light smokers. The significant factors predicting intermittent and light smoking were male gender (as a biological factor); depressive symptoms and alcohol consumption (as psychological factors); and having siblings and close friends who smoke, observing teachers and other staff smoking in school, academic achievement, and participation in smoking cessation education in school (as sociocultural factors).

Conclusion: In smoking cessation programs, health care providers in both the school and community should consider the unique biological, psychological, and sociocultural characteristics of intermittent and light smoking behaviors among adolescents.

Lived Experience of Emergency Service Personnel in Pediatric Resuscitation and Unexpected Death: A Phenomenological Study

Judith Elwanda Lindsay, PhD, RN, USA

Abstract

Purpose: The purpose of this study was to understand the experiences of health care professionals who have encountered an unexpected pediatric death after an unsuccessful resuscitation in an emergency care setting. There is an emotional cost to caring and emergency health care providers are exposed to trauma and family distress on a regular basis. It is important to understand the emotional and psychological costs to health care providers, especially emergency service personnel who care for children who are dying or may have died. The research question asked of the participants was "What is it like for you when a child dies after an unsuccessful resuscitation effort?"

Methods: This was a qualitative Hermeneutic Phenomenological study guided by the philosophy of Max van Manen to uncover meaning and structures inherent in the experiences of emergency service personnel who experienced an unexpected death of a child. Study participants were recruited by snowballing, flyers and presentations. Using an open-ended format, participants (n=8-4 physicians, 3 registered nurses, and 1 respiratory therapist) were interviewed at a place of their choice and convenience. Interviews were transcribed verbatim with no identifying information. Madison's nine principles were used to ensure rigor.

Results: Van Manen's four existentials guided this study-Spatiality (lived space), Corporeality (lived body), Temporality (lived time), and Relationality (lived other). 12 subthemes emerged from the existentials that included: "what if", "dying before my eyes", "team", "what if it was my child?/being a parent", "brutality of a resuscitation", "being trapped", "wounded healer", "education", "anger", "failure", and "coping".

Conclusion: Findings from this study identified that these health care professionals experience a sense of anger, failure, and a lack of preparation to cope with an unexpected pediatric death and the unknowns of life. Implications include gaining an in-depth understanding of this experience from the perspective of those involved and developing a cadre of coping and grieving interventions for emergency service personnel. Implications for education include: pediatric end-of-life training including education on communication, relaying "bad news", debriefing, and self-care. Findings may also provide guidance for the implementation of revised emergency personnel standards, practices, and policies.

The Prevalence Rate of Deviations in Body Constitutions and Related Factors in Breast Cancer Patients

Amy Shu-Chuan Lin, MSN, RN, ARNP, Taiwan

Li-Li Chen, PhD, RN, Taiwan

Abstract

Purpose: Breast cancer is one of the most common malignancies in women worldwide, with an overall five-year survival rate of up to 90% in developed countries. The related occurrence of a second malignancy and chronic disease is increasing among breast cancer survivors because of their prolonged lifespan. Healthy lifestyle behaviors to prevent disease have become an important issue for the follow-up stages of breast cancer patients. Breast cancer patients' compliance with healthy lifestyle behaviors is lacking. Enhancing patients' motivation to change health behavior is the main goal for healthcare providers. The aim of this study was to apply a rigorous traditional Chinese medicine (TCM) body constitution questionnaire (BCQ) to survey the prevalence rate of deviations in body constitution and to explore the health-related lifestyle behavior factors of deviations in body constitution. The aim of this study was to apply a rigorous traditional Chinese medicine (TCM) body constitution questionnaire (BCQ) to survey the prevalence rate of deviations in body constitution and to explore the health-related lifestyle behavior factors of deviations in body constitution.

Methods: A cross-sectional study was administered through postal mail. Subjects were recruited from a national organization for breast cancer patients (Taiwan Breast Cancer Alliance). Data were obtained from 311 breast cancer patients by questionnaires including a demographic record sheet, lifestyle behavior scales and the BCQ (Yang-Xu, Yin-Xu, and Stasis). Differences concerning the presence of body constitutions were analyzed by Chi-square tests and analyses of variance, and potential predictive factors were analyzed using multivariate logistic regression.

Results: In total, 55.3% of the subjects had a Yang-Xu constitution, 61.0% had a Yin-Xu constitution, and 47.6% had a Stasis constitution. A total of 42.8% of the patients displayed a combination of the three types of body constitutions. Feeling stressed, physical exercise, and favoring fried food were predictors of the combined Yang-Xu, Yin-Xu and Stasis constitutions ($p < 0.05$). Staying up late was significantly associated with Yin-Xu ($p = 0.017$), and favoring salty food was significantly associated with Stasis ($p = 0.019$).

Conclusion: A high prevalence of deviations in body constitutions was observed in the follow-up stage of breast cancer patients. Increasing the adherence to healthy lifestyle behaviors might strengthen and balance body constitution, which could improve supportive care in breast cancer survivors.

RSC PST 3 - Research Poster Session 3

Light Therapy on Sleep Phase-Shift in Shift Workers: A Meta-Analysis

Min-Huey Chung, PhD, RN, Taiwan
Calvin Lam, MSc, Taiwan

Abstract

Purpose: The treatment effects of Light therapy on sleep were widely studied. However, there was limited meta-analysis had investigated the dose-response of light therapy and for shift workers. We are conducting a meta-analysis by including eligible randomized controlled trials (RCTs) to investigate whether there is dose-response of light therapy on sleep phase shift of shift workers.

Methods: We searched for relevant articles in 10 databases, included PubMed, Medline, Cochrane, Embase, LILACS, Open Grey, PsycINFO, PubPsych, SCOPUS, and CINAHL. Search keywords included "light therapy", "shift work", and "randomization". Two reviewers independently screened the articles and extracted the data. No additional data were found even after contacting the authors of the eligible studies. We finally included 9 RCTs from 1819 records. Analyses were performed using the random-effects model.

Results: Outcomes were measured by melatonin concentration and phase shift in hour. Light therapy exerted a significant effect on sleep phase shift, with a large pooled effect size (Hedges's $g = 1.476$, $p < 0.001$). However, There was significant high heterogeneity ($Q = 55.56$, $p < 0.001$, $I^2 = 85.6$) but low publication bias (Begg's test, $p = 0.076$; Egger's test, $p = 0.081$, no missing study in the funnel plot). There were significantly different effect sizes between the studies with the outcomes of melatonin concentration ($k = 4$, $g = 1.201$, $p = 0.07$) and phase shift in hour ($k = 5$, $g = 1.723$, $p = 0.004$). However, no significant treatment dose-response on the sleep phase shift.

Conclusion: The large effect size suggests that Light therapy is effective in sleep phase shift for shift workers. However, the high heterogeneity, inconsistent effect sizes between different measurements, and non-significant treatment dose-response turn the current findings inconclusive. Further investigation on the possible moderators, such as demographic data, and potential research bias, such as methodological quality, are needed.

RSC PST 3 - Research Poster Session 3

Mental Healthcare Utilization Among School-Based Adolescents in La Union, Philippines

Jonas Preposi Cruz, PhD, MAN, BSN, RN, Saudi Arabia

Paolo C. Colet, PhD, MAN, BSN, RN, RM, Saudi Arabia

Mehmet Sinan Iyisoy, MS (Stats), Turkey

Abstract

Purpose: Mental health problems continue to contribute a significant fraction of the global disease burden (Whiteford, Ferrari, Degenhardt, Feigin & Vos, 2015). Globally, approximately 20 percent of children and adolescents experience mental health problems, while up to 50 percent of adult mental disorders begins in adolescents (Belfer, 2008). The Philippines share similar concern on mental health among adolescents with the rest of the world. In the Philippines, the most common mental health problems among youths are depression, anxiety and mood disorders. Despite this concern, utilization of mental health care facilities across the Philippines is uneven, favoring those living in or near the National Capital Region (World Health Organization [WHO], 2007). Adolescents' utilization of mental health care services, however, has not been carefully investigated especially those in provinces where mental health facilities are lacking. Thus, this study examined the mental health care utilization among school-based adolescents in the province of La Union, Philippines.

Methods: This study employed a descriptive, cross-sectional design in assessing the mental health care utilization among a convenience sample of 683 high school (HS) students in two secondary schools in the province of La Union, Philippines. A 2-part self-administered questionnaire was utilized to gather data from September to October 2016. Part 1 collected data on the socio-demographic characteristics, which include age, gender, grade level, religious affiliation, number of family members, family structure, type of community, perceived family financial status, number of friends, if involve in intimate relationship and involvement in extra-curricular activities (participation in sports team and school organizations and leadership involvement). Part 2 consisted of dichotomous questions with yes or no response option which asked the respondents if they have visited or talked or consulted to the listed mental health care personnel or facilities due to feelings of depression, anxiety or stress in the past six months. The list was based on existing questionnaires related to mental health care utilization, as well as the availability of the said personnel or facility in the research setting. Frequency count, percentage, and mean were used to describe the demographic characteristics and mental health care utilization of the respondents, as appropriate. Pearson's Chi-square test and Fisher's exact test were used accordingly to examine the relationships between the socio-demographic characteristics and the mental health care utilization. A p-value less than 0.05 was considered significant.

Results: The average age of respondents was 14.52 years (SD= 1.37). The majority of the respondents were male (54.6%), were attending public high school (63.7 %), were Roman Catholic member (74.4%), had a nuclear family structure (74.4%), were living in an urban community (72.5%), had middle family financial status (88.0%), had more than 10 friends (68.7%) and were not involved in an intimate relationship (72.9%). Regarding involvement in extra-curricular activities in their school, more than half of the respondents were not a member of any school organization (67.9%), while 75.0% and 76.0% of them were not members of any school sports team and did not hold any leadership position, respectively.

For the utilization of mental health care, only 23.7 % and 46.9% of the respondents visited or consulted their guidance counselor and school clinic, respectively, due to feelings of depression, anxiety or stress in the last six months. More than half of the respondents did not visit or consulted their village health clinic (76.6%) and a general practitioner (65.5%) in the last six months for symptoms related to depression, anxiety or stress. Furthermore, almost all of the respondents did not consult a social worker (91.4%), a private practice psychologist, psychotherapist or psychiatrist (95.2 %), and a psychologist, psychotherapist or psychiatrist in an outpatient department of a hospital (94.7%).

A chi-square test of independence was performed to examine the relation between mental health care utilization and socio-demographic characteristics. The percentage of students who visited their guidance counselor for problems related to depression, anxiety or stress vary significantly between private and public schools, $\chi^2(1, N = 683) = 6.08, p = .014$. Public school students have less percentage/proportion (20.7%) of visiting a Guidance Counselor than private school students (29.0%). On the other hand, the proportion of the respondents who visited a village health clinic in the last 6 months differ by type of school ($\chi^2(1, N = 683) = 22.23, p < .001$), number of friends ($\chi^2(2, N = 683) = 7.62, p = .022$), perceived family financial status ($\chi^2(2, N = 683) = 7.60, p = .022$) and school organization membership ($\chi^2(1, N = 683) = 4.79, p = .029$). Private school students (13.3%) have less percentage of visiting a village health clinic than public school students (29.2%). Moreover, the percentage of the students who visited a village health clinic was higher among students with more than ten friends (26.4%) than students who had only 6 to 10 friends (17.4%) and less than five friends (16.1%). Students who perceived their family as poor (36.5%) had a higher proportion of visiting a village health clinic than those who perceived their family as rich (31.6%) and at the middle (21.8%). Also, students who were non-members of school organizations (25.9%) had a higher percentage of visiting a village health clinic than students who were involved in school organizations (18.3%).

On the other hand, the percentage of the students who consulted a general practitioner vary significantly by number of friends ($\chi^2(2, N = 683) = 6.08, p = .047$), by involvement to intimate relationship ($\chi^2(1, N = 683) = 6.36, p = .012$) and by membership to sports teams ($\chi^2(1, N = 683) = 4.90, p = .027$). Specifically, students who had less than five friends (24.7%) had a lesser proportion to consult a general practitioner than those who had 6-10 friends (31.4%) and more than ten friends (37.3%). Furthermore, the proportion of students who consulted a general practitioner was lesser in students who had a girlfriend (GF) or a boyfriend (BF, 27.0%) than those without GF or BF (37.4%), and higher in students who were members of sports team (41.5%) than those who were non-members (32.2%).

In terms of consultation to social workers, the proportions varies by community type ($\chi^2(2, N = 683) = 6.37, p = .041$) and financial status ($\chi^2(2, N = 683) = 7.04, p = .030$); the proportion is higher in students who were living in suburban communities (26.7%) than those living in rural (8.7%) or urban (8.1%) areas. Also, the percentage of students visiting a social worker is higher in students who perceived their family as poor (17.5%) than those who were rich (10.5%) or at the middle (7.7%).

Lastly, the percentage of the students who consulted a private practice psychologist, psychotherapist or psychiatrist were dependent on the school organization membership ($\chi^2(1, N = 683) = 2.85, p = .09$) and perceived financial status ($\chi^2(2, N = 683) = 11.21, p = .004$), while the percentage of students who visited an outpatient department of a hospital was dependent on school organization membership ($\chi^2(1, N = 683) = 11.22, p < .001$). The proportion of students who consulted a private practice psychologist, psychotherapist or psychiatrist was higher in students who were members of school organizations (7.9%) than those who were non-members (3.9%). Also, the proportion of students who visited an outpatient department of a hospital was higher in students who were members of school organization (10.4%) than those who were not members (3.7%). Students who perceived that they were rich (21.1%) had a higher proportion to consult a private practice psychologist, psychotherapist or psychiatrist than those who perceived that they were poor (4.8%) or at the middle (4.3%).

Conclusion: This study provided an overview of the status of mental health care utilization among school-based adolescents in the province of La Union in the Philippines. The findings suggest an underutilization of mental health care services among school-based adolescents, which is consistent with the results of a study conducted among college students in the Philippines (Tuliao, 2014). The findings also suggest existing disparities in mental health care utilization among the respondents when grouped according to their socio-demographic characteristics. The results of this study should be used to create a school-based, school nurse-led awareness program that aims to increase the awareness of the students regarding the existing mental health care services in their school and in the community, which they could utilize anytime. It should also be emphasized in the program the significance of seeking help for mental health-related problems. Lastly, collaboration with other stakeholders, such as the parents, the teachers, and the guidance counselors, should be initiated in the creation of such program, to identify their potential roles in ensuring good mental health among adolescents.

Implementation of Current Technology in Online Learning

Glenda Susan K. Jones, MSN, RN, CNS, CCRN, CCM, USA

Milena P. Staykova, EdD, APRN, FNP-BC, USA

David Halpin, PhD, USA

Abstract

Digital technologies have a significant impact on the nursing education. To meet the challenges of the U.S. health care system for excellent patient outcomes, the Institute of Medicine (IOM) recommended higher educational attainment for the nursing workforce. In 2010, the IOM released its landmark report on *The Future of Nursing*, which called for 80% increase of the number of baccalaureate-prepared nurses (BSN) in the workforce by 2020. The online nursing education has grown rapidly to aim the RN to BSN transition. In 2011, an online survey was administered to students from a private health science college to evaluate the current RN-BSN Program. Pre-survey results indicated lower scores for the use of technology, access to faculty, and student interactions. A three phase quality improvement project was initiated to address the identified needs. In 2012, the RN-BSN faculty and members of the Instructional Technology department collaborated to identify best practices in online education and to address areas for improvement in the use of technology. During phase 2, a web-based virtual synchronous conferencing also known as collaboration was implemented in the online courses. The virtual collaboration was utilized for class orientation, office hours, student presentations, lectures, skill demonstrations, guest speakers, and polling and assessments of knowledge. In 2014, a digital clinical experiences virtual program that utilizes avatars was implemented in the physical assessment course to provide students interactive activities.

Purpose: The purpose of this project is to assess the effectiveness of emerging technologies in online teaching.

Methods: Multi-phase Quality Improvement Project. Phase 1: Pre-survey. A convenience sample of 75 Post-licensure BSN students received the Distance Education Learning Environments Survey (DELES) with also included evaluation of concepts such as qualitative learning attitudes and web technology. Six sub- scales were measured by the DELES Survey: instructor support, student interaction and collaboration, personal relevance, authentic learning, active learning, and student autonomy (Sahin, 2007, Walker & Fraser, 2005). SPSS 20.0 was utilized for data entry and statistics. Phase 2: Faculty evaluation of available online educational tools, purchase of the virtual program, training of faculty, and implementation of the virtual program in the online RN-BSN courses. Phase 3: A post survey to evaluate the student satisfaction with our online nursing program post implementation of the Blackboard Ultra Collaborate and Shadow Health Virtual Programs.

Results: The 2015 post course evaluations (phase three) reflected 100% satisfaction with access to faculty, student interaction, and use of technology. 60% of the students reported enthusiasm with online learning and concluded that the online learning was stimulating. 80% of the students concluded that the virtual collaboration improved collaboration between students and faculty, and their engagement and participation in the online courses. 80% of the students reported that they liked online examination with computer camera monitoring.

Conclusion: Student engagement is essential for achieving academic outcomes and increased satisfaction with online education. The use of technology has a key role in the success of the students in the contemporary online education.

Exploring the Trajectories of Cognitive Symptoms in Advanced Cancer Patients Receiving Aggressive Immunotherapy: Preliminary Findings

Tara K. Mann, BSN, RN, USA

Robin B. Dail, PhD, RN, FAAN, USA

Shawn McClintock, PhD, MSCS, USA

Marilyn Hockenberry, PhD, RN, PPCNP-BC, FAAN, USA

Donald E. Bailey, PhD, RN, FAAN, USA

Abstract

Purpose: Patients with cancer receiving high-dose Interleukin-2 (IL-2) therapy experience alterations in cognitive functioning (Musselman et al., 2013) including changes in concentration, attention, short-term memory, executive functioning, language, and orientation (Mann, Dail, & Bailey, 2015) during treatment. Patients and care partners also report in online forums that cognitive symptoms were inadequately screened for and they were uninformed about potential cognitive alterations during and after treatment (Ejneary, 2011). Severe cognitive symptoms may result in early cessation of IL-2 treatment, which results in deficient treatment response. IL-2 is a cytokine produced naturally by the body. High-dose (HD) IL-2 is an immunotherapy produced synthetically and is used as a treatment in patients diagnosed with metastatic renal cell carcinoma (MRCC) to achieve remission or minimize the disease. HD IL-2 is defined as 600,000 IU/kg of IL-2 administered intravenously as a 15-minute bolus every 8-hours for up to 14 treatment doses. These 14 doses comprise one treatment hospitalization; patients can receive up to four treatment hospitalizations (Dutcher et al., 2014). The cognitive symptom trajectory has yet to be described. As such, a description of how symptoms change with each dose within and across hospitalizations is essential to maximize treatment delivery, potentially increasing remission rates in the IL-2 population.

The purpose of this study was to describe IL-2—induced cognitive symptoms (language, concentration, confusion, attention, short-term memory, and orientation) longitudinally from the perspective of the patient, care partner, and primary nurse who have first-hand knowledge of symptoms during the treatment course.

Methods: This exploratory, descriptive study used a mixed-methods case study approach to examine the cognitive symptom trajectory in ten IL-2 cases using qualitative and quantitative data. Each IL-2 case consisted of the IL-2 patient, care partner, and primary nurse. The patient completed two scales, the Montreal Cognitive Assessment (MoCA) and the Attentional Function Index (AFI), evaluating cognitive symptoms at pre- and post-treatment for each hospitalization, and a semi-structured recorded interview after treatment ended. The care partner completed a semi-structured journal entry every 8-hours at the time when a dose of IL-2 was administered, and a semi-structured recorded interview after treatment ended. The primary nurse completed a semi-structured recorded interview after treatment ended providing medical expertise/insight into the treatment trajectory.

The AFI is a 13-item scale with scores ranging from 0-100 measuring perceived changes in attention and working memory (Cimprich, Visovatti, & Ronis, 2011). Higher scores indicate better perceived attention and cognitive stamina (Asher & Myers, 2015). The Montreal Cognitive Assessment (MoCA) measures global cognitive functioning with a maximum total score of 30, and normal scores ranging from 26 to 30 (Rossetti, Lacritz, Cullum, & Weiner, 2011).

Results: Of the nine IL-2 cases currently enrolled, six have completed the study, and three are currently receiving treatment. Nine IL-2 patients have been admitted for two treatment hospitalizations, while three cases have completed all four treatment hospitalizations. Seven of the nine IL-2 patients were white males ranging from 37 to 60 years of age. Two of the IL-2 patients were black females ranging between 45 and 60 years of age. Seven of the IL-2 patients had their spouse as their inpatient care partner, one care partner was a daughter and one care partner was a significant other. All 19 primary nurses were

white, comprised of 18 females and 1 male. Nursing experience ranged from 1.5 to 28 years, with a mean of 13 years.

Our preliminary quantitative analysis suggests that cognitive symptoms can be grouped into three symptom trajectories: stable, mixed, or worsening. Total scores on the AFI decreased anywhere from 50 to 135 points from pre- to post-treatment time points indicating worsening perceived attentional functioning, with the largest change in cognitive fatigue during the first treatment hospitalization across all patients. In all but the first hospitalization, average total scores decreased by approximately 1-point from pre- to post-treatment measurement time points on the MoCA. For all patients, the most common changes were in the visuospatial executive function, attention, abstraction, and orientation domains.

Although quantitative measures were only administered at pre- and post-treatment, each case informant provided unique insight into the trajectory of cognitive symptoms. For example, one care partner stated, “[After dose 8], he said he felt the most ‘beat up’ so far. I can definitely tell a difference today...an increase in sleepiness, fatigue and attention span. Today was by far the worst I’d seen. He slept most of the day and he was not able to communicate very clearly. He really just had no energy.” One patient stated that his biggest challenge was, “Having the ability to focus. My brain could not multi-task. So trying to do things...if there was somebody changing the trash, and the TV on, and you know someone taking my vitals, and a doctor asking me questions, my brain couldn’t process all of those things.” One of the primary nurses noted, “Yesterday morning before [the patient] decided to quit [treatment], he said that he was having trouble and that he was just thinking slower. That he had dropped a Gatorade bottle, and it took him a minute to realize that.” These qualitative reports from the patient, care partner and nurse allowed us to identify symptom changes at the time of each IL-2 dose while also providing context into each symptom trajectory.

Conclusion: The use of a case study approach allowed for in-depth exploration of the cognitive symptom trajectory from individuals closest to the symptom experience. Although IL-2 patients only completed measurement scales at two time points (pre- and post-treatment) for each hospitalization, care partners proved to be essential in providing qualitative rich descriptions of symptoms experienced during high-dose IL-2 treatment, and how symptoms changed with each IL-2 dose. Additionally, the care partner played a unique role in identifying and reporting symptoms when the patient may be cognitively impaired. In the future, specific interventions can be developed for patients receiving IL-2 based on their cognitive symptom trajectory.

Using Cognitive Rehearsal to Address Nurse-to-Nurse Incivility: Six Months Later, How Are They Doing?

Jennette S. Logan, DNP, RN, USA

Abstract

Purpose: Despite the expectation that nurses behave in civil and caring manners towards patients and other nurses, incivility persists. Research supports however, that there are evidenced based strategies to address uncivil behavior among nurses. Cognitive rehearsal is one of the best evidenced based strategies utilized successfully to address incivility in nursing and to prepare new graduate nurses for a successful career. Nikstaitis, and Simko(2014) conducted training about incivility over a 12 week period and consequently 100% of the population of intensive care nurses were able to successfully use cognitive rehearsal. However, Clark and Griffin (2014) reported that newly licensed nurses described using the rehearsed strategies as difficult, yet successful in reducing or eliminating incivility and lateral violence. The purpose of this research project was to obtain data from new graduate nurses to determine the effectiveness of a workshop and role play about incivility, six months following the training.

Methods: In October 2015, the researcher obtained IRB approval to conduct an educational intervention to address incivility in nursing. The educational intervention was a workshop which consisted of didactics about the definition, prevalence and impact of incivility in nursing. This was followed by a role play demonstrating incivility with time allotted for nursing students to practice Cognitive Rehearsal using cue cards developed by Martha Griffin. At the end of the workshop, 100% of the sample stated that they felt confident that they would be able to utilize cognitive rehearsal to effectively address incivility. The students further agreed to be contacted periodically after graduation regarding the use of Cognitive Rehearsal as new nursing graduates.

Six months following graduation, the researcher conducted the first follow up survey. The following 3 questions were asked. 1) Are you currently employed in nursing? 2) Have you experienced incivility while in the nursing setting? If so describe. 3) Were you able to use Cognitive Rehearsal to address the uncivil behavior? Why or why not?

Comparative analysis was used to analyze and categorize the findings.

Results: A six month follow up revealed the following: Eighty percent of the new nurse graduates experienced incivility in their new employment environments. This is consistent with research findings that suggested somewhere between 27-85% of nurses experience incivility. Fifty percent of the new graduate nurses who experienced incivility used Cognitive rehearsal to address the uncivil behavior whereas 50% did not successfully use Cognitive Rehearsal. The new graduates who did not use Cognitive Rehearsal explained that because they were new to the job, they felt uncomfortable addressing the uncivil behavior. One new graduate stated "I decided to just let it go since I had only been on the job a few weeks."

The uncivil behaviors experienced were categorized as rude, dismissive behavior and withholding information. One new graduate nurse stated "I called the charged nurse to give report at the end of my shift and she yelled at me... "not now"... and hung up the phone" I confronted her the following day and documented it in the discussion forum." Another nurse graduate stated, "I made a suggestion to the nurse manager about a procedure and she dismissed my suggestion without consideration. I approached her later in a calm manner and she apologized for her behavior. Other uncivil acts were categorized as withholding information. The nurse giving report ignored the new graduate and gave report only to the preceptor. The new graduate confronted the nurse and stated, "I am a part of the health care team also and I need report in order to provide quality patient care."

Conclusion: Evidenced based strategies to address incivility such as Cognitive rehearsal are effective but should be threaded throughout the nursing curriculum to increase efficacy and confidence in new graduates. Research by Warner (2016) demonstrated that a series of workshops over a 12- week period

enabled 100% of the participants to successfully utilize incivility. A single workshop conducted by this researcher enabled 50% of the new graduate nurses to use Cognitive rehearsal to address uncivil behavior. The researcher concurs with Clark (2014) that new graduate nurses find that Cognitive rehearsal is effective in reducing or eliminating incivility but it is extremely difficult for some new graduates to utilize this strategy. The researcher would further recommend that Cognitive Rehearsal training should be threaded throughout the curriculum as part of orientation, transition classes, mental health class and simulation/lab scenarios. More training and practice may boost confidence in using the strategy. Additionally, policies should be developed to reflect a “no tolerance stance” for incivility in the class room as well as the clinical setting. The researcher would further recommend a collaborative approach to addressing incivility which would involve academia as well as new nurse residency programs. Generalization of these findings is limited due to a small sample size.

Mediator Role of Memory Function on Diabetes Self-Care Management in Older Adults

Youngshin Song, PhD, RN, Korea, Republic of (South)

Jeonghwa Cho, MSN, RN, Korea, Republic of (South)

Younghee Jun, MSN, RN, Korea, Republic of (South)

Kawoun Seo, MSN, RN, Korea, Republic of (South)

Keumok Park, MSN, RN, Korea, Republic of (South)

Bohyun Kim, BSN, RN, Korea, Republic of (South)

Abstract

Purpose: Memory function is important to perform the special intended tasks. Diabetes self-care composed of several complex tasks such as regularly check the glucose monitor, balance of diet and physical activity, and foot care. For improving diabetes self-care, higher diabetes self-efficacy as an essential factor was emphasized in studies. Despite of having higher self-efficacy in cognitively intact older adults with diabetes, individual behaviors on diabetes self-care is not same level. In order to transfer the intended behavior from self-efficacy, memory should be embedded. Memory function may help the self-initiated behavior such as diabetes self-care. However, little empirical evidences regarding the effects of memory function on self-efficacy and self-care management was found in adults with diabetes. Therefore, this study was to identify the role of memory function on the relationship between diabetes self-efficacy and self-care behavior for older adults with diabetes.

Hypothesis 1: Diabetes self-efficacy and memory function will significantly associate with diabetes self-care management.

Hypothesis 2: The relationship between diabetes self-efficacy and self-care management will be mediated by memory function.

Methods: The descriptive cross-sectional study design was conducted with a sample of 259 older adults (+65 years) with diabetes. Using structure equation model, the direct effect of diabetes self-efficacy and memory function on diabetes self-care management was estimated. After then, indirect effect of diabetes self-efficacy on self-care management after controlling for memory function as a mediator was estimated in the path diagram.

Results: The mean age of participants was 72yrs, and the mean year of diabetes was 12 yrs.

Hypothesis 1: Diabetes self-care management was positively associated with self-efficacy ($r=0.55$, $p<.001$), whereas memory function was negatively correlated with diabetes self-efficacy ($r=-0.19$, $p=.003$) and self-care management ($r= -0.29$, $p<.001$) in correlation matrix. The hypothesis 1 was confirmed

Hypothesis 2: Diabetes self-efficacy significantly predicted the diabetes self-care management ($\beta = 0.79$, $p = .009$) and memory function ($\beta = -0.22$, $p=.006$) in older adults with diabetes. Lower memory function was also significantly associated with greater self-care management ($\beta = -0.20$, $p = .043$). However, when memory function was entered as a mediator in the relationship between diabetes self-efficacy and self-care management, the direct effect between two was changed from $\beta = -0.79$ ($p=.009$) to $\beta = 0.04$ ($p = .017$). That is, the memory function was a partial mediator between diabetes self-efficacy and self-care management in older adults with diabetes. Thus, hypothesis 2 was confirmed.

Conclusion: A structural equation model confirmed the mediator role of memory function on the relationship between diabetes self-efficacy and self-care management in older adults. Therefore, for improving the diabetes self-care management in older adults with diabetes, health care provider should consider not only to enhance the diabetes self-efficacy but also to monitor individual function of memory in older adults.

RSC PST 3 - Research Poster Session 3

Collaboration With Special Olympics: Graduate Nursing Program Successful Clinical Experience

Melissa A. Murphey, DNP, FNP-C, USA
Kathleen A. Muglia, DNP, APRN-BC, USA

Abstract

Purpose: Obtaining health care for those in vulnerable populations coupled with multiple comorbidities can be difficult. Vulnerable populations include those patients with developmental and physiological impairments including those born with Down Syndrome. Caregivers and family can be challenged by insurance coverage, transportation, advanced age and life constraints when obtaining care for this vulnerable group. As more nurses return to school for further education and positions as advanced practice nurses particularly nurse practitioners, the need to obtain clinical preceptorships have become increasingly competitive. This competition leads to a decrease in available positions for adequate clinical placement. Providing quality care to vulnerable groups (i.e., Special Olympics) in a setting that is comfortable for the patient was identified by a graduate nursing program. The aim at educating and preparing graduate students who would be successful with varied experience had become paramount in one school's journey

Methods: As a nursing school in an urban setting has found, collaborating and developing clinical partnerships with vulnerable groups has become a success for both the university and the target population. The university educators embraced on a journey of travelling to secondary schools to provide much needed care to groups in great need. Two doctorally prepared nurse practitioner led clinical groups were started that provided students the opportunity to learn a variety of skills that prior clinical sites often lacked. Physical exams were performed on patients with special needs assisting them in competing in their desired extracurricular activities.

Results: Practitioners recognized the rare opportunities students would have to experience care focusing on patients affected by Down syndrome, cerebral palsy and those developmentally challenged. Educating caregivers and patients on the importance of exercise and proper nutrition led to further enrichment and understanding of risks associated with obesity. Partnering with Special Olympics, a graduate nursing program broadened the clinical residency experience of nurse practitioner students.

Conclusion: Clinical educators should capitalize on diverse learning experiences to provide a more unique learning experience for their graduate student population.

Students' Perceptions of Stress When Experiencing Loss and the Support From Academia That is Needed

Kathleen M. Bell, EdD, MS, RN, PHN, USA

Abstract

Purpose: This presentation will explore the results of a 2015 dissertation regarding students who experienced loss through death within the prior 12 months. Students attending colleges and universities often have complex lives, which may include the experience of loss of someone close during an academic year at rates of 20-30 percent (Balk, Walker, & Baker, 2010; Boynton Health Service, 2013). The demographics of the United States reflect an aging population, increasing the chance of the death of the students' close relatives (Portman, Velkoff, & Hogan 2014).

Experiencing loss and the grief that follows can jeopardize educational goals. Because of the preponderance for experiencing loss for students, this author chose to research the stresses with loss that community college students experience and possible ways colleges can support.

Students may not always be able to prioritize their education while grieving and experiencing the secondary ramifications of loss. Their familial role may change, there may be financial and/or household details to be addressed, travel may be necessary to attend the funeral, and the students may experience emotional upheaval. Missing time can be detrimental to progression in nursing programs that are attendance driven and focus on a professional track of study. Additionally, for many students, their commitment to continue academically may depend on their integration into the college experience (Tinto, 2012). Colleges have not historically been responsive to supporting students who experience grief and loss, except during catastrophic experiences that may affect a community nearby or the college itself. Additionally, staff and faculty may not know how to address the issues of grief and loss experienced by students.

Assisting students through the immediacy of experiencing loss may not be enough help. Grief from loss can linger for months, if not years, in the form of complicated grief (Fox & Jones, 2013; Shear, 2012). Anecdotal comments of those who have experienced loss may include, "After the death, all was a blur, or I don't remember how I got through that time." Therefore, academic institutions and nursing need an understanding of the short and long term ramifications of grief and loss.

While reviewing quantitative data from multi-year research of the Boynton Health Service of the University of Minnesota (2013), this researcher was struck by the following student survey response: 20 percent of students, who participate in the studies, stated that *death of someone close was their number one stressor*, the highest ranked response of the stressors' category. This response rate ranks above the intensity of stress caused by relationships and financial challenges, which college students also report as stressors (Boynton Health Service, 2013). This researcher worked in hospice care as a registered nurse for over ten years prior to making a career change to education. This involvement with dying and death, and experiencing a number of personal losses in my adult life, led to a focus on this aspect of the University of Minnesota's research. The topic had a level of being personal and the topic grew in interest. Time had passed since my personal losses and Maxwell (2013) suggests that the researcher assess personal desires regarding the choices of research questions, selection of settings and participants, data collection, and analysis to gain insight into the impact on conclusions in order to prevent a flawed or bias study.

In my recent past role as an administrator in higher education, it became necessary to counsel students who request decision-making advice regarding academic progression after experiencing recent loss of someone close. The variables are complex in a context of personal goals, prior experiences with death, the relationship with the deceased, and cultural and religious beliefs. An example is whether to stay in school while actively grieving or perhaps facing issues of missing school to attend lengthy death rituals mandatory within the student's culture.

In order to strengthen a college campus's response to students experiencing loss, there are a number of considerations. Are faculty and staff, including counselors, comfortable with loss and able to listen intently to a student's story of loss? Additionally, are staff up-to-date in the unfolding theories of loss and support for the bereaved? Does the college campus have multicultural staff to relate to students and understand bereavement responses from a cultural perspective? These are questions for each institution to evaluate so that students can continue on with their academic journey during a time of loss and mourning.

Assisting people, including students, through the complexities of bereavement or grief involves a number of disciplines with nursing being deeply involved. Therefore, it is imperative that nurse educators recognize a dual role of educating students on loss and grief as well as supporting students experiencing loss. Balk (2011) writes that the impact of bereavement on a person is physical, cognitive, emotional, interpersonal, behavioral, and spiritual, words that demonstrate nursing's holistic model of care.

Nursing historically honored the work of Elisabeth Kübler-Ross who identified five stages of grief, including denial, anger, bargaining, depression, and acceptance (Kübler-Ross Foundation, 2016). Archer (1999/2000) believes Kübler-Ross's work was inspired by Bowlby's stage theory and her work was based on observations of her dying patients, rather than bereaved individuals, and therefore, her work has also been disputed due to the stages extrapolated for bereaved individuals rather than the dying and it was observational-based rather than developed from empirical data (Bonanno, 2009; Bugless, 2010). Another model is the dual process model (DPM) of coping with bereavement, which describes coping, predicting adaptation, and strives for a better understanding of individual differences (Stroebe & Schut, 2010).

Methods: This presentation will be based on my 2015 dissertation that used mixed methods research methodology to discover aspects of what a set of community college students were experiencing after loss. The mixed-method research included a survey, interviews, and artifact review. Triangulation of data assists to broaden understanding of the issues, and add validity to the findings (Maxwell, 2013). This study used a constructivist framework because the research relied on the participants' views of the situation and recognizes the impact of the researcher's background and experiences (Mackenzie & Knipe, 2006). The constructivist paradigm was chosen with consideration to the complexities of individuals experiencing loss due to history with the deceased, roles, familial, cultural, and spiritual considerations, circumstances regarding the death, and how a person makes meaning and is able to articulate their inner thoughts. The complexity of the loss experience may interplay with the meaning attached to attending college and how the person perceives the academic institution.

The primary research question of the dissertation was: *What are community college students' perceptions of stress when experiencing loss through death of someone close?* A secondary question was: *What support is available and needed from a community college for students experiencing stress from loss?*

Results: The results of this research indicate that students were experiencing stress related to their loss. The survey analysis suggests that 78% of these community college students who had experienced loss had stress levels that were staying the same or increasing. The students reported that their feelings, difficulty studying, getting through school, keeping up with class, and finding emotional relief as the main stress concerns.

Only one-fifth of survey respondents discussed their loss with anyone on campus and classmate, instructor, and friend were the most common responses of whom the students spoke with at the college. Multicultural students spoke less with instructors and more frequently with counselors, classmates, friends, or support services' personnel. Thirty-seven percent of the students completing the survey reported experiencing the loss of more than one person and grandmother (35%) and friend (30%) were the most common reported loss. Respondents request that a place to go for privacy was the number one request for support.

All seven interviewees experienced physical illness, accidents, and/or an increase in psychological symptoms with their loss. Additionally, interviewees found that continuing with their studies provided a needed structure and they often continued as a commitment to the deceased. The interviewees were

articulate about stress management techniques that include phone apps, children, cooking, journaling, drinking, group support, and friends. Each of the student participants interviewed spent time discussing the situation surrounding the death of their loved one. The process of storytelling provides a cathartic function and creates a reality and gives words to grief (Hooghe, Neimeyer, & Rober, 2011). Six of the seven cried during the interview at multiple times, demonstrating the outpouring of grief continued and they also smiled and laughed. Those interviewed disclosed issues involving their loss and issues of negative family dynamics, mental health challenges, and experiences with specific instructors on campus. One student, who disclosed a number of personal issues, said that this researcher was the first adult to offer words of hope, a sad statement.

Conclusion: The findings of this research have implications for developing support for students by staff, faculty, and administration of community colleges and other academic institutions. Results from this study support the need for a college-wide policy for bereavement in that students had mixed responses from faculty and students did not know options for an academic leave or campus support.

How Do Student Nurses in Malawi Choose, Adapt to Career Transition, and Construct Careers?

Zione Dembo, MSc, BSc, RNM, Malawi

Evelyn Baxter Chilemba, PhD, RN/RM, Malawi

Abstract

Purpose: As demand for nurses continues to surpass supply in Malawi it is important to understand what motivates new entrants to join and remain in the profession. The objectives of this study were to understand students' motivations for choosing nursing and their future career plan which has implications for developing strategies to enhance professional satisfaction and career fulfilment.

Methods: The study used qualitative study methods. A purposively selected sample size of 37 final year students was used. There were 16 individual in depth interviews and 3 focus group discussions. The study was conducted in 2 colleges of nursing in Malawi; Nkhoma College which trains diploma students and Kamuzu College of Nursing (KCN) which trains BSc nurses. Interviews covered how and why nurses entered nursing, their training experiences and future career plans. Data were analysed using thematic analysis.

Results: The findings highlight that the choice of nursing course was influenced by desire to help people, admiration from significant others including nurse models, anticipated career rewards while almost half was by default however their training experiences were crucial to reframing nursing as a 'suitable job'. For nearly all students the impact of training experiences through contact with coursework, practical and lecturers on career choice were marked. Nursing was seen as a viable career particularly for undergraduate students from KCN, where it is regarded 'a guaranteed job with prospects'. Almost all nurses interviewed intended to seek employment in public sector citing their reason as opportunities to pursue advanced nursing qualification to satisfy career objectives; increased knowledge, skills and economic rewards. Undesirably, most students indicated preference to have non clinical job after attaining higher qualifications following observation that there are no established clinical job post for nurse specialist in Malawi.

Conclusion: Findings suggest that preservice orientation remains a key factor in choosing nursing. Students also look for a career which offer professional values and rewards. If advanced clinical nursing practitioner career path remain undefined nursing may be in danger of losing service orientated recruits to other non-clinical professions.

Walking for Our Health: Evaluation of Randomized Spousal Physical Activity Pilot Intervention

Elizabeth A. Richards, PhD, RN, CHES, USA

Melissa M. Franks, PhD, USA

Meghan M. McDonough, PhD, Canada

Sharon L. Christ, PhD, USA

Abstract

Purpose: Addressing physical inactivity among older adults is a crucial public health challenge as less than 5% of older adults meet physical activity (PA) recommendations (Troiano et al., 2008) and PA declines with age (Centers for Disease Control and Prevention, 2012; de Rezende et al., 2014). Physical inactivity and sedentary behavior are associated with a higher risk of all-cause mortality and multiple chronic conditions (Physical Activity Guidelines Advisory Committee, 2008; de Rezende, Rey-López, Matsudo, & do Carmo Luiz, 2014).

Despite concerted efforts, physical inactivity remains a major public health concern, especially among older adults who struggle to maintain PA over extended periods of time (de Rezende et al., 2014). PA interventions, particularly goal setting, have shown promise because the experience of setting and achieving goals promotes self-efficacy, a key predictor of PA behavior change (Shilts, Horowitz, & Townsend, 2004). In addition to this individual-level approach, interpersonal approaches such as social support also have promise for improving PA (Berli, Stadler, Inauen, & Scholz, 2016). However each of these approaches alone have had limited success. Currently there is a significant gap in PA intervention strategies that activate and maximize older adults' available social ties to promote PA behavior change and maintenance.

The purpose of our study was to examine the effectiveness of two couple-focused goal setting interventions to increase PA among older adults in committed relationships. These interventions leveraged the strong association between couples' PA behavior and the opportunity for regular and sustained support over time to improve PA among older adults.

Methods: Our conceptual framework for examining the effects of a dyad intervention on PA behavior change and maintenance is informed by social cognitive theory and interdependence theory (Bandura, 1997; Lewis et al., 2006). In social cognitive theory self-efficacy is the primary, proximal determinant of PA behavior, and mediates the association between other individual, social and environmental determinants, and PA behavior (Bandura, 1997). Behavior change strategies, such as goal setting, increase self-efficacy by defining and focusing effort on a manageable but challenging behavioral improvement (Locke & Latham, 2006). Behavioral change strategies that include setting and achieving goals with a significant other have the added potential of enhancing self-efficacy through role modeling and of providing encouragement and support. Drawing on interdependence theory, Lewis and colleagues (2006) conceptualize health behavior change as a process that takes place in the context of interdependent relationships and not solely a product of individual effort. We hypothesized that dyad-level interventions that coordinate interpersonal resources with goal setting techniques will promote PA behavior change. By combining key elements of these theories, we hypothesize that effective support from a significant other engaging in the same behavior change process will enhance the effects of a goal-setting intervention.

We recruited a sample of 31 couples who met the following inclusion criteria: 1) at least one partner 50 years of age or older, 2) partners living together, and 3) at least one partner has received medical advice to increase PA in the past year. We also used the following exclusion criteria: 1) unable to speak and understand English, 2) partner unwilling to participate in the intervention, and 3) failed the screening to identify contraindications to participating in PA or did not receive physician clearance to participate in PA.

Intervention methods included partners randomized (together) into a concurrent individual goal-setting group or a collaborative goal-setting group. At the start and end of the study, each partner was fitted with an accelerometer for 1 week to evaluate baseline and post-intervention PA. All partners attended a group session with other couples in their condition and received information about healthy PA targets and rates of progression for realistic and safe increases in PA. Partners in the collaborative goal-setting group set and evaluated their goals in terms of cumulative number of steps taken by both members of the couple. Each partner in the concurrent individual goal-setting condition set and evaluated her/his own goals in terms of the number of weekly steps taken. In addition, all participants received eight weekly phone calls to assess progress towards goals and assist in setting new goals or revising current goals.

Activity intensity was established using accelerometer cut-points derived specifically for older adults (Copeland & Eslinger, 2009). To analyze the data, a mixed-effects (3-level) model was estimated with a couple level random intercept and an individual level random intercept to adjust for nesting of individuals within couple and time within individual, respectively. Change in moderate to vigorous physical activity (MVPA), weight in pounds, and body mass index (BMI) between pre-intervention and post-intervention were evaluated. The change slope was also allowed to vary randomly across individual and/or couples when this random slope had statistically significant variance. In each model, participant age, sex, number of health conditions, income, education, current employment status, and relationship satisfaction were included as covariates.

Results: Twenty-eight couples completed the study. Reasons for attrition included injury (unrelated to the study) and dissatisfaction with the study pedometers. A majority of participants were Caucasian with an average age of 64.8 years and had been married for an average of 35 years. Compliance with the intervention was high. At baseline, nearly all participants (98.4%) had at least the minimum 4 days of valid accelerometer wear time with an average wear time of 838.1 minutes/day.

On average, weekly minutes of MVPA increased by 58 ($p < 0.001$) between pre-intervention and post-intervention eight weeks later. Weekly minutes of MVPA increased by 66 ($p < 0.01$), on average, for those in the concurrent individual goal setting group and by 49 minutes ($p < 0.05$), on average, for those in the collaborative goal setting group. There was no difference in these changes across the intervention groups ($p = 0.62$). Sedentary time did not change from pre- to post-intervention on average ($p = 0.41$) and there was no difference between groups.

On average, BMI decreased by 0.50 ($p < 0.01$) and weight decreased by 3.13 pounds ($p < 0.01$) between pre-intervention and post-intervention. BMI decreased by 0.57 ($p < 0.01$) and weight by 3.7 pound ($p < 0.01$), on average, for those in the concurrent individual goal setting group. BMI decreased by 0.42 ($p = 0.06$) and weight by 2.5 pounds ($p=0.07$), on average, for those in the collaborative goal setting group. There was no difference in these changes across the intervention groups ($p \geq 0.55$).

Conclusion: Our results suggest that spouse-involved PA interventions could be effective in eliciting increases in PA among married partners. Potential for spouse-involved health behavior change interventions are possible because spouses could provide assistance, social support, and feedback to one other to maximize PA promotion, as well as having the potential to improve relationship quality or satisfaction. Few PA intervention studies have been conducted at the dyad-level such as with committed partners (Richards et al., 2016). Additional research is needed to understand effective strategies for increasing PA drawing on the available support of partners or other social network members. Such dyadic interventions should address supportive interactions that may maximize PA promotion. In conclusion, demonstrating the effectiveness of these couple-level PA intervention strategies is an important step toward promoting healthy aging by facilitating a key lifestyle modification that can delay the onset of chronic illness and reduce healthcare costs for older adults, their families, and society.

RSC PST 3 - Research Poster Session 3

Applying a Nursing Framework to Understand a Governmental Health Promotion Strategy

Bridget M. O'Connor, BSN, RN, USA

Patty Hayes, MN, RN, USA

Jennifer DeYoung, MPA, USA

Abstract

Purpose: The purpose of this presentation is to describe how Dobbins evidence-based framework was used to design a case study about Best Starts for Kids (BSK), an innovative, governmental initiative to fund health promotion and early intervention for children.

Methods: Across the world, the prevalence of chronic illness is escalating, and population health disparities are widening. These international trends are prompting governments to address public health by innovatively shifting investments from illness care to prevention and health promotion.^{1,2,3,4} There is a need to describe how current governmental initiatives use evidence-based decision making in order to replicate successful strategies in other regions.^{1,2,3,4} The World Health Organization (WHO) and National Prevention Council both support the evaluation of innovative governmental health initiatives.^{2,4}

This presentation will describe the case study design and rationale, including the systematic literature analyzed to design the case. PubMed and CINAHL databases were searched using the key search terms “health policy,” “government,” and “case study” in the subject line from 2011 to present. The same search was repeated with the addition of “equity” in the subject line. Resulting articles included PubMed, 154 and CINHAL, 73 after duplicate articles were omitted. Inclusion criterion required that articles discussed analysis of comprehensive governmental approaches to health promotion and prevention. Articles that focused on individual programs were excluded.

Of the published case studies reviewed, 8 described the processes of comprehensive approaches to prevention and health promotion policy within the local government environment. Cross sector collaboration and evidence of health disparities were presented as significant factors that contributed to innovative health policy development. What is not clear from this review is how factors such as the culture, relationships, and characteristics of government leaders, organizations, community and innovation itself contributed to the development of evidenced based policies which is important for the dissemination of new approaches. Dobbins' *Dissemination and use of Research Evidence for Policy and Practice* framework was chosen to evaluate the development of BSK because it guides the user through the processes of evidenced-based decision making, including looking at factors that contributed to those decisions.⁵

Results: The process of how BSK was developed will be illustrated in a diagram, depicting the stages of the innovation development based upon Dobbins framework *Dissemination and use of Research Evidence for Policy and Practice*.⁵ One purpose of this framework is to provide a model of the process of evidenced-based decision making.⁵ This case study will integrate Roger's *Diffusion of Innovation's* stages; “knowledge,” “persuasion,” and “decision” to discover the factors that led to the development and passing of the BSK initiative. The knowledge phase is emphasized in the case study by collecting information about how evidence is sought, what evidence influenced the policy makers and stakeholders, and impact of community outreach and engagement. The “knowledge” phase will include looking at hierarchy of evidence that was sought and used. The “persuasion” phase will focus on factors that may have influenced the decision process such as individual, organizational, environmental, and innovation characteristics. The methods used to gather information about the persuasion phase will include document analysis, interviews with 5-8 key participants, and an online survey of the members of the three primary advisory groups to BSK. The “decision” phase will be used to understand types of decisions that were made such as whether to adopt the innovation and how organizational values, beliefs, and culture influenced the decision making.^{5,6} Questions about decision making factors such as the following will be asked; “Who was involved in the decision to adopt the innovation?,” “What was the stakeholder

involvement in the decision making process?” and “How did collaborations across governmental branches influence decision making?”

Conclusion: The Dobbins' *Dissemination and Use of Research Evidence for Policy and Practice* was an ideal framework to depict the environmental, individual, organizational, and innovation characteristics that propelled BSK to a levy on the ballot. This presentation is significant for nurses because it illustrates how the Dobbins' framework can be used to describe the development of a governmental initiative. Depicting the processes involved in innovative health policy is necessary in order for the innovation to be disseminated and replicated.

Application of the "Attentively Embracing Story" Theory in Older Persons Living in Long-Term Care Facilities

Hui-Wan Chuang, MS, RN, Taiwan

Abstract

Background: The "Attentively Embracing Story" is a middle-range nursing theory, which employs intentional dialogue to encourage individuals to describe events that are a challenge to their health. The "Attentively Embracing Story" helps individuals transform negative thoughts into positive thoughts, reflect on new meanings and values, and boost spiritual healing and health improvement. However, most studies had methodological shortcomings, including small sample sizes ($N < 10$), pre-post designs, lack of objective outcome, and lack of active treatment controls, which preclude clear conclusions regarding efficacy.

Purpose: The purpose of this study was to examine the effectiveness of a "Story-Centred Care Intervention Program" based on the "Attentively Embracing Story", in improving quality of life, blood pressure and heart rate variability in institutionalized older adults.

Methods: A single-blind two-group longitudinal experimental design was used. Participants ($N = 60$) were adults over 65 years of age living in long-term care facilities in northern Taiwan. Participants were randomly assigned to an experimental group ($n = 29$) or a control group ($n = 31$). The experimental group received a "story-centred care intervention program" once a week for 4 weeks. The control group received a control intervention of medical and life consultations over the same time period. Measurements were obtained in four waves: pre-intervention, post-intervention, and one month and three months after completion of the intervention. Instruments included the WHOQOL -BREF Questionnaire, an electronic blood pressure monitor (type HEM-7210, made by OMRON Co., Ltd., Japan) and 5-minute heart rate variability time-domain parameters of SDNN, and RMSSD (DailyCare BioMedical, Inc., Chungli, Taiwan). Data were analysed using Fisher's exact test, chi-square test, Mann-Whitney U test, and generalized estimating equation.

Results: At 1-month and 3-month follow-up, the group that received the story-centred care intervention program had significantly higher scores for quality of life ($p < 0.001$, $p < 0.001$, respectively) compared with the control group. Neither Blood pressure nor heart rate variability parameters did not show a statistically significant improvement, however a trend of improvement in parameters was observed in the experimental group.

Conclusion: The story-centred care intervention program was effective in improving quality of life in older adults living in long-term care facilities; however, further study is needed to demonstrate its role in improving blood pressure and heart rate variability.

Keywords: Attentively embracing story, story-centred care, quality of life

RSC PST 3 - Research Poster Session 3

Predictors of Academic Performance of Nursing Students at a University in the Western Cape, South Africa

Felicity M. Daniels, PhD, MPH, RN, RPN, CHN, RNE, South Africa
Katlego D. Mthimunye, MSN, RN, PGDipNsgEd, MEd, South Africa

Abstract

Purpose: The overall purpose of the study was to determine whether specifically selected predictor variables (cognitive, non-cognitive) influence academic performance of second-year nursing students at a University in the Western Cape, South Africa.

Methods: A non-experimental quantitative research approach with a cross-sectional predictive design was applied. The selected sample ($n=226$) included all first-time enrolled Bachelor of Nursing students for the years 2012 – 2013 at a University of the Western Cape, South Africa. An all-inclusive sampling method was applied. Data were obtained from the online Student Administrative System Integrated (SASI) and recorded in the data collection check list designed for the study purpose. The Statistical Package for Social Sciences software version 23.0 was used to sort and analyse the data. Descriptive analysis was done.

Description of variables - Cognitive variables: Grade 12 high school grade (admission points)

Grade 12 high school grade was calculated according to the university's approved point system. These points are also referred to as the Student's Admissions Points. The grade obtained for each high school subject is captured from the student's official transcripts submitted on application to the university. The sum of the grades obtained for all high school subjects determines the student's admission points. A student must achieve at least 27 admission points for acceptance to the higher education institution and a desired score of 30 or more points for admission to the Bachelor of Nursing programme.

- Previous nursing qualifications
This variable was designed to identify those students who entered the Bachelor of Nursing programme with previous nursing qualifications at certificate, diploma or degree level.
- National Benchmark Test
The student's average score on the National Benchmark Test consisted of three components namely: academic literacy (AL), quantitative literacy (QL) and knowledge health science.

Non-cognitive variables:

- English as a second language
This non-cognitive variable is defined as the student's home language or mother tongue as indicated on the application forms received by the university.
- Student's place of residence
This variable is defined according to whether the student lived in or out of the university residence during their second-year registration on the Bachelor of Nursing programme.

Ethics: The study was approved by the university's Senate Research and Ethics Committees and permission to conduct study was granted by the university's Registrar and the Director of the School of Nursing.

Results: The study found that the cognitive predictor variables, including Grade 12 high school grades; previous nursing qualifications and student's average score on the National Benchmark test, had the strongest predictive power in relation to student performance in comparison to the non-cognitive predictor variables which included English as a second language and the student's place of residence.

Conclusion: The study found that the grades which students achieved in grade 12 of high school and the National Benchmark Test, both referred to cognitive predictors, are able to predict a student's academic performance in the second year of a Bachelor of Nursing programme.

RSC PST 3 - Research Poster Session 3

Graduate Students' Perceived Genetic Knowledge: A Preliminary Study

Leighsa Sharoff, EdD, RN, NPP, AHN-BC, USA

Abstract

Purpose: Summary of a preliminary assessment of graduate nursing students' from the City University of New York [CUNY] knowledge about genetics and genomics.

Methods: Thirty-six graduate students, 7 in a DNP program, were surveyed with the Genetics and Genomics Literacy Assessment (GGLA). This consisted of 16 multiple choice questions, 7 questions related to their perceptions and attitudes about genetics and genomics integration into nursing curricula, 5 questions related to their comfort level about genetics and genomics and 4 demographic items. Data was collected via Survey Monkey converted to SPSS.

Results: Summary of categorical data revealed that the majority of participants for 8 of the survey questions answered correctly [greater than 60%] while 8 questions had significantly lower correct percentages [55% or less]. These included limited knowledge related to understanding the diagnosis of an autosomal recessive disease [26% correct]; reciprocal translocation in the genome [12% correct]; genetic testing concepts [13% correct]; understanding carrier status of X-linked recessive condition [38% correct]; understanding amniocentesis results with phenotypic abnormality [40% correct]; understanding inheritance patterns via pedigree [40% correct]; understanding the concept of penetrance [55% correct] and being able to read a pedigree [20% correct]. The majority [> 75%] of students' attitude is that it is important for nurses and nurse educators to know this content and to be able to teach this material however, the majority [>75%] were not comfortable with teaching or explaining this material.

Conclusion: All nursing students, from pre-licensure to doctoral studies, would benefit from receiving additional education on the foundational concepts of genetics. Genetics and genomics are increasingly relevant in all areas of clinical nursing practice and faculty charged with educating the future generation must have a basic understanding of this content. The required competency of genetic knowledge mandates that all nurses are able to integrate the basic concepts so they can educate and advocate for their patients. Without additional educational preparation, advanced practicing nurses will not be adequately prepared to provide this essential information.

Attitudes Toward the Elderly Among Pre-Licensure Nursing Students

Maria E. Mackey, DNP, RN, CNE, USA

Abstract

Purpose: In the United States, the baby-boomers of yesteryear are emerging as today and tomorrow's elderly population. Given this fact, health care is faced with the challenge of providing safe, quality, and compassionate care to this ageing population. According to the U.S. Census Bureau (2014), in 2010 the population of elderly (identified as 65 and older) accounted for 13.1% of the U.S. population. The U.S. Census Bureau (2014) projects that in the year 2030, the population of elderly in the U.S. will nearly double to 20.3%, and will sustain through 2060 with a projected elderly population of 20.9%. While projections are only estimates of what is to come and not definitive, it is important that health care providers be prepared to address the needs of this identified patient population. The ageing process leads to physiological, functional, cognitive and psychosocial changes; however, these changes do not suggest that ageing predictably leads to disability and dependence (Potter & Perry, 2013). Inevitably, with age-related changes individuals make assumptions and assign labels to the elderly population based on preconceived notions and inaccurate beliefs. As identified by the U.S. Department of Health and Human Services (2013), unrealistic perceptions of ageing can, and do, negatively impact the physical and mental health of the elderly. When living in an ageist society, health care professionals are often unaware of how stereotypes of ageing mold perceptions of the elderly. Perceptions become reality, and the only way to change perceptions is to create a new reality with increased sensitivity and improved attitudes. The purpose of this study was to investigate student nurses' attitudes toward the elderly after receiving gerontology specific education, in a diploma nursing program, in the Northeastern United States.

Methods: With the increased number of elderly needing healthcare and concerns of ageist attitudes towards the elderly, pre-licensure student nurses need to have a better understanding of this patient population and the implications of providing biased care. Research indicates that there are multiple variables that help form attitudes about the elderly, and the positive influence of education. This study implemented a non-experimental Single Group Before-After study design. Using Kogan's (1961) Attitudes Towards Old People (ATOP) scale, this project surveyed attitudes of pre-licensure diploma level nursing students, in a mixed rural and urban setting of the Northeastern U.S.. Surveys were conducted both before and after the completion of a seven-week gerontology specific course, guided by Miller's (1990) Functional Consequences Theory for Promoting Wellness in Older Adults. Using an independent-samples t-test, before gerontology ATOP total scores were compared to after gerontology ATOP total scores to determine if the gerontology specific education improved student nurses' attitudes toward the elderly.

Results: Results of the independent-samples t-test revealed that there was no significant difference in scores for before ($M = 124.88$, $SD = 8.47$) and after ($M = 123.55$, $SD = 9.73$; $t(26) = .39$, $p = .7$, two-tailed). Mean differences were 1.34 (95% CI: -5.8 to 8.48). The magnitude of the effect on group difference in the overall mean scores was determined using eta squared and demonstrated a very small effect at $\eta^2 = .006$. The results of this project demonstrated no significant difference in scores for before and after, suggesting that the intervention of gerontology specific education had no impact as a strategy to improve student attitudes.

Conclusion: With no significant difference in scores for before and after surveys, the implication is that the intervention of gerontology education had no impact as a strategy to improve student attitudes. The lack of improvement may have been a result of students already having positive attitudes. Or, the results may have failed to demonstrate an improvement in student attitudes after gerontology education, because the sample size may have been too small to capture a change that may have occurred with a larger sample size. Nonetheless, this study provided a means to objectively measure student attitudes and provided objective data that may or may not be captured, in the classroom and clinical learning environments.

Focus on Fidelity: Delivering What's Intended in a Multi-Site Randomized Clinical Trial

Janet D. Morrison, PhD, RN, MSCN, USA

Alexa K. Stuijbergen, PhD, RN, FAAN, USA

Abstract

Purpose: Intervention fidelity, the degree to which an intervention study is carried out as proposed, is critical to ensuring internal validity, reliability and generalizability of research findings (Gearing et al., 2011; Goense, Boendermaker, & von Yperen, 2016). Unfortunately, intervention fidelity is infrequently reported in the research literature (Corely & Kim, 2016; Stone 2015). The absence of intervention fidelity reporting may contribute to dissemination of potentially low-efficacy or ineffective interventions into clinical practice. The purpose of this abstract is to explicate the strategies used to assess and monitor intervention fidelity in an ongoing multi-site clinical trial. The intervention fidelity strategies used in the current study were guided by best practice recommendations put forth by the Treatment Fidelity Workgroup of the National Institutes of Health Behavior Change Consortium (BCC) (Bellg et al., 2004). The BCC's recommendations encompass five strategy domains: (1) study design, (2) facilitator training, (3) intervention delivery, (4) intervention receipt, and (5) intervention enactment.

Methods: Strategies promoting intervention fidelity were developed a priori for use in a multi-site randomized clinical trial testing the efficacy of a computer-assisted cognitive rehabilitation intervention for adults with multiple sclerosis. Data were collected continuously throughout the study to assess and monitor intervention fidelity related to study design, facilitator training, intervention delivery, and intervention enactment.

Results: Fidelity data from 10 cohorts were gathered throughout the study's 8-week long intervention and again at 2 and 4-months after the intervention ended. Data were extracted from audio-recordings of intervention sessions, session attendance records, audits of computer exercises completed at home by the participants, and post-intervention goal attainment scaling that suggested reasonably high fidelity to the intervention protocol.

Conclusion: This research project demonstrates how nurse researchers may examine and report intervention fidelity guided by best-practice recommendations. Detailed attention to, and documentation of, intervention fidelity strategies may serve to promote scientific rigor in future studies and foster translation of effective interventions into nursing practice.

Assessing Learning Styles: How Do Nursing Students in a Baccalaureate Nursing Program Learn?

Anne White, PhD, RN, USA

Jane Brannan, EdD, RN, USA

Abstract

Purpose: Nursing faculty throughout the world strive to provide quality education that can be effectively translated to positive learning outcomes. The learners in the university today are dramatically different from those of the past. Educators are being challenged to re-shape the curriculum to address the contemporary learner and understand their approaches to learning. Research has focused on various aspects of learning, yet gaps remain in our understanding and assessment of how students learn. The Felder-Solomon Index of Learning Styles (ILS) instrument has been used sparsely in nursing education, but is one that may serve the assessment need well. It has been identified as a more theoretically well rounded approach to determine learning styles. It can also be used by international colleagues as its psychometric properties have been explored and the instrument has been translated into several languages. Classes are typically composed of students from varied backgrounds and needs. Few studies have investigated the learning styles of baccalaureate degree student nurses to determine if there are differences in learning preferences by program type (accelerated versus traditional), gender, race, or age group. Given the changed nature of today's learner, it is important that faculty have a greater understanding of the learning process to better facilitate the classroom and assure that there are options that best address the needs of today's students. The purpose of the study was to examine the learning preferences of nursing students in a baccalaureate degree nursing program to determine if there are differences in learning preferences by program type (accelerated or traditional), gender, race, or age group.

Methods: A cross-sectional, descriptive design was used for this study to examine learning preferences of senior nursing students in a baccalaureate degree nursing program. The research questions were: 1) What are the learning preferences of senior nursing students in a baccalaureate degree nursing program that offers accelerated and traditional program options?, 2) What are the differences in nursing students' learning preferences by program type, gender, race and age group? The Felder-Soloman Index of Learning Styles (ILS) instrument was administered to 331 senior nursing students prior to the first class day during a four-year period. Demographic information was collected from each participant. The ILS is an instrument containing 44 forced choice questions that classifies learning styles into four domains: processing (active vs reflective), perceiving (sensing vs intuitive), receiving (visual vs verbal), and understanding (sequential vs global). Scores indicate students' learning preferences within each of the domains. The ILS results were compared with program type, student gender, race, and age to determine relationships between student characteristics and learning styles.

Results: Predominant learning styles included active, sensing, visual, and sequential preferences. There were no significant relationships by age, race, or gender and learning style domain. There was a significance difference found in program type between traditional and accelerated programs. The traditional program nursing students were 2.4 times more likely to be visual learners than accelerated degree students.

Conclusion: It is beneficial for all students to determine their own learning style in order for them to begin to grow and strengthen their repertoire of learning capabilities. The National League for Nursing (NLN) has noted in the list of core competencies for nurse educators that awareness of student learning styles is important for designing effective nursing education. Assessment of learning styles of each cohort may guide teaching strategies appropriate for the needs of those students. Simulation has been identified as an effective strategy for incorporating different learning style preferences which may be useful for a cohort of students that have a wide variety of learning styles. The instrument has been used with students of multiple nationalities and has been found to be valid and reliable. The study also is clinically relevant in

that a nurse's understanding of learning styles may affect the selection of effective patient teaching techniques and potentially improve patient outcomes.

Chronic Disease Burden and the Impact on Nursing Practice in South Texas

Jean Dowling Dols, PhD, RN, NEA-BC, FACHE, USA
Mary M. Hoke, PhD, RN-BC, APHN-BC, ANEF, USA
Karen L. Weis, PhD, RNC-OB, FAAN, USA
M. Danielle Gunter, PhD, RN, CPN, USA

Abstract

Purpose: Chronic diseases are the leading causes of death in the United States, with 45% of the population having at least one chronic disease.¹ Americans aged 65+ with one or more chronic disease has risen from 86.9% in 1998 to 92.2% ten years later in 2008.² The healthcare costs associated with treatment of chronic diseases accounts for almost 99% of the total Medicare spending and 83% of Medicaid spending.³ It is anticipated that by 2025, chronic diseases will affect about half of the population.³

Understanding the patterns of health and chronic disease burden by region is important in order to provide nurses appropriately prepared to address the regional issues of health and chronic illness. Today's graduates are expected to understand broad concepts and assess evidence-based information rather than just memorize facts. Applying information and knowledge to specific nursing situations requires well-developed curriculum that aligns with local and regional individual and population health needs. Understanding the disease burden by region is essential to develop appropriate nursing curricula with pertinent exemplars for this unique patient and nursing population.⁴

The 43 South Texas counties included in the study's region are predominately rural (n =28, 65%), with a substantial number considered border counties (n=17, 39.5%) on the U.S. border of Mexico.⁵ While the global burden of disease has been reported, the results primarily reflect 2010 data and do not provide a perspective of regional disease burden.⁶

The purpose of this study is to describe the scope and change in chronic disease burden across 43 counties in South Texas for a 10-year period in order to systematically assess health and chronic disease shifts to identify appropriate exemplars and continually assess and update nursing curriculum for a concept-based nursing curriculum.

Methods: De-identified data from the Texas Healthcare Information Collection (THCIC) will be used to determine the scope and the change in chronic disease burden across 43 counties in South Texas from 1st Quarter 2005 to 1st Quarter 2015.⁷ The THCIC database, built with healthcare data collected by the THCIC, a department within the Department of Health & Human Services (DSHS), was created in 1995 by the Texas Legislature.⁷ The data reports healthcare activity in Texas hospitals and health maintenance organizations. THCIC data contains the billing information for all inpatient admissions, excluding exempt facilities, including demographic data, hospital, admission/discharge information, payment information, principal and secondary diagnoses, E-codes, MS DRGs, charges, physician data, and a unique patient identifier. THCIC data also contains the emergency room utilization and charge procedure codes.

Hospitalizations for the disease codes of Diabetes, Coronary Artery Disease, COPD, arthritis, depression, cirrhosis, chronic kidney disease, respiratory tract infections, asthma, and stroke will be reviewed. Data will be exported from the THCIC database to SPSS version 21.

Descriptive statistics will be used to describe the disease categories. Differences between 2005 and 2015 disease burden by category will be analyzed with paired *t*-tests. Comparisons of disease burden with the presence of greater numbers of licensed nurses will be compared using parametric testing including Pearson's *r*.

Results: Results are pending the completion of the data analysis in January 2017.

Conclusions: As schools of nursing struggle with increasing educational content requirements while also being urged to create seamless transitions to the workforce, there is a need for innovative approaches focused on the healthcare needs of the populations in which the students will most likely be immersed. This requires detailed knowledge and understanding of the chronic disease burden affecting the region in which the nursing schools reside. The results from this study will inform the faculty and administration of healthcare needs and priorities for the region. Exemplars for the 22 nursing programs in South Texas counties may then be focused on the change in disease burden.

RSC PST 3 - Research Poster Session 3

Auscultation Skills: Gown Versus Skin?

Jane Brannan, EdD, RN, USA
Anne White, PhD, RN, USA

Abstract

Purpose: Current nursing education programs throughout the world, typically include physical assessment courses with specific procedures for heart and lung auscultation. Students practice in a variety of ways through, manikins, sounders, recorders, and live patients. With traditional teaching, students are taught to place a stethoscope directly against the skin for auscultation. However, practitioners have been observed in many settings performing auscultation through the patient gown or clothing. A concern of this practice is the potential for missing soft added sounds in heart auscultation and mistaking rubbing of gown on the stethoscope as pulmonary crackles. Despite this prevalent observation in clinical settings, few studies have been conducted to determine if this is acceptable practice. The purpose of this research is to provide evidence for or against the generally-accepted practice of teaching graduate nursing students to auscultate heart sounds and lung sounds by placing the stethoscope directly against the skin.

Methods: The study was a non-experimental repeated measures design to determine if there was a difference in correct identification of heart and breath sounds using a stethoscope placed directly against the skin versus through a gown. Research Questions: 1) Is there a difference between heart sound and lung sound interpretation when auscultated with a stethoscope against the skin and auscultated through a gown?, 2) Does auscultation directly against the skin improve accuracy of heart sound and lung sound auscultation when compared to auscultation through a gown? The sample consisted of 30 graduate students in their final semester of a nurse practitioner program who had successfully completed the advanced health assessment course. Participants were asked to perform basic auscultation maneuvers typically used in clinical practice. The sounds were produced using a simulation manikin specifically designed for auscultation of heart and lung sounds (Harvey® The Cardiopulmonary Patient Simulator). Four breath sounds and four cardiac sounds were programmed. A high quality stethoscope (provided with manikin) was used during auscultation. Participants were individually scheduled to perform auscultations. After orientation to the simulator sounds, participants auscultated four heart sounds with the stethoscope placed directly on the skin. Following each sound, the participant identified the sound on a written form. Then, four heart sounds were repeated in a different order and participants auscultated through a gown. This procedure was repeated with breath sounds.

Results: There was no significant effect of auscultation on skin or gown. There was a significant difference in participant ability to identify correct breath sounds over cardiac sounds.

Conclusion: In practice, many practitioners auscultate through hospital gowns, possibly related to dignity and privacy issues in patient care. Further research is needed to determine the impact of the practice to determine if sounds are being overlooked or misidentified. Further efforts in nursing education of nurse practitioner students should focus on repeated practice of cardiac sounds, normal and abnormal, to further hone their capabilities and expertise in diagnostics. The importance of auscultatory skills should not be underestimated in favor of higher technology readily available. While such diagnostics tools are necessary, they cannot replace skillful assessment techniques that may provide early detection of slight changes in a patient's condition

Effects of Forest Therapy on Children in Socially Disadvantaged Families: A Systematic Review

Kyung-Sook Bang, PhD, RN, Korea, Republic of (South)

Sungjae Kim, PhD, RN, Korea, Republic of (South)

Minkyung Song, MSN, RN, Korea, Republic of (South)

KyungIm Kang, BSN, RN, Korea, Republic of (South)

Abstract

Purpose: Children in socially disadvantaged families and welfare facilities have higher level of aggressiveness, socio-psychological problems such as depression, shrinkage, low self-esteem and social maladaptation than other children. Forest therapy refers to a visit to forest areas or various activities which take place in forest areas for relaxation, healing, and wellness. In spite of the increasing attention to the various health benefits of forest therapy, until now, systematic review on the body of evidence for the effect of forest therapy on vulnerable children has not been conducted. A clearer and comprehensive understanding of the effects of forest therapy on vulnerable children is needed for further refinements of forest therapy programs. The purpose of this study is to systematically review the forest therapy programs designed for vulnerable children to identify contents, format, and strategies essential for effective forest therapy programs.

Methods: This systematic review was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Various databases including PubMed, EMBASE, CINAHL, KISS, RISS, and DBpia were used to identify relevant studies published up to September 2016. The two authors independently screened the full text articles using the following criteria: 1) intervention studies assessing the effects of forest therapy among vulnerable children ages 8 and 13; 2) unpublished thesis; and 3) articles or thesis written in English or Korean. The Methodological Index for Non-Randomized Studies (MINORS) measurement tool was used to assess the risk of bias in each trial.

Results: A total of 4,813 records, including 3,915 records published in English and 898 records published in Korean, were retrieved from initial database searches. Finally, 8 articles in total (English: 0, Korean: 8) were included in the present systematic review. The most common research design was quasi-experimental pre-test and post-test study. None of the studies used randomized controlled trial (RCT) and the sample size ranged from 16 to 308. Walking, observation in the forest and playing with natural objects were the key components of the forest therapy. The length of time over which the interventions were undertaken ranged from 1 day to 15weeks. Only one study had a 4-week follow-up. The most common variable was sociability among those of forest therapy effects and the next was psychological health-related variables such as depression, anxiety, and stress level. Most of studies used self-reported questionnaires and only one study used both self-reported questionnaires and physiological measures. Regarding the quality assessment based on the MINORS criteria, 7 studies were rated 17.7 (out of 24) and 1 study without control groups was rated 8 (out of 16). Regardless of the diversity in format and contents of forest therapies, most of studies showed significant positive effects on vulnerable children.

Conclusion: This systematic review showed that forest therapy is one of the emerging and effective intervention approaches to improve sociability and psychological health among vulnerable children. Limitations on the current programs identified from the review were as follows; 1) small sample size; 2) inadequate information about research process. Future studies assessing the long-term effects of forest therapy on vulnerable children using rigorous study designs are needed.

Health Professionals' Knowledge, Attitudes, Experiences, Confidence, and Behaviors Regarding Advance Directives

Shu-Fen Wu, MSN, RN, Taiwan

Hong-Yi Tung, MS, MD, Taiwan

Yu-Hua Lin, PhD, RN, Taiwan

Chao-Hsien Lee, PhD, Taiwan

Hsiu-Chen Liao, BSN, RN, Taiwan

Ching-Yun Ching, BSN, RN, Taiwan

Abstract

Purpose: Advance directives (ADs) are one of the few means for people to indicate their end-of-life treatment decision preference. The purpose of this study was to determine the ADs compaction knowledge, attitudes, experiences, confidence, and behaviors of health professions.

Methods: This was a descriptive correlational research that targeted 765 subjects (included 43 physicians, 424 nurses, 85 other medical staffs, and 213 administration staffs) working in a regional hospital in southern Taiwan. The structured questionnaires gathered the knowledge, attitudes, experiential survey on advance directives (KAESAD) instrument and basic demographic data with regard to advance directives. Data were analyzed by using SPSS 20.0 software. Descriptive statistics, independent *t* test, chi-square test (χ^2), Pearson product-moment correlation, one way ANOVA, and Binary logistic regression were used for data analysis.

Results: The results indicated that signing advance directives consent form is low. Only 1.8% of the health professionals had completed advance directives, although 86.3% indicated their willingness to have one. The first two reasons for signing include: not want to be burden on their family (85.9%), and ensure the quality at end-of-life (85.5%). The first two reasons why health professionals do not want to sign are: they still have plenty of time to make end-of-life decision (33.3%), and self-perceived health status (31.0%). Age, working years, and attitudes were found to correlate positively with knowledge. Knowledge, attitudes, and experiences were found to correlate positively with confidence. The result of questionnaire survey, the total knowledge, experience of ADs scores and total confidences is low, held positive attitudes toward ADs. Between groups that physicians have more knowledge, attitudes, experiences, and confidence of ADs compared with other groups. In addition the mean scores for professional experiences with end of life decision-making were low in physicians with nurses (physicians 56.00 ± 3.54 ; nurses 57.16 ± 4.80). Have "relatives and friends suffering from serious illness experience" and heard "advance hospice palliative care & life-sustaining treatment choices of intent" could be used as predictive factors for ADs in nurse group (Nagelkerke R Square= .082). The self is the primary medical decision maker and have "relatives and friends suffering from serious illness experience" could be used as predictive factors for ADs in other medical staffs group (Nagelkerke R Square= .292). Have "relatives and friends were suffering from serious illness experience", not heard "any advance hospice palliative care document" and "have experience of ADs" could be used as predictive factors for ADs in administration staffs group (Nagelkerke R Square= .123).

Conclusion: The study findings showed that health professionals' have insufficient knowledge, inadequate practices, and had lower completion rate of ADs. Such indicates the need for designing different of clinical educational programming to provide health personnel's knowledge and experience and enhance ADs facilitation effectiveness.

RSC PST 3 - Research Poster Session 3

Toxic Stress and Protective Factors in Multiethnic School-Age Children

Eileen M. Condon, MSN, APRN, FNP-BC, USA

Abstract

Purpose: Exposure to stress in early childhood is associated with poor health and developmental outcomes that extend across the lifespan (McEwen, 2008a). To explain this link, researchers have proposed a conceptual taxonomy consisting of three types of stress response in early childhood: positive stress, tolerable stress, and toxic stress (Shonkoff et al., 2012). The most potent stress response, toxic stress, results from exposure to chronic stressors such as poverty, violence, or parental mental illness. Without the protection of a nurturing caregiver, this exposure can result in persistent elevation of the child's stress response system, and in turn impair brain development and contribute to disruption in the neuroendocrine, immune, metabolic and cardiovascular systems (Juster, McEwen, & Lupien, 2010; McEwen, 2008b). These physiological disruptions are associated with poor long-term health and behavioral outcomes, including growth delay, obesity, depression, alcoholism, and cardiovascular disease (Garner, 2013). Identifying factors that protect against toxic stress is of significant importance to nursing research and clinical practice, as toxic stress prevention is essential for health promotion, disease prevention, and reduction of health disparities among families at risk.

Although toxic stress is a metaphor that cannot be empirically measured, examining the physiological, health, and behavioral outcomes associated with chronic stress exposure in childhood may provide important insight into the mechanisms through which toxic stress can be prevented. Studies of animals and maltreated children demonstrate that supportive caregiving can buffer against exposure to chronic stress, but the specific positive caregiving patterns that best protect children against chronic stress are poorly understood (Hostinar, Sullivan, & Gunnar, 2014). Past maternal experiences and maternal mental health can also impact the caregiver-child relationship, but the relationship between these maternal characteristics and indicators of exposure to chronic stress in children remain largely unexplored (Goodman et al., 2011). Racial discrimination can also be a significant source of stress for racial and ethnic minority families, but the relationships among maternal experiences of racism, racial socialization parenting behaviors, and indicators of exposure to chronic stress in children have not been examined (Yasui, 2015). Therefore, the purpose of this study is to describe and examine associations among maternal characteristics (past maternal experiences and maternal mental health), maternal caregiving patterns, and indicators of exposure to chronic stress in a multiethnic, urban sample of mothers and children at early school age (4-9 years).

This study is framed by the ecobiodevelopmental (EBD) model, which guides understanding of the link between early childhood adversity and lifelong health via the toxic stress response. Within this framework, a child's biology interacts with the early social environment to influence long-term health and development (Shonkoff et al., 2012).

Methods: This ongoing descriptive study employs a cross-sectional design and includes a sample of maternal-child dyads living in socioeconomically disadvantaged neighborhoods in New Haven, Connecticut. Families in the sample are anticipated to primarily self-identify as Latina and Black, and the targeted sample size is 58 dyads. Families are eligible for inclusion if the child is between 4-9 years of age and the child's mother has regular contact with the child. Maternal variables include past maternal experiences (adverse childhood experiences, family strengths, experiences of discrimination), maternal mental health (PTSD symptoms), and current caregiving patterns (parental reflective functioning, parenting behaviors, racial socialization behaviors). Child variables include neuroendocrine functioning (hair cortisol), immune functioning (salivary cytokines and c-reactive protein), cardiovascular functioning (blood pressure), health (body mass index, growth delay, health history), behavior (internalizing/externalizing behaviors), and learning (school performance). At the completion of data collection, univariate statistics will be used to describe maternal characteristics, maternal caregiving patterns, and child indicators of exposure to chronic stress in the sample population. Bivariate analyses

will be used to examine the strength and direction of relationships between the maternal and child variables.

Results: Completion of data collection is expected in Spring 2017. Preliminary descriptive results will be presented, with a focus on associations among maternal protective factors and physiological indicators of exposure to chronic stress in children.

This study is innovative in its use of biological outcome measures to explore the effects of maternal protective factors within families at risk for toxic stress. However, physiological indicators of toxic stress are poorly defined in the literature, and thus biomarkers for the current study were selected based on available knowledge and feasibility. Another limitation is the study's small sample size, which may not be adequate to use multivariate statistical methods to study the relationships between variables. However, it is expected that this exploratory study will provide an important foundation for future research on toxic stress and protective factors in young children at risk.

Conclusion: Given the cascade of poor outcomes associated with toxic stress, there is a pressing need to understand the mechanisms through which toxic stress can be prevented in early childhood. The results of this study will lay important groundwork for future nursing research studies focused on promoting health and reducing disparities in vulnerable families at risk for toxic stress. The findings of this study will also make a valuable contribution to nursing clinical care, as the protective caregiving strategies identified can be encouraged both in the primary care setting and as part of in-depth interventions. Furthermore, identifying links among maternal characteristics, current caregiving patterns, and indicators of exposure to chronic stress in children may play an important role in the development of social and economic policies that reduce maternal stressors, promote family strengths, prevent intergenerational transmission of trauma, and empower socioeconomically disadvantaged communities.

Evaluation of a Comprehensive Pro-Active Intervention on Quality of Life for Community Frail Older Adults

Yen-Chun Lin, PhD, RN, Taiwan

Lian-Hua Huang, PhD, RN, FAAN, Taiwan

Meei-Fang Lou, PhD, RN, Taiwan

Abstract

Purpose: To evaluate a comprehensive pro-active intervention for community frail older adults and examine its effectiveness.

Methods: This is a pilot experimental study. The older adults who consented and met the frail or pre-frail status assessed by Fried Frailty Criteria were randomly assigned into experimental (N=55) and control groups (n=54). The experimental group received a 6-month comprehensive pro-active intervention. We provided a comprehensive assessment for each participants. Based on their individual needs, we provided physical activity practice, health education, community resource referrals, community support groups, group community activity participation, counseling, self-management skills teaching, regular telephone follow-up, and home visits every two weeks or monthly. The control group received the usual primary care. Both the intervention and control groups completed the Health Related Quality of Life (WHOQOL-BREF) at baseline and again at a 6-month follow up. Analysis of covariance (ANCOVA) was used to compare the outcome across groups with post-test as outcome and baseline values as a covariate.

Results: There were 109 clients participated in this study. The overall average age of participants was 76.96 years old. The 57.8% participants were male. Assessed by Fried Frailty Criteria, 12 participants (11.0%) were frail, and 97 participants (89.0 %) were pre-frail. During the research process, 7 participants in experimental group and 8 participants in control group withdraw from the study. Finally, 48 participants in experimental group and 46 participants in control group completed the post-test. The differences of mean scores of quality of life between pre and post-test were assessed by paired t-test. The results showed that quality of life of post-test in experimental group were improved compared to that of pre-test except for social relationship domain. After adjusted the pre-test scores, the results showed that the mean scores of quality of life for physical domain in experimental group were statistically increased compared to that of control group ($F=5.343$, $p=0.023$).

Conclusion: The results showed that the interventions were significantly improved the quality of life for physical domain. Future research to investigate effective interventions for other domains is recommended.

What Is My Role As Professional Nurse in Guiding Students to Professionalism?

Magda Cunze, BaCur (NsgEd/Mng), RN, RM, RT, RCN, RNM, South Africa

Gisela H. Van Rensburg, DLittetPhil, MACur, BACur (Hons), BACur, RN, RM, RCN, RPN, RNE, RNM, RON, South Africa

Abstract

Purpose: The purpose of the presentation is to inform, guide and support professional nurses regarding their role in guiding students to professionalism

Methods: An exploratory-descriptive qualitative approach was followed. The population constituted for this study are the final year students of the programme: Diploma in General Nursing, R683 of the South African Nursing Council. Non-probability, purposive sampling was done to select the participants. The study was conducted at two campuses of the private nursing education institution situated in one of the nine provinces in South Africa. Two World Café conversation focus groups were conducted to collect the data. A total of thirty participants formed part of each conversation. After two sessions of the World Café conversations during which 60 students participated, data saturation was achieved.

Results: Three major themes were identified namely the professionalism of professional nurses, need for student support and factors related to the teaching and learning environment. This presentation will focus on the role of professional nurses in the clinical environment to guide students to professionalism.

Exposure to positive behaviours by professional nurses in the clinical environment will give students the opportunity to develop their own professional behaviours by observation and imitation of professional nurses. The categories identified for factors related to the professionalism of professional nurses are professional attitude and behaviour, the professional role and the professional image of the professional nurse.

Perry (2009) wrote that the attitude of professional nurses as role models is reflected to the student through actions and behaviours, that influences the nature of the relationships the professional nurse has with the student.

Professional attitude and behaviour of professional nurses were clear in the participants' identification of the need for role models, values of the profession and communication as they requested professional nurses to portray characteristics such as positive attitudes and behaviour, high self-esteem, honesty, trustworthiness, reliability, self-respect, integrity, fairness and energy. Professional nurses as role models are resourceful and confident; approachable, available and friendly; helpful and understanding; welcoming and have the students' interests at heart. The role model therefor must be an advocate for students.

Brown et al (2012:606) described the professional role concept as the "development of a nursing identity over a period of time and is the expected function of a member of a specific profession" and is of the opinion that the development of a nursing identity is an important factor during the students' professional development process. Leadership, professional support and lifelong learning was identified as important attributes needed by professional nurses in supporting students. In his/her professional role, the nurse is responsible for teaching students how to care for patients, colleagues, themselves and their profession and to accept responsibility for their own professional roles. To do this, they need to role model effective and ethical behaviours and actions.

Portraying the image of nursing depends on how the members of the profession portray themselves. Oosthuizen (2012) stated that it is up to the nursing profession itself to look at the image of the profession as portrayed in the media and to change that image positively.

Brown et al (2013) revealed that nursing education institutions' curricula and workforce policies must be developed in such a way that students are able to develop an understanding of their role, are successfully acculturated and assimilated into the profession and organisation, and acquire the correct professional knowledge, skills and values from expert role models. This related to the findings in this study where participants expressed their desire for professional nurses to show them professionalism which they, the students, would imitate.

Conclusion: Role models are valuable resources in any clinical health setting, however given the sophistication of skills and attributes associated with ideal role models it is evident that many professional nurses will only provide partial opportunities to imitate their behaviours as role models to student nurses.

Student nurses will continue to practice the behaviours imitated by role models they believe to be important. Therefore it is important that professional nurses are aware of the key role that their behaviour plays in the process of socialising students into the profession. Forming role models of tomorrow is largely dependent on the present practices of professional nurses in the clinical environment.

To answer my question in the title, professional nurses need to ensure:

- Role models who act professional and portraying professional attitudes and behaviours;
- who live the professional role; and
- portray a professional image.

Predicting Success: An Analysis of the Characteristics of Applicants to the Ontario PHCNP Program

Elsabeth Jensen, PhD, RN, Canada

Shelley Walkerley, PhD, RN-EC, Canada

Abstract

Purpose: This project is an extension of the previous study focusing on the predictive value of personal essays for admission to the PHCNP Program at York University. The original study findings revealed that while the scores on admissions essays were not associated with success or failure in the program, other characteristics or attributes such as years of nursing experience may be related to a successful outcome. The current project is aimed at further describing the characteristics of the applicants as well as exploring relationships between those characteristics and applicant success.

Methods: This study expanded the study population by including three additional provincial Primary Health Care Nurse Practitioner sites, one of which enrolls francophone students. This is a retrospective quantitative analysis of data normally collected for enrollment decision-making, i.e., common admission criteria and information including demographic information, UGPA, scores on nursing theory and research courses in the applicant's undergraduate program, number of years of nursing experience, and type of clinical experience. Applicants to the PHCNP program at the 4 participating universities were approached for consent.

Results: The data from the study is informative in describing the education and experience successful applicants bring to the program. As all of the 53 participants are now registered as Nurse Practitioners, this data give no insight into those graduates who are unsuccessful on the exam. Few of our students are not successful in licensing; most of those who fail first writing go on to be successful on second writing

Conclusion: As we continue to work forward to meet the Ontario's need for PHCNP services, it is important to select applicants to the program who have the greatest potential to complete the program in a timely fashion, pass the registration exam, and successfully enter practice. The next stage of this program of research will explore the characteristics of those who were admitted but did not complete to see if they differ from those who complete.

RSC PST 3 - Research Poster Session 3

Integrative Review of Virtual Simulation in Nursing

Hyunsook Shin, PhD, RN, CPNP-PC, Korea, Republic of (South)

Hyojin Kim, MSN, RN, Korea, Republic of (South)

Da Hae Rim, MSN, RN, Korea, Republic of (South)

Sojeong Park, BA, RN, Korea, Republic of (South)

Abstract

Purpose: Presence of virtual reality allows nursing educators to design innovative educational platforms for the pre-service education as well as in-service education. An integrative review of the simulation literature was conducted to identify effective characteristics of virtual simulation for nursing education.

Methods: An integrative review was conducted from three major electronic databases: Ovid MEDLINE, PubMed and the Cumulative Index of Nursing and Allied Health Literature (CINAHL) using the keywords; patient simulation, computer-user interface or computer-user training, and virtual in English. The initial review of titles and abstracts produced 170 results. Out of the initial 170 articles retrieved, 85 articles, mostly intervention studies and a few descriptive studies were analyzed. The research questions focused on the characteristics of virtual simulation approaches including the virtual type, realism methods, participant representation and outcome indicators to suggest the effective virtual simulation design for nurse educators.

Results: The literature suggests the effective use of virtual simulation approaches that allow for multi-user interaction and more accessible training opportunities for learners. Most of the studies had incorporated virtual environments in different ways involving 2D images to augmented reality. Length of the virtual simulation and type of virtual platforms were greatly varied. Use of augmented reality or screen, use of commercial platforms such as Second Life or Unity 3D or newly developed, designed feedback system or not, presence of self as an avatar or use of script are identified as design characteristics of virtual simulation approaches. Constructive educational tradition was identified as major theoretical framework of virtual simulation through experiential learning or active learning. However, knowledge acquisition and clinical reasoning rather than clinical competency and clinical outcomes had been found as major outcome indicators of virtual simulation, which represented to be inferior for training outcomes in Kirkpatrick's model of training

Conclusions: Design characteristics for virtual simulation should be selected based on the evidence to support effective educational strategies. Effectively designed virtual simulation can lead to improvements in knowledge and clinical reasoning skills, but there is less evidence directly linking virtual simulation to improved performance and clinical outcomes.

RSC PST 3 - Research Poster Session 3

Transition to College Campus Living With a Chronic Condition: Type 1 Diabetes Exemplar

Jennifer L. Saylor, PhD, MSN, BSN, RN, APRN-BC, USA
Christina Calmaro, PhD, RN, CRNP-BC, USA

Abstract

Purpose: The purpose of this study is to examine sleep, resilience, and diabetes related quality of life (DQOL) and their effect on diabetes management in young adults ages 18-24 living on university/college campuses. RQ1: What is the relationship between sleep and HgbA1c (HgbA1c) and resilience and HgbA1c and quality of life and HgbA1c among those with type 1 diabetes 18-24 years of age living in dormitories. RQ2: What are the inter-relationships between sleep and HgbA1c and quality of life among those with type 1 diabetes 18-24 years of age living in dormitories?

Significance/Literature Review: Young adults with chronic conditions, like their healthy counterparts, have the same excitement and goals as they look forward to the independence of college. Yet for those living with a chronic condition, the diagnosis can create serious intrusions into the lives of young adults as they transition to campus life. While transitioning, the young adult with a chronic condition like type 1 diabetes (T1D) must negotiate a delicate balance between adhering to a management regimen that supports a stable blood glucose level while attempting to integrate into campus life. There are 1.25 million Americans with T1D and a 23% increase is expected over the next 40 years among those < 20 years of age (American Diabetes Association, 2012; SEARCH for diabetes in youth, 2015). T1D is becoming more common in the United States. Between 2001 and 2009 there was a 21% increase in the prevalence of T1D in people under age 20 (Dabelea et al., 2014). More than 18,000 new cases of T1D are estimated to be diagnosed among U.S. youth < 20 years of age each year. This may result in more students entering college and living on campuses. By 2050 in the U.S., 5 million people are expected to have T1D by 2050, including nearly 600,000 youth (Dabelea et al., 2014; Imperatore et al., 2012). This will dramatically increase the number of college students matriculating with T1D. Students with a chronic condition had impaired health related quality of life (QOL) compared to those without a chronic condition and a higher level of loneliness (Herts, Wallis, & Maslow, 2014; Maslow, Haydon, McRee, Ford, & Halpern, 2011). Surprisingly, only 7% of first year college students with chronic conditions knew another student with a chronic illness and 57% reported not knowing anyone with chronic illness (Herts, Wallis, & Maslow, 2014). Many young adults without a chronic condition have difficulty adjusting to this campus living and balancing academic, social life, and psychological well-being. This balancing act is even more complex for students with T1D who require vigilant self-management that includes consistent insulin administration, regular nutrition, and physical activity and sleep patterns. Therefore, inconsistency occurs because of new-found freedoms in an unstructured living environment. There is a paucity of information on effect of campus life for students with T1D and potential effects on diabetes management and long-term health outcomes.

Campus life is not only about academics and socialization, but potentially encompasses changing patterns of sleep, nutrition, physical activity, mental health, and risk behaviors. For optimal health, students must manage many changing patterns and behaviors that are unique to the college environment. This can be exacerbated in young adults managing a chronic condition such as T1D. Campus experiences can aggressively affect those students with T1D from new student ice-cream social with unknown nutritional information for insulin administration to late night studying and lacking sleep. Using T1D as an exemplar, this proposal will examine sleep, resilience, and Diabetes related QOL as potential components of campus living that have not been fully explored in the literature. This allows universities to implement programs/interventions to better support the needs of those with T1D and possibly other chronic conditions. By surveying young adults with T1D, ages 18 to 24 years, this proposed study will provide further information on potential components of campus life effect diabetes management in college. This work will contribute to the body of knowledge on T1D to further identify barriers to a successful campus living and effect on diabetes management HgbA1c. Also, this will inform a larger research body focused on young adults with chronic conditions during campus life transition.

Methods: This research study used a descriptive, cross-sectional research design to examine how much sleep (sleep duration) (Calamaro, Mason, & Ratcliffe, 2009; Eliasson, Lettieri, & Eliasson, 2010), how adaptation to changes and stress (resilience) (Santos, Bernardo, Gabbay, Dib, & Sigulem, 2013) and level of quality of life (Varni et al., 2003) among young adults ages 18-24 living on university/college campuses.

Sample: A total of 50 participants will be enrolled in the study with the exploratory research questions. Participants will be recruited with the agreed upon assistance of the Disability Support Services (DSS) and the College Diabetes Network (CDN). The *inclusion criteria* includes participants must be at least 18 years old, have a formal diagnosis of T1D, and live on campus during the undergraduate college years. Participants are considered properly diagnosed if they are fully dependent on insulin administration via a vial and syringe or an insulin pump. The *exclusion criteria* include a diagnosis of Type 2 Diabetes, no diagnosis of T1D, younger than 18 years of age, unable to read or write English, or does not live on college/university campus housing.

Variables/Outcomes/Measurements: The outcome or dependent variable is HgbA1c determines extent of diabetes management. This is self-reported on the electronic questionnaire. HgbA1c is an average of blood sugar control over the past 2-3 months. Thus, this laboratory blood test is typically completed every 3 months for those with T1D and it shows how well their diabetes is being management. Sleep, Resilience and Diabetes Quality of Life are the independent variables. Sleep is measured using the Sleep, Caffeine Intake, and Technology Use questionnaire. This is a 36-item, 3-concept instrument that measures intake of caffeinated drinks, use of nighttime media-related technology, and sleep behaviors (Calamaro et al., 2009). Content and face validity were established by using 5 sleep experts to judge the relevancy of each item to the intent of the questionnaire (Calamaro et al., 2009). The instrument that takes approximately 10-15 minutes to complete is validated in adolescents and young adults. Resilience is measured using the *Resilience Scale (RS-14)*. This 14-item scale Likert scale format measures one's individual resilience and take about 2-4 minutes to complete. The higher the score, the greater his/her resilience in response to an event (Resilience Center, 2015; Wagnild, 1993) The RS-14 in use since 2008; it is significantly correlated with the longer RS ($r=.97$) and internal consistency reliability for the RS-14 is $\alpha = .93$. The Diabetes-Related Quality of Life (DQOL) will be assessed using a modified version of Ingersoll and Marrero 1991 DQOL scale (Ingersoll & Marrero, 1991). This 5-point Likert Scale is the most commonly used quality of life scale for youths and young adults with T1D. The modified electronic tool takes approximately 15-20 minutes and includes subscales for life satisfaction (17 items), disease impact (23 items), disease-related worries (11 items), and 1 item relating to health (Hanna, Weaver, Slaven, Fortenberry, & DiMeglio, 2014). The test-retest reliability ranged from 0.78-0.92 (Ingersoll & Marrero, 1991).

Procedure: After receiving Human Subjects approval, emails will be sent to participants via DSS. Also, the CDN will post an IRB approved Facebook and twitter post to their members. Using REDCap (Research Electronic Data Capture) the participants will be screened by answering a few inclusion/exclusion criteria. After the screening, the participants will receive the electronic consent, followed by the survey. The confidentiality of the participant information was protected. All identifiers were be removed and each participant was assigned a unique anonymized subject identifier. Also, all study data will be on password protected computers in a locked office (double lock principle). Updated anti-virus protection will be on researchers' computers used to access data. The key to the data set will be kept separately in a locked cabinet in a locked office (double lock principle). For this study we apply principles of the Market Model to justify our compensation (Dickert & Grady, 1999; Grady, 2005). Incentives are given to enhance the likelihood of participation, and money is justifiable as an incentive for a healthy individual or one who would otherwise not benefit from participation. Therefore, to enhance the likelihood of enrollment of busy college students, participants will receive remuneration in the form electronic gift cards in the amount of \$10.

Data Analysis: All statistical procedures will be completed using the Statistical Package for Social Sciences. Standard descriptive statistics will be used to describe the outcomes, demographic and independent variables of interest. Internal reliability of the questionnaires and instruments included in the surveys will be examined using Coefficient α for each of the constructs identified and included in the

survey, i.e. sleep, diabetes-specific quality of life, and resilience. All of these measures will be correlated with diabetes management (HgbA1c) using a Pearson correlation.

Results: The data collection will occur November 2016 through March, 2017.

Conclusion: A conclusion will be presented on the poster as data collection and analysis will be complete before the 28th International Nursing Research Congress.

Breastfeeding Practices: Attachment and Positioning, a Health Center Level Study in Sinazongwe District, Zambia

Jerry John Nutor, MSN, BSN, RN, USA

Shannon Marquez, PhD, MEng, USA

Jaime C. Slaughter-Acey, PhD, MPH, USA

Abstract

Purpose: Breastfeeding has been accepted as one of the most important intervention to enhance growth and development of a child. It satisfies an infant's nutritional and emotional needs better than any other methods of infant feeding (Haga et al., 2012). At the Innocenti Declaration in 1990, the World Health Organization (WHO) in collaboration with United Nations Children's Fund (UNICEF) recommended exclusive breastfeeding, this recommendation encourages mothers to feed their infants the first 6 months of life with breastmilk alone and then up to 2 years of age and beyond (World Health Organization, 1991). In order to achieve maximum benefit of breastfeeding for both mother and infant, there is a need for good attachment and adequate positioning. Positioning an infant appropriately is one of the easiest ways to ensure postural support that has impact on both the infant and the mother's comfort. It could also affect the infant's neurobehavioral and neuromotor development temporarily or permanently (Waitzman, 2007). Attachment is defined as the connection from infant to the mother and it is the initiation of the bond that exist between them. Effective breastfeeding means adequate positioning of mother and baby and attachment of child to the mother's breast (Dongre et al 2010). Positioning of the infant's body is essential for good attachment, comfortable and successful breastfeeding. Good attachment during infant breastfeeding could also prevent many emotional and psychological problems for both mother and the infant (Goyal et al 2011). The purpose of this project was to educate mothers on good attachment during breastfeeding and important of breastfeeding to the mother, infant and the society.

Methods: In commemoration of the 2016 world breastfeeding day, the Sinazongwe district health center and the Sinazongwe Area Development Project of World Vision joined the rest of world from August 1st to August 7th to celebrate world breastfeeding day on the theme "Raising Awareness of the Links between Breastfeeding and the Sustainable Development Goals". In all forty-eight breastfeeding mothers were selected from Sinazongwe district hospital postnatal clinic to undergo a day's workshop on the importance of breastfeeding, attachment and position during breastfeeding. Three mothers were randomly selected to demonstrate how they usually breastfeed their infants. After every demonstration, other participants were given the opportunity to debrief the sessions.

Results: None of the three mothers was able to demonstrate infant breastfeeding with good attachment and positioning. In addition, majority of the women could not identify what their colleagues did wrong while demonstrating the breastfeeding. Workshop facilitators including nurses and midwives educated the mothers on proper breastfeeding position and attachment. The mothers were also taught proper hygiene technics such as hand washing before and after breastfeeding and oral hygiene for infants. Other topics including benefits of breastfeeding to the mother, infants, community and the nation were also covered.

Conclusion: Good attachment and positioning during breastfeeding make the difference between a happy, comfortable and successful breastfeeding and one that is painful for mothers and frustrating for the baby. Given that none of the three mothers could not demonstrate proper positioning and attachment during the demonstration, a need exists to develop breastfeeding education program and also use culturally appropriate methods to disseminate this program among postpartum women in the Sinagongwe district.

Does Playing the Role or Wearing Clinical Attire Improve Self-efficacy in Culturally Diverse Nursing Students?

Mary Elizabeth Fortier, EdD, MA, BSN, RN, CNL, USA

Abstract

Purpose: In light of the recent IOM Report and Patricia Benner's study: A Call for Radical Transformation, we, as nurse educators, need to identify the barriers to a baccalaureate degree in nursing for culturally diverse students and create academic environments that will promote their achievement of obtaining a baccalaureate degree in nursing.

Recent media spotlight on the RN shortage has highlighted nursing as a lucrative and secure field, providing practice opportunities beyond traditional roles. Government analysis data projects an explosion of new nursing positions through 2020. This fact makes the profession of nursing one of the nation's top professions in terms of projected job growth. Therefore; if the healthcare needs of society, now and in the future are to be met then improving recruitment, retention, and graduation rates of the culturally diverse baccalaureate nursing students is critical.

The purpose of this presentation is to inform the attendees of the significance that self-efficacy plays in the success of culturally diverse baccalaureate nursing students in their first clinical course and again at the end of their coursework. Self-efficacy is a necessary criterion for achieving student success, developing critical thinking and reasoning skills. Psychologist Albert Bandura has defined self-efficacy as one's belief in one's ability to succeed in specific situation; suggesting that self-efficacy plays a critical role in how we think, feel, and behave.

Methods: The results of this exploratory research determined that faculty and schools need to explore and identify exemplars for academic practices; such as, developing peer-mentor support services: study groups and writing support services that would improve not only the self-efficacy of this student population but would ensure their future success as licensed professional nurses. Additionally, this research assisted in identifying exemplars for clinical practice settings that were not considered "traditional" settings; such as, community centers and rent-assisted apartment houses.

Results: All of these solutions can provide diverse nursing students with clinical knowledge and a learning environment conducive to growth and the development of critical thinking and reasoning, ensuring a future of culturally diverse and sensitive Professional nurses for our changing global populations and society.

Colleges continue to study admission criteria in order to fine tune their selection processes and enhance the guidance of our culturally diverse BSN students towards academic success. The time has come for faculty and colleges not to focus on only admission criteria but on identifying criteria that will ensure this success throughout the academic progression timeline: entry, midpoint, and exit points.

There is a fair amount of literature regarding self-efficacy in senior nursing students and patient education with most of the focus on patient self-efficacy and registered nurses and many are older publications. Of the limited available studies, most explore self-efficacy in an academic, rather than a clinical context. Few exploratory studies of this nature have been done in this population of students, considering how fast nursing school admissions have risen in the past five years. This research would add to the literature, providing a springboard for additional inquires.

Conclusion: This study may provide the needed socialization to the professional role of nursing for those students with low self-efficacy perceptions and our culturally diverse student population.

In addition, the results of this study would be of great interest to the field of nursing education and may be considered for publication in one of the following noteworthy healthcare professional journals: Nursing Education, Nursing Research, Nurse Educator, and Journal of Nursing Education and Practice.

The target population for this presentation is nurse researchers, educators, clinicians, college administrators, clinical practice partners and future employers of our diverse BSN graduates.

RSC PST 3 - Research Poster Session 3

Meta-Synthesis of Studies on Self-Stigma in Chronic Disease

Kawoun Seo, MSN, RN, Korea, Republic of (South)
Yoonhee Lee, MSN, RN, Korea, Republic of (South)
Bohyun Kim, BSN, RN, Korea, Republic of (South)
Youngshin Song, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: Kato et al. stated that self-stigma is to the biased attitude in which individuals develop negative attitudes toward themselves because of their various conditions. This condition can be referred to as internalized stigma. Contrast with social-stigma, self-stigma may particularly affect to individual belief and behaviors toward disease self-management in patients with chronic disease. The literatures have reported that the self-stigma under chronic diseases conditions would be associated with a poor attitude toward self-care behaviors, and its results may negatively impacts on their health outcome such as quality of life. Recently, the importance of self-stigma was emphasized in mental health and AID study, and comprehensive review study was also published in prior.

However, self-stigma in patients with chronic disease such as diabetes has not yet been investigated. Thus, the purpose of this study was to comprehensively review the concept of self-stigma in patients with chronic disease, and to synthesize the attributes of self-stigma using published literatures. Based on the findings from this meta-synthesis, the concept of self-stigma in chronic disease conditions can be distinguished from mental health, and classified the attributes of self-stigma for patients with chronic disease. Ultimately, the instrument for measuring the self-stigma under chronic disease condition can be developed in future study.

Methods: A systematic literature search was conducted using electronic databases such as Pubmed, Cochrane and CINAHL from 1986 to 2016 years. Mesh terms such as 'self' or 'internalized' and 'stigma' were used. The inclusion criteria were as follows; a) English literatures, b) human study, c) original studies using qualitative/quantitative methods, and d) sample with chronic diseases condition such as cancer, diabetes, hypertension etc. The exclusion criteria were sample with a) mental health problem, b) HIV/AIDS, c) non-chronic condition such as smoking, and d) concept was not clearly presented in studies. Two researchers were searched and coded using coding scheme independently. If there was found the discrepancies between reviewers, principal investigator was resolved. Coding scheme consist of study characteristics (sample size, clinical condition of participants, study design etc.) and the definition or attributes of self-stigma.

Results: Total 878 studies were initially searched using three electronic databases. Among them, 237 duplicated studies were removed, and the remained 641 were reviewed its abstracts. However, 491 studies did not meet the inclusion criteria. In the next step, 150 studies were reviewed the full-text by researchers, but 117 studies were excluded due to have not the concept of self-stigma. Finally, 33 literatures were analyzed in meta-synthesis.

The final 33 studies included 12,831 samples with chronic diseases such as diabetes mellitus, hepatitis C, liver cirrhosis, stutter, epilepsy, leprosy, TB, ESRD, neuromuscular disease, lung cancer, and overweight/obesity. Research methods of twenty-seven studies were quantitative research, and remained six were qualitative research.

The attributes of the self-stigma in chronic disease were divided into two categories: interpersonal focused self-stigma and self-blamed focused self-stigma in this meta-synthesis. The attributes of interpersonal focused self-stigma included stereotype agreement, withdrawal from social relationships, and fear of disclosure of the illness. It would include avoiding the social relationships with people due to fear of discrimination or disadvantage because of their disease. This behavior was related to the social stereotypes that some of the chronic disease was considered to be a lifestyle-related. This phenomenon was appeared in patients who have more focused on interpersonal relationship. They were even

disconnecting from social networks because they have worrisome about their illness that would affect social activities. On the other hand, self-blamed focused self-stigma might be associated with negative thoughts or feelings about themselves. It included self-blame, guilt/shame, lower sense of self-worth, feeling unhealthy, and anxiety or low expectations of the future. Those attributes were related to prejudices about one self. The patients who have self-blamed or feeling guilty, and show reduced confidence in self-care management tend to be thought that the cause of their illness is their own mistakes.

Conclusion: The finding showed that the attributes of self-stigma stigma in patients with chronic disease were different from mental health and other conditions. The attributes of self-stigma from this meta-synthesis were divided into two folds such as interpersonal focused self-stigma and self-blamed focused self-stigma. However, those attributes were affected by patients' situations. Based on this meta-synthesis, self-stigma in patients with chronic disease can be understood and classified, but little information was remained on how to measure the self-stigma. Therefore, it should be needed to investigate the systematic review again for self-stigma measurement tool in further study.

RSC PST 3 - Research Poster Session 3

Integrative Review of Self-Care Measurement in Diabetes Nephropathy

Younghee Jun, MSN, RN, Korea, Republic of (South)
Jeonghwa Cho, MSN, RN, Korea, Republic of (South)
Keumok Park, MSN, RN, Korea, Republic of (South)
Youngshin Song, PhD, RN, Korea, Republic of (South)

Abstract

Purpose: According to the International Diabetes Federation (IDF) Diabetes Atlas, 415 million people have diabetes mellitus (DM) in 2015. Along with increasing number of diabetes prevalence, its complications are also currently increasing. Among diabetes complications, the rate of prevalence for nephropathy was 30- 40 % of diabetes patients in literature. For controlling the diabetes nephropathy (DN), patients should have the complicated self-care competence. The self-care for DN should be included the proper behaviors not only to control their glucose level, but also to manage their kidney dysfunction. Lots of patients have experienced the difficulties for managing those complicated situations. For example, studies reported that diabetes patients have confused of what kinds of food they can eat during hemodialysis. As such, self-care management for diet, physical activity, glucose monitoring, and medications according to changing their diabetes progress should be monitored and educated by health care providers. However, lots of studies have researched the DN self-care behavior as measuring the diabetes focused self-care behaviors. For better understanding the research trend in terms of measuring tool for assessing the DN self-care behaviors, integrative review is needed. Thus, this purpose of this study was to describe self-care research related to diabetic nephropathy patients and to analyze instrument for measurement of self-care. The findings from this review can be provided the information on what kinds of measurement the studies were used for DN and what limitations those instruments.

The review questions were as follows;

Q1) How many studies were focused on self-care behavior for DN, and what study characteristics they reported

Q2) What kinds of instruments they used for measuring the self-care for DN?

Methods: Literature search was conducted using computerized databases such as Pubmed, CINAHL, Embase, and Cochrane (2005-2016). The search terms of this study were “diabetes mellitus”, “Self-Care”, and “Kidney disease”. The inclusion criteria were studies of self-care for DN, English literatures, and qualitative studies. If the studies designed using qualitative method, systematic review and meta-analysis, non-English paper, non-original study, and non-human sample, those studies were excluded. The literatures were searched by two researchers independently. The coding schemes for study consist of two folds such as population characteristics (sample size, age distribution, gender, clinical status, etc.) and study characteristics (design, instrument, main variables and its outcomes, methodological quality level, etc). Two researchers were coded those information from individual studies independently. The discrepancies in coding schemes between two coders were resolved by principal investigator.

Results: Q1 How many studies were focused on self-care behavior for DN, and what study characteristics they reported?

Total 1135 articles were reviewed the titles and abstracts. Of total, 939 studies were excluded because they were duplicated and did not meet the inclusion criteria. In the next step, 183 studies were excluded during full text review because the removed studies mentioned the concept of self-care without tools and some studies were not original papers. Thus, 13 studies were selected for final analysis.

The 6 studies out of 13 were cross-sectional design, and 4 studies were experimental design. The remained 2 studies were case study and mixed method study. The number of studies that included only DN patients was 8 articles. The numbers of sample size in 6 studies were less than 100, whereas the four

studies were from 100 to 200. In remained three studies, more than 200 participants were recruited for study. Various academic areas such as Nursing, Medical, Pharmacology and Psychology were involved in studies. In 13 studies, the clinical factors such as biochemical results (BUN, Cr, HbA1c, etc.) and psycho-cognitive-emotional variables (self-efficacy, quality of life, knowledge of disease, self-management capacity, depression, feeling of loneliness, hopelessness, etc.) were used.

Q2) What kinds of instruments they used for measuring the self-care for DN?

Twelve instruments for measuring self-care behaviors in DN were found. Summary of Diabetes Self-Care Activities (SDSCA) revised instrument was used in five studies. The Self-Management Capacities Scale (SMCS), Dialysis Diet, and Fluid Non-Adherence Questionnaire (DDFQ) were used in 2 studies. The Morisky Medication Adherence Scale (MMAS)-4 items and 8 items (MMAS-8) were also measured in 2 studies for assessing the self-care in DN. Moreover, the Partners In Health (PIH), the cognitive restraint subscale of Three Factor Eating Questionnaire (TFEQ), and Self-care Ability Scale were used in 3 studies. Of total, 10 studies reported the reliabilities of their used self-care instrument, but remained 3 did not report the reliability and validity.

Conclusion: In this integrative review, relatively small studies (13 studies) during past 10 years were conducted for DN self-care. Included studies were assessing the self-care for DN using non-DN specific instruments. That is, half of studies measured the self-care for DN using diabetes focused instrument, whereas several studies used the self-care instruments that can assess hypertension or kidney disease. Thus, DN specific instrument for measuring the self-care should be developed in future study. The appropriate DN specific self-care instrument will be contributed to measure the complicated self-care behavior in DN, and its information can be help to use for patients education.

RSC PST 3 - Research Poster Session 3

An Application of Machine Learning for the Identification of Adolescent Smoking Risk Factors

Sophia J. Chung, PhD, MSN, RN, Korea, Republic of (South)
Youngji Lee, PhD, MS, RN, USA

Abstract

Purpose: Smoking is known to be a modifiable risk behavior that causes various health problems that include cancer and respiratory disease. Moreover, the literature reveals that adolescent smoking behaviors are likely to persist through adulthood, and this is the case in countries worldwide. In South Korea, despite many efforts to reduce smoking among Korean adolescents, this modifiable risk behavior remains a significant social problem. An effective intervention to target and modify the behavior of adolescents concerning smoking must understand and address the factors that underlie and influence the behavior of smoking. These factors can be surfaced in data using an appropriate approach. Machine learning is an approach that is well suited to reveal patterns of information in large, complex datasets that are useful in predicting outcomes (Chekroud, 2016). For example, machine learning has been used to predict readmission in in-patients (Mortazavi, 2016; Frizzell, 2016). However, this approach had not yet been applied to address an adolescent's risk behavior, such as smoking. Therefore, the goal of this study was to identify the predictors of adolescents' smoking behaviors in South Korea using a machine-learning approach.

Methods: The 2015 Korean Youth Risk Behaviors Web-based Survey (KYRBS) was used as the data source of this study. The KYRBS is an annual, nationwide survey conducted in South Korea to examine health behaviors that include cigarette smoking, individual hygiene, and alcohol consumption. Data gathered in the 2015 KYRBS was collected via self-report questionnaires responded to by 68,043 students in grades 7 through 12 in randomly-selected 800 schools in South Korea. For this study, we used 5,123 surveys which completed items concerning smoking on the questionnaires. This study utilized the machine-learning pipeline developed by Fayyad (1996) and Yoon (2015). To reduce the "curse of dimensionality," in which a high number of inter-related variables in large dataset interfere with the accuracy of the machine-learning model, we selected clinically meaningful features based on the conceptual framework for adolescent risk behaviors (Jessor, 1991). Then, we applied three machine learning algorithms embedded in Weka (i.e., J48, Naïve Bayes, and Logistic Regression) to build a predictive model for the smoking behavior of the adolescents represented by the KYRBY dataset. The final model was selected based on the accuracy of not only the predictive model, but also the F-measure calculated using precision and recall rate.

Results: Through the feature selection process, we classified 40 features into three predictive categories. Among three machine algorithms we applied, we found that the Logistic Regression algorithm demonstrated the highest level of accuracy (i.e., 84.0% of adolescent smokers were correctly classified; F-measure = 0.795). Using this model, grade (-0.06) and alcohol consumption (-0.56) were the top two features with the highest coefficients. In other words, middle school students and students who had never drunk alcohol were highly associated with the behavior of smoking.

Conclusion: Our study demonstrates that a machine-learning approach is effective in identifying behavioral predictors from a large, complex dataset—in this case, the behavioral predictors associated with smoking using the KYRBY. However, our study results were inconsistent with those reported in the literature. Previous studies showed that increasing grade and previous alcohol consumption were associated with adolescents' smoking behaviors (Mendol, 2013; Talip, 2015). Further study with association between smoking behaviors and alcohol consumption among Korean adolescents is needed. Although this study did have some limitations (e.g., the data from the KYRBY is cross-sectional), our machine-learning approach shows promise, and subsequent research using longitudinal data can take into account the trends of association implicit in creating a predictive model.

Perceptions of Baccalaureate Nursing Students Before and After Placement on a Behavioral Health Unit

Margaret M. Egan Touw, DNP, MS, RN, USA
Susan Reimann Jackson, EdD, RN, USA

Abstract:

The focus of this paper is to determine if the Baccalaureate nursing student has changed their preconceived perceptions of their training in nursing education as well as fears or anxieties for being on a Behavioral Health unit both prior to and after placement. Both inpatient and outpatient behavioral health units provide clinical interventions for mental health or substance use diagnosis in medically staffed psychiatric supervised treatment environments. Information from this research will enhance the future education of the undergraduate in the behavioral health specialty area. The clinical rotation on an acute unit for nursing students may be challenging as well as anxiety provoking. As faculty, the intent is to provide the best clinical experience that is constructive to learning, to reduce negative attitudes or misperceptions that the students may have regarding clients with a mental illness.

The question is how to best efficaciously generate knowledge acquisition of mental and emotional disorders and promote therapeutic communication within the context of a clinical placement for students in a baccalaureate nursing program?

This research study may not specifically be a measurement tool to identify specific teaching strategies but rather lead the pathway towards the enhancing of the clinical education of bachelor degree undergraduate nursing students in behavioral health nursing. The intent is to provide a glimpse of different areas or gaps in student knowledge, as well as changes in perceptions, that once identified, might indicate a necessity to investigate methodologies available for faculty to provide the best teaching practices for active learning.

Purpose: The main focus as a professor of nursing is to prepare the student nurses for practice in an environment that they might encounter when they enter the profession. The utilization of a framework to organize the development of the program in designing courses and clinical practicum experience becomes paramount in this changing environment of mental health. The concerns of today also may be related to the consequences of insurance changes within the psychiatric illness continuum of care that is provided for patients today. Recent changes within the acute setting require that more patients are discharged to outside services and clinics. The student must be competent not only in the content that is required on the licensing examination but provided the foundation in meeting the quality care outcomes for this mental health population of patients. The reduction of anxiety and stress by implementation of support services, and better communication between faculty and students may increase positive influences of well-being for the baccalaureate nursing students. The focus upon research to provide the best possible evidenced based practice in nursing education for future behavioral health clients is imperative to generate a future of well-prepared professional nurses.

Methods: A descriptive, non-experimental study design was used to explore whether and in what ways that psychiatric nursing students in a baccalaureate nursing program have been influenced pre and post rotation in an acute behavioral health unit as well as in outpatient service settings. A comparative survey was designed to explore whether the perceptions of the students had been altered by the immersion within this educational experience

Results: Pending

Conclusion: Pending

Cultural Humility and Nursing Education for Study Abroad Nursing Students

Dalit Wilhelm, MA, RN, Israel

Cheryl Zlotnick, DrPH, MPH, MS, RN, Israel

Abstract

Purpose: Bachelor's nursing students in a study abroad program are plunged in a different society, with a different culture, language, and orientation. Universities repeatedly note the importance of transcultural nursing experiences that study abroad programs can provide. These programs often report broadening perspectives and bringing awareness to the lack of cultural humility. Ethnocentrism influences our ability to absorb and learn about cultures, and determines how we filter information ("environmental sensitivity"), why we focus on an observation, and what we think about the experience. Thus, lack of cultural humility influences our learning. Educators are challenged to address this problem in study abroad nursing students by finding methods and processes to help them acclimate, learn, and function as student nurses. This project describes a program designed to make ethnocentrism visible and enable students to access their biases.

Methods: Norwegian nursing students come to Israel for a semester-long, study abroad program in Israel. The program provides a two-facet strategy to enable them to view their perspectives on population behaviors and health care services: (1) theoretical learning; and (2) clinical practice. Within the theoretical course, students learn about the basics of cultural humility. They receive a framework on how to self-examine their own perspective of their and other's culture (Hays' ADDRESSING MODEL), have the opportunity to an exercise (theater) to practice the model, and to implement these principles in "real-life" situations within clinical practice.

Results: Nursing students are challenged by their experiences in clinical practice. The students write about their internal discussions between what they believed at the outset and how those beliefs have been reframed. The cycle and process of these newly evolving beliefs demonstrate the ability of nursing students to make better understand the impact of having a set of cultural beliefs, and projecting these beliefs on others. They describe surprising themselves with their former rigid thinking, and feeling less judgmental and having more flexible thinking as a result.

Conclusion: Although this program is useful in a study abroad program where the vast different cultures are emphasized, this program would be useful in all nursing programs where students encounter patients who are different from them in Age, Development/Disability, Religion, Ethnicity, Sex, Socioeconomic, Immigration/Indigenous, Nation, Gender (ADDRESSING). This process allows students working with individuals of different cultures to create their own internal language that facilitates their evolution - to make the invisible, more visible and - to become transculturally aware professionals.

Professional Formation: Facilitating Integration of Personal and Professional Values in Nursing Education

Margaret (Betsy) Babb Kennedy, PhD, RN, CNE, USA
Abigail Parish, DNP, AGPNCP-BC, GNP-BC, FNAP, USA

Abstract

Purpose: Intentional activities related to professional formation and integration of personally held and collective professional values are often lost in an already laden nursing education curricula. Cognitive and psychomotor skills are central to nursing education, but the affective domain of learning is often neglected. Students are faced with moral dilemmas, the hidden curriculum, and other challenges in the learning environment that can erode purpose and commitment to the detriment of self and practice. Exploration of these issues can only be done in ways that feel safe for students and faculty, in a community of inquiry that is relationship-centered. Intentional focus on acknowledgment of personal healing qualities, experiences of personal courage, and strengthening of the intentions that drew them into nursing is critical. The purpose of this study is to describe themes and perceived benefits for students and faculty facilitators after implementation of an innovative, experiential approach to supporting professional growth and development in the affective domain.

Methods: The Power of Nursing elective course will be offered for the third time in Spring 2017 by two course directors and faculty facilitators. To date, two cohorts of students have participated in the course. In the course, students engage with each other and faculty facilitators in a non-judgmental, non-competitive space to offer an experience that differs from typical nursing curricula. Topics include authenticity and wholeness, grief and loss, personal healing qualities, courage to enact power, and remembering the calling and commitment to values. Concepts central to the experience such as listening and presence are introduced as habits of interaction within the group.

Results: Qualitative thematic analysis will be performed on narrative evaluation results of student and faculty facilitator participants across three cohorts [Spring 2015 (n=24), Spring 2016 (n=44), Spring 2017 (n=x)]. Student data includes personal values repressed as a part of nursing education, perceived personal healing qualities, personal mission statements, and valuable personal and professional insights gained from engaging in the elective course. Faculty data includes comparisons of teaching this elective course as opposed to others in the curriculum, how the course might have changed impressions of students, thoughts on teaching in general, or changes in the way they relate to students. Themes for each will be presented and potential benefits of participation examined. Quantitative responses to evaluation questionnaires will also be analyzed.

Conclusion: Nursing education curricula require attention, intention, and adaptation to support students as they develop professional identity. Learning experiences in the affective domain can assist students to recognize and reinforce the foundation of personal strengths, values, and professional principles that is needed to navigate the hidden curriculum and future career in a profession with inevitable moral conflicts.

Second Career Nurses' First Year of Nursing Practice Experiences

Jessica G. Rainbow, BSN, BA, RN, USA

Abstract

Purpose: There continues to be a global nursing shortage and high turnover among new nurses (Oulton, 2006). Nurses are key in providing quality patient care (Aiken et al., 2013). One strategy to increase the number of nurses in the workforce is to attract individuals to pursue nursing as a second career. This has led to innovative new educational programs and approaches for these learners, but little is known about the transition to nursing practice experiences and turnover among second career nurses (Auerbach, Staiger, Muench, & Buerhaus, 2013). In order to discover potential differences in experiences during the transition to practice of second career nurses, exploration of both first and second career new graduate nurses in the same setting is needed. The purpose of this mixed method study was to explore the experiences of first and second career nurses as they transitioned to nursing practice.

Methods: The study approach included semi-structured interviews and a longitudinal survey of both first career and second career nurses during their first year of practice. For the interviews, fifteen nurses with between one and two years of nursing experience who either had or did not have a career prior to nursing were recruited through a residency program listserv at an Academic Medical Center. Participants took part in hour-long semi-structured interviews. Interview questions queried prior work experiences, experiences with stress and coping during the transition to practice, and future career plans. Interview transcripts were analyzed using latent inductive thematic analysis (Braun & Clarke, 2006).

Survey participants were recruited in the month prior to their graduation from nursing school from a nursing program in the Midwestern United States, and completed follow-up surveys at 6 and 12 months following their graduation. The initial survey had 115 respondents, at 6 months there were 50 respondents and at 12 months there were 30 respondents. Survey respondents answered questions about prior career experiences, demographics, and future plans, in addition to validated scales on coping skills, stress and burnout levels.

Results: Themes identified during analysis of interview transcripts included: Difficulty defining nursing, improved coping with second career, and prevalence of burnout and presenteeism among nurses. All participants were unable to define nursing as a career and describe their days at work. They expressed how this made it difficult to relate to other non-nurses, which hindered coping. Second career nurses had developed coping strategies and support systems, and did not feel the need for support from coworkers. All participants relayed experiences of coworkers exhibiting presenteeism, physical presence at work when impaired, and burnout behaviors on their units and the consequences of these behaviors. However, first career nurses discussed how these experiences with coworkers made them question how long they would stay in their current position. Survey data analysis of the longitudinal descriptive correlation data is ongoing, but initial results indicate that lack of coping skills is a predictor of burnout. In particular, self-blame is a predictor of the emotional exhaustion component of burnout. Positive coping strategies, like positive reframing and active coping, are significantly correlated with self-compassion. Further analysis of the difference between first and second career respondents over the entire first year is in progress.

Conclusion: There were differences in the transition to practice experiences of second and first career nurses identified in the interviews. The difficulty that participants discussed in describing nursing reflects an ongoing challenge in defining nursing's professional identity (Öhlén & Segesten, 1998). Multiple participants stated that they did not understand what nursing was when they chose to become nurses and still struggle to define it, which could be a factor in recruitment and retention. First career nurses often lacked the coping strategies and social support of second career nurses, and turned to their coworkers for support. Prior work on coping within nurses has highlighted the importance of developing these skills early in a nursing career (Crary, 2013). However, their coworkers were often burned out, and leaving their positions. Further analysis of all of the time points in the longitudinal survey data, which will be completed in Spring 2017, has potential to reveal differences in how first career and second career students cope

with the transition to nursing practices. Findings from this study can offer important insight and recommendations for nursing education and transition programs on future interventions aimed at each of these groups.

Using Art to Boost the Self-Confidence of BSN Graduating Nurses

Denise A. Gray, EdD, MSN, MBA, BSN, RN, USA

Abstract

The purpose of this study was twofold: 1) to help BSN graduating nurses increase their self-confidence and 2) to encourage their self-expression using a selection of a personal motto and art materials. Attainment of knowledge is a precursor to self-confidence. Graduating nurses from a BSN program have attained the requisite clinical skills and theory knowledge base to be competent entry level nurses. Self-confidence is a valued attribute in which an individual believes in their abilities. Support is needed for new BSN graduates to encourage their self-confidence. This was a phenomenological study. It was based on earlier works of Kroner and Biermann that found that low self-confidence makes others feel uncomfortable. The study used a phenomenological approach to this qualitative research. Emphasis was on the meaning of the "lived experience" of each participant. Using in depth interviews with each participating nursing student was the means of data collection. Each participant described their artistic expression. Feedback from the nursing students and others has been strongly positive. All students reported that they had never considered a personal motto before this study. They reported that this motto would become part of their persona as it increased their self-confidence. Nursing educators have the challenge of preparing nursing students who can practice as safe, competent, and self-confident entry level nurses upon graduation. This study highlights the importance of developing self-confidence among senior nursing students using innovative, artistic expression within a nursing theory course.

Purpose: The purpose of this study was twofold: 1) to help BSN graduating nurses increase their self-confidence and 2) to encourage their self-expression using a selection of a personal motto and art materials.

Methods: This study was a phenomenological study. It was based on earlier works of Kroner and Biermann that found that low self-confidence makes others feel uncomfortable.

Results: Feedback from the nursing students and others has been strongly positive. All students reported that they had never considered a personal motto before this study. They reported that this motto would become a part of themselves as it increased their self-confidence.

Conclusion: Nursing educators have the challenge of preparing nursing students who can practice as safe, competent, and self-confident entry level nurses upon graduation. This study highlights the importance of developing self-confidence among senior baccalaureate nursing students using an innovative, artistic expression within a nursing theory course.

The Influence of Transcultural Nursing Course on Stereotypes of Foreign Spouses in Taiwanese Nursing Students

I-Chen Lu, PhD, MSN, BSN, RN, Taiwan

Abstract

Purpose: More and more women from South-east Asia who married Taiwanese men are living in Taiwan. These foreign spouses are starting the transformation of Taiwan into a multicultural society. Nursing students might have some stereotypes of foreign spouses which may affect the caring attitude and quality for foreign spouses. Previous study showed stereotypes of foreign spouses had some significant association with culturally competent nursing care ability in nursing students. The purpose of this experimental study was to 1) assess the effect of a course of transcultural nursing on the change of stereotypes of foreign spouses in nursing students in Taiwan, and 2) examine which teaching strategy was more helpful for decreasing stereotypes.

Methods: A quasi- experimental study design was applied. A total of 126 eligible nursing students were assigned to group course of transcultural nursing (experimental group) and control group. Students assigned to experimental group received the intervention program (course of transcultural nursing) which contained 16-weeks sections including history, theory and practice of cross-cultural nursing, the influence of stereotype, culturally competent assessment and communication, and management and coordination of cultural conflict, while controlled group did not receive any intervention. All participants completed the consent forms and the questionnaires. A demographic questionnaire, the Stereotype of Foreign Spouse Questionnaire and Teaching Strategies Questionnaire were used to collect data. Data were analyzed by utilizing the SPSS Version 22.0 for Windows including descriptive statistical techniques and T-test.

Results: 126 students in total (65 in the intervention group and 61 in the control group) were recruited in this study. The result revealed course of cross- cultural nursing was effective for significantly reducing stereotypes of foreign spouses ($164.32 \pm 35.90 \rightarrow 132.12 \pm 32.13$) ($T= 8.84$, $p = 0.000$). In addition, students pointed the teaching strategies which were helpful for reducing stereotype included the speech provided by foreign spouse, role play, and visit and interview of foreign spouses.

Conclusion: The results showed the effectiveness of course of transcultural nursing on reducing stereotypes of foreign spouses in nursing students in Taiwan. The findings can be used in the future to make a better design of transcultural nursing course in nursing college to help nursing students to have fewer stereotypes of foreign spouses and to enhance the knowledge of transcultural nursing for clinical practice. The evidence- based research method can be utilized in other countries to develop appropriate course content for transcultural nursing.

Incivility Between Nursing Students in the Classroom: A Review of the Literature

Abby Grammer Horton, MSN, RN, USA
Norma Graciela Cuellar, PhD, DSN, RN, USA

Abstract

Background: Nearly 62% of students and faculty in nursing education have reported incivility in an academic setting (Clark & Springer, 2007). In a national survey, 24.8% of faculty have been physically assaulted and 42.8% had experienced verbal abuse while in the clinical setting (Lashley & de Menese, 2001). Vertical incivility/violence may occur between faculty:students, nurse:students, and administration:employees. Horizontal incivility/violence may occur between nurse:nurse, faculty:faculty, and student:student. However, there is very little evidence of incivility reported between student:student.

Purpose: The purpose of this review of the literature was to identify the evidence of incivility between student and student in the classroom in undergraduate nursing education. The Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) was used to guide the review of the literature.

Methods: A comprehensive review of the literature was conducted in Medline, Pubmed, CINAHL, ERIC, and PsycInfo. Inclusion criteria included 1) peer-review journals, 2) original publications, 3) no limitation to time, 4) quantitative or qualitative designs, and 5) studies identifying student to student incivility. Exclusion criteria was any vertical incivility in nursing education (faculty:student, clinical nurse:student, administrator:student/faculty). Terms used in the search included nursing, nursing education, nursing students, incivility, bullying, and micro-aggressions utilizing Boolean terms. The search was conducted in June/July 2016 and in several phases.

Results: We found six articles on incivility between students. These included two articles that were qualitative and one article that was quantitative. Additionally, three articles were listed as mixed- methods studies. Five of the studies were conducted in the USA and one study was conducted in Egypt. Incivility exists between students in nursing programs. Incivility in undergraduate programs is reported as a problem both in the classroom and in clinical settings. Incivility can result in poor performance in the classroom and higher attrition rates in nursing programs. As well, incivility experienced by nursing students may impact the role of professional behavior in those that are both the perpetrators and the victims of incivility.

Conclusion: The negative consequences of incivility to students will impact attitudes towards the profession after graduation resulting in uncivil nurses. During the nurse education experience, students must learn how to be civil to each other to be prepared to work with other nurses and health care providers in their professional careers. There is a lack of knowledge in faculty on how to address incivility. Faculty must be able to identify incivility and stop it when it occurs. As well, further research is needed to examine the psychological and social consequences of incivility in undergraduate nursing students which may include coping, self-efficacy, stress, anxiety, depression, health and wellness.

The Work Readiness of Senior Nursing Students in Turkey

Abdullah Beyhan, MSc, RN, Turkey

Ayşe Ergun, PhD, RN, Turkey

Abstract

Purpose: The present study was conducted to identify work readiness among senior nursing students in Turkey.

Methods: This descriptive study was carried out with 1008 nursing senior year students from 15 universities 6 of which are state and 9 of private universities. Data were collected with the Work Readiness Scale (WRS). The Work Readiness Scale has 53 items with a 10-point Likert scale (0= strongly disagree and 10= strongly agree) and 4 subscale that are work competence (WC), social intelligence (SI), organizational acumen (OA) and personal work characteristics (PWC) (Walker et al, 2015, Caballero et al. 2011). Cronbach Alpha Value varies from .84 to .88 for the sub-scales. Descriptive statistics (mean, SD, min, max, percent), Mann-Whitney-U test and Kruskal Wallis test were used to analyze the data.

Results: Mean age of students was 22.53 ± 1.37 and 81.9% was girls. Subscale score means of Work Readiness Scale was found the following results respectively; work competence mean was $6,68 \pm 1,47$, social intelligence mean was $7,35 \pm 1,56$, organizational acumen mean was $7,91 \pm 1,31$ and personal work characteristics mean was $4,76 \pm 1,85$. Girls had higher scores on organizational acumen ($p < 0.01$) and personal work characteristics ($p < 0.05$). According to type of school there are significance differences between the private and state universities on three subscales (except PWC) ($p < 0.01$). Another significance difference is that the schools which have 50 and less students have higher scores according to the others on three subscales (except PWC) ($p < 0.01$). Among the students who choose the nursing consciously and still love his/her job have higher scores according to the other (except PWC) ($p < 0.01$). The student who gave 7 and more marks for their theoretical and clinical education has higher marks than the other ($p < 0.05$).

Conclusion: In Turkey there was no study regarding work readiness for nursing because of that, we suggest that to understand this concept better various studies should be carry out.

RSC PST 3 - Research Poster Session 3

Comparison of Negative Stereotypes Toward Aging in Students of Nursing in Mexico and Peru

Erika Ramos-Cabrera, MSN, RN, Mexico

Ana Laura Carrillo-Cervantes, MSN, RN, Mexico

María de los Angeles Villarreal-Reyna, PhD, RN, Mexico

Maria Magdalena Delabra-Salinas, MSN, RN, Mexico

Abstract

Purpose: To compare the presence of negative stereotypes towards aging and its relationship with socio-demographic and coexistence variables with the elderly in college level students of nursing in the cities of Saltillo, Mexico and Lima, Peru

Methods: Correlational-Descriptive design. A stratified random simple with proportional allocation by gender will be taken from a public university in Saltillo, Mexico and Lima, Peru. According to Sarabia and Pfeifer (2015) the expected percentage of people with negative stereotypes towards aging is of 60%; the size of this sample will have a have an associated statistical confidence of 95% and an error of 5%, based on the finite population calculation.

The instruments that will be applied are the following: template of coexistence with the Elderly and a questionnaire about Negative stereotypes towards aging, which shows an acceptable confidence (Cronbach's $\alpha=0.845$). Descriptive statistics will be used to characterize the sample. A Kolmogorov-Smirnov test, with Lilliefors' correction, will be carried out to contrast the normality hypothesis in the allocation of continuous variables, considering them significant on a value $p < 0.05$; this will allow the selection of parametrical tests in the case of normality, or non-parametrical for results with random distribution.

In case of normality, to measure the relationship of negative stereotypes towards aging, with socio-demographic and coexistence with the elderly variables, the Pearson coefficient will be processed. If no normality exists, non-parametrical tests will be done, such as Spearman's correlation.

Results: As a first analysis we will obtain reliability through the Cronbach Alpha test of the CENVE instrument, describe the sociodemographic characteristics of the subjects to be studied, after which we proceed to describe negative stereotypes towards aging and compare the Results of Mexican and Peruvian students.

Conclusions: This study will discuss the importance of the identification of negative stereotypes and their relationship with sociodemographic variables in students from Saltillo Mexico and Lima Peru, which will allow in the near future the implementation of nursing interventions to modify stereotypes And to be able to improve the integral formation of the future nurses.

Predictors in Titulation Exam of Nursing at University of Coahuila, Mexico

María de los Angeles Villarreal-Reyna, PhD, RN, Mexico

José Luis Nuncio-Domínguez, MSN, RN, Mexico

Raul Adrian Castillo-Vargas, MSN, RN, Mexico

Irving Arnoldo Viera-Villanueva, BSN, RN, Mexico

Zabdiely E. Vargas-Rangel, RN, BSN, Mexico

Maria Ascencion Tello, MSN, RN, Mexico

Abstract

Background: In México, one of the processes of external evaluation about the domain of general and specific knowledge that it has attained by them graduates of bachelor's degree in the Institution of Higher Education (IHE), is the General Exam of Degree Egress (EGEL). That is applied by the National Center of Evaluation CENEVAL. This external evaluation provides objective, valid and reliable information about their academic preparation and represents a highly recommended activity by the organizations that carry out the certification of nursing's education programs. In the last three years, only 40% of the supporters which applied the EGEL-ENFER in an IHE, in Coahuila, obtained a performance attestation, and their results were situated below the national average.

Purpose: To identify the variables that produce academic success in the EGEL-ENFER test for graduated students in nursing, in an IHE of Coahuila, Mexico.

Methods: Predictive-Correlational study. The sample will be composed by graduated students from the bachelor's degree of nursing, in the 2013-2016 periods. Sociodemographic and academic performance data (from high school, the Academic Aptitude Test from the College Board and the grades at the end of the nursing's career) will be collected as independent variables. The obtained score in the EGEL-ENFER will be the dependent variable. The assessment of data will be carried out with the SPSS Version 24 Statistical Package.

Results: Sociodemographic characteristics of the subjects and their relationship with their academic performance will be described, using the predictive variables from the EGEL-ENFER test.

Conclusion: It will be discussed which ones of the variables: sociodemographic characteristics, the previous academic performance in high school, the result in the AAT for access to nursing school and the grades in the nursing career; are the best predictors for the EGEL-ENFER test results, along with the implications for the improvement of the results of quality indicators for the nursing career in the bachelor's degree, and the adequate inclusion of graduated students in the working market.

RSC PST 3 - Research Poster Session 3

The Feasibility of Developing an Evidence-Based Workplace Violence Simulation for Undergraduate Nursing Students

Angel Johann Solorzano Martinez, MSN, MBA, RN, USA

Abstract

Purpose: The main purpose of this poster is to present an overview of workplace violence in the nursing field and also provide strategies and recommendations for nursing faculty to develop an evidence-based workplace violence nursing simulation in a university setting.

Methods: Nurses are at risk of encountering incidents of workplace violence in clinical settings (Baby, Swain, & Gale, 2016). The major forms of violence encountered by nurses in clinical settings are verbal and physical (Edward, Ousey, Warelou, & Lui, 2014). Nurses who are victims of workplace violence sometimes do not report those incidents because they feel that violence is part of their job (Magnavita & Heponiemi, 2014). Nursing students are also at risk of encountering incidents of aggression and violence in the workplace during their clinical training (Magnavita & Heponiemi, 2014). It is critical to identify and implement innovative methods to train nursing students to prevent and manage incidents of workplace violence. A nursing simulation focusing on management and prevention of workplace violence can provide an opportunity for nursing students to learn and employ evidence-based interventions to combat this unwanted phenomenon.

Nursing simulations with an emphasis on management and prevention of workplace violence should contain evidence-based content found in the literature. Heckemann, Zeller, Hahn, Dassen, Schols, and Halfens (2015) reviewed the effects of training programs on aggression management for nursing students and nurses working in hospital settings. Their review showed that training programs implemented in nursing schools encompassed homogenous topics such as de-escalation techniques, theoretical models of aggression, triggers, causes, verbal and non-verbal communication skills (Hechemann et al., 2015).

Simulated scenarios employing a standardized patient (SP) provide the opportunity to enhance the nursing students' learning experience (Alexander & Dearsley, 2013). A nursing simulation with a SP behaving as an agitated patient can help simulate interactive and challenging scenarios in a controlled environment. Nursing simulations focusing primarily on preventing and managing workplace violence are limited. Evidence-based nursing simulation programs employing a SP have the potential to enhance the student's knowledge and confidence dealing with mental health patients (Lyng, Cocoman, Ward, & McGrath, 2012; Goh, Selvarajan, Chng, M., Tan, C., & Yobas, 2016; Doolen, Giddings, Johnson, de Nathan, & Badia, 2014).

Learning the development of nursing simulations is essential for nursing faculty's professional growth. Designing the scenario for a mental health nursing simulation requires a series of steps. The nursing simulation's goal statement, content, objectives, and the SP's psychosocial history, and family history must be clearly stated (Sideras, McKenzie, Noone, Markle, Frazier, & Sullivan, 2013). The scenario should address the learning concepts and the SP's appropriate symptoms, body language, responses, dialogue, and interaction with the nursing student (Sideras et al., 2013).

Ethical considerations and university regulations should be addressed before implementing a nursing simulation. Researchers attempting to implement a nursing simulation in a university setting should consult with the IRB department of the chosen institution.

Results: Nursing simulations can supplement the nursing content for nursing students. A nursing simulation focusing on management and prevention of workplace violence has the potential to enhance the student's learning experience in a controlled setting. It can also improve their confidence preventing and managing incidents of workplace violence in their clinical settings.

Conclusion: A nursing simulation focusing on management and prevention of workplace violence can provide an opportunity for nursing students to learn and employ evidence-based interventions to combat this unwanted phenomenon. Learning the development of nursing simulations can assist nursing faculty create mental health nursing simulations in their university settings.

How Does Negotiating a Partnership Agreement Influence Relationships in a BSN Clinical Experience?

Kimberly D. Belcik, PhD, RN-BC, CNE, USA
Shirley Ann Levenson, PhD, FNP-BC, USA

Abstract

Purpose: Partnership agreements are negotiated among partners to air out wishes, fears and concerns and to spell out expectations prior to jumping into collaborations. They have been used among partners in writing collaborations with success. To date, no one has explored their use with clinical students in baccalaureate nursing education. After one author experienced the positive influence of a partnership agreement within a professional relationship, she was curious about how negotiating one with her clinical students might influence their relationships with her and with one another. This project examines the influence of breaking down principles of domination inherent in nursing education and pedagogy and instead creates a partnership-based relationship. The partnership agreement is a concrete device to open a dialogue between the student and teacher. Such an agreement recognizes and values their worries and concerns as well as their prior experience and knowledge. It also give credence to their desires and wants from the clinical experience. Furthermore, the teacher is also given the opportunity to share their wishes, fears and concerns, thus potentially deepening the relationship between student and teacher.

Methods: This project was initiated in the fall semester of 2015 and repeated in the fall semester of 2016 with senior nursing students completing their adult medical-surgical clinical. On the last day of clinical, students were asked to anonymously handwrite their answers to the following questions: 1) How did negotiating a partnership agreement this semester affect your relationships with each other as a clinical group? 2) How did negotiating a partnership agreement affect your relationship with me? Forty students responded to the questions. Handwritten responses were transcribed to a word processing program and analyzed for recurring themes.

Results: Preliminary content analysis reveals a positive influence on the relationships between nursing students and between nursing students and their teacher.

Conclusion: Findings have implications for using partnership agreements to positively impact the relationships between nursing students and their peers and with their teachers.

RSC PST 3 - Research Poster Session 3

Attitudes Change During an Interprofessional Simulation With Physical Therapy and Nursing Students

Dawn Ferry, MSN, APRN, CNP, CHSE, USA

Robert Wellmon, PhD, PT, DPT, NCS, Aland Islands

Kristin Lefebvre, PhD, PT, CCS, USA

Abstract

Purpose: Providing effective patient-centered care requires collaboration among healthcare professionals from different disciplines. Across multiple practice settings, physical therapists (PT) and nurses (RN) interact around patient care and management issues. The skills needed for effective interprofessional collaboration (IPC), important to improving patient outcomes, have to be taught prior to licensure. This requires that students from different professions learn together. High-fidelity human simulations (HFHS) provide safe and authentic learning opportunities to practice the skills needed for IPC. The purpose of this study was to examine changes in PT and RN student attitudes towards interprofessional learning (IPL) and IPC following an opportunity to engage in curricular experience that featured a simulated cardiac arrest scenario. It was hypothesized that the learning experience would positively affect attitudes toward IPL and IPC.

Methods: PT (n=42) and RN (n=35) students participated in a 90-minute IPL experience featuring HFHS. Interprofessional teams reviewed the patient's medical chart prior to the HFHS. The goal for HFHS encounter was to collaborate to get the patient out of bed while closely monitoring the physiological responses to activity. RN students assisted the PT students with the bed to chair transfer. Once in the chair, the patient's vital signs deteriorated and ventricular tachycardia appeared on the EKG monitor. A full code ensued, which required the students to work together in responding to the medical emergency. The encounter concluded with a 45 minute debriefing. A control group consisting of PT (n=41) and RN (n=33) students was also included. Three surveys were completed pre and post-simulation: the Interdisciplinary Education Perception Scale (IEPS), the Readiness for Interprofessional Learning Scale (RIPLS), and the Attitudes Toward Healthcare Teams Scale (ATHCTS).

Results: A 2 (group – learning intervention vs. control) by 2 (time - pre vs post) repeated measures ANOVA revealed a statistically significant interaction. The learning intervention group demonstrated a statistically significant within group increase in post-test scores on the IEPS subscales examining competency and autonomy ($p < .001$), perceived need for cooperation ($p < .001$), and perceptions of actual cooperation ($p < .001$), the RIPLS subscales examining teamwork and collaboration ($p < .001$) and professional identity ($p < .001$), and the ATHCTS subscales for team value ($p < .001$) and efficiency ($p = .006$). For each of the previously identified subscales, statistically significant between group differences appeared at the post-test ($p \leq .003$) indicating more positive attitudes toward IPL and IPC in the learning intervention group. The control group was not significantly different from the learning intervention group at the start of the study and did not change significantly from pre to post-test.

Conclusion: The results of the study support the effectiveness of including HFHS as part of an IPL experience designed to foster the skills necessary for IPC. In the learning intervention group, the patterns of within group differences are supportive improvements in attitudes toward IPL and teamwork. Simulation provided a meaningful context for students to work collaboratively and actually implement the skills needed to work interprofessionally. Participation in the simulation and the related education activities positively altered student attitudes toward learning from and working with peers in other healthcare disciplines. A 90-minute learning experience had the capacity to positively change attitudes toward IPL and IPC, which is an important step in developing the skills needed to work effectively with other healthcare professionals.

RSC PST 3 - Research Poster Session 3

Students' Perceptions of Front-End Loading of Didactic and Simulation Classes in a Maternal Child Course

Judy Comeaux, DNP, ARNP, CRNI, USA

Julie A. Baker-Townsend, DNP, FNP-BC, WHNP-BC, USA

Abstract

Purpose: The purpose of the presentation is to share an innovative approach to teaching undergraduate BSN students' concepts and practices essential to maternal child nursing prior to inpatient clinical experiences.

Methods: In an effort to improve confidence and ensure acceptable skill level in the maternal child specialty areas, all didactic and simulation experiences were front-end loaded during the first two weeks of the semester. This concept was developed to improve knowledge of maternal child principles to promote safe practices in various inpatient clinical areas of maternal child health. Evidence-based studies have shown the use of laboratory simulators help students become better providers of quality care, increases confidence in the delivery of care, and provides a safe learning environment (Samawi, Miller, & Haras, 2014; Kim, Park, & Shin, 2016).

Clinical readiness after simulation activities is essential to success and deeper understanding of nurses processes of the maternal child settings. A six question qualitative survey evaluated students' perceptions of teaching methods employed by maternal child faculty. Students appreciated the novel teaching technique. They expressed an increase in knowledge and confidence prior to entering the specialty areas. The didactic portion of the class afforded the opportunity to understand the evidence-based concepts prior to simulation experiences. The simulation activities led to increased confidence in students' abilities to apply safe quality best practices.

Results: Students appreciated the novel teaching technique. They expressed an increase in knowledge and confidence prior to entering the specialty areas. The didactic portion of the class afforded the opportunity to understand the evidence-based concepts prior to simulation experiences. The simulation activities led to increased confidence in students' abilities to apply safe quality best practices.

Conclusion: Teaching undergraduate nursing students maternal child concepts is both challenging and rewarding. Preparing lectures to stimulate students while maintaining their interest in the content is difficult. The students need to be able to apply the knowledge acquired from the classroom and textbooks to inpatient clinical settings. Empowering students to become self-directed learners and promoting the development of critical thinking skills is a key component of teaching. Providing students with the resources to be successful in the classroom while holding them accountable for their own learning leads to academic success (Yang & Jiang, 2014). Utilizing innovative methods of instruction to accommodate the diverse learning skills of individuals' aids in promoting confidence and success in the clinical setting (Davis, 2013). Students need to be engaged in their learning; they need to actively participate in classroom and simulation experiences (Brannan, White, & Long, 2016; Sin, Sok, Hyun, & Kim, 2015).

RSC PST 3 - Research Poster Session 3

Impact of an Integrated Care Clinical Experience on Skills and Confidence of Nurse Practitioner Students

Joyce M. Shea, DNSc, APRN, PMHCNS-BC, USA

Abstract

Purpose: Approximately one in four adults, and one in five youth between the ages of 13 and 18, experience some form of mental illness (MI) in a given year. The majority receive assistance from providers outside of behavioral health specialties, particularly in primary care settings. In addition, those with severe forms of MI face an increased risk of serious medical co-morbidities and significantly shorter life spans than the general population. Experts have increasingly called for the integration of behavioral health and primary care to more effectively treat mental, substance-use, and general health problems. The integration of behavioral health services into primary care has been found to have improved outcomes both clinically and financially. However, finding clinical staff with the necessary skills and knowledge to bridge the behavioral and primary care systems has been difficult, and there have been few reports of the effectiveness of educational programs that aim to prepare future healthcare providers in the provision of evidence-based integrated care (IC). The purpose of this mixed methods pilot study was to determine the impact of a comprehensive didactic and clinical education experience that prepares nurse practitioners to deliver effective integrated care services in community-based primary care settings.

Methods: An innovative educational program was developed to provide coordinated clinical practicums for dyads of Family Nurse Practitioner (FNP) and Psychiatric-Mental Health Nurse Practitioner (PMHNP) students. Three pairs of students have been matched with preceptors working within primary care centers or School-Based Health Centers (SBHCs), and will be providing direct care to under-served clients across the lifespan for a 14-week semester. Services offered include primary medical, behavioral health, and dental care, along with a wide range of supportive services such as intensive case management, prenatal education and lactation support services, and family violence prevention and education. The unique educational model of pairing a FNP student with a PMHNP student is expected to result in maximum cross-disciplinary learning as well as better role preparation, along with demonstrated skills in delivering effective integrated care by the completion of the clinical rotation. Students are scheduled to be evaluated by their preceptor at the end of the practicum on their integrated care skills and competencies using the 26-item, Likert style Integrated Care Competency Assessment Tool (ICCAT). They will also complete a self-report on their experience of the integrated care practices at the clinical site using either the Primary Care Provider (PCP) Self-Report Questionnaire or the Behavioral Health Provider (BHP) Self-Report Questionnaire, and participate in a Focus Group that will elicit information about their experiences in the program. Finally, students will self-report, at the beginning and end of the practicum, on their level of comfort with providing integrated care by use of an analogue scale.

Results: Analysis of the results from the ICCAT, the Self-Report Questionnaires, the analogue scales and the Focus Group will be shared; the overview will determine the impact of the innovative clinical educational experience.

Conclusion: Results from the pilot study are expected to indicate that the students both enjoyed and benefitted from the innovative educational program.

Do Nursing Residency Programs Influence New Graduate Nurses' Professional Self-Concept?

Allison Bautista, SN, SN, USA

Sarah Elizabeth Kelly, PhD, RN, USA

Molly Naft, SN, SN, USA

Maria LoGrippto, PhD, RN, NE-BC, USA

Abstract

Purpose: During the course of study, students learn and grow to become proficient in the delivery of quality healthcare (AACN, 2008). However, according to the Joint Commission (2010), many new graduate nurses are clinically unprepared for the practice environment and lack the expertise to ensure patient safety (Letourneau & Fater, 2015). The first few months when new graduates work as registered nurses have been reported to be the most stressful time period, as they struggle with their role expectations, seek emotional support, and develop their professional communication (Cheng, Liou, Tsai, & Chang, 2015). Traditional orientation programs require a new graduate nurse to work with a designated preceptor over a period of several months; the new graduate nurse relies on her preceptor in her progression as a professional nurse and healthcare role model. Unfortunately, a lack of adequate training can have severe consequences on retention rates among new graduates. The National Council of State Boards of Nursing (2015) estimated that approximately 25% of new nurses leave their initial place of employment within one year of hire. One method utilized by hospitals to combat the revolving door of nurses is the development of hospital-based nurse residency programs, which are increasingly evolving as a means of transition into the nursing role. Nurse residency programs allow new graduate nurses the opportunity to develop and establish nursing skills, adapt to the professional environment, and encourage the new graduate to assume greater responsibility in a structured setting (Letourneau & Fater, 2015). Therefore, the purpose of this study is to explore the differences between participation in a nurse residency program versus a traditional orientation program and the effect they may have on new graduate nurses' professional self-concept.

Methods: This study is a non-experimental cross-sectional quantitative research design that used an online survey method. The participants were asked to complete a demographic informational questionnaire, which includes a question related to involvement in a hospital-based nursing residency program. In addition to the demographic information, the participants were asked to complete the Professional Self-Concept Nurses Instrument (PSCNI), a 27-item based survey measuring professional practice, job satisfaction, and communication. The questionnaire takes an estimated 15 to 20 minutes for completion, and the range of possible scores is 27-108 (Arthur, 1995). Cronbach's Alpha for this study was 0.81.

A convenience sample of new graduate nurses in the state of New Jersey (N = 199) was invited to participate in this study. An email list serve from the New Jersey Board of Nursing with new graduate nurses' email information was used to recruit participants; a new graduate nurse was defined as a successful NCLEX test taker between May 2014 and April 2015. Descriptive statistics were used to characterize the demographics of the sample. Outcome measures were studied using non-parametric analysis: Mann-Whitney U test. SPSS version 23 was used to manage the data. Power Analysis indicated that a minimum of 87 participants were needed in order to determine statistical significance with an Alpha = .05, Power = .80, and Effect size at .20.

Results: One hundred twenty-four (124) new graduate nurses participated in this study. The majority of participants were female (n = 109, 88.6%), single (n = 84, 68%), and baccalaureate-prepared (n = 87, 71%). Most nurses worked in an acute care environment; the unit of employment varied from a general medical-surgical floor (n = 45, 39%) to a pediatric unit (n = 7, 6%). More than half of the nurses had been employed for over 5 months (63%) and were oriented using a traditional program (n = 83, 78%) versus a residency program (n = 23, 22%).

The scores on the PSCNI ranged from 61-108 with an average score of 78 (SD = 8.0). To address the purpose of this study, a Mann-Whitney U test was conducted to explore the correlation between orientation methods and levels of professional self-concept. There were no significant differences in levels of professional self-concept between nurses who participated in a traditional orientation program and those who were involved in a residency program. There were also no significant differences in levels of professional practice, job satisfaction, and communication based on the type of orientation.

Conclusion: The study explored the impact of nurse residency programs versus traditional orientation programs on new graduate nurses' professional self-concept during their first year of employment. Data analysis revealed that many new graduate nurses were employed in a hospital-based environment, with the greatest percentage working on a medical-surgical unit. Many nurses reported a high level of professional self-concept. Although this study did not find significant differences between orientation methods in improving new graduate nurses' self-concept, the literature shows that nurses involved in residency programs have higher retention rates than those who do not participate (Bérubé et al., 2012). Perhaps an alternate strategy to address levels of self-concept and retention rates may not be the *type* of the orientation program but the *quality* of educational and clinical training. There are many intrinsic and extrinsic factors that influence self-concept, performance, and job satisfaction of a new graduate nurse, including the nurse's learning style and the type of unit on which he or she works. Therefore, the individualization of education and orientation may better prepare new graduate nurses for the nursing role and its many responsibilities.

Understanding Work Value Profiles and Exploring Factors Affecting Work Values of Student Nurses

Chia-Hsin Cheng, MS, RN, Taiwan

Abstract

Purpose: To understand the work value profiles and explore factors affecting the work values of student nurses.

Methods: A cross-sectional design involving 164 junior and senior baccalaureate student nurses in Southern Taiwan was employed to explore the work value profiles and the factors influencing the perceived work values of nursing students. Surveys were completed anonymously, and contained three categories: demographic characteristics, the Chinese version of the short-form revised Eysenck Personality Questionnaire (EPQR-S; Liao, 2001), and Adolescents' Work Values Inventory (Li & Ou, 2011). Internal consistency of Cronbach Alpha was shown to be .666, .722, .462, .042 on the four dimensions of extraversion, neuroticism, lying, and psychoticism on personality questionnaire, and .881, .942, .870, .867, .883, .911, .937, .856 on the eight dimensions of beyond, realistic, growth, respect, organization, relationship, security, and comfort on the work values inventory. The first four dimensions of the work values inventory represented "terminal (intrinsic) values", while the latter four dimensions represented "instrumental (extrinsic) values". Perceived work values were measured on a 6-point Likert scale with sum scores of 48 indicating "very important" and 8 meaning "not important" on each 8-item dimension. Descriptive statistics, t tests, One-way ANOVA, Pearson correlation coefficient, and stepwise multiple linear regression analyses were carried out through SPSS 18.0.

Results: Overall, students perceived realistic ($M \pm SD = 30.01 \pm 4.93$), relationship (30.23 ± 4.56), and security (30.24 ± 4.98) as their three most important work values. Junior students perceived realistic ($M = 31.26$) and security ($M = 31.01$) values, while senior students perceived relationship ($M = 29.81$) and security ($M = 29.67$) values as their most important work values. Also, juniors' perceptions of the importance of realistic ($F = 3.44, p < .01$) and growth ($F = .96, p < .05$) values were significantly greater than those of seniors. Comparing across different levels of students' self-reported average practice grades, significant differences were shown on the beyond values ($F = 3.19, p < .05$). Age ($r = -.22, p < .01$) and parents' marriage status ($r = .17, p < .05$) were negatively and positively correlated with the realistic and organization values, respectively. Among the eight work value dimensions, the beyond dimension showed the most significantly positive correlation with the demographic characteristics of willingness to do nursing work ($r = .19, p < .05$), levels of self-reported average practice grades ($r = .17, p < .05$), satisfaction toward practice grades ($r = .20, p < .01$), and satisfaction toward the clinical practice arrangement ($r = .30, p < .001$). The personality trait of extraversion revealed a significantly positive correlation with beyond ($r = .27, p < .01$), growth ($r = .25, p < .01$), and relationship values ($r = .16, p < .05$). Finally, students' satisfaction toward the clinical practice arrangement and extraversion accounted for 16.00% of the variance in predicting students' terminal values.

Conclusion: Students' practice performances could potentially influence their terminal values, thus affecting their willingness to do nursing work. And, strategies should be applied by educators when arranging clinical placements for students in order to enhance their experiences and satisfaction toward clinical practice. Finally, it is important for nurse managers to identify work value profiles and address work value conflicts between newly graduated student nurses with specific personality traits and the nursing unit as a whole in order to foster greater job satisfaction thus stabilize the retention rate of new nurses.

RSC PST 3 - Research Poster Session 3

A Longitudinal Study of Body Weight Loss in Patients Receiving Radiotherapy for Head/Neck Cancers

Shu-Chiung Lee, MSN, RN, Taiwan

Tsae-Jyy Wang, PhD, ARNP, RN, Taiwan

Abstract

Purpose: 1. to describe body weight change over time in patients receiving RT for head neck cancer.

3. to explore the influence of mucositis and nutritional support on weight change over time.

4.

Methods: The study uses a longitudinal design. A convenient sample of 101 H&NC patients scheduled for RT was recruited from a medical center in Taiwan. Data on patients' demographics and clinical variables were collected prior to RT. Body weight and mucositis were measured repeatedly at baseline (T1), one month (T2), the completion of radiotherapy (T3), and one month after completing radiotherapy (T4).

Results: The mean age of the sample was 54.3 (SD=10.8). Majority of the patients were male (n = 87), married (n = 80), and had a middle school (n = 30) education level. Thirty-seven patients had oral cancer, 29 had *nasopharyngeal cancer*, 23 had oropharynx cancer, and 12 had pharynx cancer. Their cancer stages were 11 in stage I or II, 23 in stage III, and 67 in stage IV. The average body weight was 69.4 Kg (SD = 13.2) at T1, 66.3 (SD = 12.0) at T2, 64.5 (SD = 11.9) at T3, and 63.4 (SD =10.7) at T4. Results of GEE showed a significant time effect [$F = 2802.6, P < .001$] on body weight. As for the parameter estimates, the patients' body weight dropped from the baseline by 5.96 kg at T4, 4.82 kg at T3, and 3.09 kg at T2. Results of GEE also showed a significant main effect of mucositis and interaction effects of nutritional support by time on body weight after controlling for the patients' height, age, and the dose of radiation. Patients with a higher grade of mucositis had a lower body weight. The changes of body weight over time were significantly different among patients with different types of nutritional support. Those who had oral intake during the entire course of RT or had enteral tube feeding part-way through the course of RT had more weight loss than those who received enteral tube feeding during the course of RT.

Conclusion: The results of the study supported that H&NC patients are at a great risk for body weight loss while receiving RT, especially for those with severe mucositis. Enteral tube feeding may provide better nutritional support than oral intake in this population. However, more studies are needed to verify this finding.

Exchanging Expertise: Collaborative Teaching Opportunities in Research Courses

Joyce A. Brill, PhD, RN, CPNP, USA

Paulette Dorney, PhD, RN, USA

Robert T. Brill, PhD, USA

Abstract

Purpose: Research courses for undergraduate nursing education can present challenges for the professor to bring real world research experiences into the classroom. Generating research experiences within an undergraduate nursing course can be limited by multiple factors, such as constraints of multiple ethical reviews by the college and medical institution and narrow time frames for student time available to complete data collection and analyses. A collaborative effort between a social science research course and nursing research course allowed the professors to incorporate expertise from each discipline. Students from two courses assisted in the design, implementation, and evaluation of a real world research experience. The purpose of this research partnership experience was to evaluate nurses' perceptions of stress, coping, and intention to return to school. The social science research course (in this case an upper level psychology seminar course on organizational stress that required an empirical project component) laid the theoretical foundation for work stress and coping. The nursing research course added the nursing perspective to these concepts.

Methods: In the context of this pedagogical endeavor, methods will refer to the joint efforts of the instructors to create this substantive research opportunity at the undergraduate level for students in both academic majors. Three professors from the same college, one from the social science department and two from the nursing department, developed the idea for joining their respective research courses to evaluate nurses' stress, coping, and intent / incentive for returning to school. Recognizing that both courses had parallel learning outcomes for developing undergraduates' competency in research, the collaborative team honed in on hypotheses that would be of mutual interest and relevance for both courses. The social science professor guided the search for appropriate tools for evaluation of stress and coping in nurses. The nursing department professors assisted in the literature review for the significance of the problem and the development of open-ended questions to evaluate nurses' intent to return to school.

Results: In this case of this pedagogical initiative, the results are the actual parallel research project assignments created for each course. A survey was developed based on literature reviews from both classes. For measures, the instructors decided to use the Nursing Stress Index (NSI), the brief COPE scale, and three open ended questions related to incentives to return to school, barriers to return to school, and factors that assisted returning to school. This provided both quantitative and qualitative sources of data. Students assisted in translating the instrument to an online electronic format and helped to pilot test that it ran smoothly and to estimate how long it would take to complete. The survey was distributed via SurveyMonkey to all currently enrolled Registered Nurses (RNs) in the college's RN to BSN, Master's degree in Nursing, and Nurse Practitioner programs. Students from both the nursing and social science course participated in data analyses in their separate respective classes. During each session the social science and one of the nursing instructors was present to discuss the rationale for each analysis as linked to the hypotheses, discuss theoretical connections, and provide multiple discipline-based perspectives on student questions and the overall implications of the data. Quantitative data analyses were facilitated for students in both classes by the social science professor and one nursing professor using SPSS Version 23. Qualitative data analysis was facilitated by the nursing professors with both classes. The students participated using thematic analysis and emergent themes were identified. Nursing students developed presentations based on their independent research focus areas. In addition to sharing and disseminating the development of this pedagogical multidisciplinary collaboration, pending comments from student course evaluations will also be presented.

Conclusion: Students from both courses benefited from this collaboration. Students were able to experience data collection from a sample of nurses. Students also participated in quantitative and qualitative data analyses including interpretation of the results. The joining of these classes allowed the students to evaluate the research process from a nursing and social science perspective in a real world research experience. The joining of these courses also allowed for the use of the expertise from professors experienced in quantitative and qualitative research techniques.

RSC PST 3 - Research Poster Session 3

An Assessment of Errors and Near-Misses From Pre-Licensure Student Nurses

Megan Wolfe, DNP, FNP, RN, RD, CMSRN, CNE, USA

Abstract

Purpose: Approximately one-half of new nurses with less than one year of experience who were involved in adverse patient events identified that their formal education preparation was a causal factor in their error (Saintsing, Gibson & Pennington, 2011). However, the concern arises that there is little to no standardized measurement or assessment practice that measures safe and effective practice at various points in the time frame that precedes graduation (Docherty & Dieckmann, 2015). As there is little consensus and often contention in the determination of what precise behaviors and attitudes constitute a passing nursing student clinical grade, and as there is often further pressure amongst academic administrations and schools of nursing to demonstrate a significant student success percentage, these variables may in fact promote an academic climate of failing to fail. Students being rated as successful in a clinical setting that actually employ behaviors that do not promote a culture of safety have serious, immediate and long-lasting consequences that will affect public health, safety, and welfare (NCSBN, 2011).

To assist with the identification of students and clinical errors and near misses, a Student Opportunity for Improvement (SOFI) form is completed by our clinical faculty for each error or near miss at our hospital based Associate Degree Nursing (ADN) Program research site. SOFI reporting forms are considered part of the institution's clinical paperwork and all of the faculty at this hospital based ADN program have been trained regarding the criterion standards for the completion of the SOFI.

The purpose of the SOFI is to assist the student in the identification of the event, potential patient consequences, and actions that might have prevented the event(s) in question. Secondary purposes of the SOFI are to assist in the identification of student(s) requiring remediation as well as to assist in the identification and tracking of trends. This identification and measurement intervention process is essential to the provision of optimal, safe care.

An examination of quality and safety measures of a current hospital based associate degree nursing (ADN) educational program provided data regarding errors committed by prelicensure students. Tracking and analysis of frequency and type of student clinical errors provided for identification of similarities and an opportunity for system evaluation and improvements. The purpose of my project was to identify the number, types and categories of Student Opportunity for Improvement (SOFI) reports from a hospital based ADN program over a four-year period from July 30th 2012 through July 30th 2016 and compare the numbers of SOFIs by academic term, the student's previous healthcare experience, and student age. My project also examined the number of errors in the ADN hospital based program after a curricular change was implemented to condense the previously existing 24-month program to 18 months.

Methods: A twenty-four month retrospective comparative design was utilized, in a private, non-profit 2-year associate degree nursing program in the northeastern region of the United States with an enrollment of approximately 300 students. The target population was all enrolled prelicensure nursing students between the ages of 18 and 60 who have had a SOFI report filed. A convenience sample was utilized. Students who were dismissed from the program due to either academic or clinical failures but who have had at least one SOFI filed were included in the study population. The number and types of SOFI reports generated with the previously discussed demographic variables were measured.

The SOFI forms were physically stored in a locked cabinet in the Assistant Dean's or her designee's office. All data from the SOFI reporting forms since 2012 was available to all faculty in an Excel spreadsheet in a secure faculty share hard drive. This Excel spreadsheet was downloaded to the secure research computer, and data entered for the student SOFI category, student semester, student age, program option, and previous healthcare experience. The program option, student age, and previous healthcare experience demographic information was available to all faculty on a shared drive. The

student course and therefore semester of enrollment is recorded on the SOFI form. Names were permanently removed prior to analysis. Approximately every 5th SOFI form entry was verified with the secure access Excel spreadsheet data as compared to the original SOFI forms for accuracy, and the Assistant Dean or her designee performed the check of each data entry from the SOFI to the Excel spreadsheet to verify accuracy. Data entries that were determined to be inaccurate were modified in the secure spreadsheet after consultation with the Assistant Dean or her designee. A running total of inaccurate entries was tabulated for further analysis if inaccurate entries are found. Once the data was cleaned and verified for accuracy it was downloaded from Excel to SPSS for data analysis.

Data from the SOFI reporting form have never been used in a pilot study, nor has the instrument been used in a related population or research study.

Results: Ongoing research

Conclusion: Ongoing research

The "Lived Experience" of Nursing Faculty Following the Sudden Death of a Student

Paulette Dorney, PhD, RN, USA

Abstract

Purpose: The purpose of this phenomenological qualitative research study is to explore the grief experiences and reactions of nursing faculty following the unanticipated, sudden death of a nursing student. According to the Essentials of Baccalaureate Education for Nursing Practice, "the baccalaureate generalist graduate nurse is "...prepared to engage in care of self in order to care for others" (AACN, 2008, p. 8). While nursing faculty teach students how to care for patients and their families at end of life, little is known about the impact of a student's death on faculty. Nursing faculty serve as teachers, role models, coaches, and mentors not only in the classroom, but also in the clinical setting. The unique closeness of this relationship poses an additional challenge to both students and faculty when a classmate suddenly dies. Nurses by the pure nature of their discipline, are perceived as providers of compassionate and supportive care to the dying and bereaved. Society presumes nursing faculty are more prepared to cope with such a stressful and devastating event since they are indeed nurses themselves, however, gaps exist in the literature regarding what support is appropriate to offer by nursing faculty. Since little is known about this phenomenon, the following research question will guide this inquiry: What is the lived experience of nursing faculty following the sudden unanticipated death of a student?

Methods: The phenomenon of "the grief experience of nursing faculty following the sudden unanticipated death of a student" lacks both exploration and description in nursing literature. An understanding of this experience has failed to be elucidated in nursing education, warranting a need to explore this understudied phenomenon. As Field and Morse (1985) stated, "qualitative methods should be used ...when the research question pertains to understanding or describing a particular event about which little is known" (p.11). Phenomenology as a qualitative research method, seeks to describe and unfold a phenomenon before the eyes of the researcher and reader so the essence of the participant's narratives can be experienced and understood (Munhall, 1994). This approach was the most suitable method of inquiry for studying the richness and complexity of bereavement. By utilizing the phenomenological method of inquiry rooted in Husserl's philosophy and data analysis as described by Paul Colaizzi (1978), the researcher will obtain a full description and understanding of the essence of this experience.

Results: The source of qualitative data included a demographic questionnaire and in-depth interviews with each participant. Interviews were digitally recorded, and verbatim transcriptions were analyzed utilizing the seven-step Colaizzi's (1978) method. Findings of this study support contemporary models of grief and bereavement. Researcher will explore the unique aspects of grief that emerged for nursing faculty.

Conclusions: This study yields a rich understanding of the grief experience of nursing faculty, while providing insights for policy development and supportive interventions for students, faculty and college administrators.

RSC PST 3 - Research Poster Session 3

Use of Crib Sheets and Exam Performance in an Undergraduate Nursing Course

Ann Malecha, PhD, RN, CNE, USA
Pinky Budhrani-Shani, PhD, RN, USA

Abstract

Purpose: A correlational study was conducted to assess the outcomes of allowing baccalaureate nursing students to use authorized crib sheets during exams.

Methods: Senior nursing students ($N=86$), enrolled in a community health nursing course, received a blank crib sheet (10 cm X 15 cm index card) one week before each unit exam ($n=2$) and the final exam. The students were allowed to write on the front and back of the index card and then use the card during the exam. Use of the card was not required. The crib sheet was collected after each exam and the students immediately completed a post-exam survey developed by the researchers. The survey included five scaled questions assessing the benefits of using the crib sheet across the domains of Exam Confidence, Exam Preparedness, Test Anxiety, Assistance during Exam, and Recommend for Future Exams. Other survey items collected data on amount of time spent creating the crib sheet and number of times crib sheet was used during exam. One open-ended question requested additional written feedback.

Results: This study is ongoing and the last data point of the study will be collected during the final exam in December 2016. Preliminary results indicate that all students created and used the crib sheet for the first 2 exams of the semester. Data to be analyzed includes mean time to create the crib sheet, mean number of times used card during exam, and Spearman rank order correlations will examine relationships between confidence, preparedness, anxiety, assistance, future use, and grades for unit exams 1 and 3 and final exam. Preliminary qualitative data indicates an emerging theme that creating the card "helped me memorize," and "I accidentally learned while making the card." All study results will be presented in July 2017.

Conclusion: There is a growing body of evidence that the use of student-prepared testing aids (cheat sheets or crib notes) can have a positive impact on student outcomes such as test anxiety and exam performance. Some researchers have suggested that the actual preparation of a crib sheet can help students to organize course content, reduce the need for memorization, and focus on conceptual knowledge and learning. A review of the literature indicates faculty-approved crib sheets during exams are becoming more common in the disciplines of math, engineering, psychology, and other sciences. This study will be one of the first to report on the use of authorized crib sheets with nursing students.

The Value of the Caring Moment in Patient Advocacy

Lorraine Emeghebo, EdD, MS, BSN, BS, RN, USA
Kathleen M. Lamaute, EdD, FNP-BC, NEA-BC, CNE, USA
Kathleen Maree Daus, BSN, RN, USA
Sonia Ponton, BSN, RN, USA
Antoinette Kunz, BSN, RN, USA

Abstract

Purpose: As student nurses navigate their way through clinical experiences, they may not understand how to learn the value of caring through patient advocacy. According to a study conducted by Archarya Pandey & Chalise, (2015), nursing students have low levels of self-esteem. They therefore, may feel that they do not have the necessary education to advocate for their patients. The American Nurses Association (ANA) states that high quality practice should include advocacy as an integral component of patient safety (ANA, n.d.). The purpose of this research study was to explore the experience of nursing students' caring advocacy using the basic concepts of human-to-human caring during the therapeutic relationship with their patients in the clinical setting. According to Ozam and Oumus (2015), the four basic concepts of Human-to-Human Caring include healing processes, interpersonal maintenance of relationship, the caring moment, and awareness of healing. The basic question was: "when you are a student nurse, where does advocacy begin?" Advocacy is the pillar of nursing and nursing students may not be aware of the extent that they advocate for their patients.

Methods: This is a qualitative study, based on Dr. Jean Watson's Theory of Human Caring. Watson's theoretical framework was used to capture the essences of the participant's experiences. A convenient purposive sampling of 26 senior level nursing students from a baccalaureate Nursing program in the Northeastern region of the United States completed a survey of three statements: 1) describe a caring moment you have experienced in the clinical setting; 2) identify the phase of the therapeutic relationship where the caring moment happened; 3) what specific actions, if any, did you take? Four themes synthesized from the data were: 1) communication 2) relationship 3) advocacy and 4) presence.

Results: Rich data was unearthed as participants clearly described moments in their relationship with their patient when their presence communicated advocating for their patient and their family. They all described feeling a rewarding moment, although they did not recognize that advocacy was what they were doing.

Conclusion: Findings from this study illuminated the interaction between students' motivation to be present for their patients and their clinical experience. Findings from this research study may also add to nursing education curriculum by emphasizing caring moments during the phases of the therapeutic relationship.

RSC PST 3 - Research Poster Session 3

An Investigation of the Integration of Technology to Enhance Consistency in Grading Clinical Skills

Sabine S. S. Dunbar, RN, NM, USA

Abstract

Background: A vital aspect of health professional education is the evaluation of clinical competence (Snodgrass, Ashby, Onyango, Russell, & Rivet, 2014). Moreover, nurse educators ensure that students become safe and competent practitioners (Hodson Carlton, 2012). The development of competence begins during pre-licensure nursing education (Vernon, Chiarella, & Papps, 2011) hence, students utilize learning opportunities to become proficient in clinical skills prior to practicing these on real patients. In light of the current focus on quality and safety in health care, there is a need to accurately evaluate performance to ensure safe clinical practice (Zazadny & Bull, 2015). In nursing education, clinical skills laboratories serve the purpose of evaluating student performance of clinical skills (Houghton, Casey, Shaw, & Murphy, 2012), which are an important component of nursing competence. Clinical skills commonly taught in prelicensure nursing programs include physical assessment skills, with summative evaluation taking place through student demonstration of a physical examination on a simulated patient. Nurse educators evaluate student performance via direct observation (Bourke & Ihrke, 2012), which may predispose inconsistency in grading (Donaldson & Gray, 2012; Zazadny & Bull, 2015). Students report such inconsistency in a baccalaureate, prelicensure health assessment course as educators grade summative examinations. Professional education programs utilize audio-visual technology for student learning and evaluation in health professional education programs. Audio visual recording may potentially enhance consistency among faculty evaluating clinical skills.

Purpose: This project investigated consistency among nursing faculty who grade summative physical examinations in a health assessment course through the utilization of audio-visual technology to compare live review and video review methods of grading.

Methods: A descriptive, comparative design was used to compare live grading to grading based on a video recording, and to measure reliability among six nurse educators teaching a health assessment course. Educators graded the performance of a physical examination by student and patient actors in a simulation laboratory. Grading was based on a pre-established checklist used in the nursing course for grading physical examinations performed by students. The physical examination was simultaneously recorded, allowing for measurement of inter-rater and intra-rater reliability, and a comparison of live and video grading of the examination by the same faculty approximately one month later.

Results: The study is ongoing until January, 2017, at which time data will be analyzed and results will be available.

Conclusion: Conclusions of this project will be dependent upon the results. However, it is anticipated that conclusions may be drawn related to consistency among faculty grading physical examinations, potentially leading to consideration of methods to improve consistency among multiple faculty members. Additionally, the results may provide evidence for the integration of audio-visual technology for grading clinical skills in nursing education.

Pandora's Box: Unveiling the Hidden Curriculum in a Military Teaching and Learning Environment

Karen Zagenhagen, MPhil, BACur (Hons), BACur, BCur, RN, RM, RCN, RPN, RNE, RNA, South Africa
Gisela H. Van Rensburg, DLittetPhil, MACur, BACur (Hons), BACur, RN, RM, RCN, RPN, RNE, RNM, RON, South Africa

Abstract

Purpose: The South African Military Health Service (SAMHS) Nursing College is responsible for the education and training of student nurses in order to provide the South African National Defence Force with competent professional nurses to care for its members, their dependants as well as for operationally deployed soldiers.

These students undergo six months of basic military training and six months of officer's training prior to commencing with their nursing training. The SAMHS Nursing College currently offers a 4-year diploma course leading to registration as a general nurse, community nurse, psychiatric nurse and midwife. The theoretical as well as most of the clinical component of the nursing training take place within a military environment.

Hafferty and O'Donnell (2015:7-9) point out that much of what students learn is not taking place in the classroom or the clinical environment, but that they are learning knowledge, values and behaviours unrelated to what is required through a multitude of other learning opportunities and educational settings which they labelled the "hidden curriculum".

Because of the unique context, the professional socialisation of students at the SAMHS Nursing College is compounded by simultaneous military socialisation within a teaching and learning environment inundated with military culture. Given the unique teaching and learning environment in which these students find themselves, it is difficult to determine whether the military nursing education environment nourishes the desirable professional attributes or whether it inhibits the development of these attributes. Is it thus likely that factors implicit in the military organisational structure, culture and learning environment may influence the professional socialisation of these students.

The purpose of this presentation is to convey and discuss the themes which emerged from the findings related to the influence of the hidden curriculum on the professional socialisation of students in the military nursing context.

Methods: The findings that will be discussed in this presentation form part of a constructivist grounded theory study that was done to answer the research question: "*What is the influence of the hidden curriculum on the professional socialisation of students in a military nursing context?*" The researcher employed focus-group interviews and critical-incident narratives to address the research question. In keeping with the constructivist paradigm adopted for the study, Charmaz's (2014:109-136) approach to data analysis was applied.

Results: Four themes emerged from the findings namely:

Theme 1, "You're in the army now", was described in terms of the process of military acculturation where the student undergoes a transition from civilian life to military life and is being introduced to military culture.

Theme 2, "Off to boot camp", reflected the processes taking place in the theoretical learning environment where students are taught the knowledge and skills necessary to execute their roles as nurses.

Theme 3, "Off to battle field" represented the clinical environment where students are placed to apply the knowledge and skills they acquired in the theoretical learning environment.

Theme 4, "Fighting a dichotomy" reflected on the professional role conflict experienced by nurse educators and students alike.

Conclusion: Conclusions made regarding the elements of the hidden curriculum present in a military teaching and learning environment and their influence on the professional socialisation of students revealed that the hidden curriculum were found to be present in people, processes and places to which the students are exposed to during the course of their training. Most of the elements could be related to a consequence which in turn could influence professional socialisation. This study not only revealed the complexity of the military teaching and learning environment but also exposed the many forms and facets of the hidden curriculum and its power and influences. It was found that the hidden curriculum in the military teaching and learning environment can function as a positive as well as a negative force.

Treatment Options for Chronic Lymphocytic Leukemia Tumors Chimeric Antigen Receptor Modified T Cells Therapy (CART-19)

Felicia M. Morrison, MSN, MBA, RN, USA

Abstract

Purpose: The National Cancer Institute (2016) estimates that there will be eighteen thousand, nine hundred and sixty thousand new cases of Chronic Lymphocytic Leukemia (CLL) in 2016. With the survival rate of only five years, there is a need for new and improved treatment options with sustained remissions and improved patient outcomes (National Cancer Institute, 2016).

The purpose of this presentation is to increase nursing awareness of a new treatment option available for Chronic Lymphocytic Leukemia (CLL) patients. In 2010, a new treatment module was developed for CLL patients with the goal of sustained remissions. This new treatment option called: Chimeric Antigen Receptor T-cells therapy (CART-19) are laboratory created T-cells (white blood cells) that have the ability to target the CD19 antigens found on all B-cell malignant tumors (Porter, 2013). Currently, this treatment option is only received in a clinical trial; however, these patients can have serious adverse reactions causing them to seek management in the emergency department. There is a nursing knowledge and skill deficit related to this treatment option. Therefore, formal education is warranted in order to increase awareness and promote health literacy.

Methods: A quantitative analysis of ten advance beginner oncology nurses was presented to determine their knowledge of CART-19 therapy as a treatment option for CLL patients. In mid November of 2016 a face to face in-service was developed. Several days before the start of the in-service participants were asked to complete a learning needs assessment tool (LNA). The LNA demonstrated a significant knowledge deficit related to newness of information and lack of exposure as evidenced by written deficiency in knowledge. The results of the LNA tool was used to developed an educational module that would educate both visual and auditory learning styles. The in-service included: a lecture, discussion outline, Likert style pre and posttest, PowerPoint presentation, instructor course evaluation, and time to process and ask questions. At the beginning of the in-service participants were also asked to complete a pretest. The purpose of the pre- test was to asses' current knowledge, to elicit participant's curiosity, measure written response, and determine if there were any knowledge gaps. After completion of the in-service, the participants completed a posttest that was identical to the pre-test. The purpose of the posttest was to measure learning and analyze the objectives with a goal that the learners would demonstrate an increase understanding of treatment options for CLL patients as evidenced by a score of seventy percent or greater on posttest and written assessments.

Results: The mean pretest score of the nurses was 10%, with a range from 0-100%. The pretest statistical demonstrated a knowledge deficit related to, understanding, ability to manage, awareness, side effects, comfort level and antidote for patients undergoing CART-19 therapy. Subsequently, after the in-service the posttest showed an increase in overall knowledge by 70%. There was an increase in awareness and comfort level of caring for CART-19 therapy patients by 50- 60 %, and an additional 30% of the nurses were ability to identify the signs and symptoms of Cytokine Release Syndrome (CRS) and Tumor Lysis Syndrome (TLS) per written examine. The in-service ended with a course evaluation. The overall course rating was superb with a mean of 90%. The instructor was rated as excellent at 90% for effectiveness, which shows an obvious interest in subject matter and knowledge gained in all areas.

Conclusion: Chronic lymphocytic leukemia (CLL) is the most prevalent adult leukemia in the Western world (National Cancer Institute, 2016). Of the new cases, it is probable that over twenty-four thousand people will die from leukemia (National Cancer Institute, 2016). The gold standard for CLL treatment has been chemotherapy, radiation therapy, and stem cell transplant. However, the review of literature evidently demonstrates the need for increased treatment options and nursing education on managing patients undergoing CART-19 cell therapy for CLL. For this presentation, a CLL treatment option education was developed and applied in a magnet teaching hospital in Philadelphia. The course focused

on the anatomy, physiology, etiology, mortality, morbidity, statistics, and current treatment options for CLL, as well as nursing management for patient post CART19 therapy patients. The workshop also included a PowerPoint presentation and course outline. The course was presented to ten advance beginner oncology nurses. Because this treatment is relatively new and still in the clinical trial phase, most patients are unaware of its existence. Equally, most nurses are also unaware of this treatment, therefore they are unable to share knowledge, or care for a patient who received this regimen. Hence, the goal to increase awareness was met as evidenced by posttest results. Participants in the in-service verbalized increased feeling of edification, confidence and preparedness to care for post CART-19 therapy patients, with an increased probability of sharing the eligibility criteria to CLL patient seeking a clinical trial. The learning objectives and the LNA tool were effective to gauge test questions. The statistics showed a 70% increase in nursing knowledge. As a result of this presentation the author plans to turn this presentation into a manuscript and present this treatment option to nurses around the globe increasing awareness and promoting health literacy.

Relationship Between Japanese Nursing Faculty Activities for Prevention Nursing Student's Medical Accident and Their Attributes

Wakako Sadahiro, DNSc, RN, Japan
Naomi Funashima, DNSc, RN, Japan

Abstract

Purpose: The purpose of this research is to clarify the relationship between the quality of nursing faculty activities for the prevention of nursing student's medical accidents and their personal attributes in Japan.

Conceptual Framework: The Conceptual Framework is based on a literature review for the prevention of nursing student's medical accidents during the nursing clinical practicum. It included 25 attributes of the nursing faculty as independent variables, and the quality of faculty's teaching activity for the prevention of medical accidents as the dependent variable.

Methods: Instrument: The Teaching Activities of Nursing Faculty for Prevention Medical Accidents by Nursing Students in Clinical settings –Selected version- (TAPMA-S) was used to collect data of quality of nursing faculty activities for the prevention of nursing student's medical accidents. It was a five-point Likert Scale developed based on a qualitative inductive research (Sadahiro & Funashima et al., 2013) with 40 items being grouped into 8 subscales. The total score (TAPMA-S) was ranging from 40 to 200. Higher scores indicate the perception of better teaching activity for the prevention of nursing student's medical accidents. Criterion-related validity, content validity, construction validity, internal consistency, and stability of TAPMA-S were ensured (Sadahiro, Funashima et al., 2015). Nursing Faculty Attributes Questionnaire (FAQ) were used to collect data of Attributes of Japanese nursing faculty. It consists of 26 items to measure demographic variables, attributes as a teacher, attributes as a person as a learner, and attributes as a nurse. It has adopted Self Evaluation Scale of Oriented Problem Solving Behavior in Nursing Practice (OPSN) to measure attributes as a nurse. The "OPSN" was developed based on a qualitative inductive research (Sadahiro & Funashima et al., 1997). It has 25 items with 5-point Likert scale with total scores ranging from 25 to 125. Higher scores indicate the perception of better ability of nursing practice. Validity and Reliability of OPSN was ensured through research for the Japanese Nurses (Sadahiro & Yamashita, 2002). The Construction Validity for Nursing Faculty was ensured through a factor analysis. The internal consistency was ensured by the Cronbach's coefficient alpha of 0.959. (Sadahiro & Funashima et al., 2015)

Data Collection Procedure: After obtaining the ethical approval from the Sapporo City University Ethics Committee, a total of 462 directors in nursing education who were randomly sampled from baccalaureate programs, associate degree programs, and diploma programs in Japan were asked by mail to participate in the study. The instrument packets were distributed to 2,028 nursing faculty members who belonged to nursing educational institutions and agreed to participate in the study. The instrument packets in self-addressed envelopes were returned anonymously.

Statistical Analysis: The Statistical Package for Social Science ver.20 (SPSS) was used for the analysis of data. Descriptive analysis was conducted for the background characteristics of the participants. Because the total score of the TAPMA-S did not follow the normal distribution, Spearman's correlations were employed to examine the relation with the total score of the "OPSN", the age, and the years of teaching experiences. Man Whitney U test and Kruskal-Wallis one-way analysis of variance were employed to examine other variables. The Stepwise multiple regression analysis was used to examine the extent to which the object variable TAPMA-S score was related to the explanation variable of Faculties attributes which identified the relation by univariate analysis.

Results: A total of 881(43.4%) subjects returned the instruments by mail, and 786 of them were valid and analyzed. A total of 214 subjects in BSN/ ADN and 540 in diploma programs participated. The mean age was 45.9 (SD=8.2). The mean year of teaching experiences was 9.6 (SD=7.5). The mean year of clinical experiences was 13.6 (SD=7.7). The "TAPMA-O" scores ranged from 106 to 198 points, with a mean

score of 160.5 (SD=18.8). The highest mean score of Subscale was 4.5 (SD=0.5), which was found for "VIII Self-Managing health of not only students but also teachers themselves", and the second one was 4.3(SD=0.6), which was found for "VI providing students with a learning opportunity needed for the patient safety". The lowest mean score was 3.5 (SD=0.6), which was found for I Making all necessary preparations prior to the nursing clinical practicum" and the second one was 3.7(SD=0.6), which was found for "V. Establishing a close communication with the students and the staff". Univariate analysis was performed for 9 attributes related to the score of TAPMA-S. Those are the kind of school, a qualification as a nurse, conducting the practical training in collaboration with nurses, the satisfaction with their clinical nursing practicum, the satisfaction with their role as a teacher, ability of nursing practice, perception about nursing, having/not having a mentor, and membership of Academic Societies. Step-wise multiple regression analysis was performed by using the score of TAPMA-S as objective variables and using 9 attributes as explanation variables. Three attributes were retained, resulting in an R² of 0.426 (F=32.17, p<.001) Three attributes that proved most valuable in the score of TAPMA-S were ability of nursing practice (beta=.497), the satisfaction with their clinical nursing practicum (beta=.234), and conducting the practical training in collaboration with nurses (beta=.179).

Conclusion: In this study it was suggested that nursing faculty having a high quality of teaching activity for the prevention of medical accidents by students have the following attributes. They possess a high capability in terms of nursing practice and have established a system to conduct practical trainings in cooperation with clinical instructors. In addition, they feel satisfied with their nursing clinical practicum. The followings are important to improve the quality of faculty's teaching activity for the prevention of medical accidents by students during the nursing clinical practicum: First, faculty should find the meaning of instruction in nursing clinical practicum, and maintain/improve their ability of nursing practice and cooperation with nursing colleague. Second, the quality of the faculty's ability to prevent medical accidents by students will be high, if they make their preparations before the nursing clinical practicums with the most studious care and communication with students, patients and the people involved in clinical nursing practicum during the clinical nursing practicum, including getting those abilities.

One Million+ Nurses Become Second Victims Annually: Nursing Education's Role in Prevention?

Jackie H. Jones, EdD, MSN, RN, USA

Linda A. Treiber, PhD, RN, USA

Abstract

Purpose: Nurses function in fast-paced, stressful, complex, unpredictable environments. In these environments, errors are made. They are made by well-intentioned, conscientious nurses. The impact of that error-making has been likened to post-traumatic stress syndrome. There are feelings of guilt, shame, and remorse. There is loss of professional and personal self-esteem. Nurses have quit their jobs, been criminally charged, sued, deemed incompetent, been fired, committed suicide and have left their professions.

They have also become the “second victims,” of the error, a term originally coined by Dr. Albert Wu (2000). Although he applied the concept to medical residents, the term has evolved and expanded to include any “healthcare provider who is involved in an unanticipated adverse patient event, in a medical error and/or a patient related injury and becomes victimized in the sense that the provider is traumatized by the event” (Scott et al., 2009).

The number of nurses that become second victims annually is unknown. Attempts to quantify are problematic. Second victimhood occurs as a result of error. We know that the IOM (2007) estimated that 1.5 million people are harmed each year by medication errors in hospitals. We know that preventable medical errors are now the third leading cause of death in the United States, with up to 440,000 Americans dying each year (Makary & Daniel, 2016). Every one of these error represents a potential second victim. However, because nurses who have made errors can suffer even in the absence of harm to their patients, these numbers cannot come close to representing the true number of nurses who suffer as second victims.

The literature is replete with information about the need to support healthcare professionals who become second victims. Denham (2007) developed the 5 rights of second victims. There are second victim rapid response teams, there are caring for the caregiver programs. There are peer support programs such as R.I.S.E. (Resilience in Stressful Events) (Trossman, 2016). There are recommendations, tools, programs, initiatives, white papers, and calls for a just culture. The overwhelming preponderance of these efforts have been developed and implemented at an organizational level.

The role that nursing education plays in preventing this phenomenon, or even if it has a role, is less well understood and there is an almost complete lack of information about it in the literature. These authors have researched medication errors and the second victim phenomenon for several years. This paper will present a study designed to investigate recent graduate students' opinions about medication error.

Methods: A survey was conducted in February of 2015 which surveyed graduates from the preceding 5 years from a prominent undergraduate nursing program in the southeast. The survey sought to determine the graduates' perceptions of how well the nursing program had prepared them for administering medications in the clinical environment. It also asked questions about whether they had made a medication error since becoming a nurse and, if so, to describe the circumstances and their feelings associated with the error-making. In addition to asking whether the program had prepared them for medication administration, it also asked their perceptions of how well the program taught them to advocate for patients and for themselves. Both quantitative and qualitative data were collected and analyzed.

Results: 168 graduate nurses participated in the study. Of those, 166 respondents indicated that the nursing program had prepared them adequately, well, or very well to administer medications. When asked whether they had made a medication error since becoming a nurse, 89 (56%) stated yes. Details

regarding the event, the organizational follow up, and their own feelings were elicited. There was a significant difference in the number of respondents who felt that they had been prepared to advocate for patients and advocate for self.

Conclusion: The comments provided indicate that both the errorless imperative and the second victim phenomenon were experienced by our graduates. It is also clear that these students were taught patient advocacy but much less about self-advocacy.

Ultimately, this study raised as many questions as it answered. What role does nursing education play in preventing the second victim experience? Most, if not all, nursing programs have incorporated teaching their students all the recognized safety and quality competencies. They strive to teach their students how to do it all perfectly and without error. However, have we failed to teach them how to survive in an environment that is demanding and rife with opportunity for error? What are the best practices for nursing education to prevent their graduates from becoming second victims?

Postgraduate Student Support in Open Distance Learning: Using a Caring Curriculum Approach

Gisela H. Van Rensburg, DLittetPhil, MACur, BACur (Hons), BACur, RN, RM, RCN, RPN, RNE, RNM, RON, South Africa

Abstract

Purpose: Student support is at the core of enhancing student success. Educators who are preparing students to reach the highest academic levels are continuously faced with the question on what is required to assist students to meet their learning outcomes and become successful in their studies. Open and interactive approaches to the teaching and learning environment of postgraduate students enhance a reflective culture and develop self-directed learning. The purpose of this study was to explore a caring approach to postgraduate student support in an open distance learning context.

Methods: Features of open distance learning that reduce transactional distance, create presence, and foster engagement were explored. A qualitative design was used and data were collected by means of reflective essays and workshop feedback that was in the form of semi-structured narratives. The reflections were used to understand the support needs and the students' experiences in an open distance learning institution in a developing country. Data were analysed using the eight steps for qualitative data analysis as proposed by Tesch. The themes identified were then discussed within the theoretical context of the Nodding's model of a caring curriculum.

Results: Learning activities that create purposeful interactions within the context of a caring relationship between and among postgraduate students and their supervisors were identified. Nodding's four features of a caring curriculum was used as theoretical underpinning: modeling, practice, authentic dialogue and confirmation/affirmation. Integrating these four features with open distance learning strengthens student interaction and engagement beyond levels that are normally experienced in this context. The findings further revealed that 'caring for' and 'caring about' have become an integral part of the caring curriculum.

Conclusion: Open distance learning aims at bridging the time, geographical, economic, social, educational and communication distance between student and institution, student and academics, student and courseware and student and peers. It widens access to learning, provides for flexibility of learning provision, focuses on student centredness, and supports students by constructing learning programmes with the expectation that students can succeed. Supporting students within a caring curriculum during the postgraduate supervision journey enhances the quality of learning during research capacity development. A student-centered approach with a reflective practice paradigm provides a flexible approach to self-directedness of postgraduate students. Constructive alignment of all activities and elements of effective learning opportunities are essential in creating reflective practices that could enhance student support. These elements include authenticity, activating of existing knowledge, creating a community of learning, engaging with new learning material, demonstrating competence and applying it to the real world, all within a caring philosophy.

Holistic Review Impacts Success of Underrepresented Minority Nursing Students: A Case Study

Joana Velasquez, MS, RN, CNOR, USA

Carleen Graham, MSN, RN, NYSAFE, USA

Sandra Ellen Bell, MSN/Ed, RN, USA

Abstract

Purpose: The purpose of this project is to increase the enrollment, retention, and graduation of individuals from disadvantaged backgrounds, including ethnic and racial minorities, in the accelerated Associate's Degree in Nursing (aADN) program at the Phillips School of Nursing at Mount Sinai Beth Israel (PSoN).

Our target populations for this initiative reflect the demographics of the five boroughs of New York City (NYC), the most populous city in the US (NYC Planning, 2014) as well as disparity in the nursing workforce in our region: 1) Latinos; 2) blacks; 3) individuals who are economically disadvantaged; and 4) individuals who are educationally disadvantaged. As the demographic data demonstrates, these populations often overlap. Hence, we anticipate that the majority of applicants identified as racial/ethnic minorities may also be economically and/or educationally disadvantaged.

Background and Significance: The nursing profession has been working towards increasing the diversity of nursing students in an attempt to keep up with changing demographics and complex healthcare systems. It is projected that racial and ethnic minorities will comprise more than half of the US population in the next 20 years; however, this prevalence is not reflected in nursing education or practice (Scott & Zerwic, 2015).

In the American Association of Colleges of Nursing (AACN) report (2016), it was noted that there was an increase in enrollment of ethnic minority groups in generic (entry-level) baccalaureate programs from 25.2% in 2006 to 31.6% in 2015. Nonetheless, recruiting and retaining more minority nurses still remains as an objective of nursing education. Nursing programs could facilitate increased minority representation in the nursing workforce by increasing recruitment and improving retention of minority nursing students (Loftin, Newman, Dumas, Gilden & Bond, 2012). Anecdotally speaking, faculty and administration have come to the realization that diversity in the classroom goes beyond ethnicity and race, and, are further realizing that this increase in diversity is also associated with many socio-cultural issues.

Culturally diverse nursing students are considered a vulnerable population due to social isolation and lack of faculty support and supportive services (Muronda, 2015). According to Degazon and Mancha (2012), the benefits of having a diverse student body are twofold: it will increase the likelihood that patients from diverse backgrounds will receive culturally congruent care and it will contribute to the development of more effective health policies. Consequently, a diverse nursing workforce will lead to narrowing of disparities in health outcomes. Numerous studies had been conducted to explore barriers and facilitators to success of minority nursing students (Loftin, Newman, Dumas, Gilden & Bond, 2012; Tabi, Thornton, Garno & Rushing, 2013). Similarly, best practices to attract and retain minority nursing students had been reviewed (Condon, Morgan, Miller, Mamier, Zimmerman & Mazhar, 2013; Dapremont, 2013; Carthon, Nguyen, Chittams, Park & Guevara, 2014).

Scott and Zerwic (2015) proposed that another strategy that can be used to diversify the nursing students is through the use of holistic admissions review. Holistic review, as described by the American Association of Medical Colleges (AAMC), is "a flexible, individualized way of assessing an applicant's capabilities by which balanced consideration is given to experiences, attributes and academic metrics and, when considered in combination, how the individual might contribute value as a medical and future physician" (Addams, Bletzing, Sondheimer, White & Johnson, 2010, p. 10). While a few nursing schools have started implementing the use of holistic review as part of the admission process, there is a gap in

the current literature on using holistic review as part of the academic progression of students throughout the program.

Methods: An innovative program initiative at PSoN has been a program of support for returning students. Few schools of nursing permit students who have dropped out to return. Given the barriers and challenges minority students in particular face, we realize that many students drop out due to unanticipated personal or family circumstances, work obligations, or financial challenges.

PSoN will implement a holistic review admissions process that comprises the four basic principles of holistic review: 1) alignment with our School's mission and goals; 2) assessment of applicants' experiences, attributes, and academic metrics in the context of social determinants; 3) individualized consideration; and 4) consideration of race and ethnicity as factors in the selection of students for admission to the aADN program.

We will adjust the current admission rubric to reflect a new scale of assessment for the pre-admission test, define with greater precision and clarity factors that may constitute non-academic criteria, redesign the application form and personal interview questions/guidelines to capture this information, as legal and appropriate, and broaden the scope of personal essay questions. In order to create a new rubric, we will review models developed by schools of nursing currently employing a holistic review process.

During the admission process, applicants who were previously enrolled in a nursing program but were unsuccessful and consider themselves as part of underrepresented minority (URM) will be identified. The project will be explained to the potential candidates and consent to participate will be obtained. A case study following the students from admission to graduation from the program will be conducted highlighting how holistic review was used throughout their academic progression.

To support a systematic, integrated, and consistent holistic review process we will create a Holistic Review Toolkit, based on current best practices (Glazer, 2016), which will include: a) rationale; b) goals and objectives; c) legal issues; d) an overview of the holistic review process; e) copies of the new application forms; f) new rubric(s); g) information on non-academic criteria; h) guidelines for personal interviews; and i) expected outcomes. Non-academic criteria may include: race/ethnicity; community of origin; first generation college student; languages spoken and level of proficiency; socioeconomic status; work status; quality and rigor of prior educational experience; breadth of the applicant's prior education, training, and experience; competence in non-traditional areas of learning; academic achievement within the context of non-academic challenges; significant personal challenges; and leadership experience.

Holistic review will also be used in following the participants' progression in the program. Final course grades, interactions with faculty, staff and peers, professionalism, as well as participation in extracurricular activities will be reviewed and documented. The Grants and Scholarships Committee will award the participants with partial scholarships and stipends. A reduction in the cost of tuition in combination with funds for basic living expenses will provide a substantive source of support for students in the initiative's target populations. Peer mentoring, Career Development and Readiness Program (i.e., boot camp) and enhanced tutoring services will be made available to the students.

Our long-term goal is to contribute to the development of a highly skilled, adept, and adaptable workforce that reflects, and is prepared to serve, the most diverse urban communities in the country, the residents of NYC. Additionally, we aim to support URM nursing students at PSoN throughout the entire educational pipeline, from enrollment through graduation, to become registered nurses (RNs) and find employment in our region.

Results: Based on the assumptions, as outlined in the Logic Model and the specific interventions we have designed to achieve our goals and objectives, we expect the initiative to result in the following outcomes: 1) Enrollment of students in the target populations will increase by 10%; 2) 100% of the participants will complete the program within 15 months of enrollment; 3) students' licensure first-time pass rate will be at or above the state and national means; 4) At least 85% of the scholarship recipients who do not enroll in the RN-BSN program will obtain employment within 12 months following RN

licensure; 5) At least 90% of the participants will be satisfied with the education they received; 6) PSoN retention rates will improve by a minimum of 5% for the target populations; 7) PSoN graduation rates will improve by a minimum of 5% for students in the target population; 8) At least one student in the cohort will enroll in the RN-BSN program following licensure.

Conclusion: Fostering a culture of diversity and inclusion is integral to our School's mission, vision, and philosophy, and aligns with our academic approach. Every course in the curriculum includes an objective related to the development of cultural competency and students are evaluated on their ability to communicate in a culturally sensitive manner and to deliver culturally-competent patient care. Creating a nursing workforce that reflects the city's unusually diverse population and is adept at inter-cultural communication and prepared to provide culturally sensitive and competent care will be critical to meeting the city's changing and increasingly complex healthcare needs.

Nursing educators are at a unique vantage point of influencing global health. Educators are able to design curricula that strengthen the teaching of health policy development, thereby, increasing nursing presence in policymaking. According to CDC, as described by Shishani, Allen, Shubnikov., Salman, LaPorte, & Linkov (2012), global/public health is not routinely taught in nursing schools; however, most nurses have basic knowledge of disease prevention strategies, which can be harnessed to improve global health . Educators can provide nursing students with introductory concepts that support global health work that transcends borders.

Faculty Collaboration for Horizontal Integration of Nursing Curriculum: Innovative Teaching Strategy

Manju Daniel, PhD, MSN, FNP-BC, USA
Jeanette Rossetti, EdD, RN, USA

Abstract

Background: Baccalaureate nursing education plays a significant role in the development of critical thinking skills. Critical thinking is a core competency that nursing students need to have so they can efficiently address simple to complex clinical situations. Attainment of critical thinking skills during the undergraduate nursing program can positively impact students' future nursing practice across a variety of in-patient and out-patient settings. The utilization of discipline-specific "teaching-learning strategies", which facilitate the development of critical thinking among nursing students, is important. Horizontal integration of an undergraduate nursing curriculum is an innovative discipline-specific "teaching-learning strategy. Horizontal integration involves fusion of nursing curriculum content across different courses within the same phase of the curriculum. Integration of knowledge that is gained throughout different nursing courses can help students to use critical thinking for developing patient-centered comprehensive nursing care plans. In addition, the horizontal integration of nursing curriculum can facilitate nursing students' competency for problem solving, development of good communication skills and team building. There is a need for innovative teaching-learning strategies that could facilitate horizontal integration of an undergraduate nursing curriculum. Collaboration among intra-professional nursing faculty is a key element for implementing horizontal integration of an undergraduate nursing curriculum.

Purpose: The purpose of the study was to examine the impact of nursing faculty collaboration for horizontal integration of a nursing curriculum on: a) students' attendance, b) student collaboration for interactive learning and critical thinking, c) course grades reflecting achievement of course goals, and d) student satisfaction with the course learning outcomes.

Methods: A mixed methodology design (descriptive quantitative and qualitative data for students' perspectives) to pilot the intervention of a horizontal integration of nursing curriculum from two undergraduate courses (nursing research and mental health nursing) was used. All undergraduate nursing students enrolled in the nursing research class, in three consecutive semesters, were recruited. The observation phase included 52 students for the first semester and 39 for the second semester. The intervention phase included 40 students for the third semester. Purposive sampling was used. Students were divided into eight groups. Mental health nursing curriculum was integrated into the nursing research class for the written assignments, as well as for the in-class group activities, such as data collection for a phenomenological study from participants suffering with bipolar disorder. Descriptive statistics (frequencies, means, and standard deviations) were calculated for the demographics, students' attendance, collaboration, and grades. Students' perspectives related to the curriculum integration were categorized into themes.

Results: The mean age of the students was 22 years and the majority were (n=428, 69.1%) Caucasians and n=78 (12.6%) were Hispanics, n=45 (7.3%) were Asians, and n=43 (6.9%) were African Americans. Findings revealed that class attendance and student collaboration improved by 60-65% for the third semester (intervention phase) students. Increased comprehension of research concepts and additional learning opportunity were two main themes for student satisfaction with the course learning outcomes.

Conclusion: Horizontal integration of a nursing curriculum with the intra-professional collaboration is an innovative teaching-learning strategy which leads to enhanced critical thinking, quality student learning outcomes, and attainment of desired course goals. The administrative teams at nursing schools should consider supporting nursing faculty collaboration to implement horizontal integration of undergraduate nursing curriculums, in order to achieve quality teaching and learning outcomes.

The Meaning Baccalaureate Nurse Educators Ascribe to Their Remediation Experiences: Qualitative Study

Nancy L. Sarpy, PhD, RN, USA

Abstract

Purpose: The purpose of this study was to investigate the meaning nurse educators ascribe to their experiences using remediation for at-risk, pre-licensure baccalaureate nursing students. According to the research literature on remediation, nurse educators require students to undertake some type of remediation intervention when they do not perform well academically (Corrigan-Magaldi et al., 2014; Evans & Harder, 2013). At-risk nursing students who do not receive needed academic assistance will not be successful in their nursing program or licensure exam (Lynn & Twigg, 2011). Unfortunately, remediation programs in nursing education are highly variable without evidence of what interventions work the best (Sosa & Sethares, 2015). Schnee (2014) discussed the positive impacts of remediation for academically challenged students in higher education and remediation's role in increased persistence to degree completion. Nurse educators are responsible for incorporating remediation strategies into the curricula in order to prepare at-risk nursing students to practice in today's complex healthcare settings (Lauer & Yoho, 2013). The current qualitative research study was conducted to report and analyze interview findings to understand the meaning of the experiences nurse faculty have when using remediation for at-risk pre-licensure baccalaureate students in the context of nursing education programs.

Methods: A basic qualitative methodology was used for the research study. According to Patton (2015), qualitative inquiry is conducted to understand how people engage in making meaning of their experiences. Six nurse educators from two undergraduate nursing programs in southern California volunteered to participate in this basic qualitative research study after meeting the inclusion criteria. Data were gathered from semi-structured interviews of the participants that were conducted face-to-face or via Skype/phone. Nonprobability purposive sampling was the sampling procedure that was used. Data analysis followed the thematic and constant comparative method that was first developed by Glaser and Strauss (1967).

Results: The findings from this research study revealed the following four themes that emerged from the data analysis: (a) faculty as facilitators, (b) active, individualized learning strategies, (c) issues affecting student engagement, and (d) formal versus informal faculty mentoring. Adult learning or andragogy was the theoretical framework used for this study. Implications of the findings for practice provided insight into the remediation experiences of nurse educators that guide their remediation practices. Based on the findings of this study, the main implications for nurse educators are that remediation policies and strategies need to be incorporated into the overall curriculum of baccalaureate nursing programs.

Conclusion: Recommendations for further inquiry included increasing the number of participants from different geographical areas and using a mixed methods approach to gain further insight into the research topic. Research on remediation could also be expanded to include ethical considerations for nurse educators. A further recommendation for future research included exploring faculty mentoring experiences specifically for remediation.

The findings of this study suggest the need for an organized and comprehensive faculty development and curriculum plan for nurse educators to facilitate remediation strategies for at-risk, pre-licensure baccalaureate nursing students.

RSC PST 3 - Research Poster Session 3

Exploring the Impact of International Field School Experiences on Nursing Students and Their International Hosts

Marlene C. Welsh, MHS, RN, Canada

Renate Gibbs, MA, RN, Canada

Lorelei Newton, PhD, RN, Canada

Catherine McDonald, MA, RN, Canada

Abstract

Purpose: International field schools have been a cornerstone of global health education within the Camosun College (Victoria, B.C. Canada) Nursing Department for over a decade. While anecdotal evidence and student feedback support International Learning Experiences (ILEs) as positive, there has been no researched-based review to clearly identify the added value of ILEs to the overall educational experience of nursing students.

Reviewing the global health and related education literature provides some guidance for ILEs (Kulbok, Mitchell, Glick and Greiner, 2012) as well as opportunities for shared educational experiences for student nurses internationally (Shishani, Allen, Shubnikov, Salman, LaPorte, and Linkov, 2012); however, there is little research exploring the student uptake of core global health concepts, the subsequent effects on future student clinical placements in their own country (Curtin, Martins, Schwartz-Barcott, DiMaria and Soler Ogando, 2015), or the perspectives of the related host country (Kulbok et al, 2012). In addition, the notion of 'global health diplomacy' has not been fully explored in terms of cultivating diplomacy in nurse educators as well as future nurses (Hunter, Wilson, Stanhope, Hatcher, Hattar, Hilfinger Messias, and Powell, 2013). Indeed, attention to global health competencies and diplomacy skills can be seen as essential to the education of the next generation of nurses (Wilson, Harper, Tami-Maury, Zarate, Salas, Farley, Warren, Mendes and Ventura, 2012).

Methods: In order to address the gaps identified above, we conducted an interpretive descriptive research study (Thorne, 2016) from April to December 2016 in two countries, New Zealand and the Philippines, where our first and second year nursing students (n=21) were hosted for their five week consolidated clinical placements. Students were placed in acute specialty areas (intensive care, emergency rooms, neonatal intensive care, labor and delivery, surgical and medical placements, pediatrics) in addition to community-based clinics and outreach work (Maori and Pacific populations in New Zealand and rural and urban scavenger communities in the Philippines).

A combination of data collection techniques were employed to analyze the impact of ILEs on host countries and nursing students to strengthen these unique international placements. Structured questionnaires (n=60) were administered to host nurses following their shifts with Canadian nursing students to gather their perspective on the benefits and detriments of the ILEs. Focus group discussions with students (4 in total) were held before and after their placements, in conjunction with in-country global health themed critical reflections (n=24) to explore personal and professional growth, motivating factors and specifically global health knowledge acquisition (based on adapted framework, Riner, 2011; Curtin, Martins, Schwartz-Barcott, DiMaria and Soler Ogando, 2015) which included health promotion, social determinants of health, and infectious disease transmission. A review of students' academic and clinical performance post-ILE was conducted to examine success rates.

Results: Rich data emerged from the study revealing student's deeper understanding of the social determinants of health and their impact on vulnerable population's morbidity and mortality. Poverty, resource allocation, culture and the divergent role of nurses in different countries were dominant themes. Cultural competency and the ethics of nursing abroad were highlighted. Health promotion was a critical dimension of this study and student's enhanced knowledge levels regarding upstream thinking and effective health education strategies; specifically related to dengue fever, diarrheal disease, lung disease (asthma, pediatric community acquired pneumonia, tuberculosis), cardiac disease and culturally appropriate diet for diabetic Maori patients.

Conclusion: Preliminary research findings will be presented along with significant lessons learned, including recommendations to inform best practice for future ILEs.

Conference participants will develop an enhanced understanding of the complexities involved when planning ILEs, the potential for rich learning related to the unique ethical and cultural differences in divergent nursing climates, and specific ways to capitalize on critical global health concepts necessary for improving population health.

RSC PST 3 - Research Poster Session 3

Reducing Test Anxiety Through Mind Relaxation

Kathleen R. Ward, MSN, RN, USA
Tanya L. Smith, MSN, RN, USA
Lindsey Gordon, MS, TLMLP, USA

Abstract

Purpose: The purpose of this study is to identify the effect of a Tai Chi (mind relaxation) intervention on test anxiety.

Methods: Anxiety and stress are relative in situations that provoke feelings of “fight or flight” (Selye, 1976). These feelings are often experienced by nursing students during course exams. According to Gibson (2014, p.267), test anxiety attributes include: “administration of a test, negative subjective feelings, behavioral aspects, physical signs, and cognitive aspects”. The greater the stimulus the less effective the performance on any given task (Yerkes & Dodson, 1908). According to the Yerkes-Dodson Law (1908), low and high levels of anxiety hinder optimum performance, whereas performance is enhanced at mid-levels of arousal or anxiety. Systematic reviews and meta-analysis have shown Tai Chi to be an effective intervention for anxiety reduction and psychological well-being (Sharma & Haider, 2015; Wang et al., 2013)

Tai Chi is a form of Chinese exercise that incorporates “slow, smooth body movements to achieve a state of relaxation of both mind and body” (The Free Dictionary, n. d.). The use of Tai Chi in education is well documented. Wall (2005), conducted a study using Tai Chi and mindfulness-based stress reduction on middle school students. These results demonstrated that Tai Chi instilled “well-being, calmness, and relaxation” in middle school students. Tai chi interventions have also been incorporated into high school and college settings with mixed results. Lee et al., (2012), noted no difference in stress levels of secondary (junior) school students before and after the Tai Chi intervention. On the college level, the physical and mental health of college students were significantly improved after a Tai Chi intervention (Wang, Taylor, Pearl, & Chang, 2004).

Specific to nursing, Edelman & Ficorelli (2005) conducted a qualitative study to determine the lived experience of nursing student’s test anxiety. The analysis of the data reflected three themes; one of those being the fear of not becoming a nurse relative to not passing nursing tests, increasing test anxiety. Malinski & Todaro-Franceschi (2011) implemented a co-meditation intervention that successfully reduced anxiety in a nursing school setting. Specific to test anxiety, Prato & Yucha (2013) provided training in biofeedback-assisted relaxation intervention producing a decrease in physiological responses to stress, lacking change in subjective test anxiety scores. A Tai Chi intervention was utilized in a study by Mulcahy, Gosselin, Holland, & Pittman (2016) to determine the effect on simulation anxiety. The findings indicated that Tai Chi was effective in reducing student anxiety as well as improving simulation performance. Despite the number of studies on nursing students and the use of a Tai Chi intervention, the number of studies relative to test anxiety and nursing students is limited.

Based on this information the researchers hypothesized utilizing a Tai Chi intervention prior to nursing examinations to assess the effect on test anxiety. Approval was obtained from the University’s Institutional Review Board. At the beginning of the spring 2017 semester nursing students in the Health and Illness II course will be invited to participate in the investigation. Informed consents will be obtained. Consenting students will be randomly assigned to the control and experimental groups. Baseline anxiety levels and pulse rates will be obtained on all participating students. Baseline anxiety levels of all students will be assessed utilizing the Generalized Anxiety Disorder 7-item Scale (GAD)-7. The GAD-7 has been shown to be a valid tool for assessing Generalized Anxiety in practice and research (Spitzer, Kroenke, Willimas, & Lowe, 2006). The anxiety levels and pulse rates will be obtained prior to the Tai Chi intervention and again immediately prior to the exam. Students in the experimental group will engage in a fifteen-minute beginning Tai Chi intervention prior to each exam during the semester. The control group will continue in their normal routine prior to exams with anxiety levels and

pulse rates being obtained immediately prior to the exams. All anxiety levels during the study will be assessed utilizing the self-report Zero-to-Ten Anxiety Scale and all pulse rates will be assessed utilizing the Smart Pulse Advanced Finger Oximeter. According to Crandall, Lammers, Senders, Savedra, & Braun (2007), the Zero-to-Ten Anxiety Scale has been shown to have validity as a self-report scale to assess state anxiety in children.

Results: After the final exam in the course the data will be analyzed to answer the specific research questions for this study. Is there a difference in participants' state anxiety scores before and after the Tai Chi intervention? Is there a difference in participant's pulse rate before and after Tia Chi? Does a Tai Chi intervention reduce anxiety to a mid-level for optimum performance? Utilizing a Statistical Package for the Social Science (SPSS) software system, the projected data methods of independent and dependent t-tests will be employed to analyze the data. Findings from this study will be shared as aggregate data during the 28th International Nursing Research Congress. During the fall 2016 semester a pilot study was conducted prior to one exam utilizing a different cohort than projected for the spring 2017 semester. The pilot study only measured anxiety after eight minutes of Tai Chi. Findings demonstrated a reduction in test anxiety prior to the exam for the majority of the class. One student experienced an adverse level of test anxiety due to having to wait eight more minutes to take the test.

Conclusion: If there is a positive association between mind relaxation and a reduction of test anxiety to a level that improves student outcomes the intervention may continue to benefit students and others, in all education venues and lifetime experiences. This interprofessional collaboration of nursing and psychology conforms to the core competencies for interprofessional collaborative practice specifically: core competency TT3: Engage other health professionals—appropriate to the specific care situation—in shared patient (student)-centered problem-solving (Interprofessional Education Collaborative Expert Panel, 2011). The collaboration with psychology enhances the value of the results, as the outcomes have been analyzed by an individual within the discipline of psychology. This also emphasizes to students that nursing is an interprofessional discipline.

Development and Testing of the Global Interprofessional Therapeutic Communication Scale (GITCS®)

Suzanne H. Campbell, PhD, RN, IBCLC, Canada
Natalia Del Angelo Aredes, RN, Brazil

Abstract

Background: Simulation is a valuable tool to educate health professionals on effective communication. It also is a method that can bring educators together to create, evaluate, and test new instruments for assessment. Communication is a key component for safe, effective health care delivery and has the potential to enhance patients' experiences within the health care system, empowering them to be active partners in the process, as well as impacting patient outcomes. Researchers have identified a connection between miscommunication and adverse events/errors in clinical practice, which affects the quality of care (Fay-Hillier, Regan, & Gallagher Gordon, 2012). In order to minimize miscommunication, a variety of strategies and tools have been utilized to measure and assess health communication between practitioners, patients, and families. The Global Interprofessional Therapeutic Communication Scale (GITCS®) was developed for health educators to facilitate formative and summative evaluation of students' communication skills in simulation and clinical settings.

Purpose: To describe the development and reliability/validity testing of the GITCS®.

Methods: The GITCS® was developed using theoretical references of therapeutic communication and refined using a reiterative process of expert review. First, a panel of nursing educators with extensive teaching experience in simulation settings was convened to review existing therapeutic communication assessment tools, identify gaps, and contribute to the initial item generation for GITCS®. Second, two rounds of expert reviews by nursing and allied health sciences educators was conducted to pare down the number of items, determine corresponding constructs and domains, and craft the item statements for appropriate context and grammar. Third, to obtain psychometric data for reliability and validity, an international sample of simulation educators affiliated with nursing and allied health postsecondary institutions were invited to help test the GITCS®. The international sample is asked to log into an online portal to view videos featuring a public health nurse on a home visit, and using a digital version of the GITCS®, rate the nurse's therapeutic communication skills as she interacts with the patient. Three videos were professionally produced (professional actors, videographer/editor) depicting "bad," "good," and "mixed" communication skills. The scripts were carefully tailored based on the GITCS® items.

Results: Initial item generation included those related to active listening, empathy, empowerment, verbal and non-verbal communication, rapport and trust building, barriers, and cultural boundaries. The two rounds of expert reviews pared the scale to 43 items, identifying 4 corresponding constructs: education, empathy, power sharing and rapport/trust building. We will present results of initial reliability and validity testing of the GITCS, expounding on our chosen methods in examining construct validity, internal consistency and interrater reliability.

Conclusion: The GITCS® aims to support faculty, students and health professionals as a summative and formative assessment tool in measuring therapeutic communication outcomes during clinical practice or simulation in educational setting. Data will be shared on the reliability and validity of GITCS® as tested by an international, interdisciplinary group of health simulation educators using an online portal featuring three professionally developed videos demonstrating "good," "bad," and "mixed" therapeutic communication between a public health nurse and older female client during a home visit.

The Effect of Hybrid Team-Based Learning in a Professional Nursing Course

Hui-Chen Tseng, PhD, RN, Taiwan
Wei-Che Weng, MS, MD, Taiwan
Lih-Mih Chen, PhD, RN, Taiwan

Abstract

Purpose: We used the concept of flip-pedagogy to reform the traditional teaching model in Taiwan. The method of hybrid team-based learning (hybrid TBL) aims at the paradigm shifts of learning and teaching. The teaching behavior shifts from “sage on stage” to “guide at side”, and the responsibility for learning shifts from instructors to students. This study investigated the effectiveness of adopting hybrid TBL in a professional nursing course for Taiwanese baccalaureate nursing students.

Methods: A quasi-experimental design with experimental and control groups was used to evaluate the effectiveness of hybrid TBL method. A convenience sample of 71 Grade III nursing students participated in this study, with 40 in the experimental group and 31 in the control group. For the experimental group, 3 topics were selected for TBL out of overall 31 topics of a professional nursing course. The control group received the other professional nursing course with traditional method. We collected data from Self-Directed Learning Readiness scale and the Learning Outcome of TBL Self-evaluation before the professional course at the first time, and the second collection of data was collected after the intervention of TBL courses. The TBL method included IRT, GRT, application exercises and appeal. We examined the effect of students' learning outcomes from two scales: Self-Directed Learning Readiness scale and the Learning Outcome of TBL self-evaluation.

Results: Our study showed that nursing student increased the hours of self-directed learning from 11.2 hours to 14.3 hours every week, and got the references of study from lectures of instructors (89.2%), textbook (64.6%), internet (64.6%) and book references (41.5%). The learning behaviors of team engagement and the overall effect of TBL self-evaluation had significant statistical differences between the experimental and control groups, but the learning behaviors of learning motivation, active learning and self-directed learning readiness rarely changed.

Conclusion: TBL is a teaching method of extrinsic motivation, thence the correlation between TBL and active learning behaviors is still a debate. This study provides the evidenced data of improvement in team engagement for adopting the hybrid team-based learning method in nursing courses. The proper frequency of team-based learning methods in a professional lecture nursing course still needs more evaluation to set on.

The Development of Professional Self-Concept and Leadership Skills Among New Graduate Nurses

Sarah Elizabeth Kelly, PhD, RN, USA

Molly Naft, SN, SN, USA

Allison Bautista, SN, SN, USA

Maria LoGrippo, PhD, RN, NE-BC, USA

Abstract

Purpose: Nurses are responsible for providing holistic care to individuals and meeting their healthcare needs. Because of this responsibility, it is imperative to adequately prepare nursing students for their professional role. Leading professional nursing organizations such as the American Association of Colleges of Nursing (AACN) believe that nursing education should address appropriate competencies geared toward the professional role of nurses (AACN, 2014). Upon the point of graduation, nurses are expected to have the critical thinking skills, leadership capabilities, and problem solving abilities necessary to provide safe and effective care (Gardulf et al., 2016). New graduate nurses learn through their knowledge, skill, and attitude development during their educational experiences. Equipped with appropriate skills and clinical decision-making abilities, the professional nurse is able to provide holistic care in a challenging patient care environment (AACN, 2008). Therefore, the purpose of this study is to explore how experiences of new graduate nurses impact their professional self-concept and leadership competencies.

Methods: A descriptive exploratory study will be conducted to obtain information related to new graduate nurses' professional self-concept and leadership competencies. This is a cross-sectional non-experimental research design using a web based survey method. The participants will be asked to complete two surveys: 1) The Professional Self-Concept Nurses Instrument, a 27-item scale measuring professional practice, satisfaction, and communication; 2) The Nurse Professional Competence (NPC) Scale – leadership subscale. The NPC scale is an 88-item instrument used to measure competences among nurses. The leadership subscale is a 26-item subscale that measures leadership and development. Each survey takes approximately 15-20 minutes to complete. In addition to the two surveys, the participants will be asked to complete a demographic survey.

A convenience sample of nurses, who self-identify as a new graduate nurses were invited to participate this study. A new graduate nurse is defined as a nurse who successfully passed the National of Council Licensure Examination-Registered Nurse (NCLEX) between June 2015 and May 2016 who is currently employed as a registered nurse.

Results: The institutional review board (IRB) has been approved and the study questionnaires are currently being disseminated. At this time, we do not have any initial results to report.

Conclusion: As this study is currently ongoing and we do not have an initial analysis completed, we cannot speculate on the impact or conclusion of this study.

Engaging Nursing Students in the Classroom With Cell Phones and Software

Malena Jones, PhD, MS, BS, RN, CNE, USA

Abstract

Purpose: The basis of this project was to develop and implement active student learning activities in a junior level nursing research course. The specific goals of this project were to, increase student understanding of nursing research, increase student engagement, assess student perceived effectiveness and engagement with audience response software and cellular phone use.

Methods: Student comprehension of content will be evaluated with a secure, proctored, nationally-normed exam designed to assess student understanding of research and critical thinking skill. End of the semester course evaluations will examine students' perceptions of the student learning activities. Students will also be surveyed to explore their experience with audience response software and perceived engagement in the course.

Results: Preliminary results will be obtained December 2016 and will be discussed at the time of the presentation. Results will focus on the advantages and disadvantages of audience response software and cellular phone use in the classroom setting. Results will also examine student and faculty perceived engagement and comprehension of content. Results will also compare student that utilized audience response software with students that didn't use audience response software comprehension of nursing research content.

Conclusion: Engaging the millennial generation in class is a challenge that faculty face daily. Faculty are constantly competing with students on cell phones, texting and social media. Instead of competing with cell phones use in class this project attempted to utilize cell phones and audience response software to engage students. Traditional undergraduate nursing students have difficulty grasping research concepts and tend to find research intimidating. To encourage student engagement in the course, audience response software was downloaded onto their cell phones and students were encouraged to bring them to class. In class activities included mid-lecture quizzes, case studies, student and classmate polling. The software also allowed students to question or seek clarification on content without embarrassment by sending questions directly to faculty with their cell phones.

The Creation and Implementation of a Military Veteran to Bachelor of Science in Nursing Pathway

Jene' M. Hurlbut, PhD, RN, CNE, USA

Imelda R. Revuelto, MEd, USA

Abstract

Purpose: The presentation will explain the procedures involved in creating an innovative admission pathway that facilitates veteran's abilities to obtain a Bachelor's of Science in nursing. In the summer of 2015, the nursing department at a University in the United States was awarded a three-year \$1 million HRSA grant that allowed the development and implementation of a Veteran to Bachelor of Science in Nursing Pathway (VBSN).

Methods: The VBSN pathway targets barriers that prevent veterans from transitioning into the nursing profession and accessing education. It has been estimated that over the next five years, approximately 1.5 million service members will separate from the military and will be returning to college and looking for employment (Snyder, Wick, Skillman, & Frogner, 2016). Moreover, it has been suggested that one of the top degrees sought out by veterans is a nursing degree. This is due to interest in the healthcare field and the overall demand for nurses within the job market (<http://www.bestcollegesonline.org/top-degrees-for-veterans/>). After notification of award, the necessary approvals needed to be obtained as well as the complete development of the VBSN infrastructure that included: the admission process, the awarding of credits, curriculum to support the VBSN pathway, and the development of collaborations and partnerships with internal and external constituents.

Results: The VBSN pathway developed processes that allows qualified veterans the opportunity to test out of designated courses based on demonstration of course competencies. The curriculum at this University is unique in that a block system of curricula delivery, a summative assessment paradigm, and offers veterans academic credit for experience gained during military service. An additional component of this grant was to provide faculty in-services that addressed the physical, emotional, and environmental issues affecting veterans in order to minimize barriers to their transition into the nursing profession. These in-services facilitated the development of a culture of respect for veterans returning to the University setting.

Conclusion: Given the number of veterans returning to Universities and seeking nursing degrees, it becomes imperative to share the lessons learned in creating a supportive environment for these service members.

RSC PST 3 - Research Poster Session 3

A Collaborative Program Between Academia and Practice Enhancing Preceptors' Teaching Efficacy

Shu-Yuan Chao, DNSc, MEd, BS, Taiwan

Abstract

Background: In Taiwan, adopting one to one clinical teaching, nurse preceptors play an influential role in the success of nurse education for undergraduate nursing students in their final clinical practice--" Last Mile Learning". However, evidence shows that inadequate preparation of formal education program for the preceptors, and lack of communication between the school and clinical teaching, hinders teaching efficacy. The necessity of establishing a clinical-academic partnership was advocated

Purpose: The purpose of this project was to develop, implement and evaluate a collaborative program for the preceptors in facilitating their clinical teaching efficacy for nursing students.

Methods: Workshops were implemented in middle Taiwan every other month, from March to September 2016. The lectures related to learning theory, the objects of clinical teaching, the methods of interacting with student nurse, and clinical evaluation method were performed in the first workshop. Then the participants were separated into small groups of 10-12 members per group to discuss expectations of each other between school and hospital, share teaching strategies and exchange experiences of how to resolve student's learning problems in the clinical practice. The groups were facilitated by a senior faculty who was also the person to contact if preceptors had teaching problems. Preceptors were encouraged to upload their experiences and share ideas online. Additionally, teaching materials taught by the faculties in the classroom are accessible online as well for the clinical preceptors' reference.

A total of 98 preceptors from 16 teaching hospitals were recruited for the program. A self-administered structural questionnaire including five dimensions, (i.e. "Recognition of clinical teaching", "Implementation of teaching", "Expression of caring behaviors", "Performance of empathy", "Empowerment for student"), was administered at the beginning and the end of the project to evaluate the effectiveness of this project.

Results: The results indicated that preceptors have significant improvements in their teaching efficacy after participating the program, and achieved statistical significance. In addition, there were 24 innovative teaching plans/strategies that were developed by the preceptors.

Conclusion: The collaborative program enhanced more communication between the academia and clinical practice, provided teaching resources and support for the preceptors in assisting their clinical teaching, which have reflected on their improvement of teaching efficacy and innovative teaching plans.

Empathy, Attitude Toward Dementia, and Pain Attitudes in Dementia Patients of Nursing Students in Korea

Mihyun Lee, MSN, RN, Korea, Republic of (South)

Myonghwa Park, PhD, RN, Korea, Republic of (South)

Hyun Jeong, MSN, RN, Korea, Republic of (South)

Younghye Go, MSN, RN, Korea, Democratic People's Republic of (North)

Miri Jeong, MSN, RN, Korea, Democratic People's Republic of (North)

Abstract

Purpose: In Korea, 10% of older adults have dementia, and this percentage is expected to increase very rapidly. Dementia patients are suffering from pain associated with various diseases. Especially, patients with cognitive impairment are difficult to express about pain. Empathy ability correlates with caring for patients with pain, as well as higher sensitivity to pain response. Research on nursing students' attitude toward dementia and pain attitudes in dementia patients is very limited. No studies have examined the associations between empathy and attitude toward dementia and pain attitudes of nursing students.

This cross-sectional quantitative study aimed to assess the attitudes toward dementia and pain attitudes in dementia patients of nursing students in Korea and examine associations between empathy, the attitudes toward dementia and pain attitudes of nursing students.

Methods: A total of 362 nursing students (179 Year 1 and 2 students – no clinical experience and 183 Year 3 and 4 students – clinical experience) completed a questionnaire that included demographic information, the Interpersonal Reactivity Index (IRI), Dementia Attitudes Scale (DAS), and pain attitudes in dementia patients scale. Data analyses included descriptive statistics, correlational analyses, and t-tests.

Results: There were statistically significant differences in attitude toward dementia ($t=-2.854$ $p=.005$) between the Year 1 and 2 students ($M=87.02$, $SD=12.10$) and the Year 3 and 4 students ($M=90.54$, $SD=11.34$). Pain attitudes in dementia patients were significantly lower ($t= -4.50$ $p<.001$) in the Year 1 and 2 students ($M=27.46$, $SD=2.48$) than in that of the Year 3 and 4 students ($M=28.70$, $SD=2.73$). There were no difference in empathy between the two groups. For the Year 1 and 2 students, empathy was positively correlated with attitude toward dementia, but the correlation between empathy and pain attitudes was not statistically significant. For Year 3 and 4 students, empathy, attitude toward dementia and pain attitudes were positively correlated, and the correlations were significant.

Conclusion: The findings from this study suggest that empathy, attitude toward dementia and pain attitudes in dementia patients are the important care provider attributes that can to be enhanced by nursing students' clinical practicum experience.

RSC PST 3 - Research Poster Session 3

A Conceptual Framework for Nurse Educationalists and Professional Nurses to Facilitate Professionalism Amongst Learner Nurses

Portia B. Bimray, MCur, RN, South Africa

Abstract

Purpose: To facilitate professionalism amongst undergraduate learner nurses for nursing practice in the Western Cape.

Methods: A qualitative, exploratory, descriptive, contextual research design with a case study approach was used. Focus group discussions and unstructured individual interviews were held with undergraduate learner nurses, nurse educationalists and professional nurses. The data of three cases of the experiences i) learner nurses, ii) nurse educationalists and iii) professional nurses were converged in a cross-case analysis.

Results: Six themes emerged from the cross-case analysis between the three cases that informed the conceptual framework for the facilitation of professionalism amongst undergraduate learner nurses. The findings indicated that i) nurses should demonstrate their professional values during interactions with authorities, fellow colleagues, and patients, ii) interpersonal communication style by nurses with all stakeholders in the external environment should be considered, iii) there is realisation of essential role modelling in different settings, iv) there should be support mechanisms to promote professionalism in learner nurses v) all nurses should be mindful in nursing practice and vi) teaching and learning needs in theory and practice should be recognised for professional development of the new generation and historical heritage of the profession.

Conclusion: The facilitation of professionalism takes place in the academic and clinical learning environment within higher education and nursing practice. Within these contexts, consideration should be given to the diversity in cultural and socio-economic backgrounds, the new generation in the 21st century and the ethical-legal framework within which nursing care is practiced. Furthermore, there is a need for HEI and nursing education to stay abreast of the latest developments in innovation and technology and to ensure the responsible use of social media in nursing practice. Nurse educationalists and professional nurses should use their discretion when engaging with learner nurses on social media such as Facebook and BBM as the professional boundaries between nurse educator and learner nurse should be maintained. Nursing education institutions need to invest in a counselling programme specifically designed for the academic and emotional needs of undergraduate learner nurses. The programme should include a dedicated nurse councillor who will be available on campus to provide the learner nurse with support throughout the four year of the academic undergraduate training programme. There is a need for nurse educators to communicate and collaborate with nurse professionals about the progress of the learner nurse and to ensure that the learning objectives meet the nursing care needs of the health care institution. There is a need for the provision of educational opportunities to accommodate the learning needs of undergraduate learner nurses and those learner nurses from non-degree programmes. Adequate learning resources should be available to provide in the specific learning needs of the learner nurse and that will simulate a real life situation as close as possible to reality in the nursing practice environment. Mindfulness programmes for professional nurses who work under stressful conditions should be implemented in healthcare institutions so that professional nurses are better able to relate to learner nurses when they are calm and demonstrate tolerance for the shortcomings of the learner nurse in stressful work environment. Health care institutions should have structured orientation programmes in place to welcome novice learner nurses to the profession and make known what the expectations are that will facilitate professionalism amongst learner nurses. A structured orientation programme will also allow the learner nurse to feel part of the nursing team and will create a sense of "belonging". There is a need for professional nurses to display the vision, mission and goals of the health care institution and patient care wards that lead to excellence in patient care, visible to all nursing staff. In doing so the learner nurse will be better able to follow the guidelines and policies imperative for nursing practice that will guide them in their behaving professionally. The expected professional values required for professionalism have been

identified and categorised according to the three domains i.e competence domain, connection domain and character domain, of Brown and Ferrill's (2009) taxonomy and include professional capability, interpersonal compatibility and personal reliability.

Adult Field Undergraduate Perceptions of Higher Education Involvement With Their Practice Placement Learning

Gillian Taylor, BSc, DN, RN, PGCert, United Kingdom

Abstract

Purpose: The purpose of this qualitative phenomenological study was to explore the Higher Education Institution (HEI) support adult field undergraduate nurses value whilst learning on practice placement during a three year BN Programme delivered at a Scottish University.

Methods: A small purposive sample (n=6) of final year adult field undergraduate nursing students were recruited. The purposiveness of the sampling technique was necessary to ensure that rich, relevant and current data was collected.

Gender	Male = 0 Female = 6
Age in Years	Range = 20-49 Mean = 31
Previous Undergraduate Study	Yes = 2 No = 4

In an attempt to improve validity of research findings any potential research participants who had been known to the researcher during their programme of study were excluded from participation.

The students were recruited by seeking voluntary responses to posters displayed around the university campus and a verbal presentation about the proposed study, delivered by the researcher, at a final placement learning Preparation for Practice lecture. However, difficulty recruiting research participants meant that the researcher also had to employ a form of convenience sampling with participants identifying fellow students who may consent to participate in the study. Convenience sampling continued to assure compatibility with the underlying phenomenological research methodology.

Unfortunately, no male research participants volunteered to participate in the study.

Individual, face to face voice recorded semi-structured interviews were conducted, lasting about one hour. The six interviews were conducted over a period of two months, between May 2016 and July 2016.

Face to face semi-structured interview schedules were chosen to allow for focus within the research topic whilst permitting the use of open questions with the ability to clarify specific answers and explore areas of interest more extensively.

Digital recording and individual transcription by the researcher was labour intensive but this practice enhanced and intensified the qualitative phenomenological methodology by allowing the researcher to become increasingly familiar with the data

Results: The results suggest that current models of HEI support are too reactive. This study proposes that students are reluctant to be the initiators of HEI support within the placement area and can view this as having potential negative connotations for themselves or future students.

Students view a more proactive approach to HEI support within placement learning as both personalised and supportive.

Students perceive their HEI as having overall responsibility for their learning, even within practice placement. However, adult field undergraduates are unclear about HEI academic role function within practice placement areas.

Adult field undergraduate nurses seek support from the wider clinical team and their peers rather than contacting their HEI for academic and practice placement support.

However, adult field undergraduate nurses value HEI support and re-assurance that their placement learning opportunities are valid and appropriate.

Conclusion: Initiation of HEI Support: It is evident from this small study that whilst students recognise learning contexts which are far from ideal for a variety of reasons they may choose not to initiate HEI support to resolve these issues and that this can have a negative impact for their learning.

Where students choose to initiate support for personal issues they prefer to approach their PDT or an impartial member of HEI staff.

Roles and Responsibilities: There appears to be variance in how the clinical and academic roles responsible for adult field undergraduate learning, teaching and assessment within practice placement are performed.

There may be situations where targeted proactive HEI support and re-assurance with placement learning are required dependent upon age, previous experience and position within the programme.

HEI and professional consideration needs to be given to the selection process for clinical mentors in terms of personal attributes and characteristics as well as current clinical role and potential competing demands.

Timing and Relevance: Adult field undergraduates value academic Preparation for Practice lectures but placement areas are sometimes ill-informed and ill-prepared to organise and provide suitable educational opportunities aligned with academic learning.

Ownership for Learning: All professionals involved with placement learning need to remain cognisant of the importance of the societal and contextual influences for reflexive learning.

Students appreciate their personal responsibility for effective learning but their HEI peers are also influential from an educational and supportive perspective.

Therefore, this small qualitative phenomenological study would propose further research in to targeted proactive models of HEI support for adult field undergraduate nurses during placement learning and further consideration of the who, when, what, where and how of that support.

Further research is also required to assess models of partnership learning and consider how best to allocate students to placement areas thereby maximising different models of Peer Assisted Learning and constructive alignment within the entire academic and clinical curriculum.

The further development and use of technology to enhance communities of learning and prevent feelings of isolation within placement also needs further investigation.

Responsibility for high quality placement learning needs to be a joint relationship between HEIs and service providers but effective communication between both partners requires to be enhanced. This study argues for clarity of role function for all professionals involved. Crucially, as key stakeholders and future registered practitioners, undergraduate adult field nurses need to be consulted and their views utilised to inform future models of HEI support with placement learning.

The findings from this small qualitative phenomenological research study, although not generalizable due to sample size and research methodology, could be considered transferable in terms of their depth, content and the research integrity of the study. The ultimate usefulness of this study lies in the robustness of its execution and resultant trustworthiness of the results.

Interprofessional Simulation in Nursing Education: An Integrative Review

Bette A. Mariani, PhD, RN, RN, USA
Jessica Doolen, PhD, MSN, BSN, ADN, APRN-C, CNE, USA
Christine Pariseault, MSN, RN, CEN, USA
Trisha Leann Horsley, PhD, RN, CHSE, CNE, USA
Jennifer O'Rourke, PhD, RN, APN-BC, FNP-BC, CHSE, USA

Abstract

Purpose: Interprofessional education provides a collaborative approach for providing safe quality care in health care; this requires shared knowledge, skills, and communication. Simulation-based experiential learning is recognized as an effective way to promote interprofessional education teamwork. The purpose of this integrative review was to provide an overview of research topics that have been well studied in interprofessional simulation involving the nursing discipline and which research topics require more investigation. The focus of the review was on qualitative, quantitative, and mixed methods interprofessional research.

Methods: Four research questions guided this systematic review of the literature from January 1, 2010 to July 1, 2016 focusing on interprofessional simulation research in nursing. The four questions were: 1) What research topics are well studied in IPE simulation involving the nursing discipline?; 2) What research topics in IPE simulation involving the nursing discipline require more investigation?; 3) What disciplines has nursing collaborated with in IPE simulation research?; 4) What outcomes have been studied in IPE simulation research involving the nursing discipline? Five researchers searched several databases for research articles that met the inclusion criteria. All articles included the three keywords: simulation, nursing, and interprofessional. Additional terms that were searched with the three keywords were: collaboration, multidisciplinary, collegial, and interprofessional education. The words quantitative and qualitative were also applied to narrow the search to include only research studies. The team explored which disciplines nursing has collaborated with on interprofessional simulation research as well as what outcomes have been studied. The Simulation Research Evaluation Rubric (SRR) was used to evaluate the final articles that met the inclusion/exclusion criteria. The articles were scored based on the SRR.

Results: The systematic search of several databases yielded a total of 1457 articles. These were narrowed down using inclusion and exclusion criteria. The final number of articles included in the review will be discussed. The Simulation Research Rubric was used to score the published research articles. The findings from the review will be reported and answers to the four research questions will be provided.

Conclusion: Implications for this nursing education and practice will be reported, and recommendations for future research will be discussed.

Pediatric Oral Health Interprofessional Clerkship

Judith Haber, PhD, APRN, BC, FAAN, USA
Erin Hartnett, DNP, CPNP, APRN-BC, USA

Abstract

Purpose: The goal of the NYU College of Nursing Teaching Oral-Systemic Health (TOSH) Program Pediatric Oral Health Interprofessional Clerkship is to promote acquisition of the Core Competencies for Interprofessional Collaborative Practice (IPEC, 2011) and the Interprofessional Oral Health Core Clinical Competencies (HRSA, 2014) among future primary care providers by engaging family nurse practitioner (FNP), dental (DDS), and medical (MD) students in an interprofessional oral-systemic health clinical experience. The objectives of the clerkship are for students to (1) apply pediatric oral health assessment (health history, exam, risk assessment, prevention, education and referral), (2) identify the pediatric oral-systemic connection, and (3) practice a team-based approach to improve oral-systemic health outcomes.

Methods: During this interprofessional education experience at Bellevue Pediatric Dental Clinic, teams of NYU FNP, DDS, and MD students, work together with a pediatric dental resident. Team members collaborate in reviewing the patient chart, taking the patient's medical and dental history, performing an oral assessment, applying fluoride varnish, and providing education and anticipatory guidance. The pediatric dental resident then conducts a debriefing session where the team discusses the importance of interprofessional teamwork and communication skills in providing patient-centered care. The Interprofessional Collaborative Competencies Attainment Survey (ICCAS) was selected to evaluate the degree to which students, using a pre-test/post-test approach, report a change in attitude about IP competencies following the IP learning experiences.

Results: All students had an improved mean score from pre-test to post-test after the experience, and these changes were statistically significant for the FNP students ($p < 0.01$) and the medical students ($p < 0.05$). The mean change was not significant for the dental students, the smallest group of students. The mean change from pre-test to post-test for each of the six IP competency domains was statistically significant ($p < 0.01$).

Conclusion: The experience was similarly effective among FNP and medical students in increasing the students' attitudes towards IP collaboration; however, it was less possible to detect differences in pre-test to post-test scores that are not due to chance among the dental students because the number of these students was small. As this IPE experience will be an ongoing component of the NYU nurse practitioner, medical, and dental curricula, the sample size will increase making it more likely to detect an effect that is not due to chance in the dental student sample. Ultimately, the findings suggest that a clinical approach is an effective strategy for influencing the development of IP competencies.

RSC PST 3 - Research Poster Session 3

Mastery of Core Mental Health Concepts Through Simulation, Clinical Performance, and Interactive Practices

Kim Johnson, MSN, PMHNP-BC, NP-C, RN, USA

Abstract

Purpose: To improve student progression to mastery of core concepts in mental health through simulation, clinical performance, and reflective journaling with Undergraduate Nursing students in their first year of nursing school.

Question: Does simulation, clinical performance, group projects, and other interactive learning improve students' progression to mastery of core concepts in mental health with first year undergraduate nursing students?

A Pilot project was designed for implementation for 2 consecutive semesters:

Problem: Undergraduate nursing students will play pivotal therapeutic roles in the care of patients suffering from mental illness. Their recognition of presenting symptoms and use of evidenced-based treatment to support optimal levels of functioning emphasize the need for best practices in preparing future BSN nurse advocates. Patients suffering from mental illness are represented in an array of clinical settings, thus undergraduate students need to develop competence, compassion, and judicial understanding of presenting symptoms. Moreover, core concepts linked to relatedness, vulnerability, and integrity are difficult to master from a lecture based teaching format. Educators must employ a variety of teaching methods to assess and evaluate students' competency of these core concepts.

Theoretical Framework: Constructivism provides a basis of learning by immersing students in collaborative projects to teach essential core concepts (Alt, 2015). We will use interactive based learning to improve student understanding of mental illness concepts. To provide each student with the opportunity to assimilate concepts into practice, we will assign interactive assignments that promote adaptive learning. To determine whether students have developed understanding of core concepts and can apply their learning to practice, we will employ an efficacy survey and collect self-reflective journaling. Percentages of perceived value will be aggregated to determine learning experience impact.

Methods: Students enrolled in the NURS 3111 course will be introduced to core concepts through reading materials, lecture, and presentations. Students will have the opportunity to demonstrate understanding of the concepts in a simulation day offered once a semester, weekly clinical performances, on 4 unit exams and a final exam in the course. Students will be evaluated during clinical performance over a 10-week course during weekly debriefings and will submit weekly self-reflective journals. At the end of the 15-week semester, students will complete an efficacy survey which will measure their perceived knowledge, their commitment to use the new skills in practice, and their opinion of the value of the assignment. Written comments regarding student's perceived learning both valued and non-valued comments will be evaluated.

Results: Findings will be presented based on student's scale of efficacy and self-reflective journaling. I will provide an overview of current research regarding various learning experiences used to teach mental health concepts. I will share aggregated comments of undergraduate BSN nursing students who have participated in the identified interactive and their perceived comprehension of mental health concepts.

Conclusion: Improved student progression of the mastery of core concepts in mental health through simulation, clinical performance, and reflective journaling with Undergraduate Nursing students in their first year of nursing school improves their compassion and ability to provide care to mentally ill clients in clinical scenarios.

Does a Study Aboard Program Encourage Nursing Students to Embrace Cross Cultural Experiences?

Abigail Mitchell, DHEd, MSN, RN, CNE, FHERDSA, USA
Connie Jozwiak-Shields, PhD, MSN, ANP-BC, APRN, USA

Abstract

Purpose: Today's generation of students has challenged nursing faculty to develop creative strategies and innovative methods to encourage students to experience study abroad. High School and College students in the United States have studied abroad for decades, however nursing students are often left out of these experiences due to the curriculum design and required clinical hours. The practice of studying abroad for professional development is not new and has been undertaken by scholars since medieval times, however it is a relatively new endeavor in nursing education (Edmonds, 2010). Research has shown that cultural knowledge in nursing is extremely important and the lack of it may cause deficits in practice as a result and nurses may have ethnocentric and stereotyped attitudes towards patients (Papadopoulos 2006, Takeno 2010). Globalization was first used by economists in 1981 and it refers to the development of increasingly integrated global economy, especially in trade, free flow of capital and the cheaper labor market. In nursing the globalization process has generated a need for cultural competence as nurses are required to manage multicultural patients in practice. Nursing education plays a large role in preparing students for their competent cultural care. One of the primary aims of study abroad programs is to enable student nurses to develop cultural sensitivity so that they may practice appropriately for an increasingly multicultural patient population in their own countries (Karina Martins de Oliveria & Tuohy, 2015). Madeleine Leininger is considered the founder of the theory of transcultural nursing or as known as culture of care theory. Culture is learned by each generation through both formal and informal life experiences (Leininger, 1991). Leininger guided this research study.

Methods: The purpose of this study is twofold. First the researchers will perform a systematic literature review and secondly a quantitative study will be completed. This will be accomplished by study abroad nursing students completing a 15-question survey based on their experiences. The goal of this experience is professional growth with the incorporation of new knowledge into the students' own practice, enabling them to be more culturally aware and thus provide culturally competent care (Smith & Curry, 2011). The two nursing professors incorporated study abroad opportunities linked to three courses offered in the spring 2017 semester. The courses included: Transcultural nursing for undergraduates, Adult Primary Care, and Health promotion for graduate/DNP students. This experience will take place over spring break so students will not lose time at clinical and/or class time.

Results: Are pending as the study is progress

Conclusion: Are pending

Research on the Effectiveness of the Nurse Staffs Training Program

Lee-Pin Wu, PhD, RN, Taiwan

Abstract

Purpose: The purpose of this study was to assess the efficacy of a modified on-board training program for new nurses with an emphasis on the mentorship program that implemented a training-for-trainers program to cultivate both skills and attitudes of clinical preceptors for the purpose of strengthening the preceptors' teaching ability and achieving better trainees' performance outcomes.

Methods: This study used a quasi-experimental design. During the first phase of the study, we modified the content of the on-board training program for new nurses which included the production of nursing skills video tapes and designed the mentorship program which included lectures, group discussion, and practice sessions. During the second phase of the study, 115 new nurses were divided into an experimental group (n = 50) and a control group (n = 65). The nurses in the experimental group learned the techniques and skills in the first month, practiced under supervision of their preceptors in the second month, practiced independently during the third month, and completed their clinical skills assessment at the end of the first 6 months. The control group received usual training program. Both groups were evaluated at the completion of the 3-month trial period for their satisfaction with clinical teaching and perceived learning outcomes.

Results: We completed mini nursing clinical assessment exercises (mini-CEX) for administration of analgesics and catheterization, nursing skills to operate observation (DOPS) evaluation forms for blood transfusion and phlebotomy. The Cronbach's Alpha values for each scorecard exceeded 0.9. The results showed that the retention rate of the experimental group was significantly higher in the experimental group than the control group; the retention rate increased by 10% compared with the previous year after the implementation of the new training program.

Conclusion: We also found the new nurses in the experimental group had higher levels of satisfaction with clinical teaching than those in the control group which could possibly explained the higher retention rate in the experimental group. The level of education of the preceptors also affect new nurses' learning outcomes. In light of ever-changing clinical environments, it is important to optimize on-board training programs for new nurses to help them mature from novices to experts.

The Effects of an Uncompleted Suicide Attempt: A Parent's Perspective

Kendal Klein, BSN, RN, USA

Abstract

The purpose of this study is to examine the needs of parents after their adolescent child makes a non-lethal suicide attempt. Suicide, the intentional act to end one's own life, is the third leading cause of death in adolescents, after accidents and homicides. Although quite uncommon in children, the frequency of suicide drastically increases during adolescence. This is a serious issue. There are numerous risk factors that increase the risk for adolescent suicide. These factors include possessing a psychiatric illness, lack of coping skills, emotional turmoil, a distorted view of life, a previous suicide attempt, substance abuse, family factors, and more. One of the biggest problems surrounding suicide is that it is often considered a forbidden topic of discussion. Suicide is a touchy subject to communicate. Many individuals avoid bringing up the topic of suicide all-together, giving researchers a major obstacle. After a child's non-successful suicide attempt, parents have many needs. Parents need to be able to effectively communicate these needs to a qualified professional. For example, these parents may live in fear that their child may make another attempt in the future.

The goal of this study is to obtain information on what issues are of most concern to parents after their child's suicide attempt. Although there has been a lot of research about suicide and its underlying psychological problems, little research has been done on the needs of parents. Before this study was put into action, a pilot study was conducted. During the pilot study, the perspective of this topic was sought from mental health professionals in rural and suburban areas. Mental health professionals were asked to complete two rounds of survey questions. These questions targeted what is most important to parents following their child's non-lethal suicide attempt as well as their needs. The pilot study revealed that the most important goal that all mental health experts agreed that is most important to parents after their child's non-lethal suicide attempt is keeping them safe. The pilot study consisted of both qualitative and quantitative data and was obtained by primary sources (mental health professionals). Our future research involves dispersing similar survey questions out to actual parents of those adolescents who made a non-lethal suicide attempt. Before these questions were dispersed to parents, they were evaluated by two mental health experts who work with adolescents who have attempted suicide. Once these experts validate these questions, 5 potential parents will be chosen to answer them during a scheduled home visit. This survey is delivered on paper after informed consent is obtained from the parents. This is just another step in the pilot study. The qualitative data gathered in the study are the parent's answers to open-ended survey questions. By studying the feelings and circumstances of parents, we could shed a light on suicide. The importance of this study is that it could assist in obtaining useful information that will, ultimately, help prevent youth suicide from occurring.

Psychological and Psychosocial Deficits Among Pediatric Survivors of Hematological Neoplasms and Their Risk Factors

Elizabeth J. Ross, BS, N/A, USA

Joseph D. Tariman, PhD, PhD, RN, ANP-BC, FAAN, USA

Jessica Bishop-Royse, PhD, N/A, USA

Abstract

Background: Pediatric cancer patients are surviving cancer and living long, relatively healthy lives due to advances in pediatric cancer therapeutics. Even with modern medical research and technology, pediatric cancer is still the leading cause of death for children and adolescents in the United States. Based on statistics from the American Cancer Society (ACS), hematological cancers, such as leukemia and lymphoma, are the leading type of non-solid malignancies in children (ACS, 2016). For decades pediatric cancer survival rates have steadily increased with an overall cure rate of over 75%.

While it is great that the survivor rate has and is steadily increasing year after year the intense curative therapy that is given to produce the high rates of survivorship can cause long-term effects on the body including psychological and psychosocial deficits. Based on the juvenile knowledge gained from previous studies, it is understood that some, but not all children with hematological malignancies develop late effect psychological and psychosocial deficits but it is unclear the exact cause of the deficits and the extent that those deficits may have on a survivor's life.

Search Process: DePaul WorldCat Local, PubMed, and CINAHL Complete databases search was performed. The following Medical Subject Heading (MeSH) terms and search details were used and the Boolean operator AND was utilized to get a highly relevant search yield: psychosocial adjustment AND hematologic neoplasms. CINAHL Complete search was completed using the following search terms: psychological AND survivor AND blood cancer. The search yielded 31 and 22 articles for PubMed and CINAHL Complete, respectively. DePaul WorldCat Local search was performed using the following search details: psychological deficit and cancer survivor and hematology. It yielded 179 articles. All abstracts were reviewed one by one independently by two researchers. Articles were included in the final analysis if they reported on psychological or social deficits and the patient population includes pediatrics, adolescents or young adults 21 years of age or below when diagnosed with a blood cancer. Year limit was between 1990 and 2016, and articles that focused on cognitive issues were excluded. Articles that reported psychological deficits in adults aged 21 years and older were also excluded. The final 34 articles used in this integrative literature review (ILR) were categorized by level of evidence according to Melnyk and Fineout-Overholt's hierarchy of evidence (2011) to appraise the strength of evidence for reported psychological and psychosocial deficit and their risk factors. Whitemore and Knafelz (2005) updated ILR methodology was strictly followed during the conduct of this review.

Results: A total of 34 papers with 17812 pediatric hematological cancer survivors who exhibits psychological and social deficits were incorporated in our ILR review. The weighted median age at diagnosis was 8.95 years. Of these 34 articles, 5 articles whose ages could not be used (due to being an open age range) and 2 are literature reviews, were also excluded for the median age calculation to avoid duplication. The mean follow-up time was not calculated at this time due to too many missing data from published papers. Data were analyzed using SPSS version 21. Incidences of depression (58.8%), Anxiety (44.1 %), Mood problems (32.3), Poor psycho-social domains in global QOL measure (32.2%), Social problems (26.4%), Attention problems (20.5%) Behavior problems (14.7%), Post-traumatic stress syndrome (11.7%), Conduct problems (11.7%), Risky behaviors (8.7%) were higher among pediatric hematological cancer survivors than in the normal population or matched controls. A comprehensive list of these deficits can be found in Table 1. The top risk factors found to be statistically correlated to psychological and social deficits among pediatric hematological cancer survivors include high intensity chemotherapy, total body radiation, cranial radiation, being a female, being younger in age, dysfunctional

family, and stem cell transplantation. Table 2 outlines all risk factors reported in the literature. Beck depression inventory and SF-36 were the most common measures used to identify psychological and social deficits.

Table 3 presents the strength of evidence for the reported psychological and social deficits is strong based on Melnyk-Fineout-Overholt's hierarchy of evidence (2001). Fifty two point nine percent (N=18 studies) of the studies were conducted using RCT, matched case control, siblings as control or population control study design. The remaining 47% percent of the studies (N=16) included single descriptive or qualitative studied. This study underscores the importance of developing effective interventions that address the psychological and social deficits among pediatric hematological cancer survivors.

Combating Childhood Obesity With Provider Education: A Quantitative Study

Trina Larery, DNP, MSN, RN, FNP-C, USA

Abstract

The study included an educational program to providers and nurse practitioner students in order to evaluate whether an increase in knowledge and accuracy occurred based on knowledge of evidenced-based responses to specific indicators of childhood overweight and obesity. It assessed the providers' knowledge and sought to evaluate if increased knowledge occurred after an educational program presentation. Following the educational program, a follow-up survey was distributed via email to assess the providers self-reported perceived practice change six weeks after the education. Part one measured if an increase in knowledge of the 5210 components, correct laboratory testing, and assessment of comorbidities occurred. The 5210 components include recommendations on activity, screen time, sugary drinks, and diet from the American Academy of Pediatrics (AAP) and the Institute for Clinical Systems Improvement (ICSI). Improved accuracy in applying diagnostic criteria based on current evidenced-based practice guidelines in childhood obesity after the educational session was also evaluated. The second part of the study evaluated if a self-reported perceived practice change occurred six weeks post education.

The target population was recruited from the 4-State APN (advanced practice nurse) conference in March 2016. A pretest was given to participants followed by a power point presentation and concluded with a posttest. Once the surveys were complete, a question and answer period followed. A t-test was conducted on the pretest and posttest results. A six week follow-up study was performed utilizing comparative analysis following the education. The follow-up surveys were distributed via email. The study concluded with statistical significance ($p < 0.05$) that the education provided increased providers' knowledge of current evidenced-based practice guidelines in childhood obesity. All participants ($n=41$) had an increase in posttest scores after the education was provided. Results from part two of the study indicated an increase in usage of the 5210 guideline components with patient education and an increase in comorbidity assessment. Current practice revealed low use and documentation of BMI, even though studies have established that the use of an accurate diagnosis of obesity is one of the highest indicators of treatment. Providers that participate in obesity related continuing education (CE) were found to be more familiar with the recommendations and have better adherence to current evidence-based practice guidelines. The findings of the study indicate that many providers are not aware of the current clinical practice guidelines in childhood obesity. Although information is readily available, providers must continuously update their knowledge to improve care for overweight and obese children. This study validates the need for continued educational programs for providers in childhood obesity.

Development and Testing of Cancer Treatment Shared Decision-Making Scale for Nurses (SDMS-N)

Pamela L. Katz, BA, NA, USA

Joseph D. Tariman, PhD, PhD, RN, ANP-BC, FAAN, USA

Lisa Hartle, MSN, MS, RN, AOCN, APN, USA

Katharine Szubski, BSN, RN, USA

Abstract

Background: Shared decision-making (SDM) has emerged as the preferred model for decision-making in treatment decisions for cancer patients. Patient outcomes are maximized when this model is used since the patient is more engaged and empowered to be a part of their care. Yet, there are many barriers to participation in SDM that must be overcome from the patient, practitioner, and structural perspectives. Oncology nurses are crucial in the SDM process and tend to have a higher level of involvement relative to their counterparts in other specialties. However, many of these nurses do not feel competent or comfortable participating in SDM due to a variety of reasons such as level of training (or lack thereof), differences in communication skills and styles, and organizational environmental challenges. It is important to find a way to accurately measure nurses' competency in SDM since they are the ones spending the lion's share of time with patients and need to have an active role in the decision-making process.

Theoretical Framework: The framework for SDM has evolved over the years to encompass a greater circle of participants in the model. No longer is it just the dyad of patient and practitioner, but rather it now includes individuals such as family members, nurses, and other clinicians (e.g., occupational and physical therapists, specialists). The framework was updated to reflect current practice and reflects a dynamic process with detailed steps involved with SDM that can impact day-to-day practice (Charles, Gafni, & Whelan, 1999).

Methods: This study will utilize a descriptive online survey and the SDMS-N tool will be sent to oncology nurses who are part of the Chicago Chapter of the Oncology Nursing Society. The survey will measure 23 key variables within three domains of nursing practice: knowledge, attitudes, and skills. Thus, a convenience sample of 240 nurses will be recruited to participate to account for the minimum 10 subjects per variable and any missing responses (Kellar & Kelvin, 2012). The data will be measured with a 5-point Likert scale for each subset of questions (1 Strongly disagree to 5 Strongly agree). Participation will occur both online and in-person.

Content Validity: Six oncology nurses with content expertise have initially validated the SDMS-N scale. Each of the three subscales was graded using a 10-point Likert scale (see chart below) with higher scores representing positive measures for each category.

Expert Panel's Initial Content Validity According to Different Domains				
Domain	Clarity	Relevancy	Simplicity	Consistency
Knowledge	87.70	94.37	88.95	93.33
Attitudes	90.83	96.87	93.12	96.45
Skills	91.00	97.33	91.33	96.00

Recruitment: Recruitment of study participants will immediately begin after obtaining the DePaul IRB approval to conduct the study. We anticipate that IRB approval will be obtained no later than the end of December 2016.

Analysis: Sociodemographic data will be entered into SPSS version 19 (SPSS Inc., 2010). Descriptive statistics will be used to examine study participants' characteristics. Reliability of the online survey tool will

be tested using the results from SDMS-N Scale. The overall SDMS-N tool and its subscales will be deemed reliable in measuring the knowledge, attitudes, and skills of oncology nurses on SDM if the Cronbach's alpha = 0.7 or higher (Devellis, 2017). Additionally, exploratory factor analysis will be performed to analyze the 23 variables in SDMS-N to see if there are identifiable groups of variables that are statistically related and make conceptual sense to group together. The exploratory analytic procedure will reduce the 23 variables of SDMS-N and test whether the groupings of variables under the subscales of knowledge, attitudes, and skills will theoretically hold together. Exploratory factor analysis is widely applied to both the development of scales and to the development of theory (Kellar & Kelvin, 2012).

Results: The study will be conducted over the course of the next three to six months from January to March 2017 and it is estimated that results will be completed by mid-year 2017. The goal is to better understand nurses' understanding of SDM and their role in the process, as well as the barriers to their involvement, so as to better understand how to increase participation in SDM. Ideally, it will help identify actions that can be taken from an educational training perspective to achieve this goal. Final results will be reported at the STTI International Research Conference in Dublin, Ireland in July 2017.

Harm Reduction in Nursing Practice: Compassionate Care for Persons With Addiction

Audrey Catherine Killarney, BS, N/A, USA
Michelle Esther Neuman, MSN, RN, PPCNP-BC, USA

Abstract

Substance abuse and overdose deaths are increasing at profound rates in the United States. Nurses and clinicians must evaluate their response to this growing epidemic. Harm Reduction is an alternative therapy for rehabilitation and was traditionally used in tobacco cessation, and to control the spread of HIV and HCV. The concept of harm reduction can be described as accepting the possibility that individuals will abuse harmful substances, and the goal of treatment is to reduce the harm associated with the addictive behavior; ultimately, this treatment nurtures a non-judgmental environment that facilitates a therapeutic nurse-patient relationship. Much of the literature regarding harm reduction in nursing is isolated to Canada and parts of Europe. However, the 6-fold increase in heroin overdose deaths in the United States from 2001-2013, has prompted lawmakers, parents, and clinicians to explore alternatives to standard rehabilitation practices (National Institute on Drug Abuse, 2015).

This integrative literature review sought to explore current uses of harm reduction, evaluate their efficacy, and examine harm reduction for inclusion into nursing practice in the United States. The following nursing databases were utilized for provision of literature: CINAHL complete and PubMed. Databases were searched using the following terms and Boolean phrases: “harm reduction & nurs*,” and “harm reduction & addiction,”. Articles were chosen if the language was in English, published within the last 10 years (2006-2016), published in an academic peer-reviewed journal, and were primary sources. Of the 99 articles retrieved, 10 will be analyzed in the integrative literature review. The remaining 89 articles were excluded due to the following parameters: duplicate article, application of harm reduction to alternate health disparities (fall prevention, smoking cessation, or cardiovascular disease), no clear relationship to nursing practice, or a position piece.

Results of the literature review yielded 6 studies identifying current uses of harm reduction, and 4 studies focusing on clinician perspectives about providing harm reduction therapy. Selected literature was rated using the Melnyk Fineout-Overholt Hierarchy of Evidence (2011) (Appendix A). Analysis of the literature regarding clinician perspectives revealed common themes such as: harm reduction as a bridge to abstinence; harm reduction’s ability to address the patient as a holistic being; and harm reduction as honoring a patient’s autonomy. A research matrix was created to holistically analyze and categorize the body of selected literature. Studies regarding current use of harm reduction found positive results in patients’ self-reported advocacy, self-esteem, and ability to navigate social services. Patients also experienced a decrease in problems associated with drug and alcohol use, as well as a decrease in money spent on drugs or alcohol. In addition to the evidence-based successes, the ethical components of harm reduction align with much of the nursing code of ethics. Patient autonomy, and trust in a patient’s ability to make health related decisions, is one of the key tenants of Pender’s Health Promotion Model; both perceived self-efficacy and perceived barriers to action greatly influence a patient’s commitment to action, and ultimately the adoption of a health promoting behavior (Alligood, 2013). While it is unlikely that stand-alone facilities modeled under harm reduction will be created in the United States, there are elements of harm reduction that can be readily integrated, and may be unknowingly permeating, current nursing practice.

Appendix A.

<i>Melnky Fineout-Overholt Heirarchy of Evidence Rating</i>	<i>Frequency</i>	<i>Cumulative Percentage</i>
Level 1: Systematic review & meta-analysis of randomized control trials (RCT) or evidence-based clinical practice guidelines	1	10%

Level 4: Case control & cohort studies	3	40%
Level 6: Single descriptive or qualitative study	4	80%
Level 7: Expert opinion	2	100%
Totals	10	100%

Common Adverse Effects of Novel Therapies for Multiple Myeloma (MM) and Their Self-Management Strategies

Anndria D. Cluster, BS, RN, USA

Joseph D. Tariman, PhD, PhD, RN, ANP-BC, FAAN, USA

Abstract

Background: Myeloma is a chronic B cells malignancy that affects differentiated plasma cells resulting to multiple organ damage (Dowling, Kelly, & Meenaghan, 2016). Over the past decade, there has been a surge of novel therapies to treat MM. This surge began with the introduction of intravenous proteasome inhibitor (PI), bortezomib in 2003, and has come as far as the introduction of the first oral PI, ixazomib (Moreau et al., 2016). This integrative literature review aims to describe the common adverse effects that patients may experience through treatment using the novel therapies. A secondary goal of the review is to appraise the strength of evidence of self-management strategies that have been reported to ameliorate these adverse effects. It is of utmost importance that nurses provide evidence-based patient education on self-management strategies in order to maintain and promote a good quality of life.

Theoretical framework: Orem's self care deficit theory (Orem, 1959) was utilized as the guiding framework for this integrative review given that the nurse will often be the one to provide care when a patient has a deficit in ability or knowledge. It is necessary, according to Orem, that the nurse not only provides care but also gives education to the patients on how to manage their disease state on their own.

Search Process: PubMed and CINAHL Complete databases search was performed. The following Medical Subject Heading (MeSH) terms and search details were used and the Boolean operator AND was utilized to get a highly relevant search yield: *Multiple Myeloma (MM) AND novel therapy AND adverse effects AND management*. CINAHL Complete search was completed using the following search terms: *Multiple Myeloma AND adverse effects AND management*. The search yielded 66 and 101 articles for PubMed and CINAHL Complete, respectively. Articles were included in the final analysis if they focused on MM, novel therapies, and reported adverse effects and self-management strategies. Year limit was between 2003 and 2016, and articles that focused on adverse effects of supportive therapies such as bisphosphonates or growth factors were excluded. Four articles were located utilizing the ancestry method, allowing the location of the most relevant literature. The final 36 articles used were categorized by level of evidence according to Melnyk and Fineout-Overholt's hierarchy of evidence (2011) to appraise the strength of evidence for reported self-management strategies.

Results: This integrative review included 36 articles that revealed novel treatment regimens utilized to treat MM have resulted in several common adverse effects reported by the patients. They include peripheral neuropathy, GI adverse effects (e.g., nausea, vomiting, constipation, and diarrhea), steroid-related adverse effects (e.g., mood alterations, insomnia, heartburn, and hiccups), sedation, thrombocytopenia, thromboembolism, anemia, neutropenia, myelosuppression, cutaneous rash, fatigue, infusion drug reactions, renal and cardiopulmonary complications, which are listed in Table 1.

There are many self-management strategies that correspond to the specific adverse events listed in Table 1. The majority (N=32 articles out of 34) of the self-management strategies reported to ameliorate the common adverse effects is based on single descriptive studies, review papers, or expert opinions in the form of a consensus statement from myeloma specialists, which are in the lowest levels in the hierarchy of evidence at Level 6 and 7, respectively. The use of aspirin, warfarin, and enoxaparin for VTE prophylaxis is the only strategy supported by level 2 evidence based on data from more than one randomized controlled trials. The use of antiemetic drugs, anti-diarrheal, laxative, blood transfusions, Erythrocyte Stimulating Agents, antibiotics, anti-virals, treatment dose adjustments and dose delays, monitoring and immediate reporting of adverse events such as peripheral neuropathy to health care team

are frequently used self-management strategies. Randomized controlled trials (RCTs) are lacking in the area of interventions for self-management strategies.

The findings from this ILR underscore the need for nursing interventions designed to prevent and treat adverse effects of novel therapies. These interventions need rigorous testing in the bedside. Providing an individualized evidence-based patient education to patients based on the treatment protocol is a vital component of providing care to those affected by MM. While the medications to treat MM have been revolutionized, treatment can only be considered successful if the patients undergoing the therapy are able to manage adverse effects successfully and continue to maintain and promote their own quality of life.

Exploring Staff Nurses' Perceptions of Specialty Certification at a Large Urban Academic Medical Center

Jennifer J. Clair, MS, RN, CNS-BC, USA

Abstract

Background: The Institute of Medicine's study on medical errors, *To Err is Human: Building a Safer Health System*, recommends that health professions implement periodic reexaminations and relicensing of providers (Institute of Medicine, 2000). While Registered Nurse (RN) licensure provides entry-level competence, specialty certification provides a platform to consistently validate specialty experience, knowledge, experience, and skills (Altman, 2011).

Certification of staff nurses is also an important component of Magnet designation. Magnet status indicates that a hospital is recognized by the American Nurses Credentialing Center (ANCC) for demonstrating excellence in patient care across the organization (American Nurses Credentialing Center, 2016). The large, urban academic medical center in this study is a Magnet hospital and supports and encourages nurses to become certified. However, nurse leaders express challenges getting staff to sit for specialty certification exams.

The Perceived Value of Certification Tool© (PVCT) is an existing valid and reliable survey tool that assesses nurses' perceived value of certification. The PVCT has been used in seventeen studies since 2003, totaling over 25,000 respondents.

Reliability of the tool has been shown through three psychometric studies. Sechrist, Valentine, & Carter (2006) performed factor analysis of the tool and found a two factor analysis, labeled intrinsic and extrinsic value, that explained 59.2% of the total variance; Cronbach's alpha was .94 for the measure as a whole, suggesting high inter-correlation between the subscales (Sechrist et al., 2006).

Aims: The purpose of this scholarly project is to assess staff nurses' perceived value of specialty certification at a large urban academic medical center; with a goal to better educate nursing leadership on potential facilitators and barriers that could in turn affect the number of nurses that obtain specialty certification.

Methods: Design-A quantitative descriptive design method was used.

Sample and Setting-A convenience sample was obtained by administering the web-based survey to approximately 4,000 staff nurses via email. Inclusion criteria was English-speaking staff nurses with access to hospital email that are able to read and complete an online survey. Exclusion criteria included advanced practice nurses and nurse administrators.

Permission to use the PVCT was obtained by the Competency and Credentialing Institute and all requirements of this permission adhered to throughout the project. The tool contains eighteen questions that use a five point Likert rating scale, and was modified to include basic demographic questions. The PVCT questions and demographic questions were placed into Research Electronic Data Capture (REDCap), a secure web application for building and managing surveys and databases.

The survey was sent via email to a nurse director distribution list, the directors then deployed the survey using their staff distribution lists. Reminder emails were sent twice at week two and week four using the same method. Participants were given six weeks to complete the survey.

Data Analysis-Data collection is currently in progress for this project. The survey's response rate will be determined by calculating the number of nurses the survey was sent to and the number of surveys that

were completed, reported as a percent. Descriptive statistics will also be used to summarize survey results, and chi-square analysis will be used to make comparisons.

Ethical Considerations: Institutional review board (IRB) approval by the hospital and university were obtained prior to project implementation.

Implications for Practice: Having staff nurses' baseline perception of certification will help guide intervention efforts to increase the number of certified nurses. Negative perception outcome data can reveal the barriers to certification that require intervention. Sharing this data with administration and staff nurses could lead to removal of these barriers. Additionally, positive perception outcome data can offer tools that administration and staff nurses can use for education and support of certification for nurses.

Predictors of Anti-Müllerian Hormone, a Biomarker of Ovarian Reserve: A Systematic Review of the Literature

Theresa M. Hardy, BSN, RN, USA

Donna O. McCarthy, PhD, RN, FAAN, USA

Abstract

Purpose: Anti-Müllerian hormone (AMH) is a novel biomarker of ovarian reserve, or the size of the ovarian follicle pool. Follicle stimulating hormone (FSH) and inhibin B have been the gold standard measures of ovarian reserve. However, changes in FSH and inhibin B levels are not detectable in serum until there is a significant reduction in the follicle pool (Steiner, 2013), making timely detection and intervention challenging. Several studies have explored the influence of both reproductive and lifestyle determinants on AMH concentrations (Dolleman et al., 2013; Freeman et al., 2007; La Marca et al., 2010; La Marca, Stabile, Arsenio, & Volpe, 2006; Malhotra, Bahadur, Singh, Kalaivani, & Mittal, 2013; Nelson, Stewart, Fleming, & Freeman, 2010; Steiner, Stanczyk, Patel, & Edelman, 2010; Tsepelidis et al., 2007). A systematic review of factors associated with AMH levels has not been conducted. A high level summary of the evidence is needed to evaluate the usefulness of AMH as a biomarker of ovarian reserve.

Ovarian reserve is established during fetal life. At birth, the number of primordial follicles is estimated at 1 million. This number decreases steadily during a female's lifespan and is reduced to approximately 300,000-500,000 at menarche. Throughout a female's reproductive years, follicles are recruited from the primordial pool and progress through the various stages of follicular growth. At the start of each menstrual cycle, one dominant follicle is selected for ovulation (Visser, de Jong, Laven, & Themmen, 2006). While it has proven challenging to quantify ovarian reserve, a new biomarker, anti-Müllerian hormone (AMH), has shown considerable promise (Dewailly et al., 2014). AMH is secreted by growing follicles, and is therefore reflective of the size of the primordial follicular pool. Measurable in serum, AMH offers a promising non-invasive marker of ovarian reserve. In addition, AMH levels are the earliest detectable change that occurs in the sequence of events associated with ovarian aging (Sills, Alper, & Walsh, 2009). The hormone is also ideal as a research and clinical measure because concentrations do not fluctuate across the menstrual cycle, and are independent of FSH, LH, and E₂ levels (La Marca et al., 2010; Shaw et al., 2011; Tran, Cedars, & Rosen, 2011).

While ovarian reserve naturally declines with age, age alone is not predictive of ovarian age or reproductive status. The decline of ovarian reserve is primarily due to apoptotic loss of oocytes (programmed cell death) rather than ovulation (Tremellen, Kolo, Gilmore, & Lekamge, 2005). Thirty-four percent of the variation in AMH concentrations is due to age, meaning that the remaining 66% is due to other factors (Kelsey, Wright, Nelson, Anderson, & Wallace, 2011). Identifying these factors may help to elucidate predictors of reproductive dysfunction and disease. Understanding factors that influence AMH levels in normo-ovulatory women will also help to establish reliable normative age ranges for use in clinical practice and research. While numerous studies have examined factors associated with AMH concentrations, the sensitivity of the biomarker depends on an understanding of the complex interplay of factors that influence its concentrations. The purpose of this systematic review is to provide a high level summary of the evidence on the factors associated with AMH concentrations and to develop a conceptual model based on the strengths of association for future hypothesis testing.

Methods: This systematic review will be conducted according to the PRISMA guidelines. A comprehensive literature search will be conducted using "anti-Müllerian hormone" as the search term in PubMed. Studies will be included if they meet the following criteria: 1) published in the last 10 years, 2) human subjects research, 3) research conducted with healthy females. Reference lists of selected studies will also be searched in order to identify any relevant studies missed in the primary search.

Results: Two researchers will read and independently judge all selected studies. Studies will be grouped by the factors that emerge from the systematic review. Once all relevant factors have been reviewed, a conceptual model will be developed based on the strengths of association. If there is contradicting evidence, several potential models may be proposed.

Conclusion: The conceptual models developed through this systematic review will provide the foundation for future hypothesis testing, and may improve the usefulness of AMH as a biomarker of ovarian reserve.

Evaluation of a Novel Evidence-Based Practice Mentorship Program in a Pediatric Quaternary Care Setting

Paul David Schuler, DNP, RN, CPNP-AC/PC, USA

Abstract

Purpose: Evidence Based Practice (EBP) integrates, synthesizes, and utilizes evidence from research, quality improvement initiatives, theoretical models or frameworks, expert opinion, clinical experience, and patient preferences and values, to inform clinical decision making. Informed clinical decision making is essential for the delivery of high quality care, has the potential to reduce healthcare costs, and has a greater likelihood of achieving optimal patient outcomes. Despite these known benefits, a 2012 institution-wide survey, using the Quick-EBP-VIK, revealed opportunities for improvement in the areas of knowledge and implementation of EBP. In response to these findings, the Evidence-Based Practice Subcommittee of the Nursing Research Council was charged with addressing this institutional need. The result was the development of a novel evidence-based practice mentorship program, or EBPMP.

EBPMP is a self-directed program that requires participants carry out an EBP project that addresses an important clinical practice question. Throughout the twelve-month program, participants move through the steps of the EBP process and are exposed to many EBP resources available from within and outside of their institution. The curriculum includes a step-by-step instructional workbook and ten internet-based educational modules that are designed to quickly guide the learner through the steps of EBP. The modules are presented in a standardized, easy to follow format, and are meant to take no longer than 30 minutes to complete. Suggested readings are made available to the learner to expand their knowledge, and each participant is aligned with an expert mentor to help guide and support them through the process. Upon completion of the program, the participant disseminates their work and is encouraged to serve as a resource to others by promoting EBP in their clinical environment. Key features of EBPMP include its flexible, economical and self-directed approach. EBPMP has the potential to create a self-sustaining group of EBP mentors to foster an institutional culture of mentorship and clinical inquiry.

The purpose of this research project was to evaluate the effect of the EBPMP on nurse participants' value, implementation and knowledge of EBP, as well as their mentorship experience, using a mixed methods design. The specific aims of this project were 1. To describe demographic and nursing characteristics for the first cohort of EBPMP participants, 2. To describe the change in nurse participants' value, knowledge, and EBP implementation pre- post EBPMP using Quick-EBP-VIK, 3. To understand the participant's experience with EBPMP through qualitative content analysis of individual and group interviews conducted midway through the EBPMP, and 4. To understand the participants experience with EBPMP and rationale for withdrawal from the program through individual interviews.

Methods: This study employed a mixed methods design including: Quantitative analysis of pre and post EBPMP using Quick-EBP-VIK survey results; Qualitative content analysis of EBPMP using individual or group interviews midway through the EBPMP, and individual interviews of participants who elect to withdraw from the program.

Results: This study is ongoing.

Conclusion: Findings from this study will inform stakeholders about the benefits of EBPMP and the potential need for program modifications.

RSG STR 1 - Rising Stars of Research and Scholarship Invited Student Poster Session 1 Readmission Factors of Patients With Type II Diabetes

Veronica Santos Timple, MS, BS, RN, CCRN, USA

Abstract

Purpose: The purpose of this study is to identify the factors associated with 30-day hospital readmissions in patients with type II diabetes.

Methods: This retrospective descriptive correlational study involves abstracting 500 samples from the 2014-2015 electronic health records (EHRs) located in a Southern California urban hospital. Inclusion criteria are as follows: (1) hospitalized patients and who are at least 65 years and older; (2) discharged from the acute inpatient setting with a type II diabetes regardless of their admitting diagnosis; and (3) were readmitted within 30 days. Exclusion criteria include: (1) patients who were admitted and discharged in less than 24 hours; (2) patients who were admitted due to trauma; and (3) patients readmitted within 24 hours post discharge.

Data abstracted from the EHRs include demographic characteristics (age, gender, and race); hospital discharge disposition (home, skilled nursing facility, or rehabilitation center); clinical biomarker (Hemoglobin A1C), diabetes medications (oral versus insulin therapy); disease management (whether the patient received diabetes education or was seen by an Endocrinologist); length of stay; and comorbidities. Descriptive statistics will be used to describe the characteristics of the population. Correlation statistics will be employed and multivariate analysis using logistic regression will be performed in order to determine if the data fit a model that will explain the variance in readmission.

Results: The study is currently in data collection phase, but it is expected to be completed in May 2017; results should be available for dissemination at the time of the conference.

Conclusion: Understanding the factors associated with hospital readmissions among older patients with type II diabetes will assist healthcare organizations to create and implement targeted protocols that could prevent these costly, and potentially harmful readmissions. In addition, if the factors are identified and interventions are made, there is the potential for reduced morbidity and mortality rates in patients with type II diabetes.

Abstract

Purpose: To examine the association of kangaroo mother care (KMC) on energy utilization and procedural pain as evidenced by altered biochemical markers of adenosine triphosphate (ATP) degradation, (hypoxanthine (Hx), xanthine (Xa), and uric acid (UA) and oxidative stress (allantoin).

Background: Premature infants admitted to the NICU are at a high risk of suffering the consequences of early maternal separation due to their physiological and metabolic immaturity. Bonding processes of mother and infant may also be at risk from early maternal separation. Consequently, infants become vulnerable to a myriad of internal and external events that increase energy loss. Three main factors that may negatively influence the infant's ability to meet the energy needs after birth are inadequate glycogen stores, immature glucose metabolism and increased ATP degradation due to procedural pain. Processes mediating energy conservation have not been adequately investigated.

Kangaroo mother care (KMC) has been identified as an intervention that activates mechanisms of energy preservation in this population. Direct effects of KMC are improved mortality and morbidity, by stabilization of breathing, thermal regulation, oxygen saturation, heart rate, improved breast-feeding and better parent bonding. Other notable effects are rapid quieting in the infant and analgesic properties. Kangaroo mother care mimics the relaxation found in utero, minimizes dyad separation, and maximizes a battery of physical, physiological, and behavioral effectors that are energy-conserving, and mediated by several different central and peripheral mechanisms. This study links KMC to hypothesized findings of energy conservation as measured by reduced biochemical markers of ATP degradation and oxidative stress. This is the first study that will link physiological biochemical data to the theorized physiological effects of KMC on the infant's growth, development and response to painful procedures.

Methods: A prospective randomized controlled trial design will be used to test the hypothesis that exposure to KMC will significantly alter biochemical markers of ATP utilization, oxidative stress and cell injury. The study will be conducted at a Level III neonatal intensive care unit in Southern California. The NICU is a tertiary care unit, caring for inborn and out born patients with an average daily census of 84 babies. Potential subjects are premature infants 28-34 weeks gestation who are medically stable as determined by a SNAPPE_II score of less than 9 (Score for Neonatal Acute Physiology- Perinatal extension SNAPPE –II), who have medically required heel lance. Treatment allocation is 1:1. The PI and treatment providers will not be blinded to the treatment due to the nature of this study.

PI will simultaneously collect urine at 3 different intervals for the intervention and the control groups. For the intervention group, urine will be collected on Day 3 at Time 0 - before KMC, Time 1- 3 hours after KMC, and Time 2- 6 hours post KMC. For the control group, urine concentrations of Hx, Xa, and UA will also be collected on Day 3 at Time 0 – before standard NICU incubator care, Time 1- 3 hours after incubator care, and Time 2- 6 hours post incubator care and measured using high performance liquid chromatography (HPLC 100% accuracy) and allantoin will be quantified using gas chromatography/ mass spectroscopy. The effect of KMC on procedural pain (heel lance) will be analyzed from urine samples obtained at Time 0 and Time 1-3 hours after the painful procedure. Subjects randomized to the control

(no KMC group) will receive the current standard of care for procedural pain (Sweet-Ease or 24% sucrose).

Bonding will be measured using The Mother-to-Infant Bonding Scale (MIBS). It is a self-report instrument by the mother that has been tested for its psychometric properties in the general and NICU population. It was first devised to screen the general population for postnatal difficulties relating to the maternal emotional behavior towards her baby in the first days (48-72h) postpartum. A principal components and reliability analysis demonstrated an alpha score of 0.71. The instrument is composed of 8 items (adjectives) describing feelings mothers have toward their babies in the first weeks after they are born. The items are scored from 0 to 3 with a total score ranging from 0 to 24 and high scores indicating disturbance in the mother-infant bond. The instrument is a simple questionnaire to administer. In a study validation in the NICU population MIBS satisfactorily detected difficulties in mother child bonding: The area under the ROC curve was 0.93 with a sensitivity of 0.9 and a specificity of 0.8 for a threshold score ≥ 2 . The positive predictive value for this threshold was 40.9% (IC95% (20.36-61.45) and the negative predictive value was 98.1% (IC 95% (89.93-99.95). This is a reliable instrument that generates valid data in the NICU population. Mothers of both the intervention and control groups will be assessed using the MIBS self-rating instrument 72 hours postpartum at 1 hour after incubator care or 1 hour post KMC intervention.

Inclusion and Exclusion criteria: Potential subjects are premature infants 28- 34 weeks gestation and less than 1 day of age postnatal and are medically stable as determined by a SNAPPE_II score of less than 9. All attempts will be made to enroll subjects before DOL 3.

Exclusion criteria will include: 1) requirement for surgery; 2) intraventricular hemorrhage (IVH) $>$ or equal to grade 3; 3) neonates on medication such as morphine, fentanyl, versed, muscle relaxants, phenobarbital, or Dilantin; 4) renal injury (plasma creatinine $>$ 1mg/dl; 5) severe cyanotic heart disease or severe respiratory distress; 6) known abdominal wall or intestinal anomaly or injury (NEC); 7) chromosomal anomaly; and 8) facial anomaly.

Sample size calculation: A convenient sample of 68 potential subjects of premature infants 28-34 weeks gestation will be alternately randomized 34 to the control group and 34 to the intervention group. We expect 25% change in purines to be clinically significant and a SD of 0.5, which would yield an effect size of 0.5, and would require a sample size of approximately 34 subjects in each group. For this ANCOVA approach, we calculated the power to detect differences in purine levels among premature infants 28-34 weeks gestation in terms of a moderate effect size of 0.5. The calculations assumed a single outcome, a Type I error rate (α) of .05, a Type II error rate (β) of .20 (power of .80), and a two-tailed statistical test, as is appropriate for research purposes. With 68 participants per condition and no effective covariate, this study could detect an effect size of .57. We believe this effect size is small enough that the intervention can produce these differences between conditions, but not so small as to be clinically and statistically irrelevant.

Statistical Approach: To examine the primary research question, a repeated-measures analysis of covariance (ANCOVA) will be conducted to determine whether significant differences in purine levels (energy expenditure/conservation) exist. Descriptive analysis of all ratio level measurements will be performed to characterize the study sample. All dependent measures will be examined and tested for assumptions of normalcy. Additional tests related to equality of error variances, homogeneity of regression slopes, and multicollinearity will also be conducted. Primary factors in the ANCOVA include time and treatment. Potential covariates and confounders include age, gestational age, ethnicity, FIO₂, method of oxygen support, weight, severity of illness, and medications. Appropriate post hoc comparisons will be conducted if warranted. All tests of hypotheses will be two-sided and conducted at an alpha level of 0.05.

Results: Pending

Significance: This study examines the potential biologic mechanism for KMC efficacy through measuring infant energy utilization biomarkers in urine (hypoxanthine, xanthine, and uric acid, and allantoin).

Knowledge linking biochemical evidence with physiologic benefits of KMC will further support spread of its practice. Given the prevalence, associated disability and impairment to the premature infant, and the economic burden to both health organizations and families, rigorous measures and assessment of the benefits of kangaroo mother care is imperative.

Implications: To further inform the use of kangaroo mother care in research and clinical settings.

Conclusion: This study will supply the physiological data to further support the benefits of energy conservation from KMC which would allow for recovery, repair, growth and maturation in neonates, and hopefully supply further incentive for NICU nurses to adopt KMC as the primary modality for caring for premies.

RSG STR 1 - Rising Stars of Research and Scholarship Invited Student Poster Session 1 Analyzing Influenza-Like Illness With Unsupervised Machine Learning

Monique J. Bouvier, MSN, RN, ARNP, C-PNP, USA

Mary Barger, PhD, MPH, RN, CNM, FACNM, USA

David D'Ambrosio, PhD, N/A, USA

John C. Arnold, MD, CAPT, MC, USN, USA

Abstract

Disclosure: The views expressed herein are those of the authors and do not reflect the official policy or position of the Department of the Navy, Department of Defense, or the United States Government.

Purpose: The World Health Organization reports acute respiratory infections continue to be the leading cause of global infectious disease morbidity and mortality with almost 4 million deaths annually. An acute respiratory infection is caused by an infectious agent, bacterial or viral, with a wide spectrum of symptom presentation. There are over 200 viruses that can cause influenza-like illnesses (ILI), a sub-type of acute respiratory infection, and there is developing research to understand the symptomatic differences between the virus types. However, symptom experience is very subjective, so it is difficult to determine which of the 200 viruses is causing the ILI without laboratory viral testing.

Symptoms are experiences stimulating changes in a person's feelings and biopsychosocial factors; therefore, biological, psychological, and social factors may contribute to a person's symptom experience. Several ILI symptom studies have examined the symptom experience in order to predict the diagnosis of influenza from the other causes of ILI, but did not yield satisfactory results. Other studies examining influenza symptom severity used dichotomous or linear sum analysis with few looking at symptoms over time.

Unsupervised machine learning is an approach that identifies patterns in datasets with minimal human input. Clustering is a common method of unsupervised machine learning where data are grouped together based on similarity. Recently, several studies have used clustering in medical applications such as predicting the recurrence of breast cancer or detection of Alzheimer's disease.

Studies examining patient reported ILI symptoms to predict virus type are limited, especially related to virus types other than influenza. Additionally, most research focuses on the influenza virus and its symptoms, and not the other common viruses identified as sources of ILI. The purpose of this study is to identify if symptom presentation over the course of influenza-like illness (ILI) can predict virus type using unsupervised machine learning. Additionally, we sought to identify sub-populations with similar symptom experience.

Methods: A secondary analysis of data from a prospective longitudinal study conducted by the Acute Respiratory Infection Consortium was performed. The data was collected from 2009 to 2014 at five US military medical institutions across the United States. The population was otherwise healthy active duty military members, dependents, and retirees, age 0-65 years, who presented to the clinic with influenza-like illness symptoms. A nasopharyngeal sample was collected for virus identification. Subjects reported their symptom severity at enrollment and follow-up visit days 3, 7, and 28 on an instrument designed for this study. The instrument had subjects rate their symptom severity on a 4-point nominal scale for 20 symptoms associated with influenza-like illness.

The sample used for this study was limited subjects with complete symptom severity data on days 0, 3, and 7, and no viral co-infections. The unsupervised machine learning approach, k-means clustering, was used to analyze the symptom data. For the initial analysis subjects were clustered by their individual symptom severity scores for all visits. The clusters were examined to identify if any of them represented a specific virus or group of viruses. Because it was unknown how the different viruses' symptoms were expressed, clustering was run with *k* values 5-10. The secondary analyses clustered subjects with specific

viral diagnoses, influenza A, rhinovirus, or coronavirus by symptom expression. Subject attributes of: sex, military status, age, BMI, smoking, and ethnicity, were compared amongst the clusters to identify how specific groups may experience the specified virus.

Results: The initial analysis was unable to predict virus type based on the individual symptom severity scores using a variety of scoring approaches. Only k=7 clustering revealed some promising differences, but detailed analysis identified that the clusters were not significantly different ($p>0.05$) than the overall population with the exception of one cluster. One cluster had a higher coronavirus percentage compared to the overall population. However, this cluster had eight total virus types, therefore, it is not specific for diagnostic purposes.

The secondary analyses of subject attributes for the rhinovirus (n=101), influenza A (n=107), and coronavirus (n=51) groups generated favorable results. At least one symptom cluster in each group yielded statistically significant difference based on subject attributes using one-way ANOVA or chi-square testing. The clustered rhinovirus data exhibited statistically significant differences ($p<.000$) in five out of the six attributes: sex, BMI, age, smoking history, and military status. The clustered influenza A data had statistically significant difference the attribute sex ($p<.000$), and approached significance in the military status attribute. The clustered coronavirus data only showed statistically significant differences in sex ($p<.000$), which was expected as the data set was well distributed. Overall the patients in the different virus clusters experienced symptoms differently compared to the total population for virus type.

Conclusion: Although, virus type could not be predicted based on physical symptom score, some differences in symptoms among virus types were anecdotally observed. Additionally, the results showed people with the same virus infection experience physical symptoms differently. Moreover, the secondary analyses reinforced the fact that a person's attributes may result in different physical symptom presentation. For that reason, future research should consider utilizing a symptom severity instrument that measures more than physical symptoms, and captures psychological, environmental, and other aspects as conceptualized by the symptom management theory.

Nurses track and follow the care of a patient closely, and are typically the first to see a change in a patient's status. It is important for nurses to be able to recognize a change in symptom severity and how different attributes may affect symptom presentation. A slight change in a patient's symptom presentation can be the beginning of a worsening of the illness.

Additionally, unsupervised machine learning could become a useful technique to help identify patterns in research with large data. Its technique could open new avenues of patient data analysis and may reveal knowledge and factors that may not be obvious using traditional statistical approaches. This novel approach needs to be tested against other approaches to more fully understand its usefulness.

Side Effects and Dysfunction in Patients With Gastrointestinal Stromal Tumor (GIST) Receiving Targeted Therapy

Kai-Lin You, MS, RN, Taiwan
Yeur-Hur Lai, PhD, RN, Taiwan
Ching-Yao Yang, PhD, MD, Taiwan

Abstract

Background: The five year survival time of Gastrointestinal Stromal Tumor (GIST) has dramatically improved with effective target therapy. Patients with high risk or metastatic GIST are suggested to receive oral targeted therapy for at least three years or even a lifespan after their surgery. However, long-term oral targeted therapy might also increase patients' distress from side effects and affect their daily function.

Specific Aims: This study aims to examine the perceive side effects and dysfunction for GIST patients receiving targeted therapy.

Methods: This is a cross-sectional study to recruit GIST patients from a medical center in Taiwan. Eligible subjects are those who are (1) adult and diagnosed with GIST, (2) receiving oral targeted therapy, and (3) no communication barriers. Patients with GIST are assessed of their symptom severity related to the disease or oral targeted therapy and dysfunction of cognitive, physical, and psychosocial status. The above variables are measured by Symptom Severity Scale (SSS), Karnofsky Performance Status Index (KPS) and World Health Organization Disability Assessment Scale (WHODAS). Patients were recruited in a gastrointestinal surgical outpatient clinic by a trained master research nurse.

Results: There were 70 subjects were recruited. The overall KPS is 89.3 (SD=6.29). In general, patients reported to have mild to moderate side effects. The most distressful side effects as their descending order of mean are: Pale skin, muscle cramps, fatigue, periorbital edema, sleep problems, absent minded, facial edema, lack of concentration, muscle soreness, and diarrhea. Patients reported to have mild dysfunction in their life. The top five dysfunction as the descending order of the mean scores are: (1) Emotionally affected by health condition, (2) Time spend on health condition or its consequences, (3) Levels of health been a drain on the financial resources, (4) Problem cause on family because of (your) health problems, and (5) decreasing sexual activities.

Conclusion & Discussion: Assessment and care for GIST patients' side effects from targeted therapy is important for increasing their life quality. Individualized patients' education and care with different side effects are strongly recommended.

Improving Nursing Care in Infants With Neonatal Abstinence Syndrome

Laura Ruth Watson, MSN, RNC-OB, USA

Abstract

Purpose: The purpose of the project is to improve the nursing care of infants with neonatal abstinence syndrome (NAS) through staff education and peer assessment.

Objectives: The project objective is to provide education for the healthcare staff at two Midwestern hospitals to ensure consistent care is provided to NAS infants. By providing consistent care, NAS infants will be made more comfortable and improve quicker, decreasing their length of stay.

Expanded Content Outline: Sublett (2013), identifies since 1980 the incidence of the NAS has increased by 300%. Literature has shown that infants with neonatal abstinence syndrome (NAS) encounter serious medical complications resulting in prolonged hospital stays and expensive interventions. The average hospital stay for these neonates is 22-26.1 days (Lind et al., 2015).

NAS is a collection of multi-systems withdrawal signs and symptoms experienced by the neonate due to exposure in utero to substance use and dependency by the pregnant mother. Once the infant is born, the substance is no longer available, placing the infant at risk for withdrawal. The central nervous, respiratory, gastrointestinal, and autonomic systems are negatively affected in infants with NAS. Differentiation of care may affect the progression of the NAS infant (Lucas & Knoble, 2012).

In a three year study the cumulative hospital cost at a hospital in Gainesville, Florida for 40 infants diagnosed with NAS was 1.1 million dollars for the first year. By the third year the cost was 1.8 million for 63 diagnosed infants. For infants not diagnosed with NAS, by the third year of life, 63 infants' average healthcare cost was \$109,998. That is a total variance of \$1,691,325 (Hall et al, 2014). Literature confirms that by instituting and adhering to clinical practice guidelines, a decrease in the length of hospital stay may be noted, thereby, decreasing the cost of care for the infants (Hall et al., 2014; Patrick et al., 2012).

Improvement of infant care will occur through educating staff about neonatal abstinence syndrome and the standard of care required by NAS infants. Education focusing on the value of inter-observer reliability/peer assessment will be provided. The project will lead to the development and adoption of evidence-based practice and policies recognizing the special needs of infants with NAS. Upon completion of the project, analyses will be performed to ensure the project objectives are being met and maintained. Length of hospital stay will be evaluated one year before, and one year following project implementation. Data will be collected from nursing staff to determine true effectiveness of staff education.

Evidence recommends strict care guidelines be adopted in institutions caring for NAS infants (Hall et al., 2014). The outcome for this study is to institute guidelines for the care of NAS infants admitted to nurseries of two Midwestern hospitals, with the goal to expand the project to other healthcare systems providing care to NAS infants.

RSG STR 1 - Rising Stars of Research and Scholarship Invited Student Poster Session 1 Irritable Bowel Syndrome and Probiotics: Effective or Not?

Andrea L. Morris, BSN, RN, VA-BC, USA

Abstract

Purpose: Purpose of this study is to explore the effect of irritable bowel syndrome in relationship to body systems and evaluate the benefit of adding probiotic therapy to the treatment plan.

Methods: One hundred thirty-three articles initially identified, of which 32 met the inclusion criteria. The selected articles included four Level I meta-analysis and systematic reviews of Randomized Control Trials (RCT) totaling 144 studies, seven Level II RCTs totaling 992 patients, and one Level IV, an observational study.

Results: Irritable bowel syndrome (IBS) is one of the most common gastroenterological diseases affecting 15-20 % of the Western population, and disturbance in the gastrointestinal microbiota may be implicated, according to Urgesi, Casale, Pistelli, Rapaccini, & de Vitis (2014). Diagnostic criteria utilized by physicians and clinics effect the variance in prevalence, as the looser the criteria, the higher the prevalence. The criteria may be reported utilizing the Rome II, Rome III, Manning, or other criteria. Irritable bowel syndrome is a chronic gastrointestinal disorder that effects a large percent of the population, and is costly to the medical profession and the business world (Zhang et al., 2016).

Irritable bowel syndrome is a gastrointestinal condition characterized by abdominal pain or discomfort and other various types of symptoms, which vary in type and severity including bloating, and alterations of bowel function, singularly or in any combination (Park, Byung-Hee, & Hyangsook, 2013). According to Ford et al. (2014), evidence suggests visceral hypersensitivity, disturbances in gastrointestinal (GI) flora, and chronic activation leading to a low-grade mucosal inflammation have an effect on intestinal flora. Faghihi, Agah, Masoudi, Ghafoori, & Eshraghi (2015) reported changes in the microflora of the intestine, such as recent intestinal illnesses, have been a significant factor in the search for pathogenesis of the illness. Sisson, Ayis, Sherwood, & Bjarnason (2014) shared that extra-intestinal symptoms include genitourinary, musculoskeletal (fibromyalgia, arthralgia, backache), headaches and fatigue, menstrual and sexual dysfunction, and anxiety and mood disorders are frequently present.

Traditional treatments have not been effective for long-term benefit and use of alternative therapy is increasing as patients seek answers and relief from the symptoms. Choi et al. (2015) indicated irritable bowel syndrome affects a patient physically, and may have social, mental and emotional ramifications resulting in a disruption in the quality of life for many patients. Research by Begtrup, de Muckadell, Kjeldsen, Christensen, & Jarbol (2013) suggested improving IBS symptoms may positively affect a patient's quality of life.

In 2001, the Food and Agriculture Organization of the United Nations (FAO) convened a multinational expert group of scientist who defined probiotics as "live microorganisms which, when administered in adequate amounts, confer a health benefit on the host" (Saez-Lara, Gomez-Llorente, Diaz, & Gill, 2015). Probiotics are bacteria and yeasts that are good for a person's health, especially the digestive system. Urgesi et al. (2014) reported probiotics help maintain the natural balance of organisms (microflora) in the intestines and may be beneficial for patients suffering with IBS. Choi and associates (2015) stated the gut microbiota effects many systems including the auto-immune, musculoskeletal, genitourinary, sexual dysfunction, mood and anxiety disorders, thought processes, and may generate low-grade chronic inflammation. To assist patients improve their health status and quality of life is the goal of every nurse. To be proactive and address a solution to the problem, not treat the symptoms, should be the plan. Hung, Kang, Bollom, Wolf, & Lembo (2015) indicated research into alternative modalities for those solutions may be beneficial in the treatment of IBS.

Irritable bowel syndrome is a chronic, complex gastrointestinal disorder that is usually very hard to manage. The microbiota of the gastrointestinal tract is less stable in an adult with IBS in comparison to a healthy adult, and in recent years, a closer focus has been on the gut microbiota (Begtrup et al., 2013). According to Yoon et al. (2014), the pathophysiology of IBS is not clearly understood and may involve many factors, including gut motor dysfunction, post-infection bowel changes, psychological factors, and visceral hypersensitivity. There has been a renewed interest in recent years into understanding the pathophysiological mechanisms and etiology of IBS. Mezzasalma et al. (2016) stated the role of intestinal microbiota is significant in human health and disease as the microbial community resides in the gut of the host. Research data reported by Begtrup et al. (2013) indicated probiotics can modify the gut microbiota, and may be beneficial for the treatment and prevention of IBS and other intestinal diseases. Individual strains and species of probiotics vary significantly in composition, and affect the gut microbiota differently (Ford et al., 2014); therefore, prescribing the correct strain of probiotic is important for the patient to achieve a therapeutic benefit.

Patients with IBS have a fecal flora difference from healthy clients, and may harbor bacterial overgrowth. Urgesi et al. (2014) suggested probiotics are noted to normalize the GI microflora, thus restoring gut epithelial function and the mucosal immunological barrier. As noted by Yoon et al. in 2013, it is known that the effect of probiotics is species-specific, but it remains unclear which probiotic organisms induce the change in intestinal microbiota. The possible mechanisms of action of different probiotic strains include effects on intestinal motility, visceral hypersensitivity, secretion of interleukins (e.g. IL-10) and increases in anti-inflammatory T-cell populations (Sisson et al., 2014). What does seem to be clear from the literature is that the efficacy of individual probiotics depends both on the strain(s) of bacteria and the formulation of the preparations and/or delivery methods used (Mezzasalma et al., 2016; Yoon et al., 2013; and Choi et al, 2015). This has resulted in new insights, which highlight the importance of interactions between the host and intestinal luminal microbial and nonmicrobial constituents.

Begtrup et al. (2013) signified the role of intestinal microbiota is significant in human health and disease as microbial community resides in the gut of the host, and Ford et al. (2014) believed that probiotics can modify the gut microbiota, and may be beneficial for the treatment and prevention of IBS and other intestinal diseases. Mezzasalma et al. (2016) indicated individual strains and species of probiotics vary significantly in composition, and affect the gut microbiota differently. Research conducted by Hung et al. (2015) suggested successful treatment involves understanding the benefits and effects of medications, including complementary and alternative medicine.

Conclusion: Research indicates irritable bowel syndrome affects many people, and traditional treatment is for the symptoms, not the root of the disease. Patients suffering from IBS are assessing alternative treatment modality options and are willing to try non-traditional and non-pharmaceutical means of treatment. Research further indicates probiotics may be beneficial for the IBS patient, with the evidence of diminished symptoms and increased quality of life. Various studies have not given consistent findings for conclusively validating a reason to make a change in treatment to a universal algorithm (Yoon et al., 2014). As the data suggests, future studies to assess the benefits of probiotics in multi-species combinations and in combination with other medications to understand their effect on the gastrointestinal microbiota are needed.

Is Cancer-Related Fatigue Related to Levels of Physical Activity and Body Weights in HNC Survivors?

Yuan-Yuan Fang, MS, RN, Taiwan
Yeur-Hur Lai, PhD, RN, Taiwan

Abstract

Purpose: In cancer survivors, fatigue frequently attacks and impact patients' daily life, but is usually underreported. Physical activity can decelerate the disease progress and decreases the impact of fatigue, but in head and neck cancer (HNC) patients there were few literatures and without combining the issue of body weight loss or obesity after treatment. The purposes of this study were to explore the relationship between physical activity, body weight status, and cancer-related fatigue.

Methods: This was a cross-sectional study design research and 144 HNC patients were recruited in outpatients center in medical center in Northern Taiwan after complete the treatment. Using Fatigue Symptom Inventory (FSI) and Godin Leisure-Time Exercise Questionnaire (GLTEQ) to be the interments and assessing by the senior nurses after agree to participant in the study.

Result: Most patients had good KPS (83.8 ± 7.76) and were average completed the treatment 17.2 (± 13.8) months, but only 20.8% were in met the public health exercise recommendation. Even after the treatment, nearly 80% of patients still suffer from fatigue, and first three fatigue daily interference were "general level of activity" (1.6 ± 2.1), "normal work activity" (1.4 ± 2.0), and "mood" (1.3 ± 2.1). The patients met exercise recommendation (in activity group) with normal BMI (18 to 25) were had significant lower fatigue intensity ($P = .01$) and fatigue interferences ($P = .002$) than sedentary. The trend showed that the sedentary patients in normal weight or overweight had worst fatigue intensity, inference, and duration. With BMI < 25, the patients had worst fatigue intensity, inference and duration than other participants.

Conclusion: Our study showed that the sedentary patients had worse fatigue than the patients with exercise, and the patients with BMI < 18 may have worst fatigue than the other participants. We recommend the health care givers encourage the patients have regular exercise behavior after the treatment and long-term follow up their body weight to give specific practical nutritional intervention.

Influence of Comorbidities on Symptom Severity in Cancer Patients

Eric A. Vachon, BSN, RN, USA

Barbara A. Given, PhD, RN, FAAN, USA

Abstract

Background & Purpose: The increasing use of oral oncolytic agents (OOA) and the rising incidence of multimorbidity have combined to create a population with increased needs. Cancer patients that have been prescribed OOAs and have other comorbid conditions, are at risk for poor management of their cancer and comorbidities. Oral oncolytic agents comprise more than 30% of all prescribed chemotherapy. Over 50% of Medicare beneficiaries over age 65 with cancer have four or more additional chronic conditions that require some form of medical management. Oral oncolytics administered in the home, require cancer patients to self-manage the symptoms and side effects associated with cancer and treatment. The competing demands of OOAs and multimorbidity often have the potential to culminate in increased symptom burden for the patient who has a need for symptom management strategies. The purpose of this work is to examine the impact of comorbid conditions on symptom severity among cancer patients who were newly prescribed oral oncolytic agents.

Methods & Design: Data were collected from a sample of 272 cancer patients newly-prescribed oral oncolytics (136 males, 136 females) at baseline (initiation of OOA) and 4 weeks in a multi-site RCT testing symptom management strategies, using an adapted Dodd symptom-management framework. Telephone interviewers collected medication information, comorbid conditions, and severity (range: 1-10) of 18 symptoms using the Symptom Experience Scale, among other variables. Patients were randomized into control (n=135) and experimental (n=137) groups after baseline, and the experimental group was given a toolkit and instructed to refer to it when symptom severity was $\geq 4/10$. Data were analyzed through descriptive statistics and multiple linear regression models, using STATA/IC 14.0. Baseline and 4-week symptom severity was examined in relation to sex, age, OOA drug class, treatment group, recruitment center, and number of comorbid conditions.

Results: Patients had a mean age of 61 years and presented with an average of 3.38 comorbidities, in addition to their cancer. At baseline, symptom severity was 21.7, and at 4 weeks, it was 22.1. Age was the only significant predictor of baseline symptom severity ($p < .05$). For each each increase in age by 1 year, symptom severity decreased by .22. Although not a significant predictor of baseline symptom severity, with each additional comorbid condition, symptom severity increased by 1. The only significant predictor at 4 weeks was the difference in symptom severity between two OOA classes, cytotoxics and sex hormone inhibitors (SHI). Cytotoxics's mean symptom severity was 11.6 higher than SHIs. Comorbidities were not a significant predictor of 4-week symptom severity, only increasing by 0.69 with each increase in number of comorbid conditions.

Conclusions & Implications: Comorbid conditions have the potential to impact the clinical outcomes and quality of life for cancer patients prescribed oral oncolytic agents. Although not a significant predictor, with each increase in number of chronic conditions, comorbidities increase a patient's overall symptom severity. However, after being on the new oral oncolytic treatment for 4 weeks, the effect of comorbidities is diminished. Age was a significant baseline predictor of symptom severity, but opposite of the typically observed trend. This increase in symptom severity in younger patients may be related to the harsh nature of cancer in younger adults. After being on the OOA for several weeks, drug class is the driving force of increased symptom severity. This work suggests the need for comprehensive management of both patients' cancer and their other comorbid conditions, and concern for the changes over time.

RSG STR 2 - Rising Stars of Research and Scholarship Invited Student Poster Session 2 Professional Development of Nursing Leaders: A Case Study of Canadian Nurses Association Presidents (CNA)

Laura Jane Colley, BScN, RN, Canada

Sonya Grypma, PhD, RN, Canada

Magdalena Theron, DCur, RN, Canada

Abstract

Nursing leadership is important across every domain of the nursing profession. However, nursing leadership development is not well understood or documented. This study addresses this gap in the literature by turning to an overlooked source of leadership knowledge – presidents of the Canadian Nurses Association (CNA). The CNA has had exceptional leaders during its 108-year history. Many have influenced nursing practice, changed the perception of nursing, and improved healthcare. Yet, little is known about how they became such outstanding leaders. Using a qualitative design, this study aims to inspire and inform current and future nurses by exploring the experiences and leadership journeys of CNA presidents.

Altogether, seven nurses who have held the title of President of the CNA were interviewed, face-to-face, by Skype or by telephone. These interviews focused on the participants personal experiences and perspectives about their leadership journey. Their definitions, philosophies, and motivations for pursuing this particular leadership role were also explored. Through interpretive description methodology the following six themes were identified: Embracing Opportunities, Relentless Incrementalism, a Service Mindset, Taking the Long View, Enduring Heartbreak and Taking a Seat at the Table.

The findings of this study provide a deeper understanding of how and why nursing leaders became CNA Presidents and how they contribute to the nursing profession. The findings also inform how leadership is seen and developed in all nurses as leaders. Therefore, current and future nursing leaders will benefit from the wisdom of the participants in this study as a source for ongoing development of their leadership skills. However, continuing study of high level nursing leadership development is recommended in a variety of settings. This is important for a deeper understanding of the characteristics and nuances of nursing leadership development in order to ensure empowered and effective nurses direct the profession in the years to come.

A Comparison of Fatigue Among Resectable Colorectal and Pancreatic Cancer Patients

Hsuan-Ju Kuo, MSN, RN, Taiwan
Shiow-Ching Shun, PhD, RN, Taiwan

Abstract

Purpose: Both colorectal and pancreatic cancer patients suffer from gastrointestinal associated symptoms that cause nutrition insufficiency. Under impaired nutritional status, cancer patients are prone to experience fatigue. However, there is currently no study that compares fatigue status between colorectal cancer and pancreatic cancer patients. Therefore, the aim of this study was to compare the perceived fatigue among patients with colorectal cancer and pancreatic cancer; and to explore the associated factors among demographic and clinical characteristics, functional lower extremity strength, and grip strength for fatigue in overall patients.

Methods: A cross-sectional research design was conducted. Data were collected using a structured questionnaire including demographic and clinical characteristic form, and the Chinese version of the Fatigue Symptom Inventory (FSI). Grip strength was tested by the Jamar^R plus+ digital hand dynamometer. Functional lower extremity strength was evaluated with the 30-second chair stand test. A total of 64 preoperative cancer patients, including 32 with colorectal cancer and 32 with pancreatic cancer, were recruited from a medical center in northern Taiwan. The generalized estimating equation (GEE) was used to examine the significant associated factors with fatigue for overall patients.

Results: There were no significant differences in demographic factors in the two groups. However, the disease characteristics including functional status ($p=.005$), cancer stage ($p=.005$), body mass index ($p=.020$), regular exercise habit ($p=.001$), and having comorbid chronic illness ($p=.003$) demonstrated significant statistical differences. Furthermore, there were significant differences in fatigue between the two preoperative cancer groups; and pancreatic cancer patients had higher FSI score than colorectal cancer patients. However, the statistical significance of cancer types disappeared after adjustment for functional status, cancer stage, body mass index, regular exercise habit, and having comorbid chronic illness. The significant associated factor with fatigue was functional status measured by Karnofsky Performance Status Scale (KPS). Patients who had lower KPS score ($\beta=-.976$, $p=.018$) reported higher score in FSI. There were no significant statistical differences in the 30-second chair stand test and grip strength between the two groups.

Implication for practice: Healthcare providers should pay extra attention and assess potential fatigue conditions for cancer patients with lower preoperative functional status. Nursing education regarding fatigue management may be indicated for both cancer populations who experience impaired functional status. Further research with larger sample size should be done to examine fatigue characteristics among both groups and intervention should also be developed accordingly.

Depression Screening and Glycated Hemoglobin Levels: Diabetes Follow-Up Measures

Kristel Rosemarie McGhee, BSN, RN, CNRN, USA
Katherine Kenny, DNP, RN, ANP-BC, FAANP, FAAN, USA

Abstract

Diabetes and depression often co-exist. This combination may exacerbate the progression of diabetes; therefore, diagnosis and treatment of depression may improve diabetes management. In addition to routine monitoring of glycated hemoglobin (A1C) levels, diabetic patients should receive an annual depression screen to facilitate treatment and referral. Yet in the outpatient setting, depression screening is an underutilized tool. The overarching purpose of this project is to address and treat the depression in patients with diabetes, and to decrease A1C levels and ultimately improve chronic disease outcomes.

A literature review explored interventions to improve chronic disease outcomes in adults. Selected studies revealed common themes that impacted outcomes in diabetic patients and included missed appointments, elevated A1C levels with co-existing depression, and missed depression diagnosis.

This project explored outcomes associated with implementation of scheduled depression screening for patients with diabetes age 18 to 64 in an urban community internal medicine clinic. All diabetic patients were screened with the Patient Health Questionnaire-9 (PHQ-9) at follow-up appointments over a 4-week period. Demographic data and the severity of depression measured by the PHQ-9 score will provide descriptive analysis of the screened populations. Measures of central tendency and spread will also be analyzed. The measurable outcomes include the following: number of diabetic patients who were not being treated for depression at the time they completed the questionnaire, and whose responses to the PHQ-9 would support a diagnosis of depression.

Consistent screening will support treatment and referral of diabetic patients whose PHQ-9 result indicates depression. This cost-effective intervention may reduce complications of diabetes, and help patients manage their A1C levels.

At community internal medicine practices internationally, there is room for improvement in diabetes follow-up care. Additional monitoring strategies may lessen emergency department visits and hospital readmission for all patients with diabetes. The goal is to identify these high-risk patients, screen for depression, and ensure follow-up care. Given the minimal effort and cost of depression screening, outpatient clinics internationally may consider routinely screening patients with diabetes for depression.

RSG STR 2 - Rising Stars of Research and Scholarship Invited Student Poster Session 2 Is Less More? Pediatric Intractable Migraine and OnabotulinumtoxinA Treatment

Tara Ayn Pezzuto, APRN, RN, MSN, PCNS-BC, USA

Abstract

Objectives: The objective of this study was to analyze pediatric and adolescent chronic daily migraine response rates to modified doses of onabotulinumtoxinA.

Background: Chronic migraine occurs in about three percent of pediatric headaches. Some children and adolescents are intractable to two or more preventive medications. OnabotulinumtoxinA, 155-200 units every three months was approved by the US Food and Drug Administration for the use of chronic migraine in adults in 2010. Data on effectiveness and tolerability in the pediatric population is very limited. Standard dosing is not established for children.

Methods: A retrospective chart review of forty-four patients' between 11 and 21 years of age who had 15 or more headache days a month and had been intractable to at least two different prevention medication treatments for chronic daily headache prior to receiving OnabotulinumtoxinA . There were 35 female patients and 9 male patients. Those who received onabotulinumtoxinA for treatment of chronic migraine in a pediatric headache center from February of 2014 to March of 2016 were analyzed. OnabotulinumtoxinA is offered to any pediatric or adolescent patient coming to the clinic for chronic migraine if they fail two or more preventive medications. Dosing was based on location of pain and tolerance of the procedure. Injection sites were outlined based on adult standard dosing suggestions. The review analyzed age, sex, diagnosis, location of pain reported, doses of onabotulinumtoxinA tried, quantity of injection sets, and response to treatment.

Results: Seventy percent of this population decreased their headache frequency and/or intensity by at least fifty percent. Forty-eight percent had less than two headaches a month. Ninety four percent of those that responded positively did so with less than one hundred and ten units of onabotulinumtoxinA.

Conclusions: This suggests that "less is more" in the pediatric and adolescent dosing of onabotulinumtoxinA for treatment of chronic daily migraine.

RSG STR 2 - Rising Stars of Research and Scholarship Invited Student Poster Session 2 Evolving Attitudes Toward Research in Undergraduate Nursing Honors Students

Shana Porter, BSN, RN, USA

Paige Mocek, BSN, RN, USA

Desiree Hensel, PhD, RN, PCNS-BC, CNE, USA

Abstract

Purpose: While there is a growing body of literature that supports the use of undergraduate research to capture student interest and to create enthusiasm that leads to higher levels of engagement, there are many unanswered questions about what models lead to best student learning outcomes. Q methodology, or Q for short, is a set of philosophical principles, data collection techniques, and statistical procedures to study subjectivity that can be used to generate theory, test theory, or evaluate program outcomes (Hensel, 2016a; Ramlo, 2015; Ramlo, 2016). When used for undergraduate research, Q is thought to contribute to positive student and faculty outcomes (Hensel, 2016b). The purpose of this project was to evaluate changes in attitudes about research among a cohort of five nursing students who conducted Q methodology studies as part of an undergraduate honors program.

Methods: Institutional Board Review (IRB) was obtained to conduct this Q methodology study. The five nursing honors students generated a set of statements, referred to as the concourse, which reflected both positive and negative beliefs about undergraduate research. Statements from the literature research supplemented the naturalist concourse. After reviewing all statements for range and repletion, 36 statements were retained and printed individually on a deck of cards for sorting. The 5 nursing research honors course students were asked to rank order their level of agreement and disagreement on a -4 to +4 sorting sheet with each statement based under two conditions of instructions. First they sorted the items based on their current attitudes about research, after having participated in one semester of the nursing honors program. During this semester students had completed their literature review, designed their Q study and submitted their proposal to IRB. One student had collected data, but not yet analyzed it. Next students completed a second sort based on how they felt about research before they began the honors program. Data analysis, including principal component factor analysis, was completed using a standard process described by Watts and Stenner (2012) with Ken Q software.

Results: Participants generally disagreed with the statement "research isn't important for my career." A 2-factors final solution explained 70% of the variance. Factor 1 explained 42% of the variance and was characterized by the statements "undergraduate research could distinguish me among other graduates," and "doing undergraduate research could help me get into advanced education programs, like graduate school." Seven sorts loaded on Factor 1, including all sorts completed under the current attitudes conditions of instructions. Factor 2 was characterized by the statements "undergraduate research is intimidating" and "I don't have enough time to participate in undergraduate research." This factor explained 28% of the variance with 3 positive loading of sorts done based on attitudes before engaging in the honors program.

Conclusion: This is the first study to look at outcomes from using Q methodology for undergraduate nursing honors research. This study found that while students had overall positive attitudes toward the importance of research, it was intimidating to some. After engaging in one semester of an honors program and designing a Q study all students strongly believed that they benefited professionally from participation in the program. The structured processes associated with doing a Q study are thought to support meaningful research that can be completed by undergraduates (Hensel, 2016), but what role study design played in the shifting of three students' perspectives is unclear. Future research is needed to understand how research design impacts student success in undergraduate research.

RSG STR 2 - Rising Stars of Research and Scholarship Invited Student Poster Session 2 Nurse Manager Perspectives on Internationally Educated Nurses (IENs) and Hiring Practices in Long-Term Care

Katrina Haynes, BSN, RN, Canada
Barbara Astle, PhD, RN, Canada
Margery Hawkins, PhD, RN, Canada

Abstract

Internationally Educated Nurses (IENs) are an integral part of Canada's nursing workforce. However, when nurses immigrate to Canada they often encounter many barriers, from being a newcomer to successfully practicing nursing in the Canadian context. These barriers have been well documented and include hurdles at every step of the process of becoming a Registered Nurse (RN) in Canada, for example, with immigrating; obtaining nursing certification, which may involve taking a language test, writing the RN Licensing exam, or upgrading their skills and taking additional courses, prior to finding employment; and lastly, with successfully integrating into a new workplace. Much of the literature about IENs focuses on the various issues they encounter from their perspective; however, there is a gap in the literature that fails to address the hiring practices of Nursing Managers. A better understanding of the hiring practices of Nursing Managers may benefit IENs and nurse educators by making them aware of employers' expectations. A qualitative study using Interpretive Description was used to explore the perceptions and experiences that influence the hiring practice decisions of Nursing Managers in long-term care settings who employ IENs with Canadian RN licensure. Semi-structured interviews were conducted with seven Nursing Managers in long-term care settings in Western Canada. Thematic analysis guided interpretation of the emerging themes. The three themes are 1) *Acknowledging the Complexities*, 2) *Finding the Right Fit*, and 3) *Navigating Differences*. The results will be discussed as they relate to the hiring practices of Nursing Managers of IENs in long-term care settings, as well as, the application of the findings to other practice settings, nursing education, professional nursing organizations, and immigrant serving organizations that assist IENs with their transition to nursing employment. Gaining insight into the hiring practices of Nursing Managers may provide better support for IENs finding gainful employment and ensure their successful transition into the workplace. Implications for nursing and recommendations for further research related to understanding the hiring practices of IENs by Nursing Managers in other settings will be discussed.

Use of a Wellness Coaching Model Among Urban-Dwelling, Low-Income Older Adults

Bertha Lee, BSN, RN, USA

Abstract

Older adults, age 65 years or over, currently represent 14.5% of the United States (U.S.) population. This value is projected to more than double to 98 million by 2060 (AoA, 2015) as an increasing number of older adults, both rich and poor, are living longer in the presence of chronic disease and illness symptoms (National Center for Health Statistics (US) & National Center for Health Services Research, 2012). Compared to younger individual, older adults are more likely to experience repeated hospitalizations and/or unplanned visits to their health care provider, and face increased costs to manage their health (Lehnert et al., 2011). Prolonged life, desired by many, brings new challenges. Older adults often struggle to maintain quality of life and independence in the presence of complex, chronic diseases and prevailing illness symptoms; for low-income elders with limited access to a resourceful, supportive environment, these challenges are even more profound (Huguet, Kaplan, & Feeny, 2008).

Partnering with the Boston Housing Authority (BHA), this pilot project implemented a wellness coaching model consisting of a comprehensive, geriatric assessment, an individualized healthy aging plan, and continued coach contacts to increase health self-management. Troutman's theory of successful aging, that supports individual determination of successful aging and an action plan to achieve life goals provided the theoretical foundation. Troutman's theory of successful aging involves three coping processes: 1. functional performance mechanisms, 2. intra-psycho factors, and 3. spirituality (Topaz, Troutman-Jordan, MacKenzie, 2014). Functional performance mechanisms refer to the use of conscious awareness and choice as an adaptive response to physiologic and physical aging. Intrapsychic factors are the innate features that contribute to the person's ability to adapt to change and solve problems. Spirituality consists of the person's beliefs and views that relates to something greater than self. Each of the three processes contribute to the complex process of gero-transcendence and, ultimately, successful aging.

The primary purpose of this study was to determine if low-income older adults who participate in a personalized wellness coaching model will have increased self-management behaviors (i.e. physical activity) as compared to a wait-list control group. The study sample included minority older adults residing in one of two BHA sites. Fifteen participants (5 females and 10 males, mean age 77.4 ± 7.9 years) were assigned to the intervention group and 13 older adults (7 females and 6 males, mean age 75.8 ± 9.1 years) from another BHA site made up the control group, crossing over to the intervention six months later. Assessment tools used were interRAI's Health & Social Check-up and the Lifestyle Survey.

Independent and paired t-tests ($p < 0.05$) were calculated to compare baseline and follow-up results. There was statistical improvement of physical activity in both Amory Groups 1 ($p < 0.02$) and 2 ($p < 0.016$) and the PAM score ($p < 0.05$) in Amory Group 2. Self-reported quality of life statistically decreased in the control group at Holgate.

The Prevalence and Perceived Benefit of Prescribed Anti-Anxiety Medications Used by BSN Students in Virginia

Lauren M. Atkins, SN, SN, USA

Abstract

There is no published literature that addresses the prevalence of prescribed anti-anxiety medications used by nursing students, nor are there any published studies that reveal the perceived benefit of prescribed anti-anxiety medications used by nursing students to alleviate the stress of nursing school. However, nursing students self-report widespread stress and anxiety related to the nursing education environment and the use of prescribed anti-anxiety medications to help alleviate the stress.

The literature does address the prevalence of stress in the nursing education environment and the detrimental effects of this stress on nursing students including their ability to effectively learn. There is also published literature among associated professional fields including medicine, social work, pharmacy and dental students, all addressing the negative impact of stress on the learning of students in these environments. Sources of stress include the clinical environment, tests and exams, interactions with faculty, social isolation, and simulation exercises. Interventions typically advocated for use include meditation, exercise, reflection, counseling, journaling, mindfulness and yoga. Use of prescribed medications is not typically advocated, but is thought to be in widespread use.

The purpose of this study was to begin to understand how wide-spread the use of prescribed anti-anxiety medications is among BSN students in Virginia, and to determine the perceived benefit of the medications to the nursing students. This was a descriptive study and participants were nursing students in attendance at the Virginia Nursing Students Association annual meeting.

Students completed a survey that was distributed at registration at their annual student nursing conference. The survey form asked about their experiences with nursing program related anxiety and methods they commonly use to manage the anxiety, including the use of prescribed anti-anxiety medications. Responses were tallied and descriptive statistics will be reported. Survey responses show that participants in the study overwhelmingly listed sources of stress requiring anti-anxiety management including prescriptions to manage stress associated with clinical learning, simulation experiences, assignments, exams, faculty interactions and social isolation.

RSG STR 3 - Rising Stars of Research and Scholarship Invited Student Poster Session 3 Sexual Decision-Making of Rural Men Who Have Sex With Men

Jessica A. Lecea, BSN, RN, USA

Peri L. Kane, BSN, RN, USA

Greg A. Carter, MSN, BSN, RN, CNS, USA

Desiree Hensel, PhD, RN, PCNS-BC, CNE, USA

Abstract

Background: According to the Centers for Disease Control and Prevention ([CDC], 2016b), men who have sex with men (MSM) experience greater rates of sexual transmitted infections (STIs) and sexual health disparities compared to heterosexual individuals. Sexual-orientation based discrimination, violence and stigma contributes to this issue by building larger barriers to access and utilization of sexual health services (Hubach, 2015; Satcher, Hook, & Coleman, 2015). In order to access sex without provoking physical assault, jeopardizing communal ties or creating intrapsychic dissonance, some rural MSM utilize venues and practices that are linked to flawed risk reduction behaviors and the contraction of STIs (Hubach et al., 2015; Lewnard & Berrang-Ford, 2014). While representing four percent of the national population, the MSM rate of newly diagnosed HIV cases is forty-four times that of heterosexual males (CDC, 2016a). This disproportionately affected group lacks medical treatment with only 39% of MSM living with HIV receiving care (CDC, 2016a). The World Health Organization ([WHO], 2016) released a call to action to provide comprehensive and effective interventions aimed at HIV prevention and treatment of MSM in all countries regardless of income. Previous research stresses the importance of not viewing the MSM community as a homogenous group, but rather recognizing the existence of MSM subcultures and crafting interventions based on their individual beliefs and behaviors (Prestage et al., 2015). Yet, current literature has not fully explored factors that influence sexual decision making of rural MSM.

Purpose: The purpose of this study is to explore which factors in sexual decision making are most important to men that have sex with men from rural communities.

Method: The research study uses Q methodology, a mixed methods approach that uses a set of philosophical principles, data collection techniques and statistical procedures to quantitatively study subjective beliefs and attitudes in regards to a particular topic (Ramlo, 2016; Watts & Stenner, 2012). Q methodology begins by populating the concourse, which is a complete set of opinions a group may say or think about a specific topic (Watts & Stenner, 2012). The concourse for this study was derived from previously conducted in-depth qualitative interviews with rural MSM and extant literature on sexual decision making patterns of rural MSM. The statements reflected sexual decisions based in social/intrapsychic safety, such as "I feel as though I would be physically attacked if I was found engaging in sex with men in a rural area" and sexual health risks, such as "I am not concerned with STIs because they can be treated". After inspection of range and repletion, a subset of 44 subjective statements were retained to create the Q sample. The Q sample was reproduced on individual cards to be used in the sorting process. The recruited sample consisted of no more than 20 men that are 18 years of age or older, have resided in a rural area during childhood (ages 3-18), and has engaged in sexual activities with men. The Index of Relative Rurality will be used to determined rurality. Eligible participants will be asked to complete a demographic questionnaire and Q sort. The Q sort involves each participant reviewing and ranking the statements based on his level of agreement and disagreement to factors in sexual decision making. Each participant will record his rankings on a -5 to +5 distribution sorting sheet. Two follow-up questions will be used to obtain deeper insight of participants' top rankings. The study was approved through the Indiana University Institutional Review Board (IRB).

Results: This research study is ongoing. The results of this study will reveal which factors related to sexual decision making are most important to rural men that have sex with other men. Data will be analyzed using a standard process through principle component factor analysis and varimax rotation followed by calculating factor scores (Watts & Stenner, 2012). Data analysis will be completed using KenQ web-based software. The factor array will be used to identify common factors and viewpoints. This

information will be interpreted through the lens of Simon and Gagnon's sexual scripting theory in context of the demographic questionnaires and the follow-up questions.

Discussion: The results gathered from this study will inform the development of targeted sexual health-based interventions tailored to this at-risk population. As a frontline provider addressing health disparities, nurses are essential to intervening on this pressing issue. In order to do so, nurses must be informed of the STI/HIV epidemic and able to identify underlying decision-making factors perpetuating the ongoing outbreak. By engaging nurses in the care of at-risk populations to address one of the most significant and devastating epidemic in recent history, healthcare professionals will be able to optimize the health of this disproportionately affected group on a global level.

Association Among Cachexia Syndrome, Symptom Distress, and Quality of Life in Pancreatic Cancer Patients

Yun-Jen Chou, MS, RN, Taiwan
Shiow-Ching Shun, PhD, RN, Taiwan

Abstract

Background: Cachexia syndrome is common in pancreatic cancer patients, and it will increase the mortality rate and decrease quality of life (QoL). However, there is no study with longitudinal design to explore the relationship among cachexia syndrome, symptom distress and QoL. Therefore, this study was to explore if the cachexia syndrome pre-operation was the significant factors to predict the longitudinal QoL after operation.

Methods: A longitudinal design was used in this study, and the data collected at 1–2 weeks before operation (T0), 2 months (T1), 3 months (T2), and 6 months (T3) after operation. Patients who scheduled to operate were recruited from surgery clinics at a medical center in Taipei. A structured questionnaire with Fatigue Symptom Inventory, Symptom Severity Scale, and Functional Assessment of Cancer Therapy-General Scale were used to collect patients' fatigue, symptom distress and QoL, respectively. In addition, the questionnaire included patients' demographic and clinical characteristic. In this study, cachexia syndrome was defined as patients' total body weight loss > 5% over the past 6 months. The generalized estimating equation (GEE) was used to examine the significant associated factors with QoL after operation.

Results: Totally, 45 pancreatic cancer patients participated in this study. Among patients, 64.6% (N=29) was recognized as cachexia syndrome. Patients with cachexia syndrome had more percentage to accept chemotherapy ($\chi^2=9.504$; $p=.002$), suffer from fistula after operation ($\chi^2=5.237$; $p=.022$), and had higher level of fatigue intensity ($t= -2.889$; $p=.06$) and duration ($t=-2.363$; $p=.023$) than those with non-cachexia syndrome. In the GEE analysis, the patients with higher level of symptom distress had lower level of QoL ($\beta = -.323$, $p < .0001$) after control the significant different factors at baseline between the two groups.

Conclusions: This study found that cachexia syndrome wasn't a significant associated factor with QoL. In addition, symptom distress was the significant factor affecting longitudinal QoL in pancreatic cancer patients. Therefore, healthcare providers should pay more attention and assist pancreatic cancer patients to manage symptom distress since they diagnosed to increase the level of QoL.

Decisions of Chinese Dialysis Patients and Caregivers About Care Priorities at Final Stage of Life

Paul Chi-wai Lee, MSocSc, MHA, BN, RN, FHKAN, Australia

Glenda Parmenter, PhD, RN, MRCNA, MAAG, Australia

Yoni Luxford, PhD, GradDipPHC, GradCertTertTeach, BSW, CertMidwifery, CertNurs, RN, Australia

Abstract

Background: End-stage renal disease involves progressive and irreversible kidney damage leading to permanent loss of renal function. The progression of the underlying disease, emergence of complications, and gradual decline in functional status and quality of life leads many patients to withdraw from dialysis, and in Hong Kong, this withdrawal is a common cause of death (28.5%) (Hong Kong Renal Registry, 2013). Despite this high mortality rate, the decision-making process about care priorities at end-of-life (EOL) has not been stressed within this dialysis population (Bristowe et al., 2015; Ceccarelli, Castner, & Haras, 2008; Haras, 2008). Traditionally, death and dying that has long been a taboo in Chinese culture and patients and health care professionals avoid discussion of the topic (Leung, 2010). Therefore, healthcare professionals and the patients' family members often encounter dilemmas when patients undergoing dialysis reach the terminal phase of their disease but have never discussed their end-of-life care priorities or made decisions related to withdrawal of life-sustaining therapy (Baharoon et al., 2010; Davison, 2012; Kurella Tamura, Goldstein, & Perez-Stable, 2010). In addition, the mixed Eastern and Western culture in Hong Kong as it was the British colony for over 150 years, might affect the thought and belief of the local population towards the decision-making process at end-of-life.

Purpose: Given that few studies have explored the decision-making processes of dialysis patients and their carers regarding end-of-life care, especially in the Chinese context, the purpose of this study was to fill this research gap. This study also aimed to explore the effect of culture on communication about the decision-making process, to learn more about a previously hidden topic in Hong Kong. The findings of this study will also inform healthcare professionals about strategies for communication with Chinese renal dialysis patients concerning decision-making at the patient's final stage of life.

Methods: A mixed methods, sequential, explanatory design was adopted and purposive sampling was used to recruit dialysis patient and carer informants in a regional renal dialysis centre in Hong Kong. The quantitative, descriptive data were analysed and Spearman's rho correlation was applied to test the associations between the characteristics of dialysis patients and their carers as well as the variables of decision-making. The results were used to guide the formulation of the questions to be asked in subsequent focus group interviews. As the researcher adopted a qualitative driven mixed methods design in this study, by applying the ethn nursing qualitative research method, the researcher identified the domain of inquiry, formulated the research questions, reviewed the literature to distinguish gaps related to the domain of inquiry, and developed the research plan and method of data analysis. Likewise, the qualitative data were analysed according to the Leininger's phases of ethn nursing data analysis. Themes were synthesised to inform the renal speciality practice.

Results and findings: Of the 121 dialysis patients and 61 carers informants who participated in this research project, 86% of patients and 80.3% of carers preferred their family members to make treatment decisions when reaching the terminal phase of their disease. However, majority of the patient informants had not discussed their preferences or care priorities with anyone. While 42.1% of dialysis patients reported knowledge of the end-of-life care, the majority (81.8%) were not aware of advance directives but 83.5% of them claimed would adopt advance directives if it were available. Comparing with the dialysis patients, it seems carers had more knowledge on end-of-life care (50.8%) and advance directives (36.1%). Whereas, 90.2% of carers were willing to make an advance directive if it were available. Both groups expressed their opposition to life-sustaining measures, such as mechanical ventilation, in the event of terminal illness. However, they felt constrained from asking or talking to medical professionals

about EOL care during the clinic consultations. Based on the findings from the focus group interviews, the patient informants considered communication barriers, Chinese cultural norm and dying in dignity were the major themes in the decision-making process at their EOL domain. Whereas, personalising care, normalising life, sharing burdens and carer's plight were expressed and delineated from the carer informants.

Discussions: There are universalities and diversities in the findings between the present study and the current literature. As shown, majority of the dialysis patient and carer informants preferred their families to make the decision of EOL care for them that is similar to other local studies (Chu et al., 2011; Mok, Ting, & Lau, 2010; Wong et al., 2012). In fact, the majority of the American dialysis patients chose to make the decision themselves (Davison, 2012). As reflecting in the collectivistic Chinese culture that families should make important medical decision for the patients; contrary, patients with the belief of individualism from the Western culture grasp their autonomy in the decision-making process. Commonly, dialysis patients seldom discuss EOL care preferences with others (Davison, 2010; Janssen et al., 2013; Miura et al., 2006). Whenever there are discussions on the preferences of care, the majority of the patients and carers in this study would like to involve the families as first priority, comparing with some oversea studies that doctors would be primarily involved (Lockett et al., 2014; Morton, Tong, Howard, Snelling, and Webster, 2010). In the present study, the interrelated effects of communication barriers, family dynamics, sharing burdens and existential distress were formulated from the emic views of the informants. The central philosophy of the decision-making process of care priority at the final stage of life for dialysis patients is established as "dying with dignity". The end-of-life communication allows patients to express their preferences for life-sustaining treatments, knowing and respecting the end-of-life wishes can improve the patients' sense of control as well as preparing for good death. Efficient and honest communication among patients, carers and healthcare professionals not only can enhance the independency and autonomy in making medical decision but also can facilitate the family-centred system for the purpose of shared decision-making. Importantly, it should be acknowledged that the dialysis patients and carers always have tension and struggle in the decision-making process, shifting between Eastern and Western culture in the context of Hong Kong. Moreover, the family relationship and filial piety are the major components of the traditional Chinese culture although there is growing demand for the western autonomy system from the patient informants. By knowing the specific cultural pattern in Hong Kong, healthcare professionals can be more understandable from the emic & etic views of care priorities at dialysis patients' final stage of life. Hence, the decision outcomes are perceived as individualised, situational, and contextual in which culture plays a central influence.

Implications for practice: Throughout the research process, informants in the quantitative and qualitative strands were surely stimulated and affected by the survey questions or the questions asked in the focus group interviews. In fact, strategies have to be developed to enhancing the communication channel among dialysis patients, carers and healthcare professionals; and facilitating shared decision-making for the patients at their final stage of life. It helps to focus on the discussions about the dialysis patients' understanding of their illness, personal experiences with death, their goals and values towards the final stage of life. Further, service innovation project is recommended to develop culturally oriented advance care planning at the time of commencing the dialysis and in consultation with patients and carers.

Conclusions: The overarching influence of culture supports the main findings from the study and answers the research questions derived from the domain of inquiry. Findings from the quantitative or qualitative strand could articulate the aim of this study, and they inform healthcare professionals about the culture related, perspectives of care priorities for dialysis patients. Moreover, the dialysis patients should have understood their physiological and psychological needs to face the changes in the trajectory of the disease process so as to prepare and plan appropriately and accordingly. Obviously, advance care planning should be promoted for the patient's body and mind. Let them have a sense of integrity and ready to die. Crucially, every dialysis patient should have the right to leave the world in the manner of dying with dignity.

RSG STR 3 - Rising Stars of Research and Scholarship Invited Student Poster Session 3 Screening for Palliative Care Patients By Utilizing Clinical Decision Support Within the Electronic Health Record

Tanja Baum, PhD, RN, USA
Ruth A. Bush, PhD, MPH, USA
Caroline Etland, PhD, RN, USA
Cynthia D. Connelly, PhD, RN, FAAN, USA

Abstract

Purpose: Approximately \$1.3 million annually can be saved when 500 palliative care consults are completed within the acute care setting. With 90 million Americans, of whom 20% are Medicare recipients that suffer from chronic medical conditions, 500 consults are not a distant number. The electronic clinical decision support and utilization of triggers to identify individuals who might benefit from palliative care using an algorithm within the electronic health record (EHR) can enable the multidisciplinary team to facilitate palliative care services.

The purpose of this feasibility study was to utilize variables available in the EHR of palliative care patients receiving palliative care services (PCS) in the acute care setting.

Aim 1) Characterize EHR data related to palliative care consultations among severely and chronically ill patients in the acute care

Aim 2) Examine relationships between the list of clinical EHR data, and select demographics (age, gender, race, ethnicity, religion), in a sample of palliative care patients

Methods: A descriptive, correlational study using de-identified retrospective data, collected from January 1, 2013 to December 31, 2015. An institutionally derived list of variables was used to provide a foundation for clinical decision support and patient identification integrated into the Cerner EHR system. Data were derived from three hospitals of a large multi-community healthcare system in San Diego County, California (USA). Descriptive and inferential statistical analyses conducted using SPSS version 23.

Results: A randomized sample yielded 694 palliative care patients seeking acute care treatment at one of the three hospitals. Significant associations were found between patients' race/ethnicity and code status ($X^2= 11.26, p .16$), and language and the presence of an advance directive or physician orders for life-sustaining treatment (POLST) ($X^2= 13.845, p .008$).

Conclusion: Using a large sample, a number of statistically significant demographic, physiologic, and clinical variables were found. Integrating the EHR system to its fullest can not only aid nursing, but the entire interdisciplinary team in enhancing quality of life of palliative care patients and their families. Documents such as the advance directive or the POLST can be saved electronically and are readily available throughout the entire hospital system. Furthermore, multiple translated versions may be available for the patient, decreasing language barriers that could prevent patients from making their wishes known. Further research is needed to include the entire hospital population and to extend beyond a single healthcare system to increase diversity.

Using Participatory Action Research to Develop Culturally Appropriate Aboriginal and Torres Strait Islander Health Resources

Rachel Margaret Peake, SN, RN, Australia

Kim Usher, PhD, MNSt, AM, RN, BADipAppSc (Nsg), FACN, FACMHN, Australia

Jackie Lea, PhD, MN (Hons), BN, RN, Australia

Debra Jackson, PhD, RN, FACN, United Kingdom

Abstract

Nationally, cardiovascular disease is responsible for 27% of the gap in fatal burden between Australian Indigenous and non-indigenous people. Improving Aboriginal and Torres Strait Islander health in Australia is thus a high priority (AIATSIS, 2012; Mikhailovich, Morrison, & Arabena, 2007).

One way to improve health is to have adequate health resources. Traditionally, Aboriginal and Torres Strait Islander communities educate their people through stories and art and the lived experience of people in their community. Health literacy for Australian Aboriginal and Torres Strait Islander people needs to be developed using these approaches to make the resource more culturally appropriate.

The purpose of the study was to evaluate the process of developing culturally appropriate localised Aboriginal and Torres Strait Islander health promotion resources that are acceptable and sustainable for Aboriginal and Torres Strait Islander community of the Gamilaraay/Gomeri people in the Peel and Mehi Sector of Hunter New England Local Health District. Thus gaining an understanding of the processes and collaborative approach involved in developing stroke health resources for the Gomeri/Gamilaraay people.

The community wanted a research project that could plan for change by acting then reflecting on what they found and observing the consequences, to inform further action and change. The community used the analogy of the ever changing river system, never static always moving changing and evolving to make sense of what they wanted from the research project.

Participatory Action Research (PAR) was used to guide the development of culturally appropriate educational resources. It was considered a collaborative and safe way to uncover vital information and concepts to underpin the development of health resources. PAR reflects the way Aboriginal people embrace learning through action, collective decision-making and empowerment, which occurs via group activity over time. The mutual inquiry and learning experience in this study was aimed at reaching agreement and mutual understanding of the situation, resulting in an unforced consensus about what to do and what can be achieved together (Kemmis & McTaggart, 2005, p. 577).

The paper will discuss the adoption of the PAR approach and describe how PAR helped to promote self-determination, self-reliance and the creation of a useful, localised health resource that is relevant to the community involved.

Impact of Motivational Workshops on Lifestyle Modification to Increase Physical Activity

Manju Daniel, PhD, MSN, FNP-BC, USA

Gagandeep Singh, BSN, N/A, USA

Courtney Crutchfield, BSN, N/A, USA

Abstract

Background: More than 68% of the people in all racial categories in the United States are either overweight (BMI 25-29.9) or obese (BMI 30+). Overweight and obesity are two significant risk factors for type 2 diabetes and heart disease (National Institute of Diabetes and Digestive and Kidney Disease, 2012). Approximately 29 million people have diabetes in the United States. Heart disease is one of the serious complications associated with diabetes. More than 70% of the people diagnosed with diabetes were found to have hypertension. In addition, the cardiovascular disease death rates were about 1.7 times higher in adults with diabetes (Centers for Disease Control and Prevention, 2012). About five million adults age 35 years and older with diabetes in the United States also have coronary heart disease (Centers for Disease Control and Prevention, 2017 a). Heart disease is the leading cause of death for both men and women. More than 600,000 people die of heart disease in the United States every year. Coronary heart disease is the most common type of heart disease and about 370,000 people die of coronary heart disease in the United States every year. The number of people getting first heart attack is even higher (about 525,000) in the United States every year (Centers for Disease Control and Prevention, 2017 b). These chronic health issues can have a negative impact on a person's quality of life and can add undue financial burden to the healthcare system in the United States. Routine physical activity component as a part of one's daily routine activities, can help lower one's risk of coronary heart disease, blood pressure and cholesterol level (National Institutes of Health, 2016). Regular physical activity, which includes participation in moderate and vigorous physical activities, is important to lower the risk of such chronic illnesses and to maintain as well as improve the health and quality of life (United States Department of Health and Human Services, 2008). Despite being aware of the benefits of physical activity, many people fail to prioritize incorporating physical activity into their daily routine. More than 80 percent of adults fail to meet the recommend physical activity guidelines (at least 150 minutes a week of moderate-intensity, or 75 minutes a week of vigorous-intensity aerobic activity, or an equivalent combination of moderate- and vigorous- intensity aerobic activity) in the United States (Office of Disease Prevention and Health Promotion, n.d., United States Department of Health and Human Services, 2008). Therefore, there is a need for creative strategies that could motivate people to find ways be more physically active to meet the recommended physical activity guidelines. Motivational workshops that focus on physical activity could help people to learn how to prioritize routine physical activity as one of their daily lifestyle activities.

Purpose: The purpose of this study was to perform an integrative review to identify and analyze the existing research literature on motivational workshops to increase physical activity.

Methods: A literature review was performed by searching computerized databases, including Medline, Medline Science, ProQuest, and Cumulative Index of Nursing and Allied Health (CINAHL), focusing on social cognitive theory, motivational workshops and physical activity. The literature review included the studies published within the last ten years. Using the keywords motivational workshops and social cognitive theory, a total of 810 published studies were found (2 CINAHL, 787 ProQuest, 2 Medline and 19 Medline Science). Using the keywords motivational workshops, social cognitive theory, and physical activity, a total of 610 published studies were found (1 CINAHL, 601 ProQuest, 1 Medline and 7 Medline Science). Using the keywords motivational workshops, social cognitive theory, and physical activity, and restricting by English only total of 608 published studies were found (1 CINAHL, 599 ProQuest, 1 Medline and 7 Medline Science). Using the keywords motivational workshops, social cognitive theory, and physical activity, and restricting by English and adults only total of 60 published studies were found (1

CINAHL, 51 ProQuest, 1 Medline and 7 Medline Science). Further, the studies that were duplicate and that focused on areas other than physical activity such as mental health issues, addictions, pain management, infections were excluded. Thus, a total of eight interventional studies that focused on motivational workshops for physical activity were included in the final review. The physical activity framework for South Asian Indian Immigrants and Bandura's social cognitive theory guided the development of data collection tools. The data collection tools included background and intrapersonal characteristics. The measures of background characteristics included current health, social interaction, and anthropometric measurements. The measures of intrapersonal characteristics included motivational workshops. In addition, the measures of physical activity included subjective and objective measures. The subjective measures of physical activity included self-reported number of days and time spent in physical activity and the objective measures included pedometers and accelerometers. In addition, the measure of six step approach was used to evaluate the impact of motivational workshops on lifestyle modification to increase physical activity.

Results: The main components of motivational workshops were onsite physical activity sessions and telephone counseling sessions. All studies reported that lifestyle modification workshops resulted in increased aerobic physical activity. In addition, the motivational workshops had a positive impact on background correlates of physical activity including decreased body weight, decreased blood pressure, decreased blood sugar level, increased quality of life, increased physical functioning, and increased social interaction. Similarly, the motivational workshops had a positive impact on intrapersonal correlates of physical activity that included increased self-efficacy for physical activity and increased motivation to be more physically active.

Conclusion: Motivational workshops have a positive impact on lifestyle modification for increasing physical activity. Motivational workshops need to focus on personal as well community awareness about the positive impact of lifestyle modification for lowering the risk of chronic preventable illnesses, healthy weight management, mental and emotional wellbeing. Six-step approach that focuses on creativity in incorporating physical activity in a person's daily routine, is found to be effective for the motivational workshops in successfully resulting in positive lifestyle behavior modification in increasing physical activity and healthy nutrition. The six-step approach includes: a) building a partnership, b) negotiating an agenda, c) assessing resistance and motivation, d) enhancing mutual understanding, e) implementing a plan, and f) following through. Healthcare professionals need to change their professional approach from giving information and advice to acting as a motivational guide for patients. Findings from these studies will be utilized in designing the motivational workshops for the clinical settings for lowering the risk of cardiovascular disease, diabetes, and obesity.

Fear of Cancer Recurrence: Experiences and Related Factors in Early Stage Lung Cancer Patients

Yu-Ying Chou, MS, RN, Taiwan
Yeur-Hur Lai, PhD, RN, Taiwan

Abstract

Background: In recent years, early lung cancer became the most common cancer in the worldwide and most of them have psychological problems (anxiety and depression). However, few study was discussed about fear of cancer recurrence (FCR) in the patients after surgery.

Objective: The aim of this study was to explore experiences and related factors of FCR in early stage lung cancer patients in Taiwan.

Methods: A cross-sectional correlation study was conducted and total 200 early stage (stage I-3A) lung cancer patients were recruited in outpatient center after post-surgery. We measured by the structure questionnaire including the Karnofsky performance score (KPS), Hospital Anxiety and Depression Scale (HADS), and Fear of Cancer Recurrence Inventory-Short Form (FCRI-SF, range: 0-36). Using independent t-test, one-way ANOVA, and Pearson's correlation coefficient to identify the significant factors were related to FCR.

Results: Mean age was 59.4(SD=11.7) years and more than half of patients were male (59.5%), low income (51.5%), non- smoker (71%), unemployment (60.5%), good of pulmonary (FVC=95.6±15.4), and well physical function (KPS>90=70%).

The results revealed most of patients without anxiety or depression problems (mean score:3.8±4.1, 3.8±3.9, respectively) but underwent mild to moderate levels of FCR (mean score: 13.0±6.0). The top severe item in FCRI-SF was "When I think about FCR, other unpleasant thoughts or images come to mind (death, suffering, consequences for my family)". Younger age, higher education level, anxiety, and depression were significant associated with more serious of FCR. The most use of coping strategy was "I try to convince myself that everything will be fine or I think positively." Female, has religious belief, non-smoker, and good pulmonary function were significant related to better of FCR coping strategies.

Conclusions: Age, education, and psychological status (anxiety and depression) were the important factors were associated with FCR, but most patients even had well psychological status not mean that they without FCR problem. In future, the rapid of convenience and brief assessment have to develop and practice in clinical practice, and giving efficient intervention to the patients with higher levels of FCR.

Comparative Analysis of Nursing Faculty and Student Measures of Entitlement, Narcissism, and Perceptions of Support

Peyton Marie O'Kain, BSN, SN, USA

Abstract

Purpose: Internationally, attrition of nurses and nursing faculty is well-documented (Aiken, Sloane, Bruyneel, Van den Heede, Sermeus, & RN4CAST Consortium, 2013; Van den Heede, Florquin, Bruyneel, Aiken, Diya, Lesaffre, & Sermeus, 2013). Intergenerational antagonism between the millennial generation of nursing students who are entering practice and older generations of nurses and nursing faculty may lead to high professional attrition and therefore, poor patient outcomes due to the lack of dedicated, young nurses who feel supported by those who should be mentoring them for the future. Vast generational differences exist between the upcoming cohorts of nurses, i.e. "Millennials" entering practice and those who educate, supervise, and design these millennials' education and career pathways. Older generations of nurses and nursing faculty often view students and younger nurses as entitled and unprofessional, yet the evidence supporting these assumptions and perceptions is virtually nonexistent.

The scope and purpose is to globally disseminate the results of this innovative nursing research that generated new knowledge of entitlement and narcissism plus organizational support as perceived by intergenerational nursing faculty and student participants. Investigating generational divides between faculty and students is imperative, as such divisions exist in nursing academia, research, and practice. This study demonstrated that students, particularly undergraduate, feel less supported than what faculty believe they provide in supportiveness. Millennial nursing students likely have vastly different expectations of support than previous generations (Goldman & Martin, 2016); anecdotally, such expectations are often perceived by nursing faculty as unbridled entitlement. This generational disconnect between nursing students and faculty can cause tension, miscommunication, and possibly obstruct learning and effective teaching. Exhaustive review of extant literature revealed little-to-no investigation of the relationships between perceived support and measures of entitlement and narcissism in nursing students.

Methods: After institutional review board (IRB) approval, 329 participants were recruited via email and social media; total participants were 110: 56 undergraduate students, 29 graduate students, and 25 faculty. Using psychometrically superb instruments such as the perceived organizational support scale (POSS) (Kottke & Sharafinski, 1988) and the Narcissistic Personality Inventory (NPI) (Ackerman, Donnellan, & Robins, 2012), participants responded anonymously after granting informed consent. The POSS has high internal consistency with a Cronbach's alpha of .97; the NPI has a high Cronbach's alpha of .84.

Results: Multivariate analyses revealed significant differences and predictions of generational perceptions between nursing faculty, undergraduate, and graduate students. We also ran nonparametric analyses (Kruskal-Wallis) to confirm results among the three groups of median scores. Perceptions of support, plus measures of narcissism and entitlement, differed significantly between groups and categories ($p < .05$; .01; .005; .0005). Despite nursing practice experience and presumed maturity, perceived support, entitlement, and narcissism differed significantly between nursing student groups and nursing faculty. Generational assignment does not appear to influence entitlement as heavily as hypothesized. Faculty feel they are supportive beyond what students reported. There were also strong disparities between participant beliefs regarding what elements of student performance should be factored into grades.

Conclusions: Despite pervasive cultural stereotypes of millennials, all participants plus categorical designations scored differently than hypothesized on measures of entitlement and narcissism. These new results from this innovative research are supported by previous investigation indicating that millennial

learners have different expectations of faculty than older or previous generations (Johanson, 2012). Faculty must begin to consistently examine their own generational characteristics and understand how that influences teaching and students (Roberts, Newman, & Schwartzstein, 2012). Students feel more supported by faculty when interpersonal initiatives bridge generational gaps (Roberts et. al, 2012), such as incorporated technology (Montenery, Walker, Sorensen, Thompson, Kirklin, White, & Ross, 2013). This research should be presented internationally to educate nurse scientists and educators to improve intergenerational relationships in nursing education and throughout the workforce.

Evidence-Based Symposia

D 01 - A Collaborative Curricular Response to Rehabilitative Challenges in a Global Setting

Development of a Collaborative Relationship With a Baccalaureate Nursing Program in a Developing Country

Barbara A. Ihrke, PhD, RN, USA

Abstract

After the 2010 earthquake in Haiti, teams from Indiana Wesleyan University (IWU) participated in various service projects on the Island of La Gonave. The fledgling nursing school on La Gonave, Wesleyan University of Haiti Division of Nursing Sciences (WUH), and the IWU School of Nursing, developed a collaborative relationship. It includes resource sharing, curriculum development, common didactic and clinical learning experiences, and mentoring. Since there are 3.5 nurses per 10,000 Haitians compared to 111.4 per 10,000 Americans (Pan American Health Organization, 2005), there is a shortage of nurse educators, nurse clinicians, and nurse researchers.

The collaborative relationship was developed following several on-site visits and focused on educational and clinical experiences. Goals of the collaboration are to increase the number of professional nurses in Haiti, empower the local health providers, and support the improvement of health outcomes.

Resources unavailable locally are transported as requested, for example supplies for dissection during anatomy labs. Mannequins from the IWU nursing simulation laboratory were donated and transported to the new nursing program per request of the Haitian nursing school.

Nurse educators from IWU provide lectures during each visit to La Gonave. Doctoral students from IWU gain global healthcare experiences, teaching opportunities and develop training sessions for traditional birth attendants. Haitian nursing students gain English skills, study transcultural nursing, and translate for IWU sophomore semester aboard students. Students develop friendships, study together, and learn from each other. The richness of the experiences is invaluable for all students.

DeSanti's counterpart concepts were used to evaluate the collaborative partnership (George & Meadows-Oliver, 2013). The partnership supports visiting professors, works to develop capacity of local nurses/nursing students, examines cultural and economic factors, and ascertains that all participants are full partners. The partnership is relatively new but the goal is for long-term involvement. Future goals include interprofessional research projects, conducting community needs assessments, and leadership development activities for future nurse educators.

Adapting Rehabilitative Activities to Improve Clinical Outcomes in a Limited Resource Setting

Connie J. Crump, DPT, PT, USA

Abstract

Researchers have presented evidence which has correlated the early onset of physical activity, postural control, and exercise with improved functional outcomes and physical activity (Veerbeek et al., 2014). As soon as medically safe and feasible to do so, patients should be assisted with exercise and mobility to prevent the loss of strength and function. In resource-limited areas such as La Gonave, Haiti, the most readily available health professionals are nurses. Therefore, the inclusion of several key components of physical therapy practice were integrated into nursing education at La Gonave, thus providing rehabilitative activities to neurologically impaired individuals who would not have access to therapist-provided services.

Mobilizing medically stable patients as early and as frequently as possible has the potential to stimulate recovery from neurological diagnoses like stroke, traumatic brain injury, spina bifida, and cerebral palsy in addition to diminishing complications from conditions such as microcephaly. Early assessment and implementation of rehabilitative activities to maintain or gain strength following neurological conditions can greatly impact the eventual level of independence and function throughout the recovery and rehabilitation period. The significance of educating patients and caregivers to assist with mobilization and positioning to protect against spasticity and contractures cannot be understated. Utilizing client-centered instruction for patients and caregivers regarding the appropriate use of adaptive equipment and energy conservation strategies has been linked to higher clinical and functional outcomes for patients of all ages (Pollock, St. George, Fenton, & Firkins, 2014).

Following illness or disability, one of the foremost problems acknowledged among both patients and health care professionals has been injuries resultant from unsafe patient handling techniques. The American Physical Therapy Association (2012) has endorsed physical therapists as leaders in interprofessional training for safe patient handling programs. Collaboration between physical therapists and nurse educators during the curriculum planning and didactic implementation resulted in baccalaureate nursing students using evidence-based techniques for strengthening, transferring, ambulating, and utilization of adaptive equipment or adaptive techniques fostering safety in function for patients and caregivers.

The Integration of Rehabilitative Practices in a Baccalaureate Nursing Curriculum in Haiti

Janice L. Cotrone, DNP, RN, USA

Abstract

Patients in Haiti needing rehabilitative services are often unable to access quality healthcare thus not achieving expected and desired outcomes. A four-year baccalaureate program of nursing developed and integrated numerous nurse-appropriate rehabilitative treatment modalities in collaboration with doctorally prepared physical therapists. Rehabilitative practices for infants with spina bifida, cerebral palsy, and zika-related complications, young and middle-aged adults with injuries secondary to athletic and motorcycle injuries, and older adults with stroke were developed. Interprofessional collaboration supported the integration of rehabilitative therapy into the nursing curriculum. Students learned and

practiced skills and techniques in the care of hospitalized patients and in outpatient arenas. Physiotherapy and rehabilitative techniques focused on “early mobilization, task-oriented exercises related to daily activities, and preparing individuals with different disabilities for optimal capacity and physical function” (Langhammer & Verheyden, 2013, p. 67) from admission to discharge.

First-year nursing students studied the physiology of disease pertaining to the concepts of disability, impairment, and handicap. Fundamentals of Nursing included basic bedside care of patients with functional disabilities. Second-year students studied treatments for patients with illness and injury requiring rehabilitative therapies. Skills taught included assessment of functional mobility, range of motion, and specific muscle-strengthening techniques (Hafsteinsdóttir, et al., 2012). Such techniques were taught to caregivers as well. Third-year studies focused on transitioning from the acute care setting to the home setting. Restorative practices began on the first day of hospitalization and continued throughout the restoration process, regardless of whether the disability was mild, moderate, or severe. The goal of restorative care is to improve the physical performance of the patient, enhancing the ability to perform activities of daily living as independently as possible. Frequent evaluation and re-evaluation of patients resulted in the revision of the plan of care. Additionally, students assessed home and community environments, evaluating the presence or absence of resources. As students enter the fourth year of baccalaureate nursing studies, the focus broadens to include public health models. Village health fairs and school-based education provided opportunities to explain how to prevent and decrease injuries and thus disability with the ultimate goal of offering hope to patients and families.

Opportunities for further research include measuring levels of progression (or regression) and evaluating caregiver knowledge of rehabilitative practices post-teaching sessions. Rehabilitative practices will help overcome the challenges of the disability.

D 02 - The Doctor of Nursing Practice: Reflections on the Past and the Vision for the Future

The Doctor of Nursing Practice: Reflections on the Past and Visions for the Future

Bernadette Mazurek Melnyk, PhD, RN, CPNP/PMHNP, FAANP, FNAP, FAAN, USA

Abstract

The rapid expansion of DNP programs in the United States has resulted in great variability in curriculum and the final DNP project. However, the principles upon which the DNP was endorsed by the American Colleges of Nursing remain unchanged and include: (1) advanced competencies for increasingly complex clinical, faculty and leadership roles; (2) enhanced knowledge to improve nursing practice and patient outcomes; (3) advanced leadership skills; (4) parity with other health professionals; (5) increased faculty for clinical instruction; (6) improved image (AACN, 2004, p.7). As outlined by the DNP Essentials document, the objective of the DNP is not to conduct rigorous research (AACN, 2006). The DNP prepared nurse is a healthcare leader with expertise in translating research into practice to improve health care quality and patient outcomes (Melynk, 2013; Melynk, 2016).

Many DNP programs continue to require their DNP students to conduct research as their final scholarly project. This has resulted in increasing confusion among both academic institutions and health care systems. This issue is in part perpetuated by the fact that many nursing faculty are new to evidence-based practice (EBP), having never had formal education and skill development in EBP. Faculty cannot teach what they themselves do not know (Melynk, 2013). Improving DNP curricula will require that nursing colleges invest in EBP education for their faculty including EBP skill building workshops so the faculty is best positioned to mentor and advise DNP students (Melynk, 2013).

Administrators in the service setting must also have a clear understanding of the preparation of the DNP nurse so that they can align role responsibilities to the practice/service setting. This includes providing career advancement opportunities such as clinical ladders.

PhD prepared nurses and DNP prepared nurses have great opportunities to transform healthcare through collaborative efforts steeped in their combined expertise: the PhD as the generator of external evidence from rigorous research; and the DNP as the best generator of internal evidence from quality improvement, outcomes management, and evidence-based projects (Melynk, 2013; Melynk, 2016). This model of PhD-DNP collaboration offers tremendous opportunities for nursing science as we move forward in closing the gap of moving research from the academic sphere into the practice setting.

Integrating the Doctor of Nursing Practice in Practice Settings: Implications for Clinical Outcomes and Scholarship

Mary G. Nash, PhD, MSN, MBA, BSN, RN, FAAN, FACHE, USA
Esther M. Chipps, PhD, MS, BSN, NEA-BC, USA

Abstract

The Doctorate of Nursing Practice (DNP) has now moved into its' first decade of existence. Early discussions among nursing thought leaders were focused on promoting the development, assessment and evaluation of DNP curriculums to meet the American Associations of the Colleges of Nursing (AACN) recommendations (Melnyk, 2013). As the profession of nursing has gained experience with the DNP graduates, we are entering the next phase of discussion; the integration and operationalization of the role within healthcare systems. Nurse leaders in academic and practice settings have the opportunity to collaborate on ways to identify and measure the impact of this new level of education on the outcomes that matter most in today's health care delivery system. To date, there is still a gap in demonstrating the outcomes of the DNP in patient care and healthcare delivery system transformations.

As a result of our increased collaboration with our College of Nursing, our academic medical center has experienced a rapid increase in the number of DNP prepared staff. The DNP roles in our health care system have crossed all areas of nursing practice including senior and mid-level nurse leaders, advanced practice nurses, and nurse educators. To effectively measure the difference that the addition of DNP nurses made we examined the best practices and strategies to determine what outcomes were potentially impacted, and what difference moving to a more doctorally influenced nursing practice environment had on staff.

One best practice was the formulation of a DNP workgroup open to all DNP prepared nurses in our health system. The goal of this group was to complete a gap analyses and make recommendations to enhance roles and practice to the Chief Nurse Executive's Council. The DNP workgroup aimed to: (1) examine the AACN DNP competencies in relation to our job descriptions/roles and to our working environment; (2) examine the impact of DNP prepared nurses in rapid translation of research findings and the implementation of evidence; (3) examine how our organization can increase nursing scholarly output and maximize nursing's' contribution to our academic medical center and the nursing community at large; (4) increase our collaborative efforts in evidence-based practice and research with the College of Nursing and; (5) increase job satisfaction among doctorally prepared staff. To achieve this, we did a crosswalk comparing the current job descriptions of our DNP prepared nurse leaders, nurse practitioners, clinical nurse specialists and nurse educators with the core competencies of *The Essentials of Doctoral Education for Advanced Nursing Practice*. Working in smaller subgroups by job title, the following questions were examined for each of the eight AACN DNP competencies: (1) What are we currently accomplishing within our current job descriptions/roles?; (2) What could we potentially accomplish?; and (3) What strategies could we apply to enhance our accomplishments and maximize our contributions to the organization? After reviewing the work of each subgroup, we identified eight major themes. Using these themes, we reviewed the literature and prepared recommendations for the Chief Nurse Executive's Council.

Improving Care Coordination: Impact of a Doctorate of Nursing Practice Prepared Clinical Nurse Specialist

Deborah Francis, DNP, RN, MS, ACNS-BC, USA

Abstract

Transformations in healthcare have challenged organizations to control costs while continuing to provide high quality care. Simultaneously, patients continue to present with higher acuities and increased complexity of healthcare needs. These organizational challenges have provided an opportunity for the doctorate of nursing practice (DNP) prepared advance practice nurse to utilize the core competencies outlined by the American Association of Colleges of Nursing (AACN) to improve quality of patient care (AACN, 2006).

Consistent with the 2010 Institute of Medicine Report, *The Future of Nursing: Leading Change, Advancing Health*, we identified opportunities for improvements in the coordination of care (Institute of Medicine, 2010). Our organization concentrated its' efforts on re-examining our model for delivering patient care. After conducting an extensive literature review, the project goal was established: to create, implement and evaluate an innovative new nursing role, the Clinical Coordinator. This new role focused on patient-centered care and overall facilitation of care coordination. To initiate this major transformation in care delivery, our newly DNP prepared Clinical Nurse Specialist (CNS), was identified as the individual who possessed both the knowledge and skills to lead the interdisciplinary team in this major initiative.

Utilizing *The Essentials of Doctoral Education for Advance Nursing Practice* (AACN, 2006) as the guiding framework with a focus on organizational and systems leadership, inter-professional collaboration, and advanced nursing practice, the DNP prepared CNS began the project. The overarching project goals and outcomes were selected. A role description for the Clinical Coordinator was developed which included core competencies, ideal attributes, and key responsibilities. Three medical-surgical units were initially selected to pilot the transformation. Specific measureable project outcomes selected included length of stay, hospital readmissions, and select patient satisfaction scores. Staff RN's who were interested in the new role were interviewed and then selected. This was followed by targeted educational and on-boarding programs for the entire staff. The outcomes of the initial pilot were successful demonstrating improvement in patient satisfaction, and decrease in length of stay with adoption of the new role Clinical Coordinator role. Based on these outcomes, the program was extended to five other medical surgical units at our organization.

Our DNP prepared CNS continues to lead this initiative by expanding this program throughout our organization with a focus on refining and individualizing the Clinical Coordinator role based on specific unit needs and metrics. This effort provides an excellent exemplar of the added benefit of a DNP prepared CNS with respect to the management of quality initiatives and the ability to respond to health care policy challenges (Melynk, 2013).

D 03 - Supporting the Needs of Low-Income Families to Improve Parent and Child Outcomes

Perceived Benefits of a Mindfulness-Based Intervention Among Homeless Women and Young Children

Jeanne L. Alhusen, PhD, FNP-BC, RN, USA

Abstract

Introduction: Family homelessness remains a significant public health issue associated with negative physical and mental health outcomes for those impacted. The impact of homelessness on children, particularly young children, includes an increased risk of poor mental health, socio-emotional problems, and cognitive delays.¹ Homeless women experience disproportionately high rates of adverse physical and mental health outcomes including higher rates of depression.² Compounding this issue is that services for homeless families are often directed toward housing and other essential services, and few resources are available to address the mental health needs of homeless mothers and their children. There is an urgent need for evidence-based programs to support homeless families, particularly those with young children. Mindfulness practice has been increasingly incorporated into the treatment of chronic diseases, with promising results noted in the management of depression, stress and pregnancy-specific stress, overall physical function, and quality of life.³⁻¹² Yet, to our knowledge no study has examined the benefit of mindfulness on the mother-infant relationship. The purpose of this mixed methods study is to describe the perceived benefits of a mindfulness intervention that was implemented in a Therapeutic Nursery (TN) serving homeless children under the age of three and their caregivers in an urban setting in the United States.

Method: Mothers of young children participating in an 8-week, group-based, Mindfulness Based Stress Reduction (MBSR) intervention were recruited from an urban TN to participate in post-intervention qualitative interviews to explore perceived benefits of MBSR. Quantitative data on maternal depression (via the Center for Epidemiologic Studies Depression Scale: CES-D), was collected pre-and post-intervention. The in-depth qualitative interview narratives were analyzed using conventional content analysis. After all transcripts were coded, the data within each code was examined and ultimately organized into a hierarchical structure and assessed to provide context and further understanding of the influence of MBSR on maternal and child outcomes.

Results: Seventeen mothers participated in the qualitative interviews, and maternal age ranged from 24-44 (M=30.9). The majority of the mothers were African American, single, and reported receiving less than a high school education. At the time of the interview, the majority of mothers (65%) were living in shelters, and the remaining mothers reported being in unstable housing (17.5%) or transitional housing (17.5%). On average, women attended 6.8 mindfulness sessions (85% of sessions) and 100% of mothers participated in at least 5 of the 8 sessions. At baseline, 82% of mothers exceeded the cut-off score for depressive symptomatology pre-intervention. Post-intervention, 53% of mothers exceeded the cut-off score for depressive symptomatology demonstrating a 35% reduction in high rates of depression. Four themes were derived from the data regarding the perceived benefits of the mindfulness program including. Participants described now establishing “me” time, “...instead of reacting right away when [child] does something wrong, I take a minute to myself. Instead of yelling ‘leave mommy alone’ I say ‘give mommy a couple minutes to get herself together.’” Maternal self-regulation was another identified theme, with one participant noting, “I don’t stress about the things I can’t change and control like I used to. It’s more like this is a test, this is a trial, let’s figure it out.” Related to the mother-child relationship, dyadic connectedness was another identified theme with one participant commenting “I’m opening my arms rather than pushing away,” linking her change in behavior to a significant decrease in her child’s outbursts. Finally, child well-being was a theme identified by participants who uniformly noted improvements in their children’s behavior and well-being through their own participation in MBSR. One participant commented, “I showed her [child] other ways of how to get my attention without having to throw stuff at me or kick me or force her toys on me...and it worked!”

Conclusion: The parent-child relationship is the most salient moderator of the relationship between children experiencing homelessness and early childhood outcomes. Thus, interventions to reduce stress thereby improving the parent-child relationship are needed, particularly for very young children. Findings from the current study suggest mindfulness as a promising strategy to support maternal mental health, and subsequently, the socioemotional development of young children. The concept of self-compassion is particularly important for homeless mothers who are confronted with many stressors that often take precedence over their own well-being. By giving mothers the opportunity to practice these skills with their child within the weekly relationship-based program at the TN, the quality of the parent-child interaction is enhanced. Further, mothers are supported in incorporating these same skills in their activities outside of the TN. If young children are exposed to supportive, nurturing relationships, the deleterious effects of homelessness and its related indicators may be attenuated. Our research demonstrates that a mindfulness intervention may foster the development of positive parent-child interaction.

Baby Beep: A Tele-Health Intervention for Depressed, Low-income Mothers

Linda Bullock, PhD, RN, FAAN, USA

Emily Evans, PhD, RN, USA

Abstract

Introduction: The link between stress and antepartum depression (APD) is well established, with as many as 20 % of all pregnant women and 47 % of rural, low-income, pregnant women in the United States reporting symptoms. Depressed women are less likely to obtain adequate health care and more likely to engage in poor health behaviors such as abusing drugs, cigarettes, or alcohol, and to experience postpartum depression. Many of these women go on to have difficulty providing the type of care-giving necessary for normal child-development to occur. Rural women who are depressed and living on low-

incomes have many economic, social and logistical barriers to overcome in obtaining treatment. These barriers include lack of insurance or other ways to pay for care, inability to afford missed time at work, limited childcare options, lack of public or private transportation in addition to the social stigmas associated with seeking psychiatric help. One economical and feasible way to provide care to this vulnerable group is to deliver nursing care via tele-health. The Baby BEEP study provides a model for a well-received, workable nursing intervention where low-income women living in a rural setting received nursing care through weekly telephone support calls from a registered nurse. The interactions that occurred during these phone calls reflected Peplau's theory of Interpersonal Relations. Peplau was an early nurse theorist who described and identified roles and phases of the nurse-patient interaction that are core to nursing care and essential in providing psychiatric nursing care. Using Peplau's theory as a framework, and Miles and Huberman's qualitative methodology to characterize the nursing care provided by the Baby BEEP nurses, this study reports on the differences in nurse-patient interactions between two groups of women who began their pregnancies with scores indicative of depression on the Mental Health Index-5. The first group experienced a rapid improvement in mental health scores, while the second group experienced a more gradual improvement. By the end of the tele-health intervention, both groups who had consistently interacted with nurses on the phone had mental health scores in the range of normal.

Methods: A secondary mixed methods data analysis was conducted using original data from a randomized controlled trial (NR05313: Nursing Smoking Cessation Intervention during Pregnancy: Baby BEEP). As part of the Baby BEEP study, 695 low-income, rural, pregnant women were recruited from the rural Midwestern United States. Of these women, 345 were randomized to a telephone social support intervention delivered by baccalaureate prepared registered nurses. The purpose of the weekly telephone support intervention was to use "empathetic listening skills and provide social, emotional and/or informational support". The nurses kept detailed records of every phone contact they made with women in their caseload throughout pregnancy and up to six-weeks post-partum. Over 3,000 pages of single spaced notes detailing the interactions between nurse and patient were generated. The initial sampling strategy for this secondary analysis was purposive, ensuring a sample of women who began the study with MHI-5 scores indicative of depression and then split into two subgroups based on scores at the end of pregnancy. Consideration was also given to obtaining an unbiased sample by equal sampling from each of the six nurses who provided the intervention.

Results: A total of 24 women's telephone logs were analyzed. All women in this study were similar in age (mean = 23 years), marital and education status. The group whose mental health status improved more rapidly over the course of pregnancy (referred to as the "non-depressed group") received 21 calls during the study period and had an average improvement in mental health scores of 17 by the end of pregnancy. Women whose mental health scores did not improve as rapidly (referred to as the "depressed group") received 18 calls and showed an average improvement of 8 over the same time. Although mental health scores differed significantly at the onset of the study, by the end, there was no statistically significant difference between groups in mental health scores. The minutes/call was nine minutes for the non-depressed group versus 11 minutes for the depressed group. Total minutes of support provided throughout the study was 2338 minutes for the non-depressed group versus 2348 minutes for the depressed group.

Evidence of all Peplau's roles (stranger, surrogate, resource, teacher, counselor and leader) were found in the data, but most nursing care occurred as nurses acted as a resource, teacher and counsellor. Direct quotes from the logs will be presented to illustrate that as a counselor the nurses addressed the woman's emotional and psychological state by restating, reframing, probing and pointing out the woman's personal successes. Additionally, evidence of Peplau's phases (orientation, identification, exploitation and resolution) were found. Both groups of women moved from the orientation to identification phase of the relationship quickly, but the amount of time spent in the identification phase varied. For those who were longer in this phase, the time seemed to be spent trying to reach a point of mutual alignment, trust and readiness to work. The women in the depressed group took longer to progress during this phase. However, when the depressed women could progress through these two phases and moved into the exploitation phase, the length of the weekly telephone calls became longer with the nurse having to use more roles during the call than she did with women in the non-depressed group.

Conclusions: Although Peplau's Theory of Interpersonal Relationships has been applied to nursing care in more traditional clinical settings, this study makes explicit what a tele-health therapeutic relationship "looks and sounds like". This type of counselling intervention can be used in delivering nursing care to depressed rural, low-income women who may only have access to health care for their depression via a telephone. Women who are depressed may require more time talking to the nurse and the nurse may have to initiate more of Peplau's nursing roles with these women. The telephone support provided by the Baby BEEP nurses provides a model of a type of nursing intervention aimed at alleviating depressive symptoms in an extremely vulnerable and hard to reach population that have little or no current systems in place for depression treatment.

Using Condition Cash Transfer Programs for Engaging Low-Income Parents in Health Promoting Programs

Deborah Gross, DNSc, RN, FAAN, USA

Amie Bettencourt, PhD, USA

Abstract

Introduction: To boost participation rates in health promotion/prevention interventions, researchers typically pay participants cash incentives for enrolling, attending, or completing assessments. Cash incentives help meet recruitment targets and maintain statistical power. But they diminish external validity when under-resourced agencies cannot offer the same incentives for attaining comparable parent participation and adherence rates. Indeed, research shows that under real-life conditions, most parents invited to participate in parenting programs do not attend, limiting the impact and cost-effectiveness of evidence-based programs. The purpose of this study is to examine the feasibility, acceptability, sustainability, and impact of a conditional cash transfer (CCT) program for raising parent participation rates in a 12-session parenting skills training program, called the Chicago Parent Program, offered in Baltimore City schools serving low-income families. CCT programs use a behavioral economics model and provide cash incentives conditioned on completing a set of desired activities. CCT programs have been used in over 30 low resource countries and shown to improve a range of child health outcomes. However, they are rarely used in the United States to promote healthy behavior in low-income communities.

Method: Parents of 4-year old pre-kindergarten (preK) children in 9 Baltimore City Public Schools serving a low-income families (>92% low-income; 96% African American or Latino) were given a bank issued debit card and offered up to \$230 to participate in the parenting groups at their child's school; \$15 for each 2 hour session attended and \$5 for each weekly skill building "homework" assignment completed and submitted. These amounts were based on prior research estimating the opportunity costs for parents

to attend a 2-hour parent group session. Group leaders submitted weekly attendance and “homework” completion records electronically within 24 hours of the parenting sessions; incentives were loaded electronically onto parents’ debit cards within 48 hours of the session. Data were collected on attendance, homework assignment completion, quality of parent engagement in the parenting sessions, parents’ motivations for enrolling in the program, importance of cash incentives on their decision to enroll and attend the program, and how cash incentives were used. Parent reports of child behavior problems were also obtained at baseline and post-intervention (3 months later) using the Eyberg Child Behavior Inventory, a standardized measure of child behavior problems. Results were compared with participation rates previously obtained in published validation studies conducted with comparable parent samples.

Results: To date, 213 parents of 4-year old preK students have enrolled in the parenting skills training program (56.5% single-parent households; 70% African American; 67% report annual household incomes <\$20,000). Across schools, 80% of parents who enrolled attended at least one parent group session (M attendance= 65% of sessions) and 60% completed weekly homework assignments; a four-fold increase in homework completion rates without CCTs. Although 68% of parents reported that the debit cards influenced their decision to enroll, the most important reasons parents cited for signing up were to “learn better ways to manage my child’s behavior” (94%) and “always looking for ways to be a better parent” (96%). At baseline, 42% of the preschool children had behavior problems in the “clinical range” (defined as scores greater than 1 SD above the mean). At post-intervention, 22% of the children had behavior problems in the “clinical range,” representing a 48% decline in child behavior problems ($p<.001$). Parents who identified the CCTs as an important motivator for signing up for the program tended to have higher attendance rates ($F=2.8$, $p=.07$). The most common reason for not attending parent groups (53.3%) was a change in their work schedule that conflicted with the time of the group session. Observed quality of parent participation during group sessions was high and comparable to results obtained when no CCT’s were provided. Parents used debit cards for food, clothing, gas, school supplies, medicine, and other basic necessities.

Conclusion: The importance of a responsive and nurturing caregiving environment may never be more important than during the first 5 years life when children’s brain architecture is first developing and when most of what children learn centers on the home environment. Promoting healthy caregiving environments, particularly among families struggling with the stress of raising young children in poverty, is an important role for nurses. However, even the most effective interventions cannot work if parents do not participate. The results of this study suggest that CCT programs are feasible, acceptable, and useful for improving parent participation rates in health promoting programs in low-income communities. However, CCT’s remain controversial in the U.S. Features of high impact CCT programs and efforts for sustaining CCT programs in schools will be discussed.

D 04 - Career Transitions: Capitalizing on Your Leadership Competencies

The Phases of Leadership and Your Leadership Brand

Beth A. Brooks, PhD, RN, FACHE, USA

Abstract

Health care today as an industry looks nothing like it did even 10 years ago—it is not merely changing, it is being fundamentally transformed. Traditional leadership roles are continuously being redefined, which means that new possibilities are being created and new opportunities are emerging. For nurse leaders, this transformational new reality is opening doors beyond the traditional hospital and health care system roles. But all too often nurse leaders are unsure about how to begin to move into these non-traditional leadership roles, an increasing number of which are outside hospital settings.

Leaders pass through six phases of leadership (Charan, Drodder & Noel, 2000). Required during each phase is emphasizing and capitalizing on different competencies, in addition to modifying how you act and are perceived as a leader; i.e. your leadership brand. Your brand is your executive presence—from a stylish haircut, to fashionable attire, to having read the latest industry news—nurse leaders have to work on how they are perceived by others. This is not the time to passively sit back and wait to be recognized for all your hard work, which tends to be a very common approach for nurses to engage in. A more effective alternative is a proactive and appropriate use of social media, which provides a means of showcasing how you are ready for a leadership role that would otherwise be offered to a leader outside nursing. But there are also cautions as to how leaders should use social media, because it could just as easily hinder and hurt your leadership brand. Finally, it is important for leaders to maintain a work life balance and to effectively manage stress, since simply being a leader can take a toll on your health. New research suggests that extra pounds and a larger waistline can actually undermine perceptions of leadership abilities. Being confident in how you look and feel is essential for successful networking. In this symposium, three senior health care executives with a unique combination of skills in personal branding, career coaching and one who herself has moved to the very top of the leadership hierarchy, will provide insights, recommendations and time-tested strategies on how to successfully navigate the phases of leadership to claim the corner office.

Moving Up the Leadership Ladder: Using a Career Coach

Paul T. Skiem, MBA, LCS, USA

Abstract

Nurses have learned a great deal through their educational and clinical experiences and that knowledge has served them well as they perform their clinical responsibilities. Those with a desire to move up the leadership ladder need to develop a knowledge base and skill set that is wider than what they obtained as undergraduates or even in graduate school. Sophisticated nurse leaders are aware of and know how to capitalize on their competencies, and how to adapt to changes to job search and interviewing strategies needed to move up the leadership ladder. In particular, emphasizing and capitalizing on different competencies become vital when attempting to secure a leadership role outside of those in the traditional, acute-care hospital setting.

Are you curious about how some nurse leaders have been able to successfully transition from a traditional role to a new role that was, at least at first glance, outside their comfort zone? More often than not these nurse leaders are in constant consultation and dialogue with mentors, either inside or outside of nursing (or both), have worked with an executive recruiter (a head hunter), or are engaged with an outplacement firm or with a career coach. Working with a career coach can assist nurse leaders in the process of “repackaging” their expertise, experience and competencies for a desired role that is outside their comfort zone. Career coaching prepares and supports nurses so they make informed decisions about their career development and trajectory. Solution-oriented career coaching involves taking concrete steps—résumés, cover letters, Skype interview preparation, developing employment contracts and change of control agreements—all designed to help meet career trajectory goals. A career coach can assist a nurse leader in ensuring that you have the essential career evidence that reflect your readiness and fit for the new role—not just focusing on what you accomplished in the past.

Career coaching can be helpful at every point of a nurse leader’s professional path, from the early career years, to helping explore strategic options for graduate school or when exploring career options outside their traditional comfort zone. A nurse leader’s career path of today is not as direct as it has been in previous generations, nor will it prepare that nurse leader for the key leadership careers of tomorrow.

The Ultimate Leadership Suite: The Corner Office

Therese A. Fitzpatrick, PhD, RN, FAAN, USA

Abstract

There is a quiet revolution underway as the initials “RN” are appearing on corner office doors. The impact of our astounding talents is shaping corporations, health systems, and public policy across the nation. Smart, bold, and exceedingly talented nurses are blazing trails into domains once considered unheard of for nurses. Nurse leaders are running companies and health systems, becoming successful entrepreneurs and leading universities. These nurses are embracing their valuable nursing knowledge base and their unique perspectives on health and health care. Nurses possess the greatest breadth and depth of health care experience in hospitals, clinics, long-term care and the home. Nurses are a tremendous source of information on how to lower costs and raise the quality of care. They are leveraging this expertise in pursuit of the most strategic and powerful positions in government, academia, businesses, and health care organizations. There are valuable lessons to be learned from the storied careers of these leaders, in particular advice and candid accounts of both successes and failures.

The executive corner office nurses consistently report that their business and financial knowledge, skills, and perspectives positioned them well for their senior leadership or entrepreneurial roles. Their successes require study and analysis so that we can better understand what it takes to succeed in these positions of strategic importance. Leading an enterprise suggests that nurses should claim their rightful place on governance boards, a role which requires a deep understanding of our fiduciary and organizational performance responsibilities. As we rise through the levels of leadership, an evolving skill set is required to assume these sophisticated roles which require strategic insights and bold action. This session will share stories of executive nurse leaders who have demonstrated resiliency, capitalized on the power of their professional network, were keenly aware of their value, knew how to “talk the talk,” found the leadership role best aligned with their values, and leveraged their leadership brand.

D 06 - Strategies for Educating Nursing Students to Address Social Justice and the Social Determinants of Health

Culturally Sensitive Teaching Strategies to Improve Health for Refugees in San Antonio, Texas

Rebekah J. Salt, PhD, MN, RN, USA

Abstract

It is well known that social determinants of health (SDH) affect health. In the United States, researchers are challenged to focus attention on social and economic factors related to health and to investigate the links between SDH and vulnerable populations. Refugees in the United States are a vulnerable population and at risk for poor health and social outcomes due to past and present circumstances. In 2015, the United Nations High Commissioner for Refugees reported that of the 65.3 million persons forcibly displaced worldwide, an estimated 21.3 million of those were refugees. The United States remains a world leader in refugee resettlement and is expected to admit 85,000 refugees in Fiscal Year 2016 with at least 10,000 of those from Syria. Texas is a national leader in refugee arrivals and provides culturally sensitive comprehensive health assessments and referrals during the resettlement process.

Resettlement can be stressful as refugees may have suffered life-threatening circumstances prior to flight from their countries. Shortly after reaching the United States, refugees face the difficult tasks of learning to speak English, finding employment, and knowing whom to ask for help. Researchers have reported four reoccurring barriers that can affect refugees' transition to the United States: 1) Culture, as health beliefs and social norms vary from country to country; 2) Language issues around verbalizing their needs; 3) Discrimination and stigmatization specifically related to mental health, religious or regional stigma; and 4) Logistical concerns around transportation, finding housing, and navigating the health care system. These internal and structural issues can create barriers to care and contribute to health disparities in this population.

In the Population-Focused Health course at the University of Texas Health Science Center at San Antonio, School of Nursing, students are introduced to social determinants of health and social justice at the community level through a community assessment process. Each clinical group is required to complete a windshield survey, analyze public health data, conduct key informant interviews and focus health promotion within specific census tracts. The Center for Refugee Services (CRS) is an independent 501(c)3 nonprofit agency that was established in 2010 and is run by volunteers who provide educational and support resources to the refugee community in Northwest San Antonio. At the CRS, the students learn about primary and secondary prevention strategies within the context of cultural sensitivity and safety. A student project may consist of a health fair, screenings, or health education presentations based on refugee request and need. In the planning and implementation of these projects, the students have to frame the message around health promotion, identify internal and structural barriers, and plan for logistics such as working with interpreters and translators. This community partnership has been transformational for both the refugees and students. The refugees appreciate the collaboration with the University of Texas Health Science Center and the students share that they can translate the concepts of social justice and cultural sensitivity and safety into their care of vulnerable populations in acute and community settings.

Impacting Practice: Using a Poverty Simulation to Develop Leadership Skills in Baccalaureate Nursing Students

Adelita G. Cantu, PhD, RN, USA

Abstract

Social determinants of health (SDH) combine in many ways to impact the health and health outcomes of individuals and communities. One of the most significant SDH is poverty. Based on a meta-analysis of nearly 50 studies, researchers found that many social factors, including poverty accounted for over a third of total deaths in the United States in a year. Thus it is mission critical that we prepare the future healthcare workforce with the attitude, knowledge and skills that prepare them to integrate SDH into their practices so as to have a positive impact on health outcomes.

Simulation is a technique for practice and learning that has been applied to nursing education. Simulation-based learning can be a way to develop health professionals' knowledge, skills, and attitudes, providing a valuable tool in learning resolve practical dilemmas. This abstract will describe how a School of Nursing integrates a poverty simulation in an undergraduate nursing population health clinical course to build knowledge about SDH and inform practice relative to the pathways of SDH that determine health and health outcomes.

For the last four years at our institution, undergraduate baccalaureate-nursing students have participated in a poverty simulation during the first day of their clinical rotation for population health. The simulation requires that each student is a member of a family that lives a month within the confines of a low-income household. During the month, they are responsible for paying their bills, dealing with challenges that arise suddenly and work to not be evicted from their home by the end of the month. The critical component is the debriefing after the simulation, which allows for discussion about SDH and their impacts on health.

After the simulation, the remainder of Population Health clinical has numerous clinical activities that are designed to reinforce the knowledge that students gained from the poverty simulation. The activities include a doing a community assessment, a public transportation day, working with a homeless transition center, understanding how food deserts impact health and how community gardens and a food bank can positivity change health outcomes. After each activity, students reflect on their experiences and one of the questions is *"Describe any nursing strategies (communication, health education, etc) that you used this week that were influenced by the awareness and knowledge gained from the poverty simulation."*

Approximately 500 answers to that question have been reviewed for common themes Three themes emerged: 1) the importance of communication and active listening; 2) the influence SDH has on how community residents prioritize behaviors, particularly health behaviors, and 3) the importance of nurses being aware of community resources and how residents can access resources. In this presentation, narratives will be shared that highlight how students engaged in nursing strategies that were influenced by these themes. Also and more importantly, students have expressed how they will use this knowledge to inform their practice as a nursing professional. Other implications for how this has social justice impact on nursing practice will be discussed.

Upstream Healthcare: Values Training for Low-Income Children Using Baccalaureate Nursing Students and Community Youth

Martha Martinez, MN, RN, USA

Socorro Escandon, PhD, MSN, BSN, RN, USA

Abstract

Evidence now supports the idea that social determinants of health (SDH) are the biggest factors in influencing population and community health. Addressing one or more of these factors can have a positive impact on health. Efforts and investments should be directed at root causes of health disparities to improve health outcomes. One of the core principles of Upstream Health Care is to focus beyond the walls of acute care settings and extend into the communities and collaborating agencies to address the root causes of health problems/issues including SDH. Community settings can provide an environment that supports and fosters character building and core values such as courage, good judgement, integrity, honesty, self-discipline and service. Focusing on SDH as part of nursing education and promoting healthcare at the community level enables nursing students to develop an expanded perception of nursing care that includes vulnerable populations. Students completed their Population-Focused Health clinical rotation at Jireh House, a faith-based community agency that provides services to residents living within a government subsidized low-income housing property. This area is known for increased health and educational disparities in San Antonio, Texas.

Moral qualities are valued by individuals, parents, and educators and are likely to benefit society as a whole. Experiences during childhood play a role in shaping an individual's life and outcomes. Providing positive learning opportunities, supporting positive relationships and teaching core values to improve health outcomes. Children, as early as two years of age, demonstrate kindness and begin to develop collaboration and teamwork abilities which increase throughout early childhood. Community settings can provide an environment that supports and fosters character building and core ethical values such as courage, good judgement, integrity, honesty, self-discipline and service. Given that experiences during childhood play a big role in shaping future life outcomes, providing positive learning opportunities, supporting positive relationships, and teaching core values may improve health outcomes. Children relate to puppets from a very early age and puppet shows provide a way to use a story format to portray a variety of situations related to misconceptions, conflicts, and coping skills. The purpose of the *Values Training Puppet Project* was to provide senior nursing students, in their Population-Focused Health clinical rotation, the opportunity to develop mutually beneficial relationships with community service organizations in San Antonio, Texas. Nursing students worked side-by-side with youth ages 13-17 at Jireh House to create and produce puppet shows for school age children who lived in the nearby low-income housing. The goal was to foster citizenship and leadership skills for the nursing students and volunteer youth through character building activities and shared development of a values training project using puppet shows for school age children attending a youth program at Jireh House.

Prior to the beginning of the project, both the nursing students and volunteer youth at Jireh House completed the *Values in Action Inventory (VIA)* Survey of Character Strengths to identify their own personal strengths and values prior to implementing values training to the children. The VIA is a self-report questionnaire designed to identify individual strengths within six virtue clusters. One focus is to identify and strengthen moral core values that will guide life experiences and decisions. Before implementing the puppet shows, the students and community youth met separately to address their VIAs and discuss perceptions of the benefits of community collaboration. The two groups then met to share reflections from their VIAs. These reflections informed The Values Training Puppet Project which focused on: 1) Engagement, active participation, and positive learning experiences and 2) the concepts of honesty, self-control and integrity. The nursing students and youth volunteers worked together to introduce creativity and imagination and engagement into three different puppet shows. For example, one group incorporated music prior to the show. At the request of the children, the groups repeated two of the puppet shows twice.

At the conclusion of the project, the nursing students were again asked to reflect on their VIA identified strengths and relate them to their work during the project. Three themes emerged: 1) Strength of teamwork, 2) Fairness, and 3) Leadership. The students used their character strengths to inform their work with the volunteer youth group, the creation and implementation of the puppet shows and how to mentor youth. The students also discussed how this experience related to growth and development theory of young adolescents and their need to be creative, yet held accountable for their work. Using innovative teaching strategies to promote character building, mentorship, and values training for at risk youth and children is one approach to upstream health care and has the potential to decrease health disparities and improve health outcomes.

D 17 - Simulation Research: Informing Best Practices in Nursing Education

Integrating Virtual Simulation into the Curriculum: An Exploratory Study

Susan Forneris, PhD, RN, CNE, CHSE-A, USA

Abstract

Simulation can take many forms, including human patient simulation using manikins and/or standardized patients, virtual and computer based simulations, simulation done to teach psychomotor skills, or role play (Society for Simulation in Healthcare, 2015). Simulation is grounded in the use of story. The many and varied patient simulation scenarios capture unique, time limited, clinical encounters within the context of nursing practice. Learning in simulation allows for situated cognition – or learning in context –and has a greater chance of being recalled and then transferred to new learning situations (Forneris & Peden-McAline, 2006).

Virtual simulation provides a unique learning opportunity for nursing students to interact with a patient in a safe, realistic environment that is available anytime, anywhere. Virtual simulation engages students through the evolving clinical stories of patient encounters. The problems encountered in these patient stories focus the student on the *process of thinking* as opposed to the process of learning factual knowledge. Contextualizing practice focuses student attention on the patient – a strategy that keeps students' thinking open and curious (Benner, Sutphen, Leonard, Day, 2010). Simulation as a teaching strategy is based on the theory of deliberate practice and thus engages students with the opportunity to repeat an activity continually to achieve mastery. The literature supports that simulation-based education with deliberate practice is effective in achieving specific clinical goals (McGaghie, Issenberg, Cohen, Barsuk, & Wayne, 2011).

Learning in context is a concept at the forefront of contemporary educational reform. Passive learning approaches are being replaced by experiential learning, i.e., active learning approaches whereby students become the center of the teaching and change from mere consumers of education to engaged active learners (Jeffries & Clochesy, 2012). The National Council of State Boards of Nursing (NCSBN) landmark, multi-site, longitudinal, study explored the role and outcomes of simulation in pre-licensure clinical nursing education in the United States (Hayden, Smiley, Alexander, Kardong-Edgren & Jeffries, 2014). The study concluded that there is substantial evidence that simulation can be substituted for up to 50 percent of traditional clinical experiences under conditions comparable to those described in the study. Simulation as an active learning teaching strategy is informing nursing education on the direction needed for educational transformation

Unique challenges exist for today's nurse educators to devise and thoughtfully integrate teaching strategies that move from highly structured to self-directed learning and reactive thinking to critically reflective proactive thinking. Contextualized learning brings classroom and clinical together; simulation engages learners with diverse perspectives to reflect and reframe the understanding of practice, bringing thinking and doing together. Thoughtful and intentional use of simulation across the curriculum, thus encompassing virtual simulation, holds great promise in moving nursing education forward transforming the way students learn and faculty teach.

This paper will discuss the findings of an exploratory study on the use of virtual simulation with faculty from a variety of programs of nursing. The focus of the study was to determine how faculty used and integrated a trial period of virtual simulation in their nursing curricula. Findings from this exploratory study inform nursing education best practice emphasizing the importance of 1) the use of context in the teaching-learning process; 2) active learning that shifts the teaching from a cognitive to a relational approach, where learners and faculty construct knowledge, attitudes, and skills collaboratively (Cheng et al., 2015). The findings from this study were used in the development of faculty curriculum implementation guides; a National League for Nursing evidence-based resource to assist faculty in

acquiring the foundational knowledge needed to ensure thoughtful integration of virtual simulation across the curriculum and engage in education best practices.

Using Simulation to Enhance Clinical Reasoning During Medication Administration: A Multi-Site Qualitative Study

Diana Odland Neal, PhD, MS, BSN, RN, PHN, USA

Abstract

Patient safety and quality care are issues of major concern worldwide and are significant challenges facing healthcare systems, clinical practice, and nursing education. The Quality and Safety Education for Nurses (QSEN) project, funded by the Robert Wood Johnson Foundation, has been pivotal in engaging nursing faculty in the important work of assuring that graduates are able to demonstrate quality and safety competencies. The purpose of the QSEN project is to prepare nurses who will improve the quality and safety of the healthcare system and individual performance. To promote quality and safety in nursing care, QSEN developed core competencies in knowledge, skills, and attitudes (KSAs) that are essential for pre-licensure nursing students. Medication administration is a common and necessary core competency in nursing care. Patient safety is especially at risk during medication administration as medication incidents are a leading cause of patient injury.

Nursing educators face many challenges ensuring that students have the knowledge and abilities to safely administer medications to patients. The simulation nursing lab is a safe environment to teach medication administration. Repetition and rote memory have traditionally been used heavily by students to acquire nursing skills such as medication administration. Although the procedure of administering medications appears to be simple and straightforward from a psychomotor domain, the student nurse's thought processes and critical judgments may contribute to medication errors.

The thought processes of student nurses during medication administration related to prevention of patient harm or errors or promoting therapeutic responses are not well known. Nursing students may be focused more on the rules and procedures rather than anticipatory problem solving, and concurrent patient teaching that occurs with practicing nurses. The QSEN project provides nursing faculty with a framework to assure that graduates are able to demonstrate quality and safety competencies, including that of medication administration.

Simulation and debriefing is gaining momentum as an active learning teaching strategy that is successfully impacting student thinking along the learning continuum. The direct effect of simulation and debriefing on learner performance and clinical reasoning is not well studied. Nurse educators continue to seek new teaching and learning strategies with the goal of engaging students in thinking that goes beyond the boundaries of memorization. With a focus on developing sound critical thinking and clinical reasoning skills, contemporary nursing education is focused on teaching students to think like a nurse (Tanner, 2006).

This paper will discuss the findings of a multi-site qualitative study, which examined student nurses' reported thinking during medication administration in a simulated experience involving care of a post-operative patient reporting pain. Forty-eight students from five baccalaureate-nursing programs in Minnesota, USA participated in a simulation with a standardized post-operative patient. Ten, second year advanced diploma student nurses at Tumbani University Kilimanjaro Christian Medical College in Moshi, Tanzania participated in a subsequent replicated study. In both studies, students independently completed a patient assessment and administered pain medication from a variety of options. Following the simulation, semi-structured debriefing interviews containing 9 open-ended questions were conducted and audiotaped.

Students administered a variety of pain medication during the simulation. Analysis of transcriptions revealed five themes including 1) safety, 2) clinical reasoning, 3) uncertainty and need for validation, 4) lessons learned, and 5) perception of realism. Safety was the most predominant theme that emerged from the data.

Students must be able to more fully understand clinical decision-making around medication administration (e.g., best practice, individual experiences with pain, patient preferences, patient conditions, etc.). Implementing teaching strategies that integrate opportunities for several valid nursing interventions encourage students to move away from a linear perspective to examine their thinking and the complexity of clinical practice. Findings will inform faculty relative to curricular design, pedagogy, and evaluation in educating nursing students to become safe and competent nurses.

Using Virtual Simulation to Enhance Student Learning: A Case-Based Approach

Jone Tiffany, DNP, RN, CNE, CHSE, ANEF, USA

Abstract

The topics of inclusivity, diversity, cultural awareness, and patient-centered care coordination are difficult to adequately explore in a traditional classroom setting. Innovative educational strategies are needed to better prepare nurses to succeed in complex healthcare environments where quality and safety are paramount. Virtual reality software and environments such as Second Life (SL) hold potential as part of

the solution by providing innovative and interactive platforms for educational experiences that simulate real world situations. These platforms offer opportunities to utilize the virtual world to expose nursing students to learning in a new way.

This presentation will describe how the virtual platform of Second Life was utilized for simulated role-play experiences. In addition, the literature surrounding the use of virtual platforms for simulated nursing education will be presented. Advances in virtual education have created an environment that presents new opportunities to help foster positive student learning and exploration. Such innovations can be implemented to aid in teaching about many concepts, including patient-centered care coordination and inclusivity.

The use of the virtual platform of Second Life (SL) afforded a unique opportunity to use virtual role-play simulation to experience what it is like to walk in another's shoes. In one study, fifteen graduate nurse educator students enrolled in a course titled "Inclusivity in Nursing Education" and were randomly assigned a customized avatar, representing a marginalized person for use in a role-play simulation in the virtual world of SL. Students indicated they increased their own capacity to understand, appreciate, and relate to people different from themselves.

In another study, a virtual ambulatory care clinic was built in Second Life and students created online avatars and engaged in an experience where they discussed concerns that accompanied clinic visits; including heart failure, diabetes, and depression. Student preparation for the virtual experience took place via a simulated electronic health record. The process of the virtual role-play simulation itself, including the facilitator's role will be discussed during this presentation. The virtual simulation role-play experience also gave students the opportunity to practice their phone-triage skills through the use a virtual role-play experience where they handled a patient phone call situation. Students found this experience to enhance the professional nursing role of patient educator. At the end of their experience, students completed a teaching plan, which further expanded the learning about the role of patient educator. Focus group discussions of the use of this technology reported enhanced learning.

Although future research is needed to determine the full extent to which virtual platforms can be used effectively in nursing education, these studies demonstrated that valuable learning regarding complex topics can take place in the virtual world.

F 01 - Innovative Evidence-Based Strategies for BSN Education

Evidence-Based Educational Strategies That Promote Handoff Effectiveness: Connecting the Dots Between Senders and Receivers

Christine A. Sump, DNP, MSN, RN, CNE, USA
Donna L. Rose, MSN, RN, USA

Abstract

Ineffective communication has long been recognized as a barrier to safe patient care (James, 2013). The World Health Organization (2007), Joint Commission (2011), and the Agency for Healthcare Research and Quality (Westat et al, 2016) have identified communication failures during handoff as a national and international challenge to safe patient care. Fifty-three percent of the approximately 447 thousand respondents in The Agency for Healthcare Research and Quality's 2016 Hospital Survey on Patient Safety Culture deemed that important patient care information is often lost during shift changes. Forty-seven percent of the respondents indicated that shift changes were problematic for patients in their respective hospital (Westat et al, 2016). The Joint Commission Center for Transforming Healthcare (2011) estimates that 80% of medical errors result from breakdowns in communication when patients are "handed off" during change of shift report. Problems with patient handoffs are an international concern. According to the World Health Organization (2007), "hand-over (handoff) problems are rooted in the way that healthcare providers are educated or not educated (in team training and communication skills)". The WHO World Alliance for Patient Safety has developed patient safety solutions focused on communication during patient handoffs. They call for educators to incorporate training on effective handoff communication into the educational curricula.

Handoff education requires thoughtful preparation and planning to maximize attainment of program outcomes and minimize potential risks while ensuring integration of best practices in the clinical setting. However, formal instruction on handoff is not typically taught in undergraduate nursing programs (Kerr, Lu, McKinlay, & Fuller, 2011). Additionally, the literature provides very little information on handoff instruction and evaluation in undergraduate nursing education. The purpose of this presentation is to discuss evidence-based educational strategies to improve effective handoff delivery and reception to maximize patient safety.

Multiple teaching and learning strategies have been incorporated into the curriculum of a midsize university's school of nursing. Strategies that promote effective handoff delivery are implemented and evaluated in the classroom, health assessment lab, simulation, and clinical settings during the first semester of nursing school and continued throughout the curriculum. A flipped classroom is initially used to introduce the handoff process. A flipped classroom is an evidence-based method to support clinical education and increase critical thinking skills, which are crucial for safe patient care (Burns, 2012; Yu, Zhang, Xu, Wu, & Wang, 2013). The students then practice handoffs using case study scenarios, and role play, using the Situation, Background, Assessment, Recommendation (SBAR) format. Case studies promote critical thinking and decision making by cultivating the connection between didactic content and clinical learning experiences (Pupil, 2011; West, Usher & Delaney, 2012). Role-playing using the SBAR format is a strategy that promotes effective handoff communication skills using a standardized method recommended by the Joint Commission and Agency for Healthcare Research and Quality (Wang, Blazek, & Greene, 2015). In health assessment and simulation labs, students have more opportunities to practice patient handoff after completing physical assessments on manikins and standardized patients. Repetition of simulated handoffs is a safe, risk-free method for students to repeat skills, receive feedback, and learn from their errors (Lee, Mast, Humbert, Bagnardi, & Richards, 2016). The Handoff CEX tool (Horwitz, 2012) is used to evaluate handoff competence after the students complete a simulated patient scenario. Handoff setting, organization, communication skills, content, judgment, and professionalism are evaluated using a nine-point Likert scale. The tool enables the faculty to provide standardized and detailed feedback on the students' handoffs.

Although researchers agree that the transmission of accurate information is vital (Cohen, Hilligoss, & Kajdacsy-Balla, 2012; Young, Wachter, O'Sullivan, & Irby, 2016) it is imperative that the receiver of the handoff is able to process the information to form necessary clinical judgments. Clinical judgment following handoff is crucial and the ability to make sound clinical judgments has been identified as an essential skill for practicing nurses and is a hallmark of professional nursing. The nurse must understand the overall patient condition in order to plan care, which involves determining priorities of care based on the actual and potential patient situation. A literature search revealed no studies in undergraduate nursing education that focus on students being the sender **and** receiver of handoff. To connect the dots and provide students an opportunity to practice *receiving* patient handoff, fourth semester students participate in a handoff simulation experience. Simulation is an effective, evidence-based (Hayden, Smiley, Alexander, Kardong-Edgren & Jeffries, 2014) experiential learning strategy that can be used to help students gain a sense of salience as well as improve clinical competence in a risk-free environment. High-fidelity simulation has been repeatedly identified as one educational strategy to improve clinical judgment in novice nurses and help bridge the practice-education gap (Dreifuerst, 2012; Lasater, 2011). Jeffries (2012) included fidelity, or realism, as a necessary component of a simulation design as well as a component of the NLN/Jeffries Simulation Framework. To increase the fidelity of the experience, students receive bedside handoff from a practicing nurse, with the use of an electronic medical record (EMR). Standardized patients are used to further create a realistic scenario. The clinical scenario is based on standardized, tested, NLN/Laerdal® simulation scenarios owned by the school of nursing. Students are allowed up to 10 minutes after the handoff to use available resources such as the patient's EMR, a nursing drug handbook and a medical-surgical textbook. Clinical competence is measured using the Crieghton Competency Evaluation Instrument (C-CEI®, Hayden et al. 2014) from a remote viewing room. The C-CEI® focuses on 23 general nursing behaviors divided into four categories: assessment, communication, clinical judgment, and patient safety.

Despite longstanding identification of the relationship between communication breakdowns during end-of-shift handoff and patient safety, errors are still occurring globally (Johnson, Barach, & Arora, 2011). Insufficient handoff education is identified as a root cause of ineffective handoff and thus patient care errors (The Joint Commission Center for Transforming Healthcare, 2011). Nurse educators must develop and validate educational strategies to address handoff deficiencies in nursing students so that they will have the knowledge and skills needed to provide safe, consistent, and person-centered care. The implementation of a variety of evidence-based handoff educational strategies throughout the curriculum uniquely encompasses handoff delivery and reception. These strategies are implemented to increase nursing students' proficiency and confidence as well as enhance clinical judgment needed for effective handoffs. This in turn, will potentially bridge the practice-education gap related to handoff communication, and promote patient safety as students transition into practice, and advance in their professional careers.

Using Service Learning to Enhance Cognitive Development of Nursing Research for Complex Social Issues

Linda K. Bennington, PhD, MSN, BSN, BS, MS, RN, USA

Abstract

Service-learning is loosely defined as a structured educational experience that links classroom knowledge to community engagement. At its best, it accommodates student growth via self-examination to find those qualities within that enable a successful transition for the common good of a community. At its worst, it may stymie association with others, be they student peers or members of a diverse culture within the community. The overall objective is to serve as an initiation into the concrete world of the lives of those rarely encountered by the student nurse in his/her typical setting in order to provoke self-reflection, compassion, selflessness, social awareness and, above all, cognitive development and insight. The succinct substance of service learning is that the combination of the two adds value to each and transforms both.

Since service learning exposes students to various situations and organizations, this provides them with the means to see firsthand the various social injustices and cultural barriers that exist in local communities. This, in turn, will hopefully produce students who are better prepared to deal with the complex social issues that plague our global populace. Although service learning has been incorporated into baccalaureate programs for at least the past 20 years, there has been little standardization as to its implementation. Actual student involvement seems to range from rigorous community participation with close integration into academic study to one week intensive service activities that are essentially unrelated to classroom concepts. Our BSN program has chosen to implement the concept through a one-year (two semester) community health course that involves assigning groups of students to various organizations within our community. These groups range from faith-based to drug court to assisted living to pregnant teens, breastfeeding promotion and prenatal education. Each group is directed by a faculty member who only serves as a resource. It is up to each group of students to assess their aggregate,

make diagnoses that are indicated from the assessment and then plan and implement their choices. This process introduces students into communal regions of which they personally have little knowledge, i.e., addicts in drug court and pregnant teenage girls.

The measure of a community's needs can often be determined through the infant mortality rate as it reflects the quality of prenatal and birth care available to both children and mothers and is a critical indicator of the overall health and welfare of a nation. Our state's infant mortality rate is higher than the national average at 6.8/1000 and the highest rate is within our own community at 9.1/1000 (Virginia.gov, 2014a). Introducing nursing students to this culture and population can serve to challenge their assumptions and bring stereotypical preconceptions to the surface. Working within and interacting with this population serves to present alternative viewpoints of issues that may conflict with what the experts profess. This revelation has provided a stimulus for the students to search the literature and nursing research to justify and compare what they observe from what they read. It has also instilled within many of them a need to be socially and politically active. The key, however, to obtaining this understanding comes with continuing faculty/student interactions through verbal 'logs' and persistent questioning. Activities that have been enhanced and developed from this group have included teaching prenatal classes at a local health clinic and high school as well as developing teen father support and educational groups. Many of the activities were developed by the students themselves after perceiving a need and discussing it with the aggregate.

Willingness to change and adapt together with somewhat informal faculty/student meetings has provided the majority of these students with the ability to establish a positive attitude toward civic engagement and a better understanding of complex social issues. This was achieved by providing a quasi-structured environment through various local organizations that play a specific role within the respective community. To summarize a few of the objectives, these students achieved the ability to analyze the complexity of a problem and devise solutions rather than focus on individual deficiencies which resulted in cognitive development.

The Use of Condition Mapping to Teach Situational Awareness

Amy M. Wagner, MSN, RN, CNE, USA

Amy Hower Lee, MSN, RN, USA

Abstract

Prelicensure clinical education (PCE) is constantly evolving and increasingly challenging. Globally, Nurse Educators (NEs) strive to deliver the Advanced Beginners the professional workplace now expects by ensuring basic tenets of Situational Awareness (SA) and Clinical Reasoning (CR) are in place. NEs must develop and refine techniques to promote Student Nurse (SN) learning and teach effective SA.

SA and CR are not topics with standardized didactic content which complicates the effective delivery of this content and development of these skills (Ashley & Stamp, 2014; Cohen, 2013; Darcy Mahoney, Hancock, Iorianni-Cimbak, & Curley, 2013; Edozen, 2015; Foote, 2013; Fore & Sculli, 2013; Gu, Ha, & Kim, 2015; Jewell, 2013; Martin & Wilson, 2011; Robert, Tilley & Peterson, 2014; Stubbings, Chaboyer, & McMurray, 2012). A further complication of ensuring effective PCE is that SNs learn differently (Jewell, 2013; Turner & Keeler, 2015). NEs must find ways to promote each style, each motivator, for each SN.

Traditional Preclinical Preparation (TPP) has come into question with regard to efficient and practical use of time and thought processes of SNs (Turner & Keeler, 2015; Spadaccini & Esteves, 2014). TPP encourages everyone into a standard format not allowing for individuality or specificity, for the SN or for the patient. A common observation that seasoned nurses share is that new graduate nurses are spending hours at the start of their shift to gather patient information which then delays patient care. Starting assessments and medication administration an hour and a half into a shift is less than ideal. This is the pattern NE are perpetuating with TPP. Also, the lack of availability and accessibility of the Electronic Medical Record (EMR) for SNs and in some instances, faculty, adds to the difficulty of effective PCE (Brady, 2014; Bowers et al., 2011; Brooks & Erickson, 2012; Gardner & Jones, 2012; Koch et al., 2013).

A more productive preclinical preparation methodology that better utilizes SNs time and decreases stress by allowing SNs to come to clinical prepared but not burdened with non-applicable information is recommended. Condition Mapping (CM) was developed as an alternative to TPP. SNs were given the admitting diagnosis of their assigned patient and were then expected to research textbook parameters regarding definition, pathophysiology, diagnostics and medications. SNs presented to clinicals with a plan of care for their assigned patient and were able to individualize assessment and diagnostic data to trend for their patient as opposed to collecting a standardized set of data on each patient and then determine applicability to patient care.

SNs were able to present to clinical with basic textbook information which allowed for decreased anxiety with a sense of being prepared. SNs were then able to correlate real time data as it relates to their patient's condition resulting in individualized patient care management. SNs, prompted by the self-directed desire to know, were more integrated into the healthcare team. SNs collaborated with bedside staff who were readily able to access the EMR and quickly locate information as staff responded to SN concerns. An additional benefit of the CM approach to preclinical preparation was more effective use of preclinical prep time allowing SNs to present to clinical well-rested with a sense of preparation for what is to come.

The use of CM to facilitate the development of SA and CR proved effective to SNs and faculty. CM promotes organization and prioritization, two skills essential for effective patient care management and SA as well as attaching itself to the internal motivators for each SN. CM also addressed the time laden TPP and EMR accessibility concerns which in turn decreased the effect of these stressors on SNs. SNs were able to identify patterns and potential risks and readily plan to intervene to promote positive patient outcomes which is the basic foundation of SA and CR. CM allows SNs that need structure to proceed with a relatively standardized format for gathering patient information while allowing for individuality with the application to patient care. Ensuring that new graduate nurses are able to function as Advanced Beginners will improve healthcare delivery and patient outcomes across the globe.

Innovative Pedagogical Approaches to Undergraduate Nursing Research: Avoiding the Cursory Critique

Jamela M. Martin, PhD, RN, CPNP, USA

Abstract

Upon entry into practice, BSN-prepared nurses are expected to contribute towards improvements in nursing practice and patient outcomes, partially through participation in evidence translation. The American Association of Colleges of Nursing's *Essentials of BSN Education* states that professional nursing practice is grounded in the translation of evidence into practice. *Essential Three: Scholarship for Evidence-based Practice* incorporates nine specific outcomes expected of BSN-prepared nurses. Yet, multi-factorial barriers to knowledge translation in practice persist. One of the key factors that facilitates EBP adoption in healthcare centers is a clinician's strong foundation of knowledge and skills, which is often cited as a prominent personal barrier. Much of the recent focus on improvements in knowledge translation have focused on interventions in the workplace. However, EBP courses in nursing education programs are an equally influential piece of the puzzle that must be explored. There is a lack of evidence that our strategies to teach research and evidence based practice concepts adequately prepare our new graduates to meet key stakeholder expectations. Nursing programs often employ lecture-based, content delivery methods to prepare nurses with basic knowledge of the research process with limited focus on application. Mastery of information at lower cognitive levels enables mastery of skills in the higher levels of the taxonomy (Bloom, 2001). Yet bachelor's prepared nurses are often prepared with only a cursory understanding of research methods (level 1 cognitive process), while still being expected to perform accurate, detailed critiques of the literature (level 4 cognitive process). For the BSN graduate, this direct, yet limited, approach translates into a lack of confidence to participate in evidence translation. Our pedagogical approaches to research and evidence-based practice must more comprehensively focus on how research is planned, conducted, and disseminated *before* expecting new nurses to accurately critique and implement findings. An alternative and potentially more effective approach to teaching difficult research concepts is constructionism: a prevailing cognitive learning theory that advocates student-

centered, discovery learning where students use information they already know to acquire more knowledge. The purpose of this presentation is to discuss the success of a project-focused, evidence-based education strategy that has been implemented into traditional undergraduate and RN-BSN nursing research courses. This strategy engages students in a hands on, experiential learning opportunity that makes nursing research more stimulating, palatable, and attainable; teaches concepts of the research process from a constructionist approach; and prepares new graduate nurses to critically analyze and implement evidence with confidence as well as collaboratively engage in the development of research proposals. Closing the know-do gap may be possible in the future, but current attempts to narrow the gap must include an examination of the role of nursing educators in preparing nurses for knowledge translation in practice.

Using Evidenced-Based Educational Practices to Improve Graduation Rates for RN-BSN Students From Disadvantaged Backgrounds

Janice E. Hawkins, PhD, RN, USA

Lynn L. Wiles, PhD, MSN, BSN, RN, CEN, USA

Karen A. Karlowicz, EdD, RN, USA

Kimberly Adams Tufts, ND, RN, WHNP-BC, FAAN, USA

Abstract

A diverse and highly educated nursing workforce is essential to improve access to quality healthcare across the globe. The purpose of this presentation is to describe an educational model employing evidence-based educational practices to improve graduation rates of nursing students from socially and economically disadvantaged backgrounds. This model was developed with funding from the United States (U.S.) federal government via a nursing workforce diversity grant. The purpose of the grant project is to increase the number and diversity of baccalaureate-educated nurses from a resource limited community in the rural southern U.S. Structural, environmental and social supports are incorporated to facilitate student academic success.

Structural support is provided through several mechanisms. The students are admitted to the program as a single cohort. The single cohort format is a proven method to reduce attrition of RN-BSN nursing students (Davidson, Metzger, & Lindgren, 2011). Individualized advising, tuition assistance, and flexible scheduling provide further structural support. Because registered nurses report a lack of assistance with advising and enrollment procedures as barriers to returning to school for a baccalaureate degree (Altmann, 2011), one evidence-based strategy employed is individualized advising to assist students with degree planning and course enrollment navigation. Further evidence suggests that structural support such as tuition assistance, flexible scheduling and academic coaching are vital to the successful academic progression of registered nurses returning to school (Altmann, 2011; Davidson, Metzger, & Lindgren, 2011; Kern, 2014; Megginson, 2008). In our model, financial support is provided in the form of grant funded scholarships and tuition assistance from the hospital partner. Courses are delivered via an online distance-learning format that allows for course scheduling that does not conflict with work schedules and does not require travel to attend class. Additionally, access to tutors and online writing support provides students with academic support to help them succeed.

Environmental support is provided through office space for the faculty mentor and a dedicated study space for students, both of which are maintained within the hospital system. The study space contains a complete set of printed course textbooks and computers with a reliable Internet connection to ensure that students have access to the online university library and other online resources. Computer labs and library resources have been identified as factors that positively impact retention of RN-BSN students (Jeffreys, 2007; Kern, 2014). The study space also provides a convenient location for students to engage with each other as well as with faculty and peer mentors.

Social support is another factor identified by Jeffreys (2007) and Kern (2014) to reduce attrition in RN-BSN students. Formal social support includes a dedicated on-site faculty mentor as well as assigned peer mentors. The literature is replete with evidence of the impact of mentorship on positive academic progression and student achievement (Aponte, 2015; Millett, Stickler, & Wang, 2015; Murray, 2015; Tabloski, 2016).

Providing structural, environmental and social support for nurses continuing their education contributes to their success and ultimately results in advancing the nursing profession. The early evaluation of this educational model is positive. Enrollments and diversity of students from the targeted community have increased with current retention rates that are promising. Highly educated nurses from socially and economically disadvantaged backgrounds contribute to a more culturally aligned nursing workforce and better patient outcomes. Therefore, developing an evidence-based educational model to increase the number and diversity of baccalaureate-educated nurses in the workforce helps to advance the nursing profession and the healthcare needs of the global community.

F 02 - Improving Nursing Care and Outcomes for Mother-Infant Dyads Impacted by Opioid Use Disorders

The Impact of Kangaroo Mother Care on Mother-Infant Dyads Affected by Neonatal Abstinence Syndrome

Lisa M. Cleveland, PhD, RN, PNP-BC, IBCLC, NTMNC, USA

Abstract

Background and Significance: Opioid use, both licit and illicit, is a growing public health concern in the United States (NIDA, 2016). Heroin use has increased among both men and women of all ages and across all socio-economic groups. Further, rates of heroin use have doubled in U.S. women (CDC, 2016). These national trends are reflected in the rising number of women who use opioids while pregnant. Between the year 2000 and 2009, the use of opioids during pregnancy increased fivefold (Patrick, et al., 2012). As a result, national rates of neonatal abstinence syndrome (NAS) have tripled since 2000 resulting in one U.S. child now being born every 25 minutes with this syndrome (NIDA, 2016). NAS is a withdrawal syndrome experienced by infants who are prenatally exposed to addicting substances, most commonly opioids, and is associated with inconsolable crying, sleep disturbance and seizures (Cleveland, in press). No universally agreed upon standard of care exists for infants impacted by NAS. Treatment is typically focused on symptom management using medications, such as morphine, and soothing techniques. Medications may alleviate some NAS symptoms; however, medication use prolongs an infant's length and cost of hospital stay (Bio, et. al, 2011; Jansson, L., 2011). Soothing techniques are nonpharmacologic comfort measures and are considered the first line in the clinical management of infants with NAS. These techniques include swaddling, providing a quiet environment and skin-to-skin mother-infant holding [kangaroo mother care] (Sublett, 2013; Valez, 2008). Of these techniques, kangaroo mother care (KMC) is unique because it offers the potential to benefit both the mother and her infant (Ludington-Hoe & Swinth, 1996). While KMC is often recommended for infants with NAS, no empirical evidence exists to support its use.

Study Purpose and Specific Aims: The purpose of this study was to determine the impact of KMC on attachment and stress-reactivity in mother-infant dyads impacted by NAS.

Methods: Institutional Review Board approval was obtained prior to the onset of data collection. All participants provided written consent to participate in this study. We used a sequential, embedded, mixed-methods design to conduct this study. Our participants were recruited prenatally from a non-residential treatment facility for pregnant and parenting women with opioid use disorders. They were enrolled in the study following informed consent and a brief educational intervention on KMC. The women then contacted our study personnel following delivery and we met with them during two separate sessions of KMC. Maternal attachment was assessed using the Maternal Attachment Inventory (MAI) at baseline and following the 2nd KMC session. Stress was measured using the Parental Stressor Scale: Neonatal Intensive Care Unit (PSS: NICU). We also assessed mother and infant heart rate and salivary cortisol levels prior to and during each session of KMC. Qualitative interviews were conducted with the mothers following discharge of their infant from the hospital. All interviews were audio-recorded, transcribed verbatim and analyzed line by line using thematic analysis.

Findings: As of October 2016, 76 women have been enrolled in the study. Forty-nine mother-infant dyads have completed data collection; 14 women are still pending delivery and 13 have been lost to follow-up. Our target sample size is 60 complete data sets and we anticipate this study to be complete no later than spring of 2017. To date, the mean age of our study participants was 27 years and 79% self-identified as Latina. Sixty-three percent of the women were married and 71% indicated that their infant's father was actively involved in their lives. Most women (67%) did not work outside of the home and 35% reported having an annual household income of less than \$9,999. Further, 46% of the women reported have a previous mental illness diagnosis. The average gestational age for the infants who participated in

this study was 38 weeks and the average birth weight was 2700 grams. Infants spent an average of 28 days on medications for management of their NAS symptoms.

Scores on the MAI indicated a high level of maternal attachment across both time points. Results from the PSS: NICU showed high scores on the "Relationship and Parental Role" subscale. The items scored as most stressful were: (a) being separated from my baby, (b) not being able to hold my baby when I want, (c) feeling helpless and unable to protect my baby from pain and painful procedures, and (d) feeling helpless about how to help my baby during this time. Further, a paired samples t-test revealed a significant decrease in mother's heart rate, from an average of 76.41 ($SD = 10.31$) beats per minute prior to engaging in KMC, to an average of 70.62 ($SD = 12.58$) beats per minute during KMC; $t(33) = 3.67, p < .01$. Infant heart rate also decreased significantly from pre-KMC at an average of 144.76 ($SD = 17.24$) beats per minute to an average of 137.79 ($SD = 18.11$) beats per minute during KMC; $t(33) = 2.33, p < .05$. Both maternal and infant saliva analysis for cortisol are underway and will be completed by Spring of 2017.

To date, our qualitative findings indicate that KMC was very meaningful to the mothers. Thematic analysis revealed the following themes: (a) Barriers to KMC, (b) In our own world, (c) Healing together, and (d) Preparing to go home. Barriers to KMC reflected the busy and often crowded environment of the intensive care nursery as well as staff attitudes and stigma surrounding addiction. Yet mothers described feeling as though they were in their own world with their infant while doing KMC in spite of this environment. They also explained how they felt they and their infant were healing together during KMC and that their infant was "forgiving" them. Finally, the mothers described preparing to go home and how many of them continued to do KMC with their infants following hospital discharge.

Infant Feeding Decisions Among Mothers Receiving Medication Assisted Treatment for an Opioid-Use Disorder

Kelly S. McGlothen, BSN, RN, IBCLC, NTMNC, USA
Lisa M. Cleveland, PhD, RN, PNP-BC, IBCLC, NTMNC, USA
Frank Puga, PhD, USA

Abstract

Background and Significance: A growing number of women of childbearing age are affected by opioid use disorders (OUD). In 2009, more than 23,000 pregnant women in the U.S. were reportedly using opioids when they delivered; a 475% increase from 2000.¹ Currently, medication assisted treatment (MAT) with methadone or buprenorphine is the standard of care for pregnant women who are dependent on opioids. The Academy of Breastfeeding Medicine recommends breastfeeding for women receiving MAT who have no other contraindications to breastfeeding.² Further, breastfeeding offers multiple benefits for infants that may be of specific significance to opioid-exposed infants such as a reduced rate of sudden infant death syndrome (SIDS), a reduction in infections in childhood, a decreased risk of neglect, and modified NAS symptoms and length of stay.^{2,3,4,5,6} In addition to health benefits and the desire to bond with their infant, mothers reported that breastfeeding helped them to atone for the guilt they felt for their infants experiencing withdrawal.⁵

Despite the known benefits and recommendations for breastfeeding, women receiving MAT often face challenges. This may be due to misconceptions about the effects of MAT on the infant and the stigma associated with addiction. According to the CDC (2012), rates of breastfeeding initiation among women receiving MAT are approximately 24-46%.⁷ This rate is low in comparison to an overall national breastfeeding initiation rate of 77%.⁷ Further, for women receiving MAT who do initiate breastfeeding, more than half discontinue within one week.⁵

In general, women make infant feeding decisions based on their perceptions of a woman's role as a mother, life experiences, and perceptions of societal response and support.^{8,9,10} While women may view infant feeding as an important part of their mothering role, multi-level, contextual factors influence the way in which women receiving MAT navigate this role. Little research exists to explain how women receiving MAT make infant feeding decisions. Therefore, the purpose of this qualitative pilot study was to explore the contextual factors that influence the infant feeding decisions of women receiving MAT.

Research Questions: How do mothers who are receiving MAT for an OUD make infant feeding decisions?

Methods: This pilot study was part of a larger study focused on the impact of kangaroo mother care on mother-infant dyads impacted by opioid use. Institutional review board approval was obtained prior to the onset of any data collection. Participants received an information sheet and provided verbal consent at enrollment. A qualitative descriptive design was used. Data were collected through semi-structured, individual, audio taped interviews with eight mothers in the early postpartum period (no more than six months post-delivery). All women were receiving MAT for an OUD at the time of the interview. Each woman was interviewed once in a private room in the hospital or the addiction treatment center where they were receiving recovery care. The interviews lasted approximately 30-60 minutes and were transcribed verbatim using a professional transcription service. We used qualitative content analysis to analyze all data.

Findings: Our data analysis revealed three common categories: 1) what I heard about breastfeeding and MAT, 2) who/what influenced my infant feeding decision, and 3) how I made my decision.

Our findings highlight the need for greater support of women who are receiving MAT during the infant feeding decision making process. In the category *what I heard about breastfeeding*, mothers reported receiving conflicting information regarding their ability to breastfeed while receiving MAT. The women also described the negative attitudes that they felt they received from healthcare providers, family members, and peers surrounding breastfeeding and MAT. One mother stated, "My dad keeps telling me about the methadone going through my milk. He's real rude about it too. He's like, I don't even know why you're pumping... you're just going to get the baby hooked."

Multiple factors contributed to the second category of *who/what influenced my infant feeding decision*. For most mothers, the knowledge of the benefits of breastfeeding for infants largely influenced their infant feeding choice. Most mothers decided to breastfeed because they wanted to, "...do anything to relieve their infant's withdrawal symptoms." Several mothers said that breastfeeding was a way for them to atone for the guilt they felt about their infants' withdrawal.

"I wasn't going to breastfeed at first. But I see all the withdrawal symptoms and I feel bad. I feel like I'm helping him and I feel better knowing that he has milk here when I'm at home and I'm not with him. He has milk here that's going to help him feel better."

In the last category, *how I made my decision*, the women reported typical breastfeeding concerns including: the embarrassment of breastfeeding in public, insufficient milk supply, maternal nutrition and health, and pain with breastfeeding. They reported that the benefits of breastfeeding were a strong contributing factor to their decision to breastfeed; however, the mothers felt that the information they received regarding the safety of breastfeeding while receiving MAT influenced their ultimate decision to breastfeed or formula feed. Additionally, the women felt that their love for their infants encouraged them to continue breastfeeding when they wanted to give up.

"But now she's home, I know what drugs I'm taking and what I'm not so I am feeding her breastmilk. Yeah, because she's my daughter and she's home with me now. So, I don't have to ask nobody anymore. I'm doing the best that I can for her."

The findings from this study contribute to the body of knowledge surrounding infant feeding decision making in mothers receiving MAT. This knowledge provides a basis for developing and testing effective and sustainable interventions to improve infant feeding outcomes in this population of mothers and infants.

Building an Inter-Professional, Community-Informed, County-Wide Neonatal Abstinence Syndrome Collaborative

Frank Puga, PhD, USA

Lisa M. Cleveland, PhD, RN, PNP-BC, IBCLC, NTMNC, USA

Abstract

Background and Significance: Effective healthcare quality improvement and patient centered outcomes research requires meaningful engagement of patients, community members and stakeholders in identifying research priorities, developing comparative effectiveness studies, and disseminating research findings. Community and patient engagement in the systematic evaluation of health outcomes is particularly important in health conditions that disproportionately affect specific populations, such as with Neonatal Abstinence Syndrome (NAS). Recent reports highlight the persistence of poor healthcare quality and patient outcomes in specific populations (low income; racial and ethnic minorities; individuals living in rural areas; and lesbian, gay, bisexual, and transgender populations). In addition to health inequity, these patient populations are disproportionately not engaged in research. Reports from the Agency for Healthcare Research and Quality (AHRQ), National Institutes of Health (NIH) and the Patient Centered Outcomes Research Institute (PCORI) stress the need to engage underserved populations in the research process in order to effectively address healthcare disparities in the nation; however, there are few venues where underrepresented patient populations can build capacity for research, connect with professionals and engage in discussions about the implications of research findings. There is an opportunity for community engaged research collaboratives to enhance capacity for patients, community members, clinicians, researchers and other stakeholders to engage in comparative effectiveness research (CER) to improve health outcomes for underrepresented populations.

Purpose: The purpose of this Tier 1 Patient Centered Outcomes Research Institute (PCORI) project is to establish a Bexar County Neonatal Abstinence Syndrome Collaborative. Rates of NAS in the United States have tripled since 2000. Bexar county, Texas, the San Antonio area, has been disproportionately affected, accounting for one third of NAS cases reported annually in the state. The goal of this collaborative is to identify community-driven research priorities and develop patient-centered CER studies to reduce NAS rates and improve care in Bexar County.

Methods: During a nine-month project period, the Bexar County NAS Collaborative focused on the following activities: 1) Enhance capacity for patients, community members, clinicians, researchers and other stakeholders for a comparative effectiveness research (CER) study focused on NAS, 2) Establish a research question and 3) Develop a CER study to compare interventions for reducing NAS rates and improving outcomes. These activities were facilitated through the establishment of an advisory council and development of a social media campaign to expand community engagement. The Advisory Council included partners that represented various stakeholders including patients and family members, state government organizations, clinicians, and researchers. These individuals guided the governance structure, decision making, and planning of community forums. A social media campaign was developed as a means for disseminating information about NAS and the collaborative, recruiting community stakeholders to participate in community forums, and facilitating active communication. Finally, the collaborative planned two community forums (December 2016 and March 2017) to identify community driven priorities to improve NAS outcomes in Bexar County.

Findings and Future Directions: This 9-month project began in August of 2016 and will be completed by May 2017. To date the Bexar County NAS Collaborative has established an advisory board and governance structure. Implementation of the social media campaign is currently in progress. Implementation is being guided by stakeholder input. Results from the community forum will be finalized in May 2017 and will be used to guide the development and implementation of a NAS related CER study in the Bexar County community.

F 03 - Leading Change Through Collaborative Partnership: Implementation of a Statewide Cultural-Competence Initiative in the United States

Leading Change: The Power of Vision and Collaborative-Partnership

Rita K. Adeniran, DrNP, RN, CMAC, NEA-BC, FAAN, USA

Sarah Hexem, JD, Esq., USA

Elizabeth W. Gonzalez, PhD, APRN, BC, USA

Abstract

Healthcare organizations and clinicians recognize the importance of cultural competency as a safety and quality variable in healthcare; however, practice varies among health professionals, and across healthcare organizations (Douglas et al., 2014; Gill, Kuwahara, & Wilce, 2016). Factors that contribute to variations in the practice of culturally competent care include the degree of personal desire to deliver culturally competent services and clinicians' knowledge, skills, and attitudes, along with an appreciation of the impact of cultural competency on optimizing health outcomes. Availability and limitations of organizational resources in the form of infrastructures, human resources, and policies also contribute to the variations in practice (Laskowski-Jones, 2012). Leadership is crucial to understanding and disentangling the complex reasons for these differences (Dauvrin & Lorant, 2015; Hisam et al., 2016). A systematic assessment of the state of cultural competency in the state of Pennsylvania was necessary to reveal opportunities and provide direction for advancing and standardizing cultural competence practices across the state of PA and beyond.

As a Robert Wood Johnson Foundation Executive Nurse Fellow with funding to complete an advanced leadership project of choice, along with the vision and passion for cultural competency, I sought the support of thought leaders across the nation, including members of the Pennsylvania Action Coalition's Nursing Diversity Council (NDC). The project's goal is to enhance the provision of culturally competent care across the state of Pennsylvania. Stakeholders who joined forces to work on this project included clinicians and non-clinicians; all shared a vision for Healthy Pennsylvania through Nursing. These leaders are primarily driven by a passion for quality healthcare for vulnerable populations. As a team, we set direction, created alignment and gained significant commitment to conduct the project. Also, the team adopted a gracious space philosophy. Team members worked collaboratively in a gracious space environment where differences, diversity of thoughts and ideas were welcomed and celebrated; members trusted enough to be vulnerable and successfully led the completion of the statewide cultural competence education and awareness survey of Pennsylvania Registered Nurses. Survey data was analyzed, and findings were used to guide development of education and training to address identified gaps. The outcome of the project underscores the value of visionary leadership in leading change by inspiring stakeholders to engage in meaningful ways for a greater cause!

State of the Evidence, Making Sense of the Data: Culturally Competent Nursing Practices in Pennsylvania

Rita K. Adeniran, DrNP, RN, CMAC, NEA-BC, FAAN, USA

Diana Jones, EdD, MS, RN, USA

Anand Bhattacharya, MHS, USA

Abstract

Substantial evidence suggests vulnerable and traditionally under-represented racial and ethnic patients experience poorer clinical outcomes compared to the general population in the United States. The differences in the incidence, prevalence, mortality and burden of disease and other adverse health conditions that exist among specific population groups in the United States is reported as health and healthcare disparities (Fink, 2009; Hebert, Sisk, & Howell, 2008). The etiologies of health and healthcare disparities are complex and multifactorial. It includes but is not limited to environmental, systemic, and organizational level factors, along with social-cultural, patient, family, and provider-level factors (Baillie & Matiti, 2013; Betancourt, Corbett, & Bondaryk, 2014; Padela & Punekar, 2009; Purnell et al., 2016). Cultural competence is identified as a strategy to mitigate health and healthcare disparities, improve patient outcomes through increased healthcare access and full engagement of patients and families in their health and healthcare. Culturally competent clinicians appreciate the uniqueness of each patient within the context of their illness, communicate respectfully, build trust, and maintain therapeutic relationships that promote optimal health outcomes.

Healthcare organizations play a vital role in facilitating cultural competence by providing resources, infrastructures, and policy that promotes cultural competency. This project was undertaken to determine opportunities for enhancing cultural competence practices by registered nurses in the state of Pennsylvania. Goals of this project include ascertaining opportunities for improve competent cultural practices among registered nurses in the state of Pennsylvania (PA) and to develop education and training to address identified gaps. Specifically, the objective of this project was to determine the level of cultural competence education/training, sources and availability of cultural competence information, access to cultural competence resources and extent to which culturally competent care is currently provided by RNs across the state of PA. A statewide survey of Registered Nurses in the state of PA was conducted from September 15, 2014, through March 31, 2015. The project asked for information about the respondents' socio-demographic characteristics, sources of availability of cultural competency information, self-reported levels of cultural competency preparedness and education, and level of culturally competent care provided by the RNs. Findings were summarized using descriptive statistics including means, frequencies, and percentages.

Results: A total of 1209 RN responses were received from survey participants. The majority of the respondents were females (92%), Caucasian (85%) and baccalaureate prepared (80%). The percentage of nurses who indicated speaking English as the primary and only language was 85%. Two out of every three participants came from a Magnet designated hospital. Just over half the respondents (57%) indicated receiving formal education in the area of cultural competency, while every three out of four nurses received cultural competency education as part of their professional development. 91% saw cultural competency as essential or crucial to their career performance, yet reported lack of time, resources and incentives surrounding cultural competency performance as significant barriers in being able to provide culturally competent care. Despite availability of language interpreters, 22% indicated they never use language interpreters, while another 31% only use it a few times a year. Two out of four RNs expressed their work did not provide cultural competency teams to help with patients, while 36% of the staff was unsure where to find such resources.

Discussion/Conclusion: While just over half of survey participants reported receiving formal education and training regarding cultural competency, participants reported a strong desire to provide culturally competent healthcare services. Registered Nurses underscored cultural competency as an essential skill

to their professional performance, but on the same token, reported lack of time, resources and incentives as sources of significant barriers to providing culturally competent care. The need for additional and ongoing education and training for nurses to enhance culturally competent services was evident, as well as healthcare organizations' responsibility to provide necessary resources to facilitate cultural competence. The findings of the survey were used to guide statewide educational interventions to address gaps and bolster RNs' cultural competence practices across the state of Pennsylvania.

Fostering Cultural Competency: The Pennsylvania Action Coalition's Exemplar

Sarah Hexem, JD, Esq., USA

Rita K. Adeniran, DrNP, RN, CMAC, NEA-BC, FAAN, USA

Diana Jones, EdD, MS, RN, USA

Abstract

Demographic trends, multiculturalism, pluralism, human, cultural, and system diversity are some of the dynamics that are changing the profile of the America populace to a more diverse society (Like, 2011). This reality presents opportunities for all leaders in the nation. Visionary leaders committed to making a positive difference, must see the transformation from these dynamics as opportunities rather than threats. Leaders can initiate programs to promote equity, improve quality, reduce and ultimately eliminate the long-standing disparities in health and healthcare. For example, in the United States, evidence suggest that blacks, when compared to their white counterparts, had higher death rates from cancer, stroke and heart disease, and experience twice the incident of infant mortality (Rossen & Schoendorf, 2014). These statistics at minimum are disturbing, deserving leadership attention and plan for sustainable solutions. Cultural competence has gained national and international attention as a strategy to eliminate racial and ethnic disparities in health and healthcare; accentuating the importance of providers' training and the recruitment of culturally diverse health professionals to achieve optimal outcomes (Henry, 2011). The benefits of increasing numbers of traditionally underrepresented racial and ethnic minorities in the medical profession is also identified as a strategy to reduce healthcare disparities. A higher proportion of traditionally underrepresented racial and ethnic professionals in the healthcare workforce increase the likelihood of concordance between patients and providers, a phenomenon proven to improve patients' adherence to treatments. Further, cultural competence training programs for all health care providers enhances their appreciation of the influence of cultural patients' ethnomedical beliefs, world views, culturally prescribed values, religion, gender specific status and roles on health care and treatment adherence (Delgado et al., 2013; Donaldson & Vacha-Haase, 2016).

Recognizing that health and healthcare disparities remain a challenge in the United States, the Nursing Diversity Council (NDC) of the Pennsylvania Action Coalition (PA-AC) that comprised of leaders in and outside of healthcare are working collaboratively to mitigate disparities. The PA-AC NDC's mission is to

increase diversity throughout healthcare and the nursing profession, endeavoring to ensure that “all Americans have access to high-quality, patient-centered care in a health care system where nurses contribute as essential partners in achieving success.” Members of the NDC are driven by their conviction to advance healthcare for ALL in Pennsylvania and guided by the Institute of Medicine’s *Future of Nursing* report recommendations. Strategies employed to achieve the NDC mission include the development and adoption of an overarching diversity and cultural competence strategic plan to guide program implementation. To date, several aspects of the strategic plan have been implemented, of note are:

- Creation and adoption of a gracious space philosophy to guide members’ work relationships
- Analysis and report of findings of the Pennsylvania Registered Nurses demographic profile that revealed opportunities for increasing gender, racial and ethnicity diversity of RNs in the Pennsylvania nursing workforce
- Development of a variety of videos that showcased individual nurse reflections on nursing from different vantage points; and nurse-led care as well as videos that specifically target recruitment of traditionally underrepresented minority youths and adults to choose nursing as a profession or second career
- Partner with philanthropic organizations and other stakeholders to raise funds to support mentoring for nursing students and leaders from traditional underrepresented minority groups
- Partner with individual leaders with funding to conduct statewide assessment that ascertained RNs desire, levels of cultural competency preparedness and education, and the availability or lack of resources in Pennsylvania healthcare organizations to provide culturally competent care
- Implementation of a statewide cultural competence education and training program delivered by nationally and regionally recognized experts in the field of cultural competency

Nurses, the single largest segment of healthcare professionals, have the unique opportunity to make sustainable change that improves the overall health care of society. The PA-AC NDC has been working conscientiously to improve quality healthcare for ALL Pennsylvania by bolstering the nursing workforce to reflect the diversity of the communities we serve, as well as enhancing the knowledge, skills, and attitudes of nurses through cultural competence education and training programs

F 04 - Ethical Considerations of Veteran- and Military Family-Focused Academic and Research Initiatives

Development of an Evidence-Based Online Veteran Healthcare Course

Dianne Morrison-Beedy, PhD, MSN, BSN, RN, WHNP-BC, FNAP, FAANP, FAAN, USA

Alicia Gill Rossiter, DNP, FNP, PCPNP-BC, FAANP, USA

Rita F. D'Aoust, PhD, ANP-BC, CNE, FAANP, FNAP, USA

Abstract

Over 2 million Americans have served in the military since 9/11. These numbers include Active Duty, Reservists and those in the National Guard. When they retire or return to their civilian lives, military service becomes far less visible. However, the time in the military has created varied, and at times, significant health risks that require special screening and monitoring. Often civilian healthcare providers are these veterans only or primary source of health care. Many civilian providers lack knowledge regarding the military, the military culture, and the effect of military service on the overall mental and physical health of veterans. This can leave the veteran at a significant disadvantage in regards to their overall healthcare needs.

The Joining Force campaign developed by First Lady Michelle Obama and Dr. Jill Biden challenged colleges of nursing around the country to work to improve the healthcare of our veterans. To date over 660 nursing programs in all 50 states have joined forces to included veteran centric healthcare issues into nursing and advanced practice nursing curriculum with several colleges including specific needs of military families in their curriculum. In 2012, the authors developed the first online "Introduction to Military and Veteran Health" course aimed at educating nurses to care for veterans in the civilian healthcare arena.

Nurses are on the frontlines of healthcare often working in clinics, hospitals, and community agencies, and may be the first to encounter a veteran in crisis or experiencing physical and/or psychological comorbidities secondary to their military service. Due to the potential correlation between military service and physical and psychological health comorbidities, it is imperative for all healthcare providers to screen veterans for a history of military service and to be educated on how to provide appropriate care to this vulnerable population. In addition, knowledge regarding resources and referrals available to veterans in the community is critical to meeting the needs of veterans and their families. Prompt identification and treatment is imperative in order to decrease the deleterious health consequences related to military service and to improve healthcare outcomes of veterans receiving in the civilian sector.

The "Introduction to Military and Veteran Health" course is an eight module online course that helps bridge the knowledge gap of civilian providers by addressing military culture, the Veteran Administration healthcare system, conflict specific risk factors and co-morbidities as well as knowledge regarding referral sources/resources in the community, physical and psychological wounds of war, impact of military service on military families, and women veteran specific healthcare needs to include military sexual trauma. Students who have taken the course indicate an awareness in the need to ask all patients if they have served in the military and an increase in knowledge and comfort level regarding addressing military service related healthcare risk factors and comorbidities as well as increase knowledge of resources and referral sources in the community.

Improving Health Outcomes of Military Children Through Research and Policy Initiatives

Margaret C. Wilmoth, PhD, FAAN, USA

Alicia Gill Rossiter, DNP, FNP, PCPNP-BC, FAANP, USA

Abstract

Approximately 2.2 million Active Duty, National Guard, and Reserve members have been tasked for upward of 3.3 million deployments since the onset of military action in Iraq and Afghanistan. Roughly 40,000 Active Duty servicemembers are married—58% of servicemembers have families and approximately 40% have at least two children. The majority of military children are in early and middle childhood—78% of the children of Active Duty parents are under the age of 11 years and 80% of reserve component children are under 15 years of age.

With the increased operations tempo, the risk for abuse and neglect among military children has increased. Historically, the healthcare needs of military children have been unrecognized outside of military healthcare settings. Military children are at higher risk for abuse and neglect, substance use, and suicide when compared with non-military connected children; stress and depression related to parental deployment or post deployment physical/psychological injuries; behavior and academic issues secondary to emotional distress, frequent moves or a parental deployment; and anxiety that can lead to changes in appetite, disrupted sleep patterns, and impaired immune response which can impact overall physical and psychological health. Upwards of 33% of military children have experienced maltreatment and/or abuse. Sadly, at least 19,000 children have experienced the wounding of a parent and over 2,200 have experienced the death of a parent secondary to military service in Iraq or Afghanistan, which can have long-term physical and psychological health implications for military children.

Research and policy initiatives aimed at identifying and decreasing the long-term effects of parental deployment, minimizing the physical and psychological sequelae, and identifying educational ramifications on children is almost nonexistent. This presentation will discuss the gaps in research and policy and provide guidance as to how to reduce barriers to access, decrease knowledge deficits of healthcare providers, and/or improve consistency in healthcare delivery to this underserved population that is the most vulnerable to aftermath of war—military children.

Conducting Ethical Research With Veterans

Catherine G. Ling, PhD, FNP-BC, FAANP, USA
Heather Johnson, DNP, FNP-BC, FAANP, USA

Abstract

Background: Considered a vulnerable and underserved population, veterans have a unique relationship with research. While on active duty, they are subject of constant data collection. Most of that data is collected and maintained within the Department of Defense and is not for public use. This creates a unique Federal big data repository. The unique nature of the repository lies in the contextual homogeneity of the participants e.g. all are employed, have a minimum of a high school education with additional training and consistent access to health care, food and housing. Finally, all are expected to maintain physical fitness standards. Very little information on working with veterans exists outside of this Federal system.

The 22 million US veterans have experienced military training, deployments, and they speak with a unique lexicon. Ethos, duty, and commitment to mission are lived values. This background does not get packed away when the individual leaves the service. Given that only 7% of the American population has served in the military, it is reasonable to assume that many researchers do not have an exposure to the lived experience of military life. That lack of exposure can lead to flawed assumptions that can skew findings. Additionally, barriers exist to veteran involvement in research. Those barriers include but are not limited to incentive issues, concerns regarding repercussions, bureaucracy, maintaining security clearance status and post military employment.

A way to involve veterans in research while addressing potential ethical conflicts draws from community based research methods. These principles hold several key components for ethical conduct with populations from different backgrounds. The primary principle would be to utilize military veterans as partners in all phases of design and analysis. Consider using KBA format:

Know where your expertise (real and contextual) ends

Be specific in your question and purpose

Ask Recruit Involve veterans.

With that format and the principles of Beneficence, Justice and Respect for Persons. Starting with the research question, think through the impact and meaning to veteran(s), beneficiary or current active duty. The design, implementation and analysis of research should respect dignity while avoiding undue exposure and coercion. Working with veterans can create a more ethical and robust expansion of science that benefits all of society.

F 06 - Family-Centered Care or Child-Centered Care? Evidence and Ethics

Family-Centred Care or Child-Centred Care: Generating the Evidence and Ethics

Linda Shields, MD (Rsch), PhD, FAAN, FACN, MAICD, Australia
Veronica D. Feeg, PhD, RN, FAAN, USA

Abstract

Family-centered care (FCC) has been considered a cornerstone of pediatric health care since the 1970s, but evidence of its effectiveness is lacking (Coch rev). Qualitative research about its implementation demonstrates that problems exist in its interpretation and applicability in health services. A new model, child-centered care (CCC), is emerging and it needs debate, philosophical argument (Coyne, Soderb, Halls) and ultimate testing to ensure it can be more effectively implemented than family-centered care. Some argue that child-centeredness cannot be done without the context of family; others believe that families, particularly parents, are called upon to participate in FCC in hospitals that is predicated on their parental roles that may be unlike their normal expectations in the home and fail to take into consideration the child's emerging autonomy.

To this end, an international collaboration comprising 18 paediatric nursing clinicians and academics has been formed to engage in discourse around the similarities and differences in their approaches to family and child-centered care. The countries to date are Australia, Iceland, Ireland, Jordan, Sweden Turkey, the UK and USA. The group has begun to dialogue via internet across oceans to develop a common ground of understanding that can suggest a framework from which to test new care models. Several of these points of view will be part of this symposium.

The debate surrounding the effectiveness of care models for hospitalized children continues; the research on FCC evolves; the execution from national points of view have been studied with weak results. The emerging viewpoint of CCC derives from philosophical and ethical foundations. Deconstructing FCC into components becomes essential, and philosophical and ethical arguments can emerge. This symposium will provide several divergent views with empirical evidence to harmonize a framework toward family-centered and child-centered care. Each of the presentations will offer a national perspective. It will include historical writings about the care of children in hospital, cultural factors from the different countries, and on-going discussion and debate. The new framework will rise from a philosophical theory with a consensus of opinions and an eclectic structure. This first step will form the base of collaboration and dialogue. Once a framework emerges from these discussions, nurse researchers from around the globe may begin to develop methods and tools to test the new model. Ultimately, the health and well-being of children and families across the world will be better understood with the convergence and divergence of perspectives enhanced by a strongly tested, empirical model of care.

Measures of Family Centeredness from the U.S.: Deconstructing Components of Decision Making and Parents Needs

Veronica D. Feeg, PhD, RN, FAAN, USA
Ann Marie M. Paraszczuk, EdD, RNC, IBCLC, USA

Abstract

As the academic dialogue around models of care for children in hospitals evolves, the discussion about Family Centered Care (FCC) also warrants a closer look into the context of the culture, sociopolitical environment and service delivery differences across countries. The literature is expansive on the universe of families of sick children with a kaleidoscope of perspectives. The effectiveness of FCC has been disappointing using measures that are as diverse as the perspectives. The debate about effectiveness is skewed using the prism of focal points and countering arguments that are within those defined margins. The purpose of this session is to (1) begin with the premise that when dissected, the notion of “family centeredness” (i.e. an internalized attitude) may be at the heart of the implementation of FCC as demonstrated by similarities and differences among countries; (2) deconstruct three specific areas that parents are clearly a necessary component of sick children’s care (NICU, chronic illness and adolescents); (3) present a mechanism to measure family centeredness and a measure of parents’ needs to supplement the arguments supporting FCC that gets at the providers’ internalized attitudes and behavior about caring for parents and caring for children.

This session will make the case that FCC is critical as we move forward with CCC. If the way it has been examined is different, we need to take into account how, especially if it translates in some cultures into parents being held responsible for caretaking in hospitals (Shields, 2016). In the U.S., avoiding any integration of caring for parents of children in health care institutions in any philosophical or ethical discussion in the service delivery language would be a problem in a country where insurance drives every interaction and cost is part of the model. It would be too easy to operationalize the terms of “care” excluding the necessary integration of parents (families) into all aspects of decision-making and support if not explicitly included in best practices models. Using the U.S. frameworks of “Person and Family Centered Care” (Barnsteiner, Disch & Walton, 2014) can help to lay the framework of identifying child-and-family (parent) as a unit of care. “Empowering patients and families to become active partners in their health care — not merely passive participants — is a critical step on the road to achieving the best care at lower cost” (IOM, 2013).

Next, there will be three brief summaries of studies that focus on aspects that justify putting parents and children together as a unit of care in attitude and services. These include (1) a study on nurses’ “family-sensitive care” in neonatal intensive care units who fail to report positively about caring for parents of critically ill newborns and the ramifications of these attitudes (Magri, 2014); (2) two studies on shared decision-making (SDM) in adolescents with chronic illnesses and specifically with HIV who report the triad of SDM, in most cases, continue to tilt heavily on “mom’s” participation (Feeg & Ledlie, 2010; Knapp, Madden, Feeg, Huang & Shenkman, 2011; and (3) a study on parents’ needs of children with cancer, end stage renal disease (ESRD), chronic illnesses, and normal children who have episodic health care issues that offers a generic model of “parenting” to be further explored.

The session will conclude with important considerations about merging FCC and CCC with recognition of specific, focused attention on particular aspects of nursing caring behaviors. A simple measure of “Family-Centeredness” that elucidates attitudes that are central to caring ought to be considered in new models that might be proposed.

Child and Family-Centered Care: Consensus Recommendations From a Panel Meeting

Mohammad Al-motlaq, PhD, MBS, BSN, RN, Jordan

Abstract

Introduction: Published literature on FCC model reached no consensus on the appropriate definition of the model. International literature fluctuates with no proven efficacy of the model and it has limitations when applied to children themselves. Consequently, differences in clinical practice may influence the expected outcomes particularly in specialized units such as PICUs and NICUs. This has led some pediatric researchers in this field to adopt several different approaches and philosophies to shape what can be called "their best view" of a child and family centered model of care. Finally, differences between countries/cultures were not considered deeply in previous investigations.

Purpose: These concerns prompted a panel of pediatric experts to adopt new strategy to develop a taxonomy to define CCC and FCC and to make recommendations regarding its core principles and research priorities.

Methods: A Delphi approach will be used to clarify all factors surrounding CCC and FCC. The goals are 1) to develop taxonomy to define CCC and FCC; 2) to offer recommendations regarding proper implementation of FCC core principles; and 3) to identify priorities for future research in CCC including expected outcomes and cultural differences. The panel also hopes to foster collaborative relationships with other interested parties for future international research on pediatric models of care.

Procedure: Members of the panel will meet in 2017 to develop an appropriate methodology to explore the consensus outcomes. The panel will also select subtopics to discuss and will seek potential experts with relevant qualifications and research track record to supplement the original members of the panel and representing as many countries/cultures as possible.

Step 1: agree upon the first symposium subtopics

Step 2: Write recommendations based on the symposium

Step 3: formulate a method for agreement on each topic; this will possibly include Likert scales for scoring, e.g. "strong agreement" can be assigned to concepts if an average of 5 out of 7 is achieved, while a "Weak agreement" can be assigned for a score less than 5. Weak statements can be re-discussed and re-evaluation is conducted.

This will give a consensus way forward for developing a plan for a comprehensive research program.

Fostering and Sustaining Family-Focused Healthcare Across the Life-Course: A Transferrable Model Between Countries?

Joanna Smith, PhD, RGN, RSCN, United Kingdom

Veronica Swallow, PhD, MMedSci, BSc (Hons), RGN, RSCN, United Kingdom

Veronica D. Feeg, PhD, RN, FAAN, USA

Abstract

Care of persons with chronic or long-term conditions is a key international health-policy priority. Around 15 million people in England live with one or more long-term condition, which impacts on the whole family's health & wellbeing with family members contributing to care. The Kings Fund report *Better Value in the NHS* (2015) predicts that improving service quality and cost-effectiveness for people with long-term conditions is critical because 70% of UK health/social-care spending is focused on individuals with long-term conditions.

International evidence indicates that long-term condition in early-life can affect not only the individuals' health and wellbeing across the life-course, but also the whole family's health and wellbeing. Although families respond differently to long-term conditions, the family response is closely related to clinical outcomes. Research indicates that family relationships have the potential for health-promoting effects and although models of family-focused care across the life-course are delivered in some countries, as yet they do not appear to be embedded within UK health and social-care systems. Family-focused care in a broad context is an approach to care delivery, whereby health professionals, respect and respond to the needs of the patient and their family as a complete unit, recognising the family role in supporting and being involved in care (Foster, et al. 2016; Grant, et al. 2016). In order to establish the extent to which family-focused care for persons with long-term conditions exists across the life-course we have established a virtual, multidisciplinary research development group: 'Family health and social-care research across the life-course' that combines expertise in long-term conditions research, psychology, nursing, social-care with patient/carer experience to meet the following objectives:

1. Systematically review the UK literature in this area;
2. Harness existing links with international family experts;
3. Establish a Patient and Public Involvement and Engagement Advisory group to advise from family perspectives;
4. Define aims/objectives for future collaborative grant application/s around support strategies where a family member has a chronic/long-term condition.

Since the project inception event in April 2016 that aimed to determine groups' aims, objectives and milestones we have:

1. Convened the PPI group;
2. Developed a project web-page to support dissemination and demonstrate collaboration <http://www.whiterose.ac.uk/collaborationfunds/fostering-and-sustaining-uk-multidisciplinary-family-focussed-care-across-the-life-course/>;
3. Delivered a 1.5 day workshop for the applicants, consumers and key UK family-focussed colleagues, and expert Master Classes with international experts;
4. Developed and begun a systematic review of reviews protocol to summarise and synthesis the findings of systematic reviews of family-focused care, family-centred care and family-focused practice across the life course in the context of supporting families where a family member has a long-term condition using the Joanna Briggs Institute methodology for 'umbrella reviews'.

Conclusion: It is anticipated that a new and potentially transferrable model for fostering and sustaining family-focused health-care across the life-course in one global region will be developed. The benefits of establishing a collaboration to identify research priorities for family-focused care for persons with long-term conditions and a Patient and Public Involvement and Engagement Advisory Group has the potential to ground the model in real-world, family insights and experiences.

F 07 - Facilitation: The Cornerstone of Practice Development and Person-Centredness, a Journey From Aristotle to the Bedside

Human Flourishing: From Notion to Reality

Lorna Peelo-Kiloe, MSc, BSc, RGN, Ireland

Abstract

Facilitation is complex and multifaceted depending on its intended purpose, whether that be education, health or counselling (Shaw et al 2008). At its simplest it can be described as a 'helping relationship' whereby individual(s) and consequently self are enabled to achieve growth, development and self-actualisation through transition (Mayeroff, 1971). A key outcome of transformational practice development, where people are the principal focus and where transformative approaches are used, is an implicit and explicit focus on human flourishing as an outcome for all involved (Titchen, 2011). In helping relationships we seek to create conditions for human flourishing to take place (McCormack and Titchen, 2014), therefore facilitation based on helping relationships and human flourishing are intertwined.

There are many interpretations of human flourishing including happiness, well-being, thriving, growth to name but a few. Although human flourishing is relatively new to health care it can be traced back to ancient philosophers such as Socrates, Plato and in particular Aristotle who wrote extensively on *eudaemonia*, and linked by Aristotle to virtue ethics. Aristotle and his followers described human flourishing as the highest point to all our endeavours and the aim to which all our actions are focused. As humans, Aristotle believed that we each have a natural obligation to achieve and pursue our true ends and goals in life (Younkins, 2003). Maintaining that happiness represents to us success as a human being, Aristotle alleged that "the happy person lives well and does well in action" and that every action, decision and investigation is aimed at some good.

If we accept the innate good of human beings; most people accepting that no baby is born wicked, then it could be said that our desire as humans is to do the right thing because it is the right thing to do. In health care today with its focus on economics, cost containment and targets, there is a very real challenge for health care professionals to consistently ensure that they are doing the right thing because it is the right thing to do. The need to critically reflect and transform practice can seem arduous and thankless in highly pressured environments where health care professionals feel burdened by the amount of change that is taking place. Coupled with that is a feeling of disempowerment in decisions about their practice and working environment. This environment is not conducive to human flourishing for staff and therefore not conducive to the flourishing for service users either. It is rare to experience organisational change that includes a focus on human flourishing (Titchen et al, 2011) however practice developers have been witnessing at firsthand the beneficial outcomes of human flourishing to individuals and teams through facilitation.

A Concept Analysis: Facilitation and Practice Development Analyzing Evidence From the Literature and Beyond

Elizabeth Breslin, MHSc, MA, BSc (Hons), HDip (Ortho), RGN, Ireland

Abstract

The aim of this exploration is to understand, as fully as possible, the concept of facilitation within practice development using a concept analysis approach. The purpose of concept analysis methodology is to distinguish between concepts (Jakimowicz and Perry, 2015) and clarify the relationships and distinguishing characteristics between concepts (Fitzgerald and McCarthy, 2016)

Early mention of the concept of facilitation in PD began to emerge within nursing literature around the mid to late 1990s. This occurred alongside references to PD as a distinct and unique change methodology and, in the early years, was specifically focused on nursing practice. Practice development, as an approach, is now considered much wider than nursing practice. Facilitation is referred to as being central to PD and although much has been written about this topic, there appears to be a lack of an agreed definition of what facilitation actually means within the systematic processes that are PD. Shaw et al's. (2008 p. 147) analysis is the most recent CA in PD and has been influential in this CA work.

Practice development provides a methodology to enhance and support cultures of person centred care delivery for clients and also for those individuals providing, organising and supporting care delivery at micro, meso and macro organisational levels. It is complex and has many components. Principle Four of the nine PD principles (Manley, McCormack and Wilson 2008, p.7) informs us that "PD integrates and enables both the development of evidence from practice and the use of evidence in practice". This principle has guided the development of this theoretical exploration of facilitation in PD.

Conceptual clarity and a shared understanding of what facilitation is, what it looks like, what it does and its' outcomes within PD adds to the growing body of nursing and healthcare knowledge. The engagement of individuals in systematic and inclusive ways of working to support and enable person centred cultures of care is considered an important component of PD approaches. This is referred to as facilitation. Concept analysis is carried out by framing the analysis within a model. Walker and Avant's (1995) model and Morse et al's (1996) guiding principles provided the theoretical framework for this concept analysis. This CA demonstrates the blending of two approaches with the purpose of clarifying what facilitation in PD is from published evidence, grey literature and expert practitioners in the field.

Defining attributes of facilitation in PD identified within this concept analysis include: process; learning; person centred practice; facilitator skills and knowledge; learning and personal (facilitator) growth; theoretical approaches, models and frameworks; culture and context; values and beliefs. A definition of what facilitation means in PD is offered. Attributes, antecedents and the consequences found from the concept analysis will be tested with practitioners in a participatory action research study.

Developing Novice/Proficient Facilitators, Two Frameworks to Create Conditions for Person-Centred Cultures: A PAR Study

Michele Hardiman, MA, RGN, RPN, Ireland

Abstract

The vision of person-centred cultures is core to all policy and standards in healthcare in Ireland (Health Information and Quality Authority, 2012) and globally (World Health Organisation, 2007) implementing these strategies and standards require focused development of staff who deliver care in our health services (Department of Health and Children, 2010). In the acute hospital setting in Ireland this staff

development has largely been technical in its approach to date. Evidence suggests that for person-centred cultures to emerge, purposeful Practice Development (PD) needs to be facilitated within the workplace (McCormack et al, 2010). The role of clinical nursing leaders is pivotal in developing and sustaining person-centred cultures and is therefore a key element of all PD activity (McCormack et al, 2010; Brown and McCormack, 2016). If PD is to become more meaningful to nursing leaders as part of their daily work, more focus must be placed on making the development and 'doing' of facilitation easier. Although complex facilitation frameworks such as Critical Companionship (Titchen, 2002) remain an exemplar in the development of expert facilitation skills, use of this particular framework has been minimal due largely to its complexity (Dewing and Wright, 2004; Greggans and Conlon, 2009). To address this gap two sequential facilitation frameworks Critical Allies and Critical Friends (Hardiman and Dewing, 2014) were developed by the author to provide a stepped approach to the development of work based facilitators. This doctoral research study uses Participatory Action Research to test the use of Critical Allies and Critical Friends within an acute hospital setting. The study is theoretically located in Critical Social Science and Person-centredness. The study is conducted using an insider researcher approach to work with clinical nursing leaders within their own workplace.

The study addresses the following research questions:

1. What does a person-centred model for work based facilitation look like?
2. How do work based facilitation skills enhance the development person-centred cultures?
3. What are the implications for existing education/training frameworks in care services in Ireland should a work based learning facilitation model be established and adopted?

It also makes a contribution to the methods for achieving communicative spaces and discourse in busy workplaces and proposes that facilitation is not stationary and can be delivered by novice and proficient facilitators in certain conditions.

Outcomes: The frameworks and the associated tools offer novice and proficient facilitators a guide to the development of work based facilitation skills that can build up over time. This enables nurses to work with colleagues to help them to learn in and from work, grow their expertise and contribute to developing person-centredness in the workplace. The study has global application to contexts interested in developing person-centred cultures. It is unique in its focus on the development of novice and proficient facilitators that can impact on the development of themselves and on person-centred cultures.

F 08 - High Reliability: Practical Application and Tips for the Journey

Psychological Safety: A Work Environment Characteristic in a High Reliability Organization

Cynthia A. Oster, PhD, MBA, ANP, ACNS-BC, CNS-BC, USA
Jane Braaten, PhD, MS, RN, USA

Abstract

Background/Significance: It is estimated 400,000 people die each year due to healthcare error (James, 2014). One strategy to reducing harm has been to institute high reliability into healthcare. High reliability science is the study of “organizations in industries like commercial aviation and nuclear power that operate under hazardous conditions while maintaining safety levels that are better than in healthcare” (Chassin and Loeb, 2013). High reliability organizations (HROs) are organizations that are high-risk, dynamic, turbulent, and potentially hazardous, yet operate nearly error-free (Weick and Sutcliffe, 2007). Becoming a HRO is now a leadership mandate from hospital boards and top executive leaders; however HRO development must permeate the entire organization. HROs have demonstrated success in minimizing errors by creating mindful environments where employees are trained to look for and report small problems that could lead to big ones. HROs view small errors and close calls as learning opportunities; correct them and share details about them across the organization (Chassin, 2012; Shabot, 2015).

A healthy work environment (HWE) is required for high reliability. The 2004 IOM report, *Keeping Patients Safe: Transforming the Work Environment of Nurses*, emphasized the dominant role of the work environment within health care organizations and the importance of the work environment in which nurses provide care to patients. A HWE is one that is safe, empowering, and satisfying. HWEs are settings with policies, procedures, and processes designed to empower nurses to meet the organizational objectives and achieve personal satisfaction (Huddleston & Gray, 2016a). It is not merely the absence of real and perceived threats to health, but a place of “physical, mental, and social well-being,” supporting optimal health and safety (ANA, 2016). A HWE includes appropriate staffing, authentic leadership, effective decision making, meaningful recognition, skilled communication and true collaboration (AACN, 2005). Huddleston and Gray (2016b) recommend the addition of two new characteristics: genuine teamwork and physical and psychological safety. Psychological safety means ensuring that no one is penalized if they ask for help or admit a mistake and they can openly disagree without fear of ridicule or punishment (Edmondson, 2008; Edmondson, 2016). Psychological safety is crucial in organizations where knowledge constantly changes, where workers need to collaborate, and where those workers must make decisions without management or leadership intervention (Edmondson & Lei, 2014).

A culture of safety and resilience is paramount in a HRO. All leaders, managers, health care workers, and ancillary staff have a responsibility as part of the patient centered team to perform with a sense of professionalism, accountability, transparency, involvement, efficiency, and effectiveness. All must be mindful of the health and safety for both the patient and the health care worker in any setting providing health care, providing a sense of physical and psychological safety, respect, and empowerment to and for all persons (ANA, 2016). HROs must adopt a fundamental HWE approach in how they communicate and how individuals interact. Organizational leaders must ensure there is a free flow of information; a safe environment in which to speak up and respectful interactions (Chassin, 2012; Chassin & Loeb, 2013; DuPree, 2013). Organizations require resiliency to achieve high reliability. A resilient organization maintains a high level of performance despite mounting pressures, threats and uncertainties, and is able to withstand disruption and recuperate while resuming operations (Boin & Van Eeten, 2013). When employees feel psychologically safe, meaning staff is empowered to have a voice without being retaliated against; they will be more likely to report concerns and near misses. Therefore, patient safety and quality outcomes improve in every day clinical practice.

Purpose: The purpose of this presentation is to describe how psychological safety in the work environment at two acute care facilities contributed to the facilitation and sustainment of a culture of safety and organizational resilience.

Scope: The scope of this project encompasses two acute care hospitals; a 50-bed community hospital and a 350-bed quaternary hospital with specialty service lines. It includes 650 clinical nurses, advanced practice nurses and nursing leadership across the spectrum of care including outpatient and ambulatory settings.

Methods: Leadership commitment to psychological safety serves as the paradigm for two organizations to be resilient, maintain gains and sustain the success of high reliability. In 2002 Dr. Amy Edmondson, a Harvard business professor expert on psychological safety in the workplace, published a seminal work describing psychological safety. Psychological safety describes individuals' perceptions about the consequences of interpersonal risks in their work environment. It consists of taken-for-granted beliefs about how others will respond when one puts oneself on the line, such as by asking a question, seeking feedback, reporting a mistake, or proposing a new idea. Nurse leaders play an important role in creating cultures that are psychologically safe. The commitment of leaders to a transformational style of leadership in order to facilitate psychological safety is essential in a resilient, learning and highly reliable organization. Transformational leaders transform organizations by motivating followers to transcend their own self-interest to improve performance through organizational learning and innovation (Grant 2012; Garcia-Morales, Jimenez-Barrionuevo, and Gutierrez-Gutierrez, 2012). Leaders within the organizations facilitate psychological safety by developing and reinforcing civility, respect, support, professionalism and accountability. Leaders insist on civility for all interactions (Blouin, 2013). Respect is the cultural norm; thereby employees are more likely to communicate with the greater team (Sutcliffe, 2011). The use of supportive language towards others is an expectation as is professionalism with accountability. Alignment of senior leadership, managers and front-line nursing staff in a psychologically safe work environment is crucial for an organization to be resilient, maintain gains and sustain the success of high reliability.

The five principles of HROs served as a guiding framework to embed safety practices into two organizations with a culture of psychological safety. HRO principles (Deference to expertise, Preoccupation with failure, Sensitivity to operations, Reluctance to simplify, and Commitment to resilience) are woven into the fabric of one small and one moderate-sized healthcare organization.

Outcomes: Perception of psychological safety improved from 66% to 74% of staff feeling free to speak up if they see something that may negatively affect patient care on the AHRQ Hospital Survey on Patient Safety Culture. Vigilance drove detection analysis and constant surveillance. Increased near miss and self-reporting demonstrate enhanced organizational transparency and professional accountability. Between 2013 and 2016, preventable harm incidents decreased 33% while patient volume and case mix index increased.

Implications for Practice: Nurse leaders play an important role in creating organizational cultures that are psychologically safe for staff to question practices, report problems or propose new ideas. Resilient organizations have high reliability, maintain a high level of performance and have a psychologically safe work environment. HRO principles translate to the point of care, apply to hospital environments of any size, and can be utilized effectively in every patient encounter to drive positive quality outcomes. Comprehensive integration of HRO principles results in exemplification of nursing staff understanding that their actions contribute to organizational quality and safety. A culture of safety encourages open discussion of tough issues, tolerance of disagreement, and nurtures contrasting points of view. Making this cultural shift is crucial to organizational resilience and proactive adverse event management.

Practical Tools for the High Reliability Journey

Jane Braaten, PhD, MS, RN, USA

Abstract

Highly reliable organizations are effective in three domains: leadership commitment to high reliability, a safety culture and robust process improvement (Chassin & Loeb, 2013). However, the nature of healthcare today creates a challenge to high reliability. Healthcare in the hospital today is a whirlwind of highly complex systems and processes, coupled with emergent conditions. Interacting within this chaos daily are human beings seeking and providing care to those who are ill and vulnerable. Human nature and the history of healthcare still lead us to fall back on expecting perfection from humans in this type of system. Current leaders in patient safety state that safety advances when human error is recognized as an attribute of the system and not the cause of it (Woods, et al, 2012). This means that we must expect vulnerability from human beings and create effective systems to mitigate the expected error. Errors occur most often, not because of lack of reliability from humans but because of lack of reliability of our system to prevent humans from error (IOM, 2009). Highly reliable organizations rely on finding system and process solutions to prevent human error in a proactive, rather than reactive manner (Weick & Sutcliffe, 2007). High reliability can become a “buzzword” unless we match the principles of high reliability with our everyday processes. Robust process improvement cannot be simplified by only adopting a process or tool. In order to create high reliability, we also need to be intentional with embedding the principles of high reliability into our process improvement tools. Root Cause Analysis (RCA) and Failure

Mode Effects Analysis (FMEA), when implemented with high reliability principles, can be effective tools to recognize and mitigate the effects of human fallibility by encouraging proactive anticipation of conditions that lead to errors and encouraging robust interventions created by interdisciplinary collaboration to mitigate error from emergent conditions. High reliability depends on crossing traditional barriers and boundaries to innovate. Boundary spanners can be people, objects, or processes that bridge differences and lead to collaboration between diverse areas. Highly reliable improvement tools can serve as boundary spanning processes that bridge the gap between traditional process improvement and highly reliable performance.

Purpose: The purpose of this presentation is to describe how two robust process improvement tools can be used to promote highly reliable error reduction in a complex hospital environment.

Methods: An effective RCA and FMEA is a key feature of a highly reliable organization's robust process improvement program. The RCA at its most effective considers system issues as causes and human errors as effects, considers and mitigates for sources of bias in the investigation , creates strong actionable, timed interventions that address the root causes found and is supported by the highest levels of organizational leadership (National Patient Safety Foundation, 2015). The RCA is generally used to analyze an event or a close call that has been identified. An FMEA, on the other hand, is used to predict and identify safety or problematic gaps in a process before an event occurs. Both methods if not intentionally facilitated can have challenges to high reliability such as bias, failure to consider system issues, failure to encourage diverse opinions in the process, choosing interventions which do not consider human factors and failure to monitor and sustain the improvement. When used effectively, the tools are a key component of a highly reliably organization, leading to sustainable improvement.

Outcomes: Implementing the robust improvement tools, RCA and FMEA, through the lens of high reliability principles has led to an increase in staff perception of patient safety and how the organization reacts to and prevents adverse events. Improvement in the AHRQ Hospital Survey on Patient Safety was realized in the items of "organizational learning from error" and "non-punitive response to error". One RCA led to a system change of the counting process in the operating room that identifies a mandatory time out for counting prior to close. After implementation, there have been no further retained foreign objects over the last year. An FMEA at the same facility identified at least 20 high risk opportunities for failure in a pediatric resuscitation event. Mitigation strategies have been implemented for all opportunities and currently, the process was tested with no deficiencies.

Implications for Nursing Practice: High reliability is dependent upon identifying conditions for adverse events before they occur and creating resilience in the system for staff to react to safety issues before harm to a patient occurs. The RCA and FMEA are tools which promote both anticipation and mitigation and can serve as boundary spanning processes, linking process improvement to high reliability.

Practical Application of High Reliability Principles in Healthcare to Promote Clinical Quality and Safety Outcomes

Cynthia A. Oster, PhD, MBA, ANP, ACNS-BC, CNS-BC, USA
Sherilyn Deakins, MS, BSN, CPPS, USA

Abstract

Background/Significance: It is estimated 400,000 people die each year due to healthcare error (James, 2014). One strategy to reducing harm has been to institute high reliability into healthcare. High reliability (HR) has long been used in aviation and nuclear energy to reduce variation and improve safety. High reliability science is the study of organizations in industries “that operate under hazardous conditions while maintaining safety levels that are better than in healthcare” (Chassin and Loeb, 2013). High reliability organizations (HROs) are organizations that are high-risk, dynamic, turbulent, and potentially hazardous, yet operate nearly error-free (Weick and Sutcliffe, 2007). HROs stay error-free by recognizing that small things that go wrong are often early warning signs of trouble (preoccupation with failure); recognizing that these warning signs are red flags that provide insight into the health of the whole system (reluctance to simplify); valuing near misses as indicators of early trouble and acting on them to prevent future failure (sensitivity to operations); being innovative and creative and valuing input from all corners of the organization (deference to expertise); and recognizing the value of preparing for the unexpected and the unknown, as failures rarely occur if they are expected (commitment to resilience). HROs have demonstrated success in minimizing errors by creating mindful environments where employees are trained to look for and report small problems that could lead to big ones. HROs view small errors and close calls as learning opportunities; correct them and share details about them across the organization (Chassin, 2012; Shabot, 2015). Healthcare application of HR principles is complicated by the complex adaptive nature of care delivery systems. Healthcare is moving from a reactive to a proactive paradigm. Near misses are influential in evaluating healthcare structures and processes prior to experiencing negative outcomes. HRO principle integration supports proactive identification of potential adverse events.

Purpose: The purpose of this presentation is to describe how application of High Reliability Organization (HRO) principles into daily healthcare work processes can successfully drive improved quality outcomes, safety, and culture change.

Scope: The scope of this project is one 350 bed acute care quaternary hospital with specialty service lines. It includes 500 clinical nurses, advanced practice nurses and nursing leadership across the spectrum inpatient care settings.

Methods: The five principles of HROs served as a guiding framework or methodology to embed safety practices into the organization. HRO principles (Deference to expertise, Preoccupation with failure, Sensitivity to operations, Reluctance to simplify, and Commitment to resilience) are woven into the fabric of the moderate-sized healthcare organization through distinctive intervention strategies. Implementation of HRO principles into 15-minute daily safety huddles enhanced an existing Just Culture environment. Partnerships translated HRO principles into clinical practice and evaluated operationalization. Resource investment led to real-time data, analysis, feedback, technology supporting low-variation practice, and rewards/recognition promoting transparency. Leaders role model their commitment to a culture of quality and safety. HRO principle integration: Deference to expertise correctly migrated responsibility from formal executive authority to experiential competency-based decision-making; Preoccupation with failure sensitized associates to be alert to small indicators before crisis situations developed and increased near miss reporting; Sensitivity to operations cultivated situational awareness; Reluctance to simplify drove drill-down enhancing learning and practice; Commitment to resilience was strengthened through TeamSTEPPS applications which led to heightened individual and organizational resilience.

Outcomes: Between 2013 and 2016, preventable harm incidents decreased 33% while patient volume and case mix index increased. Nurse sensitive indicator outcomes consistently meet or exceed national benchmarks. The 350-bed hospital reports 30% reduction in falls with injury; HAPUs stage 2+ below benchmark the majority of the time in all units; CLABSI-free in all units for greater than 3 years; and CAUTI 70% reduction in the last four fiscal years. Nursing value is \$1.7 M estimated direct cost avoidance FY12 to FY16.

Implications for Nursing Practice: HRO principles translate to the point of care and can be utilized effectively in every patient encounter driving nursing practice and positive clinical quality outcomes in a culture of safety. Comprehensive integration of HRO principles results in exemplification of nursing staff understanding that their actions contribute to nursing value and organizational quality and safety. Making this cultural shift is crucial to proactive adverse event management.

F 09 - Health Information Technology Tools to Support the Implementation of a Complex Care Management Program

Development of a Dashboard to Provide Decision Support for Complex Care Management in Primary Care

Mary L. Blankson, DNP, APRN, FNP-C, USA

Sharon Liann Taylor, MPH, USA

Katie Ann Lainas, BS, USA

Ranbir Bains, PhD, MSN, APRN, CPNP, USA

Abstract

Primary care nurses often need to take on the role of nurse care manager (NCM) as they support a provider's panel of complex patients. NCMs require access to timely information from a single source to effectively provide care management to patients. In the past, manual data registries were maintained by NCMs. In the current era of Big Data, it is important to move away from inefficient, time-consuming processes toward automatic tools. Doing so ensures better utilization of valuable clinical skills to maximize the overall benefits to patients.

An electronic dashboard was developed to provide NCMs with decision support during the implementation phase of a Complex Care Management Program across 12 clinical sites of Community Health Center, Inc. (CHCI). CHCI is a statewide agency providing care to individuals with low socioeconomic status, including many that are uninsured and underinsured. It has 14 integrated patient-centered primary care sites, delivering medical, behavioral health and dental services along with other ancillary care services such as those delivered by registered dietitians, podiatrists or chiropractors to name a few. CHCI delivers care in over 200 total service delivery sites, when school based clinics and health care for the homeless sites are included in the total count. The care management dashboard enables NCMs to identify high-risk patients who would benefit from enrollment in care management. It serves as a population management tool for groups at highest risk for adverse outcomes related to uncontrolled chronic diseases, repeated hospitalizations, and increased emergency department utilization. This ensures the NCMs can use this tool for both proactive outreach and ongoing population data tracking.

The dashboard was built through the collaboration of CHCI's frontline NCMs, Business Intelligence, the Quality Improvement Department, and the Chief Nursing Officer. The dashboard is updated daily by extracting data from individual electronic health records based on an algorithm using Uniform Data System (UDS) measures along with other clinical markers. It is then populated with the medical record numbers of patients who meet these criteria, including uncontrolled hypertension, diabetes and asthma. The dashboard lists a patient's last recorded blood pressure, hemoglobin A1c, and smoking status. It indicates whether the patient has had two or more visits to an emergency room within six months, and if the patient has 4 or more chronic conditions listed on their active problem list. Additionally, the dashboard imports claims data from the state Medicaid database, which identifies patients currently hospitalized and/or recently discharged from a hospital. The dashboard is especially important in providing this information to nurses as it is often delayed from local hospitals. Given the focus on supporting patients to achieve self-management, the date on which the last self-management goal was set or motivational interviewing was completed is listed on the dashboard. This supports NCM's ongoing tracking of each enrolled patient as they progress toward their self-management goals.

When the dashboard was implemented in August of 2014, the overall enrollment in CHCI's Complex Care Management Program was 17 patients. This number grew to 861 in year 1 of implementation and to 1724 by the end of year 2. Toward the end of year 2, NCMs were interviewed to explore their thoughts about the dashboard and to identify any changes or enhancements to improve the tool to better support their daily work. NCMs noted the value of the dashboard as an enhancement to their work. They could find information on their patients quickly and easily, and valued the tool as a means to support the ongoing

follow-up required post hospitalization. One of the primary care nurses interviewed summarized her thoughts by stating: "if we did not have a dashboard, I would spend less time on care coordination." The NCMs did identify several areas where they requested revisions or reorganization to the dashboard to enhance its overall functioning, which will be integrated into the second iteration. Implementing a Complex Care Management dashboard can improve nurses' confidence in delivering care to patients with complex needs. Since clinics that serve patients of low socioeconomic status typically have a large population of high-risk patients, the dashboard lends timely decision support and organization to NCMs to improve their ability to identify patients who would most benefit from Complex Care Management. This may lead to improvements in overall job performance and satisfaction in NCMs, and could therefore improve overall retention for key clinical team members.

Development of a Nursing Scorecard to Track Metrics to Support Complex Care Management

Tierney Elizabeth Giannotti, MPA, BA, USA
Mary L. Blankson, DNP, APRN, FNP-C, USA
Ianita Zlateva, MPH, RN, USA

Abstract

Primary care nurses often need to take on the role of nurse care manager (NCM) as they support a provider's panel of complex patients. Nurse care managers (NCMs) at the Community Health Center, Inc. (CHCI) use a clinical dashboard tool to aid in decision support to identify and manage individual patients through Complex Care Management (CCM). The NCMs identified that they needed a different tool to better support a global view of their impact as well as to identify areas needing additional focus.

A nursing scorecard was developed to track population metrics as part of the implementation of a complex care management program across 12 clinical sites of CHCI. CHCI is a statewide agency providing care to individuals with low socioeconomic status, including many that are uninsured and underinsured. It has 14 integrated patient-centered primary care sites, delivering medical, behavioral health and dental services along with other ancillary care services such as those delivered by registered dietitians, podiatrists or chiropractors to name a few. CHCI delivers care in over 200 total service delivery sites, when school based clinics and health care for the homeless sites are included in the total count.

Each CHCI nurse supports two individual primary care provider panels. CHCI's nursing scorecard quantifies care management indicators and outcomes as part of overall nursing performance with each of those panels. It provides the NCMs with data that is updated monthly. This helps the NCMs to identify which providers may follow best practices, and the overall trends for measures such as hypertension and diabetes control for each provider's panel of patients. The scorecard reinforces a measurement culture, which helps the NCMs to focus on specific patient populations or specific provider panels that are in need of intervention. When NCMs review the scorecard each month, they can make decisions on resource allocation to ensure they are addressing areas of greatest need. Furthermore, the scorecard provides opportunities for continuous improvement and accountability for the care management program. It supports NCMs in understanding the value of their work.

The scorecard is populated with data extracted from the electronic health records of all patients in a panel managed by an NCM and their two primary care providers. Data include the number of patients defined as eligible for care management (high emergency department utilization, recent hospital discharge, uncontrolled chronic illness, or multiple chronic illnesses), the number of those enrolled by a nurse in care management, and clinical measures such as the percentage of patients with uncontrolled hypertension and diabetes. The nursing scorecard was built through the collaboration of the NCMs, CHCI Business Intelligence, Quality Improvement Department, and Chief Nursing Officer.

Tracking population metrics for nurse-driven interventions for high-risk patients in primary care can help identify the impact of CCM on clinical measures for these patients, i.e., uncontrolled hypertension and diabetes, and re-admission to the hospital within 30 days of discharge. CHCI's scorecard reveals how many patients a nurse in primary care could potentially support in CCM at any given time while still fulfilling other aspects of the primary care nurse role.

The scorecard was active for all sites as of 4/14/2015, post the yearlong, stepped-wedge implementation of the overall complex care management program. The first scorecard noted that, on average, NCMs were managing about 6% of their eligible panel, with a wide range of 1% to 27%. By six months, this had grown to an average of 11% of the eligible panel, ranging from 1% to 29%. As of 12/2/2016, this has grown to 14% on average, ranging from 3% to 67%. This suggests that complex care management is now actively being performed by all nurses in the program. It does however highlight potential degrees of activity in care management activities, and that more work must be done to better quantify complexity to determine an exact panel expectation for NCMs. Both hypertension and diabetes control have improved since program and scorecard implementation by 3.7% and 2.5% respectively. CHCI's care management scorecard ensures that NCMs are better able to make decisions on resource allocation and to focus efforts to improve complex care management operational and clinical measures. Scorecards may be a solution for other clinics, regardless of geography, implementing care coordination or complex care management to support their teams toward success.

Structured Data in Electronic Health Records to Capture Nursing Work in Complex Care Management

Ianita Zlateva, MPH, RN, USA

Mary L. Blankson, DNP, APRN, FNP-C, USA

Abstract

Complex care management in primary care has proven difficult to track and measure. Electronic health records (EHRs) initially were designed to document the care of individual patients and for insurers for reimbursement of services, not for measuring population data or clinical processes. Since the implementation of EHRs, many have worked to create ways to utilize structured data to fulfill this need, but more work is needed to develop best practices particularly when it comes to the contribution of nurses in complex care management.

Various templates and structured data fields were created within Community Health Center, Inc.'s (CHCI) EHR to allow for tracking of population metrics as part of the implementation of a complex care

management program across 12 clinical sites of CHCI. CHCI is a statewide agency providing care to individuals with low socioeconomic status, including many that are uninsured and underinsured. It has 14 integrated patient-centered primary care sites, delivering medical, behavioral health and dental services along with other ancillary care services such as those delivered by registered dietitians, podiatrists or chiropractors to name a few. CHCI delivers care in over 200 total service delivery sites, when school based clinics and health care for the homeless sites are included in the total count.

CHCI faced many challenges, and celebrated some successes with adding many areas of structured data to the EHR to capture the work primary care nurses were completing every day in their role as nurse care managers. The team involved with creating the structured fields included members of leadership, frontline nurses, business intelligence and health information technology (HIT) personnel. The two main examples focused in care management were related to a template that captured important elements of transition management, and structured data fields to document motivational interviewing and self-management goal setting.

For transition management, CHCI created a template for nurses based on Coleman's Pillars (2004) to better capture structured data collection needed to support transition from hospital to home. Once the transition template is completed by the nurse, they would then choose the most appropriate template relating to the reason for admission, typically an exacerbating chronic illness. Once these templates were implemented, challenges included the length of time it took to complete overall data collection, and duplicative fields for chronic illness data that added some confusion for nurses. Nurses did, however, collect more meaningful data to support transition care than prior to implementation.

For the motivational interviewing and self-management goal structured fields, nurses are able to capture key data to support ongoing follow-up. The first data field addresses whether the patient is ready to set a self-management goal, and then if so, would prompt the nurse to document the confidence level and whether motivational interviewing was used. If the patient is not ready to set a self-management goal, then it would prompt the nurse to document whether motivational interviewing was done. If the patient is following up on a self-management goal, the template also has fields to document that along with progress toward the goal set prior. There are unstructured places for nurses to document notes on the specific goal, and any additional supportive information. This allows for some structure, but also room for the nurse to ensure more patient-specific documentation.

For both examples, nurses had varied success at completing the fields. For the transition template it was clear that nurses did not complete all data fields the majority of the time, as opposed to the self-management goal template which was much shorter. The self-management goal template was mainly used within the context of comprehensive diabetes visits, where it is embedded into this visit template. Unfortunately, the self-management template has not yet had its full intended effect, which is for nurses to access it for any situation where self-management would apply.

Structured data is extremely important to being able to create any other HIT tool. Both Dashboards and Scorecards draw on items that are structured within the EHR. Each structured field must be carefully considered and have standard definitions that address a specific clinical outcome measure. They must also address the growing trend of adding additional "clicks" to already challenging multi-tasking. Business Intelligence is key along with HIT personnel to design the most efficient approach to data capture. All in all, it appears that structured fields ensure more uniform data collection, and support standardized practice and measurement among nurses with regard to complex care management. However, more work is needed to perfect implementation and training strategies for frontline personnel to ensure wider use of these important tools.

G 08 - When Healthcare Is Needed: Violence Has Strained Relations and Law Enforcement Is Involved

When Healthcare is Needed: Violence has Strained Relations and Law Enforcement is Involved

Dianne McAdams-Jones, EdD, RN, GNE, CHSE, USA

Abstract

In our society, after many bitter wars ended e.g. the Civil War, the Cold War and apartheid in South Africa, we start to see peace building efforts. Often these peace building efforts include conversation between the two opposing forces. The strategy building begins; often it is based on experiential knowledge and not necessarily any academics of evidenced based research. Central to the issue here of conversations on race is a Registered Nurse along with a group of health care providers in Utah partnered with its Police Department agreeing with maybe the consensus of others in the rest of the world, that conversations on race and race relations maybe should take place. Or, perhaps we could borrow from Randall Stephenson, CEO of AT&T, who took a stand on racial tensions and breakdown of communication between law enforcement and the minority communities, "If this is a dialogue that's going to begin at AT&T, I feel like it probably ought to start with me" (Holland 2016).

In today's society, fraught with racial tensions and continued breakdown of communication between law enforcement and minority communities there has to be concern for cause and effect. In the wake of what certainly appears to be a quickening of racial tensions due to some recent events it could be asked '...how to mitigate or what is to be done'. Navigating uncomfortable spaces and conversations can bring discomfort. Human nature sends the spirit aflight as discomfort in social settings arise because this discomfort might be misinformation or lack of information which require 'brain checking' prior to initiating patient care. Too, biases are a reality. Health care providers are not immune to bias. In essence, humans will typically not indulge themselves in uncomfortable spaces. As health care providers, there often is not this luxury. The patient's needs will force the health care provider to immerse emotion into the discomfort as a search for some means of either chemical or emotional relief is a top priority for patient care. The health care provider champions open communication and will require a variety of skills in the midst of law enforcement peace keeping and possibly patient injury under suspected offenses. Adding to this, there can be the need to quell negative community input. These and more conversational tools will be explored.

When Healthcare is Needed, and I Feel Victimized

John King, USA

Abstract

Trust and consistency can provide feelings of safety and protection. In the wake of recent events and the looming feelings of distrust in law enforcement from some marginalized groups, communities and families have met with mourning and perceived grief yet unseen. Where do I turn?

Living accordingly in any society will provide columns and lines or guidelines. Living between columns and lines provides security but it would not be good to live as in a caged society. Then, living between columns and lines or in a caged society can provide security. Security is valuable if there is fear of the unknown. Security is valuable if there is fear of beliefs being challenged when we go beyond the columns and lines...venturing out of the cage. However, you will not build any scope of experience to share if you are not branching out beyond your assigned space. Life's experiences will challenge your beliefs; thus, you should check your brain at the door, inform your opinions, build some structure and focus on where you are going. This is not a time to be shy in discussing the stench of racism and inequalities; to some, silence is violence. Being unconcerned and avoiding the subject may give some credibility as to why prejudices and in many cases, the rot of racism continues to ruminate.

Communities can organize and approach public servants e.g. law enforcement, health care providers and local representatives with a spirit of community and caring. Conversations can take down walls and open doors for better understanding between perceived opposing forces. One community in Provo Utah did just that.

In the recent escalated racially tense incidents of Missouri and Charlotte, North Carolina, to name a few, some corporations have brought the subject to the forefront supporting conversations on race and race relations. The theme among these corporations is 'talk about it; don't sweep it under the rug'. Start ongoing conversations on race and race relations. Be honest with each other. Remember, our nation has a wound and it never healed as a wound should.

Wounds heal from the 'bottom up' and 'sides in'. When a wound heals over the top, the dead tissues underneath begin to fester and soon it erupts; our wounds as a people have erupted into violence and the hate is spewing as infection does from wound. Over the years American has struggled with race relations, which essentially just healed over the top; the real wound was festering below and now we need wide spread antibiotics in order to clean up the infection. Let's open the wound as painful as it is and clear it out with good healthy conversation which will kill the nastiness festering underneath. By doing this, the wound will heal as a wound should, from the bottom up and sides in. It will be uncomfortable, but it has to be done. Talk about it. Be an advocate for healing as a health professional should be.

Simulation in Law Enforcement: Safe Learning Spaces for Law Officers

Tirsit Valentine, USA

Abstract

Simulators can significantly reduce error in patient care provision. Pilots have used simulation for years and pilots are first in flight in a simulator. Technically speaking, the vast majority of people would never agree to flying with a pilot who has not had simulator training first. Similarly, perhaps most parents would not like to know that the first chest tube insertion the young doctor has performed is now on young Johnny who is desperately ill.

Then, as law enforcement, the safety of our community is to their charge. Simulators can massively reduce community harm and officer danger. When these simulators are used wisely, they can change our agency's culture in relation to liability, high-risk encounters, over use of force and emergency response driving. This session will address interacting with the community health care providers after an officer shooting of a community member and how simulation can enhance critical thinking. Multiple avenues of simulation use to mitigate negative community relations could change our society's approach to dealing with conflict and violence.

The world we live in is miles away from a decade ago; technology can significantly increase the officer's chances of going home safely and avoiding unnecessary injury to those it protects. Exactly as the health care environment uses the high fidelity in teaching patient care delivery and deliberate practice for expert procedure performance, critical thinking and patient safety, so it is with law enforcement and the use of high fidelity with the police simulators. The simulators high fidelity scenarios give natural recoil of the weapon and produces similar if not exact stress levels under simulated scenario cases. Utilizing health care professionals in law enforcement training and education has provided immense benefits to the Provo Police Department. The quality of the scenario delivery and the reaction of the simulation recipients have been both complementary and highly beneficial. The officers have noticed more confidence in their abilities to utilize deescalating techniques taught during simulation in policing which conceivably has saved lives.

The benefits of simulation in developing and promoting best practices, effective communication with health care professionals when injury has occurred will be examined and explored during this session.

J 01 - Building EBP Capacity and Getting Results: What a Difference One Year Makes

Building EBP Competence and Capacity by Leveraging Opportunities and Planning

Lynn Gallagher-Ford, PhD, RN, DFPNAP, NE-BC, USA

Abstract

Purpose: To describe a unique collaboration between two renowned organizations to provide an evidence-based practice education program and create effective EBP teams to address real world healthcare challenges and drive best practices.

Methods: In a new era of healthcare, success will be achieved through collaborative relationships and development of teams that can deliver evidence-based, patient-centered care to improve healthcare safety, patient and clinician outcomes, and demonstrable returns on investments. The development of evidence-based practice (EBP) knowledge, skills, and attitudes along with creation of organizational cultures and infrastructures that support EBP is a comprehensive strategy that can effectively propel organizations toward achieving and sustaining these goals, meeting required healthcare mandates, and achieving the quadruple aims of healthcare.

Many healthcare organizations have identified that their staff are not competent in EBP as demonstrated by clinicians' and leaders' lack of EBP knowledge, skills and attitude. These organizations are seeking opportunities build such competence and capacity in their settings. The Center for Transdisciplinary Evidence-based Practice has worked with a wide range of both clinical and academic organizations to build and sustain EBP with significant results achieved. This session will highlight the innovative work of The Center for Transdisciplinary Evidence-based Practice (CTEP) in advancing EBP through a collaborative relationship with a large, magnet designated Pediatric Health System to create a successful EBP education and follow-up program that is delivering improved care and significant outcomes. The details related to forging an effective relationship between these enterprises to develop and deliver an EBP education program to meet the unique needs of this Health System will be highlighted.

Results: The characteristics of the original education program designed and implemented including: the evidence-based educational pedagogies and interventions utilized to assure the successful sharing of EBP knowledge and skills; the multiple tracks offered with specific content for different practitioners (front-line clinicians, EBP mentors, educators, organizational leaders) and; the structured follow-up sessions utilized to reinforce knowledge acquisition and promote implementation of EBP initiatives. The impact of planned discussions between the collaborating entities, that led to ongoing customization of the education program as EBP capacity at the Health System was forming, then growing and ultimately performing, with also be presented.

Conclusions: An innovative, customized, and robust EBP education program with structured follow up can build EBP competence in a complex nursing department. The EBP teams forged in this program utilize an evidence-based problem solving approach, recommend effective strategies to implement to address strategic nursing challenges, and lead others in implementing best practices. Lessons learned from this collaborative experience that can inform future EBP programs in other organizations

Overcoming Buzzwords and Variability Through a Nurse EBP Mentor Program

Diedre Bricker, MSN, RN, CRRN, CPHIMS, USA

Abstract

Purpose: A comprehensive EBP Mentor Program was created to support point-of-care clinicians throughout the EBP process at a regional pediatric healthcare system.

Background: It is widely recognized that evidence-based practice (EBP) improves patient outcomes, reduces costs, and standardizes practice (Fink, Thompson, & Bonnes, 2005; Harrison, Grapham, van den Hoek, Dogherty, Carley, & Angus, 2013; Melnyk, Gallagher-Ford, Long, and Fineout-Overholt, 2014; Stevens, 2013). Yet, studies have found that many point-of-care clinicians do not utilize EBP because of their beliefs about the difficulty of EBP and lack of knowledge and experience in implementing EBP in daily practice (Dogherty, Harrison, Graham, Vandyk, & Keeping-Burke, 2013; Fink et al, 2005; Stevens, 2013). Additionally, there is lack of consistency in how EBP is taught in formal education (Fink et al, 2005) resulting in lack of consistency in how EBP is carried out by individual EBP leaders within healthcare organizations once practicing professionally. The result is wide variability in the skills, tools, and resources utilized to carry out EBP in clinical practice.

A large, Magnet designated Pediatric Health System adopted EBP into its nursing vision, mission, strategic goals, and created clear job expectations for utilization of EBP at all levels of nursing. However, wide variability in the skills, tools, and resources utilized to carry out EBP persisted. An EBP Mentor Program utilizing the Advancing Research and Clinical Practice through Close Collaboration model (Fineout-Overholt, Melnyk, & Schultz, 2005) and in collaboration with a nationally recognized university-based EBP program was created to support point-of-care clinicians throughout the EBP process.

Methods: An org assessment was conducted before implementation. A nationally recognized university-based EBP program was selected to train 100 clinical leaders. Participants developed strategies for integrating and sustaining EBP into clinical practice. Participants emerged with an action plan and tools for implementing and sustaining EBP changes and for transforming their organizational culture. Organizational tools and a web-based support system was also created to aid EBP Mentors as they coach point-of-care clinicians through EBP projects and remove barriers to implementation. EBP projects and mentors were incorporated into new graduate residency and a new shared governance council combined EBP with quality improvement and nursing research to support nursing projects from inception to dissemination. An electronic project tracking system was created to give visibility to nursing projects and to store and communicate literature reviews through a web-based portal. Continuing education was created to hone clinician's skills in mentoring and critical appraisal of research.

Results/Outcomes: Baseline organizational assessment indicated high belief in and readiness for EBP but low demonstration of behavior reflective of this practice. In just one year, results included training of 100 EBP mentors: 13 EBP mentors have been through training more than once, with 12 interdisciplinary trained partners. Over 100 EBP projects completed with 33 practice changes implemented as a result; 9 new nurse-led research studies created. An additional 24 EBP projects successfully mentored after the immersions.

Implications for Nursing Practice: Examples of changes in practice include: implementation of nurse bedside shift report/handoff; adoption of alcohol impregnated caps to reduce CLABSI; new thermometers to improve accuracy; adoption of pediatric intensive care delirium scoring tool; research on a dedicated patient/family education facility; alignment with national pediatric asthma treatment clinical care

guidelines. Through individual EBP projects, knowledge, beliefs, and skills in EBP are developed in the point-of-care staff and strengthened in EBP Mentors. Research shows a strong EBP foundation increases competence in clinical practice and the use of EBP. Having EBP Mentors strengthens clinicians' beliefs about EBP and their ability to implement it. Having standardized tools and resources reduces variability in how EBP is carried out and decreases confusion over what it means to practice EBP.

EBP in Action: Ensuring Best Practice is Standard Practice

Kathleen Martinez, MSN, RN, CPN, USA

Abstract

Purpose: EBP methodology including evidence based policies and procedures and clear, consistent dissemination and implementation processes can accelerate the move of best practice to standard practice in a complex organization.

Background: Literature suggests that 70% to 90% of complex healthcare innovations never reach the patient (Jacobs et al, 2015). An organization that incorporates an Implementation Team embedded in its policy and procedure process has the opportunity to remove barriers and implement new practice as soon as it is identified. Using EBP methodology in policy management can support rapid adoption of evidence into clinical practice.

Methods: Implementation is often the most challenging aspect of EBP. Frontline clinical nurses do not always have the resources needed to manage organizational change, especially in a complex healthcare organization. As a result, EBP projects often stall at this critical point, preventing the new knowledge and innovation from reaching the patient.

Most practice changes eventually make it to a clinical policy. The Clinical Policy Committee (CPC) includes an Implementation Team consisting of Nurse Educators, Clinical Nurse Specialists, Advance Practice Providers, Clinical Managers, Nursing Informaticists and clinical application specialists from the electronic medical record. After each Clinical Policy meeting, the Implementation Team evaluates what steps are needed to prepare staff for the practice change. A dissemination plan is developed during the meeting. Key steps are identified, action items assigned and timelines established (Dilling et al, 2013).

A monthly newsletter entitled Policy Pearls is published on the first Monday of the month, the same day in which all new or updated policies are posted. Step by step instructions, skills validation check lists, videos, patient handouts, links to manufacturer's instructions, ordering information and educational materials are all included in the policies to accelerate uptake. Each quarter 8-10 questions designed to measure knowledge and understanding of practice changes are assigned to over 1500 clinical nurses through the organization's learning management system (LMS). The team manages complex implementation processes, including communicating with Providers, EMR personnel and educators to ensure the necessary changes are in place prior to posting the policy.

Outcomes and Takeaways: A pre/post survey was administered measuring leaders satisfaction with how information of practice changes were shared with staff before and after the creation of the Implementation Team.

- Satisfaction with the implementation process increased from 12% to 100% over two years for:
 - Awareness that a policy/procedure was updated.
 - Awareness that a new policy/procedure was posted.
 - Education for staff around policy and practice changes.
 - Timeliness of process of instituting new policy and practice.
- House-wide pre/post survey of confidence and satisfaction with current Clinical Policy and Procedure system. November 2013 August 2016 N=250

	November 2013	August 2016
Confidence P&P are evidence-based	Not confident = 13 Neutral=22 Confident/Very confident=65	Not confident =1 Neutral=14 Confident/Very confident=82
Satisfaction knowing about new and updated P&P	Dissatisfied/ Very dissatisfied=24 Neutral=35 Satisfied/Very satisfied=41	Dissatisfied/ Very dissatisfied=5 Neutral=25 Satisfied/Very satisfied=70
Satisfaction with searching and finding P&P	Dissatisfied/ Very dissatisfied=29 Neutral=38 Satisfied/Very satisfied=37	Dissatisfied/ Very dissatisfied=5 Neutral=12 Satisfied/Very satisfied=83

- A question was embedded in the quarterly LMS test to measure the effectiveness of using this method to spread awareness of significant practice changes. N=1500
 - 93% of nurses “Agreed or Strongly Agreed” that “The quarterly policy and procedure module is a beneficial way to increase my awareness of new and revised policies and practices.”
- Using logistics to track how often P&P are searched for, selected and opened we know that staff members access P&P 15,000-20,000 per month in the newly developed policy management platform.

Implications for Nursing Practice: EBP methodology including clear, consistent dissemination and implementation processes can accelerate the move of best practice to standard practice in a complex organization. Embedding EBP into existing structures such as organization P&P ensures that best practice is standard practice across all settings. Establishing the expectation that evidence is required for all practice changes supports the culture of EBP within the organization. Leveraging Shared Governance structure allows for streamlined communication and education efforts. Creating supportive structures, including technology that allows for quick retrieval of P&Ps, ensures that clinicians at the point of care have the tools necessary to provide safe, evidence based care.

J 02 - Cognitive and System Factors Impacting Nurses' Postoperative Pain Management

Human Factors Engineering in Healthcare

Priyadarshini Pennathur, PhD, USA

Abstract

Health care systems face complex challenges in delivering care and maintaining patient safety. Challenges include improving operational efficiencies, while supporting health care workers' tasks and workflow with appropriate tools, technologies and organizational policies. Patient safety continues to challenge health care teams. Severe, frequent safety incidents are still occurring, and the subsequent economic burden for the hospital continues. Health care professionals work to keep patients safe, while maintaining their work productivity. Safe outcomes not only depend on the health care worker safely delivering patient care but also depend on the underlying organizational environment and culture, the policies affecting their productivity, the physical space where health care operations take place, and organizational support structures enabling patient care work. The tasks designed for health care workers to perform, and the technology provided to support these tasks must reduce errors, decrease cognitive and physical effort and workload, and increase patient safety and productivity. For example, introducing new technology without understanding health care professionals' workflow and functional needs will, in all likelihood, compromise safety, and decrease productivity by forcing health care workers to add new tasks to their already demanding workflow. Similarly, organizational policies must ensure all health care workers have a safe operating environment by designing a balanced staffing load, incorporating training and education, and promoting a safety culture. Addressing health care system challenges requires solutions addressing problems from diverse perspectives, considering people characteristics, both health care workers and patients; technology and tasks characteristics for patient care and health care system operation; an organization's environmental characteristics; and physical space constraints. Most importantly, understanding the complex, and somewhat latent, interactions among all health care elements can help in addressing health care system challenges.

Human factors engineering is directed at studying how humans interact with systems, including their physical environment, technologies and tools they use, tasks they perform, and their organizational setting. According to the International Ergonomics Association, "human factors engineering applies theory, principles, data and methods to design in order to optimize human well-being and overall system performance."

Human factors engineering aims to improve safety, enhance performance and increase user satisfaction. It builds on interdisciplinary knowledge encompassing many sub-disciplines such as psychology, cognitive science, management, and computer science. Human factors engineers apply scientific methods to the study and design of human physical and cognitive capabilities and limitations while considering people's organizational and societal settings. The three major sub-domains in human factors engineering include physical ergonomics, dealing with people's physical capabilities and limitations; cognitive ergonomics, dealing with cognitive processes such as attention and memory; and organizational or macro-ergonomics, dealing with sociotechnical system design.

Health care professionals have applied human factors engineering principles and methods to make health care systems more efficient, effective and safe. Some topics of research have been examining errors, technology and usability, teamwork and organizational culture, physical environment design, diagnostic decision-making, anthropometry and lifting, and workload.

As an example, consider a nurse's workflow when providing patient care. A nurse may care for several patients during a shift; the patients present different complexities, and consequently different needs for care, requiring the nurse to engage in teamwork with other health care professionals to provide the most effective care. Patients, when located in separate geographical spaces, may require the nurse to plan and

coordinate patient visits. Any coordination not only requires physical effort but also requires cognitive planning to meet patient needs in a timely manner. Nurses engage in patient care and secondary tasks throughout the day, sometimes amidst interruptions and distractions. Reducing nurse' workload necessitates carefully considering a care facility's physical design and layout. Additionally, the criteria used to make patient assignment decisions needs to consider the number, case complexity and unique patient needs for patients assigned to a specific nurse, and the geographical separation between different patients.

Nurses' workflow requires significant interaction with health information technologies to document the care provided. The technology should support nurses' tasks and routine workflow and facilitate planning, problem solving and decision-making activities, so the nurse can focus on providing effective care. Nurses play an important role in many care processes including admission, handoff communication to transition patients, medication administration, routine monitoring and care, ambulation, documentation, patient and family education, and discharge. The tools and technologies provided and organizational policies should help nurses seamlessly coordinate between different but connected care processes.

The significant amount of coordination, documentation and managing patients is heightened when nurses need to perform pain management. Pain affects each patient in a different way, demanding customized care from nurses. This requires nurses to perform significant cognitive work in planning and individualizing care for each patient with pain, accounting for clinical and individual characteristics, tolerance for pain, and evidence-based guidelines on pain management. The most challenging aspect of cognitive work in pain management involves constant prioritization of tasks between pain management and non-pain management patients. Additionally, a patient's condition may change quickly, requiring constant monitoring and timely responses from nurses. Changes in a patient's condition will require re-prioritizing workflow, so the nurse can effectively manage emerging problems. An informal intervention that is already successful for pain management from the nurses' perspective is the coordination and teamwork among nurses to provide peer support in managing complex health care tasks. If the same type of support can be enhanced among the interprofessional team, demands from cognitive work involved in pain management will be greatly reduced, and pain management processes will be effective from the patient's perspective. For example, the team surrounding a patient experiencing pain would involve not only the immediate care team of nurses and physicians but may involve physical therapy, pharmacy, pre-operative care, labs, and procedures. Interprofessional coordination among these entities is crucial for effective pain management. However, nurses often undertake the responsibility to coordinate among these different entities for effective pain management, further increasing their cognitive work. Managing uncertainties and dynamic changes impact nurses' workflow and requires significant cognitive work. On a typical day, nurses may perform cognitive work involving planning, prioritization, coordination, problem solving, and decision-making. Understanding nurses' cognitive work involved in caring for a patient and designing support systems to facilitate their cognitive work will ensure a safe and productive system.

In summary, knowledge on how best to implement and use evidence-based practices for pain is still lacking. Additionally, we do not know what cognitive work components are involved in pain management, how nurses engage in cognitive work for providing pain management, and how best to intervene to improve the pain management process. A nurse's workflow requires functioning within health care system constraints and encompasses other health care workers, tools and technologies, tasks, and organizational policies within a physical space. Systematically designing the work system from a human factors engineering perspective with consideration to cognitive and physical work elements can help generate design solutions to support nurses' work. When developing design solutions, designers must consider the interactions between different health care elements so the underlying system characteristics improve. Our study on cognitive work in pain management provides a case example to investigate cognitive work in pain management from a systems perspective.

Cognitive and System Factors Impacting Nurses Postoperative Pain Management

Laura Cullen, DNP, RN, FAAN, USA

Toni Tripp-Reimer, PhD, RN, FAAN, USA

Abstract

Pain is a common patient experience with evidence available to guide practice. Inadequate pain control contributes to poor functional recovery. This feasibility study aimed to identify cognitive and system factors that impact nurses' postoperative pain management practices. Complex patient conditions and nurses' workload create significant challenges for effective pain management. Nurses' increased cognitive work (e.g., cognitive shifts and interruptions, cognitive stacking, lack of care coordination) and system factors (e.g., environment, technology, social and organizational aspects) may hinder evidence-based pain assessment and pain management practices. Observations targeted nurses' pain practices for adult postoperative total knee replacement (TKR) patients who often experience severe pain. Human factors engineering, nursing, and pain experts collaborated to study the complexity in nurses' pain practices.

Human factors engineering and ethnography methods were used to identify cognitive and system factors affecting nurses' postoperative pain practices. A nurse-engineer pair conducted shadowing, interviews, workload assessments and a focus group using contextual inquiry techniques. Observers shadowed five nurses (observer pair, four hours each nurse) for a total of 40 hours during the patients' first full post-operative day. Facility design impacting nurses' work was captured using movement analysis. Coding of themes was inductive and integrated nurse and engineer observations to create a coding framework built upon human factor engineering and the nursing process. Consensus was achieved using multi-step analysis.

Postoperatively, nurses prioritize patient care for pain and used evidence-based recommendations. However, the most frequent nursing activities included computer use, paperwork or charting/documentation, care coordination, and then care for pain. Nurses caring for surgical patients postoperatively frequently adjust and reprioritize care as a result of cognitive and system factors along with the unit layout. Stacking was a recognized norm that interfered with nursing care. Workflow blocks affected nurses' ability to provide care and meeting colleagues' needs created work stoppages. Work blocks increased both stacking and cognitive load. Unit design and organizational procedures (e.g., double checks, documentation) impact work pace, while creating work blocks. Interruptions and distractions were less influential than anticipated. These nurses rated workload with ratings lowest for pain reassessment and highest for overall pain management.

Millions of patients have surgery every year across the globe. Nurses caring for post-operative patients consistently prioritize pain management. Evidence-based recommendations are available and were designed to improve pain practice for all postoperative patients. Nurses' work is highly complex and influenced by cognitive work and system factors. c offers considerable opportunity to improve pain management for this patient population.

Evidence-Based Pain Management Solutions

Michele Farrington, BSN, RN, CPHON, USA

Abstract

Provision of evidence-based practice (EBP) is a global priority, yet EBP is not consistently provided. The complexity of EBP recommendations and clinician workload present significant challenges related to integration of practice changes into day-to-day routines and workflow. Since 2001, pain has been recognized by The Joint Commission as a right of all patients, but pain assessment and management were recognized as organizational priorities at one large academic medical center in the United States well ahead of that time.

Pain remains a prevalent global health concern, and one of the most common reasons people seek health care.

Ineffectively treated pain negative impacts overall health care costs, of which the annual estimate is \$261-\$300

billion, not including the immeasurable suffering experienced by patients in pain.

Since pain is a frequent, complex, important clinical condition, there have been many evidence-based guidelines developed for different types of pain (e.g., acute, chronic, procedural), different types of clinicians (e.g., anesthesiologists, primary care clinicians), and different pain components (e.g., assessment, treatment, monitoring).

Regardless of setting, integration of evidence-based pain management (EBPM) recommendations is complex and require nurses to balance patient preferences, individual responses to interventions, risks associated with both undertreatment and over treatment of pain, expectations outlined in hospital policies, patient's other needs, needs of their other patients, and coordination with colleagues.

A clinical practice guideline (CPG) focused on management of postoperative pain was published in 2016 from the American Pain Society, the American Society of Regional Anesthesia and Pain Medicine, and the American Society of Anesthesiologists' Committee on Regional Anesthesia. This guideline includes

32 recommendations, many of which have additional subcomponents and details aimed at helping clinicians provide evidence-based pain management to surgical patients.

Accurate pain assessment is an essential first step if effective management is to occur. Pain management on medical-surgical units is complex, and acute care nurses use pain assessment scales inconsistently. The purpose of one EBP project was to offer reliable and valid pain assessment scales to hospitalized adult cardiothoracic patients on a medical-surgical step-down unit so the patients could pick their preferred pain assessment scale. Using patients' preferred pain assessment scales improves the accuracy, trending, and evaluation of pain treatment effectiveness. This EBP project aligns with recommendation #5 from the CPG related to use of a validated pain assessment tool by clinicians to reassess postoperative pain and determine effectiveness of treatment interventions. Incorporating use of the patients' preferred evidence-based pain assessment scale improved nurses' care processes and patient satisfaction as measured by the institutional patient satisfaction questionnaire.

The use of intravenous ketamine for select adult patients, as part of multimodal analgesia, was another recommendation included in the 2016 CPG. The purpose of a staff nurse-led EBP project was to improve postoperative pain for opioid-tolerant orthopedic spine surgery patients through expanded use of low-dose ketamine infusions. Opioid-tolerant patients have complex pain management needs, and untreated acute pain may lead to the development of persistent pain. The potential benefits of using ketamine as an analgesic in low doses include resetting opioid receptors, need for less opioid postoperatively and decreased opioid side effects. Results from the EBP project included proactive identification of opioid-tolerant orthopedic spine surgery patients who may benefit from ketamine infusions, as part of a comprehensive approach to postoperative pain management, in addition to development of an individualized pain treatment plan. Clinician knowledge regarding ketamine for pain, communication among the interprofessional health care team and collaboration also improved as a result of the EBP change.

As a precaution, global attention is focused on opioid side effects and safety. Patient monitoring needs to occur after administration of systemic opioid medications. Crucial monitoring components include sedation, respiratory status and other adverse events as outlined in recommendation #14 from the guideline. The purpose of an institutional EBP project was to standardize monitoring of sedation in adult and pediatric patients receiving opioid analgesia in general care areas. Standardization of monitoring was necessary to help nurses identify excessive, unintended sedation early in order to prevent patients from progressing to respiratory depression while at the same time providing the best possible pain management. Implementation of the Pasero Opioid-Induced Sedation Scale and respiratory monitoring allowed bedside nurses to improve their ability to identify patients at risk for unintended sedation when administering opioid medications. After the project was complete, the bedside nurses reported providing safer care to these patients as a result of the new sedation and respiratory monitoring policy.

Application of evidence-based recommendations through these exemplars provides some direction and solutions for addressing important clinical issues related to pain management. However, continued research is still needed to address the gaps that remain with regards to effective, efficient ways to integrate practice change recommendations into complex care environments.

J 03 - Engaging Non-Traditional and Innovative Partners Across the Nursing Research Process

Non-Traditional Community Partnerships for Recruiting Hispanic Research Participants

DeAnne K. Hilfinger Messias, PhD, MS, BAS, BS, RN, FAAN, USA

Abstract

Purpose: Language, culture, geographic, social, and economic factors are associated with health disparities. Among more recent Hispanic immigrants, limited-English-proficiency and immigration status are barriers to health information and healthcare access. Improved access to culturally and linguistically tailored health information through technology could potentially enhance healthcare access and health outcomes. However, little is known about health information-seeking through technology among Hispanics in recent settlement areas (Lopez, Gonzalez-Barrera, & Patten, 2013). This primary aim of this collaborative research was to assess access and utilization of technology for health information among Hispanics in South Carolina. To effectively reach and engage community-dwelling Hispanics in research, investigators frequently must address potential barriers related to language, culture, location, and trust (Victorson, et al., 2014). To address these barriers, we engaged with non-traditional community partners to recruit a wide range of community-dwelling Hispanics.

Methods: We developed the interviewer-administered data-collection instrument, *The Use of Technology and Health*, a Spanish-language interviewer-administered, 47-item Spanish language survey with four components: access to care, health and health care information, technology and health, and participant demographics. Trained bilingual data-collectors administered the surveys in Spanish in a variety of non-traditional research settings. Data collection occurred at the Hispanic- free clinic, local churches, *tiendas* (stores), flea markets, English-as-a Second Language classes, and Mobile Mexican Consulate events at local schools.

Results: We conducted the first wave of surveys (n= 216) in 2011 and a second wave (n=156) in 2015-2016. For the first wave we used interviewer-administered paper and pencil surveys; during the second wave the interviewers at some sites utilized smart phone technology to directly enter data. Individual interviews lasted between 10-30 minutes. The survey design was such that not all participants were asked all questions. For example, if a participant answered “no” to questions regarding access/ownership of a cell phone or computer, the interviewer skipped the follow-up questions regarding cell phone or computer usage, shortening the interview.

Conclusions: This community-based and community-engaged research was a collaborative effort involving the South Carolina Hispanic/Latino Health Coalition, the *Clínica del Buen Samaritano*, the University of South Carolina College of Nursing, and several local and bi-national non-traditional research partners. The inclusion of non-traditional community partnerships enhanced access to the target population in “naturally-occurring” settings.

Innovative Academic-Retail Partnership for Carbon Monoxide Intervention Funding

Amber P. Williams, DNP, APRN, FNP, RNC-MNN, USA

Abstract

Purpose: With more than 20,000 annual exposures, carbon monoxide (CO) poisoning is the number one cause of poison related death in the United States, with more than 20,000 annual exposures (Iqbal, Clower, King, Bell, & Yip, 2012). A CO monitor is the only means of detecting the presence of this silent, colorless, odorless, and tasteless gas (Hampson & Weaver, 2011). The majority of homes in South Carolina (SC) do not have CO monitors, nor do emergency medical services (EMS) workers have portable, personal CO monitors, leaving a large segment of the SC population at risk. To address this public health issue, we developed a unique academic-retailer partnership in collaboration with the SC CO Safety Consortium (SCCOSC). We developed a partnership consisting of nursing researchers, public service associations, a non-profit foundation, and other community partners to conduct a multi-level study aimed at addressing CO morbidity and mortality through increased access to CO alarms. Firehouse Subs Public Safety Foundation was the non-traditional funding source for this nursing research.

Methods(s): The aims of this project were to assess the effectiveness of a community partnership in 1) extending CO alarm coverage in the SC Midlands; and 2) providing portable CO alarms for EMS workers throughout SC. SCCOSC partners installed over 1200 CO alarms in private residences in 7 SC Midlands region cities, along with providing an educational intervention. We conducted follow-up surveys 3-4 months post-installation.

Results: *Aim 1:* At follow-up, 100% of those surveyed still had the working CO alarm and >70% could state common symptoms of CO exposure, sources of CO production in their homes, and the best course of action if the alarm sounded. *Aim 2:* Responding to initial grant funding, the SC EMS director provided additional monies; total funding was sufficient to provide 225 portable CO monitors, or one monitor per EMS response vehicle in SC. Monitors were distributed in 2016; prospective data collection using the EMS Performance Improvement Center (EMSPIC) database is underway.

Conclusion: We will be able to track EMS post-intervention data through the EMSPIC database in conjunction with SC EMS. At least 2 families have been saved due to alarms placed during blitz activities. Partnerships such as this academic-retailer collaboration can be an innovative means of funding effective, multi-level interventions.

Partnering With Students to Enhance the Pipeline of Future Nursing Researchers

Courtney Catledge, DNP, APRN, FNP-BC, USA

Abstract

Purpose: Research is an integral part of nursing practice, yet undergraduate nursing and high school students considering a career in nursing rarely have exposure to nursing research. Many of these students are capable of higher education, including the master's and doctoral level, but do not pursue this trajectory due to a variety of reasons, including a lack of awareness regarding nursing career options. Additionally, in rural South Carolina these students are often the first in their families to pursue any type of

post-secondary education and have limited guidance in considering a graduate education. This has a direct impact on the number of nursing faculty available to teach future nurses. Currently US nursing schools turn away almost 69,000 qualified baccalaureate and graduate applicants annually due to faculty shortages (American Association of Colleges of Nursing, 2015), limiting the number of nurses available to care for our increasingly aging population (Ortman, Velkoff, & Hogan, 2014). Recruitment and support of students capable of performing nursing research and attaining a master's or doctoral degree is critical in assuring the future production of well-prepared, professional nurses. To provide an opportunity for early and direct engagement in research, we formed a nursing research club in partnership with a local high school and engaged high school and nursing students in a collaborative research project.

Methods: The collaborative project engaged BSN students (n=28) in faculty-mentored research in which they concurrently mentored local high school (HS) students (n=6) interested in health sciences careers. Students participated in a longitudinal, prospective research study of lung capacity among school band members (n=77). The BSN students recruited participants and obtained peak flow measurements using spirometry at the beginning and end of the school year. We conducted formative and summative program evaluations using Debriefing for Meaningful Learning.

Results: Both HS and BSN students reported having gained valuable knowledge on the research process, asthma and pulmonary function testing, leadership, and communication, in addition to other skills of value in health care delivery (i.e., patient engagement, documentation). Challenges identified included a need for role clarity. Follow-up engagement opportunities have included participation in local podium and poster research presentations by 1 BSN and 2 HS students. Participation in this mentored research program facilitated another BSN student's selection for a nursing internship.

Conclusions: This unique multi-level educational partnership allowed BSN students the opportunity to concurrently participate in research and concurrently serve as role-models of nurse researchers. Initial process evaluations revealed that opportunities to participate in research early in the academic trajectory can influence students in considering a career in nursing research.

Responding to a Community-Partner Identified Knowledge Gap

Robin Dawson Estrada, PhD, RN, CPNP-PC, USA

Edward B. Card, BS, MBA, USA

Anthony Scoggin, HS, USA

Abstract

Purpose: Of the nearly 90% of U.S. adults who utilize the internet, over 70% access health-related information for themselves or their family members (Fox & Duggan, 2013). However, health-related information on the internet is of variable quality and is linked to suboptimal patient outcomes (Chisolm, Sarkar, Kelleher, & Sanders, 2015). Through a partnership with representatives of the South Carolina Office of State Fire Marshal (SCOSFM), we identified a potential for misinformation in fire safety messaging and autism. Even when successfully evacuated, individuals with autism are more likely to re-enter a structure and die due to overwhelming stimulation that occurs at a fire scene. Evidence-based information for caregivers of people with autism is needed to address this unique risk.

Methods: After clearing the computer browsing history, we conducted an internet search on Google, Bing, and Yahoo using the search terms "autism" and "fire" and related search terms. From the 1,350

search returns, we identified websites targeting caregivers (e.g., parents, family) of people with autism that also contained fire safety messaging. PDFs, blogs, and other documents were excluded, as were websites targeting other populations (e.g., emergency medical services or fire professionals). We then evaluated two domains: 1) *appropriateness, usability, and readability* using Suitability of Materials and the SMOG formula (Doak, Doak, & Root, 1996); and 2) *content* using the DISCERN tool (Charnook, 1998) for both autism (using DSM-V) and fire safety (using National Fire Protection Association Standards).

Results: Of the nine identified sites, eight contained relevant fire safety content; the remaining one was labeled as a fire safety webpage but contained dead links and no information. Content analysis revealed readability levels of 10th grade and higher, and several sites related personal stories rather than information congruent with evidence-based information on fire safety and autism.

Conclusion: Novel partners with specific expertise, such as SCOSFM representatives, facilitate the identification of previously unknown knowledge gaps and the process of conducting research. These findings will be used to inform the development of evidence-based fire safety messaging for caregivers of people with autism.

J 04 - International Collaboration: A Cross-Cultural Brazil and U.S. Perspective in Practice, Education, and Research

Establishing International Research Collaborations: A Cross Cultural Perspective

Diana Lynn Woods, PhD, RN, APRN-BC, FGSA, FAAN, USA

Priscilla Souza, PhD, RN, Brazil

Renee Pozza, PhD, MSN, RN, CNS, CFNP, FAASLD, USA

Fernando Sanches, MSN, BSN, Brazil

Celia Caldas, PhD, RN, Brazil

Abstract

Background: With the emphasis on global health and international collaborations, international research collaborations for nursing are essential. From a worldwide perspective, the process of building knowledge is directly related to the ability to disseminate this knowledge and apply it globally. Comparing different cultural challenges and solutions can lead to unique ways to solve specific social and professional problems. These solutions can be used in other cultures as a way to replicate successful models and evidenced based practice to improve nursing practice. Establishing cross cultural research collaborations including cultural experiences helps to deal with problems experienced within different cultures. Here we present steps that contributed to the establishment of a sustainable research collaboration between a university School of Nursing in Rio de Janeiro and a university School of Nursing in California, United States. The presentation will focus on the experience and insights of establishing a research collaboration, of engaging both undergraduate and graduate students in research, establishing common approaches to work from a collaborative international perspective, and future plans for sustaining this collaboration.

Methods: This study is based on the self-reported experience of faculty, preceptors, and nursing students that have participated in the collaborative partnership between Brazil and the United States (US). There is a well-established process for exchanging nursing professionals and students. An initial visit by the Dean and Associate Dean of the US School of Nursing resulted in a Memorandum of Understanding (MOU) for education and research between the universities.

Faculty and students from a School of Nursing in California, US visited the Brazilian university and university hospital in Rio de Janeiro, Brazil. Brazilian professors also visited the School of Nursing in California. Discussions ensued by e-mail and videoconference.

Results: Between 2013 and 2016, faculty members from the School of Nursing in California travelled to Brazil 3 times, while Brazilian faculty members from Rio travelled once to the US. Additionally, two groups of US students have travelled to Rio where they had the opportunity observe nursing research and practice. For example, while health care systems are very different, the population and the pressure from the growing a gerontological population is a significant consideration that is similarly shared between Brazil and the US. Moreover, there are opportunities to identify different ways to solve problems consistent with the culture of each country. Observations and discussion led to new research possibilities in child and gerontological nursing. For example issues related to the Zika virus, dementia syndromes; an application of a cognitive stimulation workshop for elderly people with dementia, a gerontological nursing care strategy (Souza, Bastos, Santana, As & Cassiano, 2008), and aging variations and ethnopharmacology (Woods, Mentis, Cadogan & Phillips, 2016) focusing on conditions common to both countries. Using similar instruments to measure outcomes will help improve cross-cultural comparisons (Jessen, Cruz, Tesoro & Lopes, 2014). Ongoing videoconferencing, monthly will maintain relationships and help to identify areas of mutual interest for research. Preliminary studies have shown that nurses who understand a variety of different people are more effective in offering ways to deal with illness and to seek wellness. According to Long (2016), the main benefit that an international experience can offer are: 1) improving cultural awareness; 2) increasing cultural sensitivity; 3) providing exposure to regional diseases

and health conditions; 4) fostering a deeper understanding of the interaction between environment and health. As the result, these benefits lead to more effective nursing care.

Conclusions: Having established relationships between universities, future efforts will focus on collaborative research and comparing populations, such as gerontological populations. This is the first stage in developing a strong sustainable collaboration. Positive responses from faculty and students indicates a positive response for nursing practice and education. We continue to share data and complete joint publications. This international collaboration helps enhance nursing abilities and achieve a better quality of care, by offering experiences that enhance a cross cultural perspectives including the strong association between the environment and health.

How International Interchange Can Bring Benefits into Professional Lives

Fernando Sanches, MSN, BSN, Brazil

Priscilla Alfradique, PhD, RN, Brazil

Diana Lynn Woods, PhD, RN, APRN-BC, FGSA, FAAN, USA

Renee Pozza, PhD, MSN, RN, CNS, CFNP, FAASLD, USA

Abstract

Background: In a globalized world, data and information are crucial to making decisions in any field of knowledge. This is especially true for nursing work. Including a global perspective in clinical decision making helps to broaden decision choices, including those that are culturally appropriate. Using this lens, nursing has an important position in the health workforce, developing and strengthening human resources for health and playing a vital role in improving health service delivery worldwide, as shown in a several World Health Assembly resolutions (WHA42.27, 45.5, 47.9, 48.8, 49.1, 54.12 and WHA59.27). Following this assertive, we recognize that international partnership and collaboration from different settings are strategies to build a bridge for nursing knowledge.

Methods: This study is based on the self-reported experience of preceptors from a 250 bed tertiary care university hospital located in Rio de Janeiro, Brazil where students from a School of Nursing in California visited hospital wards and the operating room. Conducting this experience, one leader of the coordination applied four questions to preceptors who received the students in their wards. The questions were: 1. a. What would you have to say about an international agreement? b. Do you think your hospital has this capacity? 2. How did you engage students for learning on your unit? Have there been repercussions in your unit? 3. Do you think it is important to open the experience to not only students, but experienced nurses as well? 4. Would you be interested participating in an exchange abroad? Data were analyzed using a qualitative descriptive approach focusing on thematic analysis.

Results: A total of 17 eligible preceptors were invited to participate. From this total, 12 (71%) nurses with, at range of three to thirty years of experience in this Brazilian university hospital, answered the proposed

questions. Four themes emerged from the preceptor's responses regarding the participation in the nurse students' exchange abroad: 1) Perceptions about international agreement; 2) Brazilian university hospital's capacity; 3) Repercussions about receiving students and nurses in the ward; 4) Interest in international professional exchanges. Overall, the preceptors believe to be a relevant opportunity to exchange knowledge and experience. They affirmed that the hospital has conditions to receive international students, if planned accordingly, in a productive way. Preceptors considered a great experience to exchange knowledge and experiences from different realities. Thus, receiving experienced nurses would bring even more opportunities to share scientific knowledge and enrich evidenced based nursing care. They reported the nurse team was positively surprised with the presence of international students and, at the same time, curious know more about their routines and practices related to nursing care. In addition, preceptors were highly interested in international exchanges, although some reported that the use of a second language might be a barrier.

Conclusion: A benefit of our international exchange includes learning about diverse people, cultures, belief systems, and worldviews which is essential for nurses to be effective in a person-centered profession. This experience has formed new partnerships around the world, and promoted a setting where nurses/nursing students learn to care in a worldwide perspective. Furthermore, they have an opportunity to share anxieties, curiosities, discoveries, difficulties, doubts, challenges, and methodologies. These attributes are important aspects to consider when using evidence based practice to improve and promote quality of life.

Student and Faculty International Exchanges

Renee Pozza, PhD, MSN, RN, CNS, CFNP, FAASLD, USA
Aja Lesh, PhD, RN, NP, USA

Abstract

Background and Significance: International nursing experiences are important learning opportunities for both students and faculty. The experiences provide an enrichment to nursing practice, a global perspective of healthcare and a cultural awareness and sensitivity which all serve to enhance the profession of nursing. Several methods of providing these experiences for students and nursing faculty has been cited in the literature including short term trips, semester long study abroad programs, and visiting scholar appointments. All of these opportunities involve collaboration, relationship building and sustainable programs to ensure consistent quality educational outcomes.

Purpose: This presentation will provide an example of the partnership between a US School of Nursing and a Brazilian School of Nursing in order to provide experiences for both undergraduate and graduate nursing students as well as nursing faculty in a sustainable program.

Methods and Results: A collaborative effort between both schools was begun informally 3 years ago. As the relationship developed between the leadership teams in both Schools of Nursing a vision and related goals for each school was established for an exchange. Thus began the movement to a more structured exchange program which was outlined in a contract between the two Universities. Alignment of nursing curriculum and clinical opportunities were designed in collaboration between the two nursing faculties to allow undergraduate and graduate nursing students from the US to experience an immersion into the Brazilian healthcare system. Nursing faculty from Brazil traveled to the US to experience US healthcare and develop further language skills to enhance the exchange experience and foster research efforts.

Future plans are underway for experienced nurses from Brazil to travel to the US along with nursing faculty. Technological advances have enhanced communication between the two schools and has fostered relationship and team building which is critical to the sustainability of the program. Language barriers continue to exist, although more at the faculty level compared with the student exchange.

Conclusions: The model of collaboration and exchange built upon a trusting relationship and mutual identification of goals and outcomes is an effective way to establish collaborative partnerships between two Schools of Nursing in two different countries. This model allows for efficient exchange of students and faculty to foster sustainable relationships, increase understanding of global healthcare systems and ultimately to impact nursing practice.

J 05 - Improve Nursing Practice: Outcomes, Technologies, and Clinical Supervision

Validity and Reliability of Self-Management Style Instrument

Fernanda Bastos, PhD, MsC, RN, Portugal

Alice Brito, PhD, McN, RN, Portugal

Filipe Miguel Soares Pereira, PhD, RN, Portugal

Abstract

Based on theory of self-management in chronic disease an instrument was created to identify the style of self-management. This tool is conceptualized as a synthesis of personality, attitudes and health behaviors. Identifies personal features, different ways of living with the disease, and a self-report perception of behavior towards the therapeutic regimen.

According to this theory there are self-management styles associated with greater vulnerability and therefore need more specific care. Theoretically styles are linked to seven dimensions (Internal Locus of control; self-determination; decision making; attitude to disease; attitude to regime; self-efficacy; interaction with health professionals) grouped in two major categories: flexibility and control.

Purpose: Contribute to the development of the quality of nursing practice identifying the personal attributes that interfere with self-management to better adapt the strategies of approach to the chronic patient according to their individuality.

The objective of this study is to evaluate validity and reliability of self-management styles instrument.

Methods: Instrument content was based in self-management in chronic disease theory (Bastos, 2012). The items were constructed according grounded on the content analysis of the research that is the basis of the theory. Being subsequently validated by a group of experts. Scale ranges from 0 to 4 for strongly disagree to strongly agree.

Instrument was applied to 521 participants in three different contexts. Two of them were in Primary care, in different cities of Portugal (one hundred of diabetics and two hundred and seventy-one with a chronic disease), and one was in a Portuguese hospital (one hundred and fifty of patients purpose, or already made, a transplant).

Reliability was evaluated by analysis of internal consistency (Cronbach alpha).

Results: Reliability estimates revealed good internal consistency, with the alpha coefficient for the overall scale being .77. However, the interest of this instrument is not to obtain a global score, but the identification of scores in different aspects that indicate personal characteristics and levels of vulnerability. Therefore, and considering the central axes as subscales, Flexibility (25 items) presented an alpha .58, and Control (16 items) .64.

The seven theoretical dimensions presented an alpha between .46 and .71 (internal locus of control (6 items) $\alpha = .52$; self-determination (6 items) $\alpha = .51$; decision making (5 items) $\alpha = .49$; attitude to disease (17 items) $\alpha = .54$; attitude to regime (13 items) $\alpha = .46$; self-efficacy (3 items) $\alpha = .71$; interaction with health professionals (4 items) $\alpha = .51$).

When we computed the variables to obtain the score by self-management styles, we obtain other dimensions: responsible style score (17 items) $\alpha = .72$; formally guided style score (14 items) $\alpha = .71$; independent style score (5 items) $\alpha = .10$; and negligent style score (8 items) $\alpha = .62$.

Conclusions: The instrument has proven to be easy to apply and is of interest for the identification of people with chronic disease who are particularly vulnerable. However, it showed fragility in the discrimination of the independent self-management style score, and the validity of content in this subscale was not assured.

Clinical Utility of Self-Management Style Instrument

Alice Brito, PhD, McN, RN, Portugal
Fernanda Bastos, PhD, MsC, RN, Portugal
Filipe Miguel Soares Pereira, PhD, RN, Portugal

Abstract

To identify the style of self-management in people with chronic disease an instrument of self-management style was used. This instrument, as a synthesis of personality, attitudes and health behaviors, allows to characterize and identify personal characteristics, different ways of living with the disease and a perception of self-reporting of behavior in relation to the therapeutic regime in the sense of being able to act with each according to these characteristics. These characteristics are expected to influence clinical outcomes.

Purpose: Contribute to the development of the quality of nursing practice identifying the personal attributes that interfere with self-management to better adapt the strategies of approach to the chronic patient according to their individuality.

Objective: Identify the variables that interfere with the scores in each of the self-management styles: age; sex; education; cause of disease (liver transplantation); illness intrusiveness.

Identify the clinical utility of the self-management style instrument face to clinical outcomes: empowerment; self-care activities with diabetes; readmissions at hospital

Methods: Instrument was applied to 521 participants in three different contexts and analyzed in its association with different variables, obtained by application of socio-demographic and clinical characterization questionnaires and other instruments: summary of diabetes self-care activities-SDSCA (translated and adapted to Portuguese); Adapted Illness Intrusiveness Ratings (translated to Portuguese), Individual Empowerment's Scale.

Results: Study identify some very weak correlations but statistically significant (n=521) between age and: responsible style ($r = -.133^{**}$); formally guided ($r = .284^{**}$); and Independent ($r = .115^{**}$).

Using ANOVA the study identify differences between groups of educational levels in the score of responsible, formally guided and negligent, but no in independent style. Educational level predicts in a positive way responsible score ($r^2 = .05^{**}$), also in a negative way formally guided ($r^2 = .14^{**}$) and negligent style ($r^2 = .03^{**}$).

Illness intrusiveness correlates in a significant, but weak and negative way, with the responsibility score, and moderately with negligence score ($r = .504^{**}$).

On the other hand, the responsible score predicts the empowerment score ($\beta = .556^{**}$), explaining 26% of its variability, while the negligent score predicts negatively ($\beta = -.228^{**}$), explaining about 17% of its variability.

The least empowered ($n = 203$) had a mean score of responsible (mean=3.5 (Dp 0.4)) lower than the most empowered ($n = 68$) (mean=3.8 (Dp = .2)) with the mean difference being 0.26 $p = 0.032$; when we compared the mean of the negligence score of the most and least empowered, we found a significant difference of means (0.38) $p < 0.001$.

Comparing mean scores for both responsible and negligent individuals ($n = 271$) followed in primary health care, we found that individuals who were already hospitalized ($n = 130$) had a higher mean of the negligent score (mean=29 (Dp.84)) And lower in the score responsible (mean=3.47 (Dp.42)) for those who were never hospitalized, respectively (mean=.93 (Dp.61)) and (mean=3.64 (Dp.31)) for a $p < .001$.

We observed significant correlations in people with diabetes between self-management styles scores and SDSCA subscales:

Responsible score: $r = .428^{**}$ with foot care ($n = 99$); and with SDSCA $r = .235^{*}$ ($n = 92$)

Formally guided score: $r = -.333^{**}$ with physical exercise ($n = 100$); blood glucose monitoring $r = -.237$ ($n = 97$) and with SDSCA $r = -.302^{**}$ ($n = 92$)

Negligent score: $r = -.227^{*}$ with general feeding ($n = 100$); physical exercise $r = -.225^{*}$ ($n = 100$); and with SDSCA $r = -.307^{**}$ ($n = 92$)

Conclusions: The older chronic ill person tend to be less responsible and more formally guided or independent.

Educational level predicts characteristics of greater responsibility and less tendency to score formally guided and negligent. This association is significant but rather weak.

A more negligent experience leads to more symptoms of the disease.

This study allowed to identify variables that interfere with the style of self-management and variables that may be predicted by them. In this way the instrument proved to be clinically useful.

Nursing Outcomes Related to Self-Care

Maria Joana Campos, MScN, RN, Portugal
Abel Paiva Silva, PhD, MScN, RN, Portugal

Abstract

Introduction: Outcomes are tools that allow "measuring performance ... aiming to discover certain basic information for decision making to improve quality" (Mezomo 2001, 135). Nursing outcomes are needed to show the improvement in health of the patients and families related with nursing care, " more specific" metrics, related to "... new health outcomes ..." (Campos & Ramos, 2005, P 235).

Purpose: As part as a large research with the objective of defining a model of management of quality nursing care based on reflection for / on valid information (from the learning model of Argirys & Schön, 1982), we tried to identify the outcomes of patients and families in context of long-term care at home.

Methodology: We analyzed the nurse records (software - SAPE®) and exported the data to a Microsoft Access® database.

The analysis was performed through the Statistical Package for Social Sciences - SPSS (version 18.0, SPSS Inc, Chicago, USA). A data analysis was carried out to characterize the sample through a descriptive and inferential statistical analysis (Pollit & Hungler 1995; Gil, 1999). The information records (diagnostics, interventions, outcomes) by the nurses in the clinical records (Software - SAPE®), between September and December 2012 were the material for analysis.

Results: We have gathered the outcomes by several areas, those that belong to the patient's condition like the patient's knowledge, the patient's capacities, prevention (potential problems), and those about the condition of the family caregiver like the family caregiver's knowledge, and total outcomes. It was impossible to generate outcomes in all areas in the 191 cases. Regarding the integumentary system, it was possible to generate indicators in 158 patients, 110 patients had outcomes related to their condition, 103 with the knowledge of family caregivers, 100 related to potential problems, 68 with family caregivers capacities, 40 patients had outcomes related to knowledge and 13 with the capabilities. Regarding self-care outcomes indicators were generated in 155 patients. Therefore, the indicators generated, 145 cases had outcomes related to their condition, 116 to the knowledge of the family caregiver, 100 to the capacities of the family caregiver, 67 outcomes about the patient's knowledge and 56 about the abilities.

Conclusion: In order to better understand the nursing outcomes in patients in the context of long-term care, a model based on 4 variables was generated through clusters analysis. Like the proportion of outcomes in the patient global condition, proportion of outcomes in independence, proportion of outcomes in the patient capacities and proportion of outcomes in the patient knowledge; which is good (0,6). This model has 2 clusters, the largest with 33 cases (57.9%) that we designated as "Patient with a lower percentage of outcomes"; and the lowest with 24 cases (42.1%) "Patient with a higher percentage of outcomes". The ratio of highest to lowest is 1.38. The outcomes are important to reflect the nursing practice turned to quality of care

The Value of Educational Technology in the Nursing Care: Benefits in Clinical Practice

Maria José Lumini Landeiro, PhD, MScN, RN, Portugal
Teresa Martins, PhD, MsC, RN, Portugal

Abstract

In the current scenario, it is important that health professionals use innovative educational plans using the new technologies of information and communication to address health problems. There is a need to provide health information to ensure and protect citizens from misleading information and to promote the implementation of useful, reliable and up to date health information. Citizens are increasingly requested to get involved and also become responsible in health care.

Aim of the study: To assess the influences of the educational technology "Caring for Dependent People" in some clinical indicators.

Methods: A quasi-experimental study, not randomized, of the before and after type, with a convenience sample of 65 family caregivers, from two Medicine services of a hospital in Porto, Portugal. The Control Group consisted of 33 family caregivers and the Experimental Group of 32, identified by consecutive sampling. The experimental group had access to educational technology at home. Data were collected by socio-demographic, evaluation of clinical indicators questionnaire. The assessment in both groups were made one month after discharge.

Results: The assessment of the clinical indicators such as: use to the emergency room, unscheduled consultation, home visit request of nurses, use of the INEM (National Institute of Medical Emergency), unscheduled hospitalization and pressure ulcer development, revealed no statistically significant differences between the two groups of dependents. These results, highlights the need to strengthen priority and essential information during the process of immediate recovery at clinical discharge, emphasizing the key role of nurses in the monitoring and management of this process. This technology can be used in health, particularly in hospital and essentially home context, as may be advised by the nurses in the hospital for use after discharge, as well as to remember and take questions following the instruction given.

Conclusion: We think we have contributed to the development and integration of interactive educational technologies in the clinical setting, providing a technological complement in the preparation of family caregivers by health professionals contributing to the improvement of health care

Nursing Clinical Supervision in Integrated Continuous Care Unit

Regina M. Pires, MsC, RN, Portugal
Filipe Miguel Soares Pereira, PhD, RN, Portugal

Abstract

Clinical supervision (CS) is a facilitator process of professional support and learning with the purpose to improve practice, the quality and safety of care, based on interactive functions: formative, restorative and normative (Proctor, 1987).

In Portugal the primary health care incorporate Integrated Continuous Care Units (ICCU) where nurses, providing care to people in situations of dependency, helping them to regain or maintain their independence and maximize their quality of life.

Aim: The study aimed to identify the core elements of the Clinical Supervision (CS) process for Integrated Continuous Care Units (ICCU) nurses.

Methodology: Qualitative study, data were collected using half-structured interviews, with a sample of 16 nurses from a primary health care center, between May and December of 2012.

Data analysis, through content analysis according to the principles of the grounded theory method, using the program Nvivo10. Ethical approval was granted by the Board of Director and Ethic Committee.

Results: In the nurses' discourse were identified elements of formative, restorative and normative functions, as the base of Clinical Supervision (CS) process in the Integrated Continuous Care Units (ICCU).

In formative category were identified some properties: reflection on practice; development of critical thinking; development of scientific knowledge; orientation research the best scientific evidence; continuing education; individual and professional development.

In restorative category were identified some properties: emotional support; positive reinforcement; nurses' professional motivation; supervisor collaboration in care.

In normative category were identified some properties: observation of practice; identification of training needs; formative feedback; ensure standards; ensure ethical issues.

Conclusion: This study was concluded that nurses of Integrated Continuous Care Units (ICCU) consider that Clinical Supervision (CS) process must be based on intrinsic elements of the three interactive functions of Proctor (1987), which corroborates much of the main research in this specific area, both in primary care or in a hospital organization.

D 07 - Advancing World Health Through Nursing Students' Study Abroad Experiences: Shared Insights

Preparing Nursing Students for International Learning Experiences

Karen M. Lundberg, MS, RN, CNE, USA
Cheryl A. Corbett, MSN, APRN, NP-C, USA
Debra Edmunds, MS, RN, CNE, USA

Abstract

Purpose: Faculty at a western United States university found it essential for student nurses participating in a clinical international experience to complete a preparatory course prior to in-country experience. Students prepared by learning about travel expectations, culture and people, course requirements and personal perceptions. The purpose of this presentation is to discuss the significance of cultural preparation before travel, and describe a cultural preparatory course.

Methods: Students selected to participate in an international experience are required to complete a one-credit cultural preparatory class. The course is taught the semester before student travel. Course outcomes include assisting students to understand their own personal worldview and perceived experience expectations, in addition to studying about the culture and people. Students also prepare to practice nursing in an international setting. Additional preparation includes the development of an emergency plan for possible in country disasters. Teaching methods include book reports, oral presentations on culture topics, guest lectures, videos, and reading articles. Class discussions are very helpful concerning culture shock and culture biases. These important discussions help students identify their personal risks of maladaptation to new international experiences. Students are also given opportunities to voice fears or concerns during discussions whereupon faculty can address these issues prior to travel. Presenting faculty have assisted students in preparation for a variety of international experiences including India, Vietnam, Tonga and refugee populations.

Results: Students prepared for international travel have a more rewarding encounter and adapt quicker to their new situation, allowing for earlier engagement in the international experience. End of travel student feedback provided faculty with suggestions for improved preparation such as guest speakers from different religious communities and increased language skills.

Conclusions: The benefits of cultural preparation contribute to a more enlightened international experience for both faculty and students. Continued preparation is vital for international travel. Faculty are encouraged to implement a similar type of preparatory program for international study abroad programs.

Six Continents: One Undergraduate Public and Global Health Nursing Course

Leslie W. Miles, DNP, APRN, PMHNP-BC, USA
Scott K. Summers, MS, FNP-C, USA

Abstract

Purpose: With globalization, the demand for culturally competent nurses who are prepared to provide quality care from a cultural point of view has increased. (Kokko, 2011). Research has shown a deficit of culturally sensitive care leads to “nurses [that] may have ethnocentric and stereotyped attitudes toward patients” (Kokko, 2011, p. 674). The American Association of Colleges of Nursing (2008) *Essentials of Baccalaureate Education for Professional Nursing Practice* identified global health as an essential core knowledge area for nurses.

This presentation will highlight and discuss our challenges and successes with a variety of clinical sites meeting course outcomes over the years of providing cultural and global experiences for our nursing students.

Methods: Broadening undergraduate nursing students’ global health education and experience is paramount, but current nursing literature on how to implement global education is limited (Edmonds, 2012). In the United States, only 23% of baccalaureate nursing programs offer a semester abroad opportunity with only 44% of those colleges offering clinical nursing courses taught by nursing faculty (Read, 2011). A European Union student exchange program, European region access scheme for the mobility of University students (ERASMUS) is available for nursing students for education abroad that improves student’s ability to provide culturally competent care (Milne & Cowie, 2013).

The literature has shown an increase in confidence, self-awareness and overall enrichment in students who participate in a study abroad course (Long, 2016). This transformation rarely comes with didactic work alone, students do not always retain information that is presented, but are more likely to change through lived experiences (Long, 2016).

Results: For over 16 years, an American university college of nursing has coordinated multiple clinical sites utilizing nursing faculty to provide an adaptable high quality learning environment on six continents. All undergraduate nursing students in this college are required to take the public and global health course.

To ensure curriculum consistency and enhance cultural competence opportunities, a committee was formed to develop course outcomes and learning activities to be utilized for all clinical sites – both domestic and international.

The course outcomes include: 1) Acquired a basic understanding and perform thoughtful reflection of culture, diversity, social, economic, globalization, and environmental factors as it affects health care; 2) Exhibit inter-professional values, communication skills and culturally sensitive health care that is respectful of people with different backgrounds, socio-economic status, beliefs, or perspectives; and 3) Recognize their own biases and self-limitations and increase desire to learn from others and integrate cultural competency as a life-long learning process.

Conclusion: Currently the course is offered every spring term for 128 nursing students who span the world in three domestic sites (At-Risk, Refugee, and Veterans) and eight international sites: Czech Republic, Ecuador, Finland, Ghana, Spain, Taiwan, Tonga and Vietnam. Clinical sites vary from high density populations to remote areas. Experiences include the following areas: hospitals, clinics, home care, schools, veteran facilities, public health, and international student collaboration. Each varied experience is designed to meet the course outcomes. Our collective experiences has resulted in unique know-how about how to tailor global health outcomes to diverse domestic and international sites.

Nuts and Bolts of Nursing Study Abroad: Logistics and Funding

Sondra Heaston, MS, NP-C, CEN, CNE, USA

Gaye L. Ray, MS, FNP-C, PH-C, USA

Abstract

Purpose: There is little doubt that nursing specific study abroad experiential learning facilitates the development of cultural humility and enhances cultural awareness. A well planned study abroad should be a life changing experience for participants adding richness to their education and future careers¹. However, there are logistical and funding issues that serve as hurdles to the development of study abroad programs and student ability to participate². This presentation will share insights and suggestions to address the hurdles encountered when planning and conducting nursing specific semester abroad programs.

Methods: A baccalaureate pre-licensure program at a large university located in the western United States has implemented a required Public and Global Health Clinical Practicum offering eleven location options from which students can choose. Among the location options are international sites including Tonga, Ecuador, Taiwan, Finland, Czech Republic, Samoa, and Ghana, and at least three domestic options working with vulnerable groups such as at risk teens, incarcerated populations, and refugees. Each option includes activities geared specifically to the population of the area and are distinct and varied. Nearly 100 students enroll in this course each spring term. Each site has two college of nursing faculty members acting as program directors who interface with in-country contacts, the college of nursing international representative, and the university international travel center, to develop the program including an itinerary and a budget.

A discussion of the role of program directors and how they navigate some of the aforementioned hurdles in preparing a nursing specific study abroad experiences will be presented. The discussion will include creating a budget, the method for determining student fees, and anticipating in-country expenses. Examples of sponsoring university financial and other support necessary for a successful program along with how we cover faculty expenses will be shared. Options for student funding will be discussed³. In addition, the process of determining how to honor student choice within the available options considering cost, time, desired to travel or stay home, and other variables will also be addressed.

Results: Successful navigation of the budgetary and logistical study abroad hurdles is key to building a well-planned nursing specific study abroad program. Student outcomes, as a result of participation, include an enhanced awareness of the influence of culture on health and healthcare systems, an increased understanding of social determinants of health, a heightened ability to provide culturally appropriate care for individuals, families and groups, and an expanded appreciation of diversity.

Conclusion: Study abroad experiences benefit nursing students both personally and professionally³. Participation facilitates future nurses to enrich and heighten culturally sensitive care for growing

multicultural patient populations at home^{4,5}. While designing, planning and executing nursing specific semester abroad experiences is labor intensive and can present challenging hurdles, efforts should be taken to offer these educational opportunities to nursing students to enhance their preparation for nursing practice⁶.

Outcomes of a Global Health Nursing Course: Does the End Justify the Means?

Sheri Palmer, DNP, RN, CNE, USA
Stacie Hunsaker, MSN, RN, CEN, CPEN, USA

Abstract

Purpose: Due to nursing programs being increasingly burdened with additional education expectations, study abroad may seem like an inordinate extravagance. In order to increase sustainability of study abroad courses in nursing, the benefits of such experiences need to be proven and justified. The purpose of the following studies are to exhibit the positive effects of a Global Health Nursing Course including study abroad. The studies we have completed include: long-term effects of study abroad on the career of the graduate and cultural competence attainment of the undergraduate student.

Background: For over 10 years our College of Nursing has offered study abroad experiences in a Global health course. We typically have close to 100 students travel abroad for 3-5 weeks every year. There are many challenges and successes in offering this type of course.

Methods: The "Long term effect of Study Abroad in Nursing" research included 121 nursing alumni who had graduated up to seven years ago. They completed the International Education Survey (IES) (Zorn, 1996) with additional open-ended questions. The "Cultural Competency" studies include the use of three quantitative tools to measure student cultural competency over the past few years (Braskamp, Braskamp, Merrill, 2010; Caffrey, 2004; Camphina-Bacote, 2002). Over 450 pre-/post-test surveys have been returned. In addition, other methods to determine cultural competency included student's reflective writing papers.

Results: Results of the various studies will be shared in the presentation. The "Long term effect of Study Abroad in Nursing" study showed a large statistical significance on the nurse's career from studying abroad. Quantitative and qualitative results concluded: 1) nursing alumni were positively influenced long

term by the course and 2) comparatively, students who studied abroad had significantly increased IES scores.

Results from studies measuring cultural competence were also statistically significant. Studies indicate that all students, no matter where they completed their clinical experience, improved in their global perspective skills, knowledge and attitudes.

Conclusion: The information gleaned from the studies help justify the purpose of continuing the Global health Course with study abroad courses in nursing. In addition, the information has been used for quality improvement to determine what experiences and teaching techniques best assist students to increase their cultural and global health perspectives. With the amount of student dollars and resources invested in this program, it is critical we provide deliverable data of the impact of the course on their education.

D 08 - A Transformative Vision for Health: Promoting Nursing Colleges

An Action Framework for Leading the Transformation Process

Fernanda Principe, MsD, RN, Portugal

Abstract

Purpose: Health promotion programs in community and workplaces are increasing in prominence. However, planning and implementing such programs at large bureaucratic institutions are difficult. The PEER-IESS model (Brito & Mendes, 2009) is a bottom-up participatory health research and was designed to activate high education communities for the implementation of health promoting contexts, using dialogic strategies and creative means of intervention centered in the academic community.

A healthy university aspires to create a learning environment and organizational culture that enhances health, wellbeing and sustainability of its community and enables people to achieve their full potential. Ottawa Charter (1986) sets out three key strategies: advocacy, mediation and enablement. Also highlights five action areas: build healthy policy; create supportive environments; strengthen community actions; develop personal skills; reorient health services.

Tsouros and collaborators (1998) proposed a conceptual framework that defined healthy universities approach as institutions that develops an environment that supports and promotes health and wellbeing; allows the contribution of the views, skills and experience of the whole university community; increases participation and builds collaborative partnerships; is an effective, evidence-informed mechanism to bring about and embeds cultural change; leads to sustainable changes to improve the health and wellbeing of students and staff; links research, educational, operational and outreach activities and engages students in each; provides a framework that goes beyond interventions that focus on single topics, single target groups or single elements of the university.

Universities are dynamic, complex systems with inputs, processes, outputs and impacts and are part of a greater whole, embedded in local and global communities and interacting with the wider environment. Elements of the university system have interconnectedness, interrelationships, interdependencies and integration between them. Healthy universities concern to draw upon best practice linked to organization development, learning and change.

More recently Okanagan Charter (2015) shared aspirations that health promoting universities and colleges infuse health into everyday operations, business practices and academic mandates. By doing so, health promoting universities and colleges enhance the success of our institutions; create campus cultures of compassion, well-being, equity and social justice; improve the health of the people who live, learn, work, play and love on our campuses; and strengthen the ecological, social and economic sustainability of our communities and wider society. The Charter has two Calls to Action for higher education institutions: embed health into all aspects of campus culture, across the administration, operations and academic mandates, and lead health promotion action and collaboration locally and globally.

Based on these assumptions we formulated the following research question: How conceptualize and design a participatory health research process that allows the activation of a community of higher nursing education to implement a health promoting context and increases the skills for the profession?

To answer the research question, we defined the following objective: To discuss the framework that guide the transformative process of a nursing college into a health promoting context using the PEER-IESS model.

Methods: PEER-IESS is a *bottom up* strategy to implement health promotion contexts in high education institutions. Through PEER-IESS model (Education, Engagement and Evaluation Research - Salutogenic Higher Education Institutions), is intended to enable the community mobilization in higher education institutions to develop health promotion and resolution of problems of educational communities through the use of dialogical and creative strategies to promote health intervention centered on the student community (Brito & Mendes, 2009).

Within PEER-IESS model, and through the implementation of PRECEDE-PROCEED model (Green and Kreuter, 1991), used in various cultural contexts, settings, practices and structures of intervention is intended to systematize participatory health research to mobilize youth in large-scale issues related to healthy lifestyles.

PEER-IESS aims to be a participatory health research model to activate university communities in addressing the problems faced by youth, through using Community Mobilization, Peer Education and Peer Research strategies.

Results: As results the researchers realize that to engage youth in participatory health research networks will be an asset to reduce the gap between young people of different social status, allowing students to have social contact and support socially excluded communities; the value added by participatory action research is to increase awareness of social responsibility to promote youth health and networking between universities will promote institutional commitment because they represent the key mechanisms for change and innovation and organizational forms to provide cooperative learning and reduce the uncertainty of implementation of innovation.

Conclusion: Higher education has a unique opportunity and responsibility to provide transformative education, engaging the student voice, and developing new knowledge and understanding. PEER-IESS model recognize the link between Peer Education and Peer Research strategies, building capacity for health promotion; increasing academic success; curricular infusion health promotion in the study plan of nursing undergraduate course; formulation of health promotion policies in terms of mission, values and vision in the higher nursing education institution leading to the participation of the entire academic community in building the strategic development plan of the institution.

Key Principles for Action

Liliana Mota, MsC, RN, Portugal

Abstract

Purpose: The health promotion action is a process to improve people health`s. In this context, people has an active role to enhance their well-being and wellness. The nursing college could be a health promoting context to enhance the health self-control of academic communities, and it creating a learning environment and organizational culture that enhances health. The main lines that characterized these contexts are: to adopt institutional compromises and build healthy policy, to promote well-being, knowledge in health`s area, critical health literacy, personal and social responsibility of the academic and local community.

The aim of the study was to describe the process of transforming nursing college in health promoting context using the PEER-IESS model (Brito & Mendes, 2009) and to analyse the contributions of the involvement of academic community in participatory health research. PEER-IESS intend to be a bottom-up strategy to implement health promotion contexts.

Methods: A participatory health research (ICPHR, 2013) was implemented, using a constructive case-study in a nursing college, to evaluate in which way the involvement of a “seed group” in a participatory health research process initiates the mobilization a higher education community. The participatory health research through PRECEDE-PROCEED model (*Predisposing, Reinforcing, Enabling, Constructs in Educational/ecological Diagnosis and Evaluation*)-(Policy, Regulatory, Organizational, Constructor in Educational and Environmental Development) of Green and Kreuter (1991) conceptually guided our study.

The data collection strategies were multi-method, including semi-structured interviews, focus group, participatory observation, documental analysis and questionnaires. Based on PRECEDE-PROCEED model and quality criteria of participatory health research we trained and empowered a "seed group" to implement peer-research, peer-education and health promotion strategies. The initial assessment was based in social, epidemiological, behavioural, environmental, educational, organizational, political and administrative diagnostics. This approach supported the design of health promotion interventions in the academic community.

The "seed group" was constituted by 5 students, 4 teachers and 2 staff members. The interventions of the “seed group” were implemented since 2013.

Results: The priority areas of intervention were defined and implemented, in a collaborative and participatory involvement of all the academic community with the support of the “seed group”. The main areas of intervention were targeted for nursing students, institutional policies, school health services and infusion of health promotion content in undergraduate course curriculum in nursing. The intervention strategies used were workshops, worldcafé, peer-to-peer counselling interventions with the objective to reduce risk damage during academic festivities, curricular infusion, and definition of strategic development plan of the institution, occupational health and quality management. The intervention process engages the academic community to have an active voice in promoting health and in promoting the universal responsibility of the academic community. The engagement of the nursing students in studies with the participatory health research promotes the development of personal and professional skills, preparing the students to exercise of nursing profession.

Conclusion: These results will be an important contributes to guide the formulation of health enhancing policies and practices, thereby strengthening health and sustainability in universities and colleges and local community.

Evidence of Transformation Process

Sónia Novais, MsC, RN, Portugal

Abstract

Purpose: The transformative process of a nursing college institution in a health promoting higher education institution, by applying a model bottom-up, participatory health research PEER-IESS (Brito & Mendes, 2009), promotes socio-environmental performance, cultural, political, ethical and deontological, scientific and continuous quality improvement, and requires the involvement of the academic community, helping students to acquire personal skills for the exercise of the future profession. Based on these assumptions we formulated the following research question:

How the involvement of a "seed group" in a participatory health research process mobilizes a community of higher nursing education to implement a health promoting context and increases the skills for the profession?

To answer the research question, we defined the following objective: To evaluate the process and the results of the transformative process using the PEER-IESS model from the perspective of representatives of school management boards, the degree course coordinator, student leader and local community leader.

Methods: We intend to validate the use of PEER-IESS intervention model. This model is a bottom-up intervention that mobilizes and activates the academic community to promote salutogenesis in the educational context. It should be noted that participatory health research should be understood as an empowerment so that is "transformative participation" (Springett and Ledwith, 2010, p.189), which must implicitly mean that all people can perform a self-awareness (Freire, 2001), culminating in reflection and willingness to change behaviour. Scientific knowledge is generated action and experimentation in context, democratic and social learning participation.

PEER-IESS develops in a sequential process to mobilize academic communities, focusing on dialogic procedures and creative ways to engage the community, from a "seed group", and was based on the quality criteria of participatory health research and based on the PRECEDE-PROCEED model developed by Green and Kreuter (1991).

To evaluate the process and the result of participatory health research, a semi-structured interview guide, based on the indicators defined by the American College Health Association (ACHA, 2012), the Standards of Practice for Health Promotion in Higher Education was built. The researchers interviewed the representatives of school management boards, the degree course coordinator, a student leader and local community leader, in a total of seven participants. The interviews were transcribed *verbatim* by researchers and was created a document computed in IRAMUTEQ (Interface de R pour les Analyses Multidimensionnelles de Textes et de Questionnaires). IRAMUTEQ is a GNU GPL (v2) licensed software that provides users with statistical analysis on text corpus and tables composed by individuals/words. It is based on R software and on python language.

We performed a classic lexicographical analysis. Which allowed us to identify and format text units, turns texts into textual segments and identifies word frequencies, medium frequency and hapax (words with frequency=1), searches for vocabulary and reduces the words to their primary lexical units (reduced forms) creates the reduced forms dictionary, identifies active and supplementary forms.

Then a specificities and correspondence factor analysis was performed, and this analysis associate texts with variables and allows us to analyse texts according to the characterization variables.

Another analysis performed to the data is named as method of descending hierarchical analysis (DHA). The IRAMUTEQ clustered the text segments according to their vocabularies and distributed according to the reduced forms frequencies. Using matrices that cross reduced forms with text segments, the DHA method allows us to obtain a definitive classification. A dendrogram was displayed showing clusters relations between the text segments and the participants variables. The software calculates the descriptive results of each cluster conforming to its main vocabulary (lexic) and words with asterisk (variables) and provided us with another way of presenting data, derived from a correspondence factor

analysis, because based on the chosen clusters, the software calculates and provides the most typical text segments of each cluster, giving context to them.

The similarity analysis is based on graph theory, and it is often used by social representations researchers. It allows to identify the words cooccurrences, providing information on the words connectivity thus helping to identify the structure of a text *corpus* content. It also allows to identify the shared parts and specificities according to the descriptive variables identified in the analysis (Marchand & Ratinaud, 2012). The results are also presented as word clouds, because IRAMUTEQ aggregates words and organizes them graphically according to its frequency.

Results: The results are aligned with Standards of Practice for Health Promotion in Higher Education (American College Health Association, 2012). In the standard 1 alignment with the missions of Higher Education, the results show that health promoting, student, transformative process and empowerment were the words more frequent and were in central core representation. In standard 2 socioecological-based practice, the semantic representation of the core is coincident in participants. The similarity analysis shows a strong relation between the representations of the different participants. In standard 3 collaborative practice, results demonstrate that the peer network and the health promoting practice are central in the discourse of the participants. For the 4th standard, cultural competency, the analysis showed that inclusion, cultural competence, cultural sensibility, PEER-IESS were the main words of the discourse of the participants. For the standard 5 theory-based practice, peer-education, bottom-up strategies and health promotion were in the central core representation of all the participants. Aligned with this results, is also the results of the analysis of standard 6 evidence-informed practice. The last standard, the 7th is related with continuing professional development and service. The question of this standard was only addressed to management bodies and to the coordination because of its specificity, and the answers are related to the ethical principles, professional development in clinical supervision, peer-feedback and in clinical simulation.

Conclusion: The analysis of these results allows us to conclude that participants are aware of the ACHA standards, they value the institution's transformative process in a health promoting higher education institution and we were able to validate the PEER-IESS model.

D 09 - Academic-Practice Partnerships and Dedicated Educational Units: The Past, Present, and Future of Clinical Nursing Education

Academic Practice Partnerships: Mutual Benefits and Sustainability of a Dedicated Educational Unit

Cecilia McVey, MHA, RN, USA

Donna M. Glynn, PhD, MSN, RN, ANP-BC, USA

Abstract

Purpose: In 2007, the Northeast Region VA Nursing Alliance (NERVANA) was founded. NERVANA is an academic-practice partnership between the VA Boston/Bedford Health Care Systems and six schools of nursing which include: Boston College, Northeastern University, Regis College, Simmons College, University of Massachusetts Boston and University of Massachusetts Lowell. NERVANA's mission, derived from the VA's parent mission is as follows: "To employ an innovative educational model to expand and enrich nursing students and faculty, to educate nursing students in the care of veterans, and to expose nursing students to the advanced model of medical informatics, patient safety, quality improved and integrated systems of care employed by the VA's National Healthcare System". Although the NERVANA schools are among some of the most prestigious in the nation and located in the heart of a healthcare mecca, none is a component of an academic medical center. Thus, this consortium offers unique opportunities both for the schools and the VA Boston/Bedford alike. Goals for NERVANA are in congruence with the guiding principles for Academic –Practice Partnerships developed by AACN and AONE. The VA system provides the most comprehensive healthcare system in the country and therefore provides an experience to students and residents unlike any other they have had in their clinical experiences.

The partners share the vision for sustaining the mission and supportive activities of NERVANA. The VA Boston/Bedford Healthcare Systems and the academic partners take great pride in sharing mutual expertise to develop future nurses of America as well as sharing the important work the VA Provides to the veteran population. One of the primary goals of the partnership is to create and expand the Dedicated Educational Units for clinical education. The concepts and implementation of DEU and inter-professional education are examples of collaborative undergraduate BSN education that VA nurses have embraced with the support of the academic partners.

The purpose of this research was to examine the outcomes of the Northeast Region VA Nursing Alliance with emphasis on the creation and implementation of the DEU model of education. The research will evaluate the goals of the partnership and evaluate the sustainability of the alliance.

Methods: This retrospective research reviewed the advisory board, steering committee, and Dean's committee minutes for the past 9 years. The goals and outcomes of the academic practice partnership were evaluated and the impact of the DEU intervention related to clinical education was reviewed. Specific components to maintain the success of the DEU were identified and sustainability related to partnership interactions, activities and collaborative efforts were addressed.

Results: The benefits of the academic-practice partnership related to the DEU model and sustainability were evident in the results. An increased number of VA staff nurses are currently serving in the role of NERVANA faculty. The number of nursing students has dramatically increased within the VA system and preceptor workshops have been incorporated by the academic partners to support the staff nurses. A total of 4 acute care DEUs are currently in place, 1 interprofessional acute care DEU, 2 long term care DEUs and 2 Senior Capstone DEUs have been created and implemented. Through these nursing experiences, applications for positions within the VA after graduation are expanding and the VA Boston Nurse Residency program has achieved CCNE accreditation.

The academic practice partnership created and initiated the "Care of the American Veteran" series in 2009. The academic partners host educational presentations related to veteran specific topics on campus for all members of the college communities. Topics have included traumatic brain injury, spinal cord injury, PTSD, homelessness, dementia, military sexual trauma and care of the female veteran.

Conclusion: Based on the continued creation of DEUs and clinical educational partnerships and activities, the sustainability of the DEU and expansion of the NERVANA initiative is evident. Through this ongoing partnership, high quality, veteran-centered care will be provided to the next generation of nurses. Future research should focus on specific patient care outcomes related to the academic-practice partnership and the expansion of the DEU model of education

Staff Nurses Perceptions of Utilizing the Dedicated Educational Unit Model for a Senior Capstone Experience

Grace Conley, MSN, RN, USA

Patrick Hill, MSN, RN, USA

Bonnie J. Russell, MSN, RN, CRRN, USA

Abstract

Purpose: With the success of the dedicated educational nursing clinical units (DEU) within the VA Boston Healthcare system, academic-practice partners reached a decision to expand and revise the model to include senior nursing students completing their capstone experience (Glynn, 2016). Traditionally senior BSN students are placed with an experienced nurse for a one-to-one precepted clinical rotation during their final semester. The goal of clinical experience is to provide an intensive, individualized clinical learning opportunity to improve clinical competence and clinical judgment as the students nurse transitions to professional practice. The challenges of the traditional model is the availability and willingness of experienced staff nurses to work with nursing students and the significant time commitment. The decision to establish and implement a Senior Capstone DEU to provide students with a positive clinical learning environment and to enhance the experience of the practicing clinical nurses in the role of nurse educator was agreed upon.

Senior preceptorship is a valuable experience between an experienced nurse and a senior nursing student (Rogan, 2009). The preceptorship is a clinical experience in a baccalaureate nursing program to guide students in applying their knowledge and skills typically on a medical surgical unit. Clinical staff nurses serve in the preceptor role to assist nursing students in patient care, delegation and decision-making skills. Academic educators develop the course objectives, support the preceptors and oversee the students. The preceptorship is a teaching method that is used by 85.9% of professional schools in the United States offering a Bachelor of Science in Nursing (BSN) education (Altmann, 2006).

Professional nursing needs competent providers and nursing students must demonstrate proficiency in practice prior to graduation. Nurse preceptors play a vital role in transitioning students from the classroom to the bedside. However due to the forecasted nursing shortage, the precepted experience is in jeopardy

due to a shortage of qualified nurses, increased need for staff orientations, role frustration and nursing burnout (Spann, 2005). According to American Association of Colleges of Nursing 2014-2015 report, U.S. nursing schools turned away nearly 70,000 qualified applicants from baccalaureate and graduate nursing programs due to lack of faculty, clinical site, clinical preceptors and budget constraints (Nursing, 2014-2015).

The traditional senior preceptor model is a one-to-one relationship between a nursing student and an experienced nurse who is employed by a health care agency. It is time limited with the goal to provide an intensive individualized clinical learning opportunity to improve clinical competence and clinical judgment. An alternative nursing clinical educational model is the Dedicated Educational Unit (DEU). A DEU is an example of an academic-practice partnership designed to provide students with a positive clinical learning environment. A DEU is described as an optimal teaching and learning environment through the collaborative efforts of nurses, management and faculty (Moscato, 2007). The goal is to maximize the learning outcomes not only of students, but also of practicing clinical nurses in the role of nurse educator (Moscato, 2007).

The VA Boston Healthcare System is a leader in the education of nursing students. The VA Boston has established DEUs for sophomore and junior nursing students on acute care and chronic care units. Consistent with the literature, the DEU experience at the VA Boston has documented successful outcomes (Mulready-Shick, 2014). To date, there is limited research evaluating the use of a DEU model for a Senior Capstone experience and an analysis of the staff nurses' perceived outcomes of the clinical experience. The utilization of the DEU model for a senior nursing student experience is an effort to continue to develop experienced clinical nurses, expand the care provided to the Veteran population, to enhance the availability of nurses to serve as clinical preceptors, and enable senior nursing students to transition to practice.

Methods: This descriptive study which took place in the spring 2016. The study was reviewed and deemed exempt by the VA Boston IRB. Simmons College, in partnership with the VA Boston, embarked on a collaborative effort to bring a Senior Capstone Dedicated Education Unit to an acute medical unit. A total of 40 senior nursing students from a variety of Boston area colleges completed their senior capstone at the Boston VA during the spring semester. Twelve of the nursing students were assigned to the Senior DEU unit. To gauge staff interest, an email was sent out to staff of the acute medical unit with the following inclusion criteria: at least three years of clinical experience, works at least twenty-four hours per week and will not be on any type of leave for more than two consecutive weeks during the semester. Names of interested candidates who met criteria were then forwarded to the program director and school representative to initiate the process of preceptor selection and student pairing.

Staff nurses participating in the research were oriented to the preceptor's role and clinical educational objectives. A DEU instructor power point was developed that touched upon the history of the DEU, the unique advantages it affords the students and staff. Benefits to the unit and affiliated institution are clearly spelled out. The paradigm shift from the traditional model of clinical instruction to the new DEU model was compared side by side to show the forward thinking and evolution in nursing education. The DEU instructor power point education was rooted in Malcom Knowles adult learning theory of andragogy, with the goal of maximizing learning outcomes for the educators.

At the close of the 2016 spring semester, staff nurses serving as clinical educators to senior nursing students in the DEU setting and traditional preceptor experiences were surveyed. Staff nurses serving as clinical educators were asked to complete a Qualtrics® Survey tool to assess their satisfaction and confidence in the clinical instructor role. Staff nurses at VA Boston were invited via email to participate in the confidential, voluntary online survey. In order to ensure statistically significant response rate, reminder emails were sent out at the beginning of week two and three. The survey utilized the Likert scale for 14 questions to allow for additional comments if applicable, while 7 questions focused on demographics. Descriptive and Analysis of Variance were used to determine that staff nurses' perception of the student outcomes, clinical teaching experience and effectiveness of the alternative senior experience.

Results: A total of 23 clinical nurses participated in the survey. Eleven of the clinical nurses precepted senior nursing students in a traditional preceptor experience and twelve clinical nurses precepted students in the DEU Senior Capstone model. The majority of the nurses reported a minimum of 6 years of nursing experience and with an academic preparation of BSN.

The nurse were asked a series of questions related to the senior student experience. The questions included clinical role expectations, academic partner support, available learning opportunities for students, leaning atmosphere on the clinical unit, integration of students on the patient care unit, development of critical thinking and clinical reasoning skills, necessary available resources, and preparation of the students for professional practice. Although the sample size was limiting in this study, no statistical significance was found in the staff nurses perceptions of the senior capstone DEU experiences versus the traditional one-to-one precepted experience.

Conclusion: Based on available data regarding the projected nursing shortages, the need for academic nursing faculty and qualified clinical preceptors will continue to grow. The utilization of the DEU model for a senior capstone experience is a possible solution to assist senior nursing students transition to professional practice. The results of the pilot study demonstrated no perceived difference in student outcomes when comparing the DEU experience to a traditional one-to-one senior preceptorship.

However, nursing leadership reports a change in the moral on the unit and a willingness to work with students in the Senior DEU model. As the students were assigned to all shifts with their staff nurses, leadership reports a sense of “teamwork and education” that was not present in the past. The nurse manager found that precepting in the DEU model was not viewed as a burden and researchers are now evaluating patient care outcomes on the acute medical unit.

This study will be repeated and plans to expand the model to other acute care units are being organized. Researchers are hopeful to capture the sense of “teamwork, improved moral, and education” in future studies.

Dedicated Eduational Nursing Units: Clinical Instructors Role Perceptions and Learning Needs

Judith Wendt, MSN, BSN, RN, USA

Bonnie J. Russell, MSN, RN, CRRN, USA

Abstract

Purpose: Over the past decade, health care leaders have called for a radical transformation in health care and nursing education. The 2010 Institute of Medicine Future of Nursing Report identified the need for change in nursing practice and nursing education (IOM, 2010). The report acknowledged specific goals related to an increased number of baccalaureate prepared nurses and implementation of nurse residency programs. In order to achieve these goals, academic and practice partnerships have been formed. The desired outcomes of the partnerships are to increase nursing student and practicing nurse’s satisfaction and performance, to increase research initiatives and to improve patient outcomes (Beal,

2011). With an increased acuity in patient care, the traditional “clinical placement model” is ineffective in preparing the nurse of the future for practice. Nurse educators are being challenged to develop new delivery systems of education to meet the goals of the IOM Report. Nursing education must immerse the student in the “real life” of the practice of nursing in order to prepare a proficient nursing workforce (Benner, Sutphen, Leonard & Day, 2010).

Patient care has become complex demanding succinct interprofessional communication and collaboration to optimize the care of the patient and the nurse at the bedside is the optimal leader at the point of care. Assistance with the clinical reasoning and critical thinking with nursing students is pivotal for successful patient outcomes. The expert clinical nurse at the bedside is the premier faculty to guide the young practitioner in the care of the patient.

The preceptor/clinical instructor role in undergraduate nursing education is complex and multifaceted. Undergraduate nursing students identify preceptors/clinical instructor as key to their learning in the clinical setting; however, staff nurse preceptors often feel unprepared to serve in this role (McClure & Black, 2013). Clinical educators are required to connect the classroom knowledge with the clinical practice requirement and support the students as they through both experiential and situated learning on the nursing units (Benner et al, 2010).

A Dedicated Educational Unit (DEU) is an example of an academic-practice partnership designed to provide students with a positive clinical learning environment. A DEU is defined as an “optimal teaching/learning environment through the collaborative efforts of nurses, management and faculty (Moscato, et al 2007). The goal is to maximize the learning outcomes not only of students, but also of practicing clinical nurses in the role of nurse educator (Moscato, et al 2007). In the DEU model, an expert nurse is responsible for the clinical education of 2 nursing students. The expert nurse, referred to as a Clinical Instructor (CI), provides instruction related to clinical skills and critical thinking to the nursing students in an integrated job-embedded manner (Nishiola, et al, 2014).

The nursing student’s successful outcomes in the DEU model have been well documented (Mulready-Shich & Flanagan, 2014; Edgecome & Bowden, 2013; Moore & Nahigian, 2013). However, little research has been completed evaluating the CIs perceptions of the role and perceived learning needs. The purpose of this research study was to identify the role perceptions of staff nurse’s participating as clinical instructors on a DEU and the perceived educational learning needs of the experienced staff nurses.

Methods: The study took place at the VA Boston Healthcare System. The VA Boston has a unique academic-practice partnership which includes 6 colleges of nursing. After IRB approval, staff nurses serving in the role of clinical instructors were asked to participate in the interview process. Interview questions were developed to capture the perceived role perceptions of staff nurses participating as clinical instructors on a DEU and the perceived educational learning needs of the staff nurses. Participation in the study was voluntary and the clinical instructors remained anonymous. All clinical instructors were invited to participate regarding of the academic affiliation on the DEU. A total of 8 nurses participated in the study. The audiotapes were transcribed verbatim. Content analyses were used to code and synthesize common themes from the interviews.

Results: The three themes which emerged regarding the perceptions of the role of clinical instructor by participating staff nurses on a DEU were mentoring, ensuring competency with basic skills and tasks and the critical thinking component of nursing education.

The themes which emerged related to the perceived learning needs of staff nurses participating in the role of clinical instructor on a DEU were clear objectives from the academic affiliate, more coordination and acknowledgement by the academic affiliate of the clinical instructor role and additional education in dealing with students with diverse learning needs and accommodations. An additional theme related to the commitment by all partners to work together was identified during the interviews. The CIs reported the need for a staffing commitment on the units to support the learning needs of the students and the staff nurses.

Conclusion: The DEU model represents an important collaboration between academic and practice partnerships. The restructuring of traditional nursing clinical education will allow for the nursing students to participate in high quality care and be valued on the patient care unit. The expert staff nurses are allowed to expand their expertise and develop effective teaching skills. The traditional clinical faculty role is transformed to a position of coaching and support for the CIs. These efforts will have an important impact on nursing clinical education and the potential to reduce the clinical faculty shortage.

The Academic-Practice Partnerships must demonstrate a commitment to provide the infrastructure necessary to support the nursing students and the staff nurses serving in the role of CI. AACN recognizes that academic-practice partnerships are an excellent forum to bring both partners to the table and provide involvement in both selections of nursing students and clinical instructors on the nursing care units. As the role of CI continues to expand, further research evaluating the development of clinical judgment and reasoning in nursing students needs to be measured in the DEU model.

D 10 - Global Research and International Collaborations in the Pacific Rim

Global Research and International Collaborations in the Pacific Rim

Christine Kennedy, PhD, RN, PPCNP-BC, FAAN, USA

Abstract

Purpose: Noncommunicable diseases (NCD) such as cardiovascular disease, cancers, diabetes and chronic lung diseases account for 68% of global deaths, disproportionately affecting low resource countries; and contributing to disparities in immigrant populations in high resource countries. The studies to be presented in this symposium address Goal Three of the United Nations Sustainable Development program to reduce by 2030 one third of premature mortality from NCD's through prevention and treatment.

Methods: As an introduction to the symposium the historical roots of engaged participatory collaborative partnership approach for research will be shared. A brief overview of the key elements of a three-generation mentored model documents its influence.

Results: This symposium will present current research findings based in Pacific Rim experiences. Nursing has a long history of collaborations, and yet for many decades western hemisphere beliefs and practices dominated these endeavors. To illustrate the transition in methods and research approaches an examination of 3 decades of work which fostered a relationship approach is presented. Starting in the 1980's, with nursing colleagues in Taiwan - Ida Martinsons work which influenced Kennedy's Pacific Rim studies commencing in the late 1990's in Hong Kong and China and lead to J.L Chen 2000 and onwards program of research across China, Hong Kong, Taiwan and the United States, provide one model (Martinson, 1982; Kennedy, 1998). Using this as a frame for contemporary work results from the three recent studies and their implications for children, adult and family health across these four countries with native populations and within immigrant populations are addressed.

Conclusion: Health behaviors in many countries are similarly being influence by modernization (increased media intake, sedentary behaviors, and obesity) and identification of commonalities across the globe to address these and other disparities in health will aid nurses in designing and testing interventions that are more inclusive and evidence based while still being cultured situated and relevant.

Like Mother, Like Child: Maternal Attitudes and Behaviors on Weight-Related Health Behaviors in Their Children

Jyu-Lin Chen, PhD, RN, CNS, USA

Abstract

Purpose: The increased prevalence of childhood obesity has exploded into a global epidemic and public health issue during the last two decades. China is facing childhood obesity issue as approximately 22% of Chinese children, aged two to six, are overweight or obese. Early childhood is a critical period for the development of eating patterns and activity habits that may influence weight and health outcomes in later childhood and adulthood. However, a paucity of investigators has examined the influence of *maternal* factors on dietary habits and physical activity in their children, especially in Chinese preschool-aged children. Thus, the aims of this study in preschool-aged children and their mothers (mother-child dyads) were to describe: (1) maternal feeding practices, self-efficacy for healthy eating and physical activity level; (2) maternal factors that are associated with their child's health behaviors.

Methods: A cross-sectional study design was employed with mother-child dyad participants recruited from four preschools in Hunan Province in south central China. Individuals were eligible to participate in this study if they meet the following criteria: 1) Children between the ages of three and five years 2) Identified as Chinese, 3) Able to attend regular preschool activities, and 4), Mothers of these children were able to read and write in Mandarin Chinese. Potential eligible participants were contacted by research assistants who were trained by the research team on recruitment and data collection methodology. Participant children had their weight and height measured at preschool sites while mothers completed a set of questionnaires regarding family demographic information, family eating and activity habit, child feeding practices, and maternal self-efficacy regarding their ability to influence their child's eating and sedentary behaviors. at home. Human subject approval was obtained at the University of California, San Francisco Committee on Human Research at the Central South University in China.

Multivariate regression was utilized to identify factors associated with children's health behaviors including physical activity, TV and computer viewing time, eating behaviors, and stimulus home environment. Factors included in the model were age of the child, gender, maternal health behaviors (physical activity and eating behaviors), maternal self-efficacy, and maternal feeding practices. SPSS 23.0 software was used to conduct the analysis. A P value less than .05 was considered significant.

Results: There were 222 mothers and their children included in this study with a mean age of 31.04 (SD + 4.28) and 3.68 (SD +.75), respectively. Approximately 52% of children were boys. More than half (54%) of the mothers completed college or graduate education and 29% completed high school education. About 53% of mothers worked outside of their home.

The average daily time children spent in physical activity and watching TV, playing computer/video games was 1.18 hours (71 minutes) and .75 hour (45 minutes). Higher maternal physical activity level, maternal self-efficacy for limiting screen viewing, and younger age children were related to less screen time in children. A child's eating style was associated with his/her mother's eating style ($R^2 = .44$, $p < .001$). Low maternal self-efficacy for healthy eating, a low perceived maternal feeding responsibility, child female gender, an unhealthy maternal eating style in, and older child's age was associated with a child's unhealthy eating behavior ($R^2 = .20$, $p = .001$).

Conclusion: Maternal health-related behavior and attitudes regarding feeding practices and self-efficacy are associated with their child's health-related behaviors including physical activity, sedentary activity, and eating behaviors. As the health of children is critical to the health of the nation and global development, understanding factors related to child's health-behaviors in first step toward development of tailored and culturally sensitive intervention to promote healthy lifestyle and prevent obesity. Improvement of child's health behaviors need to incorporate mothers by promoting healthy lifestyle of the mother and self-efficacy regarding providing health home environment for the child.

Disparities in Self-Rated Health Among Chinese Immigrants: Exploring Inequality Identities

Lisa L. Lommel, PhD, MPH, RN, FNP, USA

Abstract

Purpose: The purpose of this study is to investigate the degree to which self-rated health (SRH) varies by the intersection of inequality identities including gender, age, socioeconomic status, acculturation, stress and discrimination, and social position among Chinese immigrants.

Health disparities are increasing, especially among United States (U.S.) minority populations. Among one such group, Asian immigrants, studies have shown that disparities in SRH vary across Asian subpopulations, with Chinese subgroups reporting worse SRH compared to non-Hispanic whites (Seo, Chum & Shumway, 2014). The variation in health outcomes among Asian communities, including SRH, indicates that different risk factors may be at work. Therefore, it is imperative to examine potential sources of racial/ethnic disparity in SRH among the Chinese immigrant population. An intersectionality framework guided this study because of its potential to reveal and explain previously unknown health disparities. An intersectionality approach does not attribute adverse health consequences to individual inequality identities (e.g. age, ethnicity) (additive approach), but rather focuses on how inequality identities *interact* at the micro level of individual experience and *intersect* at the macro level of poverty, sexism and racism (multiplicative approach) (Bowleg, 2012). Factors shown to negatively impact SRH in Asian immigrants include female gender and increasing age, (Sentell & Braun, 2012), lower levels of education (as a proxy for socioeconomic status) (John, De Castro, Martin, Duran, & Takeuchi, 2012), limited English proficiency (as a proxy for acculturation) (Maty, Leung, Lau, & Kim, 2011), lower self-perceived social status (Gong et al., 2012), and an increase in acculturative stress (Kimbrow, Gorman, & Schachter, 2012). Although not studied in Asian immigrants, Molina, Alegría, & Mahalingam (2013) found an association between discrimination stress and worse SRH in Hispanics. Although previous studies have investigated SRH in Asian immigrants, the complex interaction between these inequality identities and SRH in Chinese immigrants has not yet been investigated.

Methods: This cross-sectional study used data from the 2002-2003 National Latino and Asian American Study. Participants were foreign-born Chinese 18 years and older (n=473). Inequality identities include: 1) gender, 2) age, 3) education, 4) language preference and co-ethnic ties, 5) acculturative stress and discrimination experiences, and 6) social position. The outcome variable, SRH, was assessed by the question: *How do you rate your current health status?* Choice of responses included: *excellent, very good, good, fair or poor*. Using an intersectionality framework, individual main effect regression models were calculated followed by an additive regression model. Multiplicatively was demonstrated by testing 15 two-way interactions between the six inequality identities. R-squared values were used to assess the magnitude of contributions in explaining SRH beyond the contributions of the main effects.

Results: In the main effects model, male gender, language preference, and higher social position were significantly associated with better SRH. Higher acculturative stress was significantly associated with poor SRH. Comparisons of R² values indicate that language preference (R²= .09), followed by social position (R²= .07), and education (R²= .06) were the strongest predictors of SRH. The multiplicative model showed five significant interactions: age and language preference, $b = .004$, 90% CI [.001, .01], social position and discrimination, $b = .07$, 90% CI [.01, .14], and gender, $b = -.05$, 90% CI [-.10, -.004], acculturative stress, $b = -.03$, 90% CI [-.05, -.01] and social position, $b = .01$, 90% CI [.001, .03], and education. Significant interactions contributed 7-11% of predicted variability in SRH beyond the additive model.

Conclusion: This study contributes to a deeper understanding of the factors associated with disparities in health among Chinese immigrants as each of the six inequality identities interacted significantly with at least one other. Women and those with lower social positions and levels of education were at greater risk of experiencing health disparities. The results of this study will help to inform interventions addressing health disparities among Chinese immigrants in the U.S.

Obesity Indicators, Accuracy of Body Weight Perception, and Chronic Illness Among Chinese-Americans

Mei R. Fu, PhD, RN, FAAN, USA

Abstract

Purpose: Compared to Chinese population in China, Chinese Americans have increased risk for obesity due to immigration and environmental changes. Obesity has been identified as a major source of unsustainable health costs, morbidity and mortality due to multiple chronic illnesses, including hypertension, type 2 diabetes, cardiovascular diseases and certain types of cancer. Obesity indicators generally include Body Mass Index (BMI), waist circumference, hip circumference, weight to hip ratio, weight to height ratio, fasting blood glucose and Glycated hemoglobin (HbA1C). Accuracy of body weight perception is an individual's perception of their body weight in comparison with actual body weight and is associated with weight related behaviors. Chinese Americans have increased risk for obesity but no studies have examined the impact of accuracy of body weight perception on obesity, obesity indicators and chronic illness.

Methods: This study used a descriptive and cross-sectional design. Participants were recruited from metropolitan New York area. Data included demographic information, accuracy of perception of body weight, anthropometric measures (weight, height, BMI, waist circumference, hip circumference, weight to height ratio, weight to hip ratio, fasting plasma glucose and HbA1C). Chronic illnesses were assessed using a researcher developed self-report checklist and verified by medical record review.

Results: Among the 162 Chinese Americans in the study, 52 participants (32%) did not perceive their body weight correctly. Significantly more male ($p=0.003$), older ($p=0.003$), and less educated ($p=0.047$) participants had incorrect accuracy of body weight perception. Participants with incorrect perception of

body weight had higher HbA1C ($p=0.004$) and hypertension ($p=0.035$). Accuracy of perception of body weight significantly predicted waist circumference ($p<.001$), hip circumference ($p<.001$), weight to height ratio ($p=0.001$), BMI ($p<.001$) and weight ($p<.001$) even after controlling for all demographic factors. Of 94 (58%) participants had fewer than three chronic illnesses and 68 (42%) had three or more chronic illnesses. The three most common chronic illnesses in this population were diabetes (65.4%), hypertension (46.9%), and eye problem (38.3%). Controlling for all demographic factors, numbers of chronic illnesses remained significant associations with obesity indicators of waist circumference ($p=0.006$), hip circumference ($p=0.020$), weight to height ratio ($p=0.011$), HbA1C ($p=0.026$). Obesity indicators also had significant associations with individual chronic illness of diabetes, hypertension, heart diseases, eye and foot problems.

Conclusion: One third of Chinese Americans did not perceive their body weight correctly. Accuracy of perception of body weight significantly predicted abnormal values of obesity indicators even after controlling for all demographic factors. General obesity indicator (BMI), central obesity indicators (waist circumference, hip circumference, weight to height ratio) and HbA1c were significantly associated with chronic illnesses. Nursing practice and interventions need to address perception of body weight, gender and age differences to promote normal values of obesity indicators so as to prevent obesity and chronic illnesses among this population.

D 11 - Building an Evidence-Based Nursing Enterprise: Critical Components for Success

Building EBP Competence and Capacity By Leveraging Opportunities and Planning Strategically

Lynn Gallagher-Ford, PhD, RN, DFPNAP, NE-BC, USA

Abstract

Purpose: To describe a unique collaboration between two renowned organizations to plan and execute an evidence-based practice education and follow up program to create effective EBP teams to efficiently address real world healthcare challenges and drive best practices.

Methods: In a new era of healthcare, success will be achieved through collaborative relationships and development of teams that can deliver evidence-based, patient-centered care to improve healthcare safety, patient and clinician outcomes, and demonstrable returns on investments. The development of evidence-based practice (EBP) knowledge, skills, and attitudes (EBP competence) along with creation of organizational culture and integration of effective infrastructures that support EBP is a comprehensive strategy that can effectively propel organizations toward achieving and sustaining these goals, and meeting required healthcare mandates and achieving the quadruple aims of healthcare.

Many healthcare organizations have identified that their staff are unprepared in EBP knowledge and skills and they are seeking opportunities build EBP capacity in their settings. The Center for Transdisciplinary Evidence-based Practice (CTEP) has worked with a wide range of both clinical and academic organizations to build and sustain EBP. CTEP's unique collaboration with a world-renowned, Magnet designated, NCI designated, comprehensive cancer center to plan and execute the creation of an evidence-based nursing enterprise to effectively and efficiently address real world healthcare challenges and drive best practices will be highlighted in this session.

Results: This presentation will focus on this organization's work in planning and executing the EBP education program created to meet their particular needs including: characteristics and actions of key innovators who drove the initial conceptualization of the unique EBP education program designed; innovative aspects of the program created for this large, complex organization; pioneering approaches utilized to deliver the program and; results of the education program initiative.

Conclusion: An innovative, customized, and robust EBP education program with structured follow up can build EBP competence in a complex nursing department. The EBP teams forged in this program utilize an evidence-based problem solving approach, recommend effective strategies to implement to address strategic nursing challenges, and lead others in implementing best practices. Lessons learned from this collaborative experience that can inform future EBP programs in other organizations.

Utilizing a High Reliability Framework to Build Evidence-Based Practice in a Complex Organization

Kevin Browne, MS, RN, CCRN, USA

Abstract

Purpose: In 2014, the department of nursing at this ANCC magnet® designated and NCI designated comprehensive cancer center underwent structural changes at the executive nursing level. Recognizing that each division could no longer exist as configured, the divisions of nursing practice, quality and education were combined under the newly created office of the Deputy Chief Nursing Officer. The Division of PQE was created.

Methods: Nursing practice, quality, and education are fundamental domains within nursing; each unique however reliant upon one another. The three create a fluid paradigm that provides a foundation for the delivery of oncology nursing services and the 3000+ registered professional nurses within the system. Using a high reliability framework, the Deputy CNO set out to strengthen the approach to evidence-based practice (EBP). A partnership was forged with The Center for Transdisciplinary Evidence -based Practice (CTEP) at the Ohio State University College of Nursing to create a customized and novel deep dive immersion into EBP immersion.

The institution invested financial resources to support the attendance of 100 + nursing leadership in a week long EBP immersion. Nursing leadership included the Chief Nursing Officer, the executive nursing leadership team, frontline nurse leaders, NP coordinators, clinical nurse specialists, nurse informatics project managers and nursing professional development specialists. The team was divided into two tracks; leader and mentor. Sixteen distinct workgroups with representatives from each of the leadership roles were created. Each workgroup was assigned a pre-defined topic that was aligned with the department of nursing's 2016 strategic goals. Twenty-one CTEP faculty provided instruction and support during the immersion, guiding leadership through EBP enculturation. Topics such as meaningful perioperative benchmarks, meaningful outpatient benchmarks, preceptor development, oral chemotherapy medication adherence, CAUTI, CLABSI, falls, peer review, hand off, communication across a complex organization, etcetera are being used to learn the methodology so as to achieve two distinct goals; lead the enculturation across the center and produce sustainable outcomes.

Results: This unique approach resulted in the immediate creation of 16 multi-level teams from varied backgrounds with the responsibility to apply an evidence based problem solving approach to the key strategic nursing goals. This included set timelines and expectations for project implementation and completion. The teams have actively engaged in developing and implementing evidence-based action plans and measuring key outcomes.

Conclusion: A strategic, planned approach to; building EBP competence; creating EBP infrastructure and support, and; leading an EBP culture can provide the underpinning to build an effective program to address critical strategic goals in a complex health enterprise. Therefore, a second cohort is being planned for second quarter 2017.

The Importance of Follow-up in the Teaching, Implementing and Sustaining of Evidence-Based Practice

Jennifer H. Dean, BS, BSN, RN, USA

Abstract

Purpose: This session will focus on the evidence-based follow-up strategies utilized to support the evidence-based practice (EBP) process and the EBP teams through discussions and meetings in the collaborative work between Memorial Sloan Kettering Cancer Center (MSKCC) and The Center for Transdisciplinary Evidence-based Practice (CTEP) at The Ohio State University College of Nursing. CTEP has anecdotally noted, in working with a variety of healthcare organizations over the past 5 years, that when follow-up interactions/sessions are completed with participants 3-months after the initial training session, these facilities were more successful at implementing and sustaining EBP efforts and projects. In addition, when others have implemented the Advancing Research and Clinical practice through close Collaboration (ARCC) Model over a 12-month period with planned follow up sessions, improved patient outcomes have been clearly demonstrated, including a reduction in ventilator days, pressure ulcer rates and congestive heart failure readmissions (Melnyk, 2012).

Methods: Based on the referenced information, anecdotal experience and the education literature, CTEP and MSKCC forged up a 15-month relationship that included an intensive educational program along with a post training follow schedule where the CTEP team met with participants every 3 months following the initial training session.

Results: This session will include how the intentional follow-up meetings addressed the EBP teams as they progressed in their moving through the steps of the EBP process: from critical appraisal to recommendations; from recommendations to action plan; from action plan to implementation and; from implementation to measurement. The meetings and discussions were completed either in person, with several members of CTEP's team traveling to MSKCC to meet with participants, via telephone or with the use of virtual meetings online. In addition to meetings, the groups were each provided with an online collaborative document that clearly laid out the expectations for the planned next steps based on where each group was in the EBP process. The presentation will include feedback from participants about the follow-up sessions and their effectiveness in assisting with the movement through the EBP process as well as results from additional data collected over the course of the follow-up.

Conclusion: Continuing to provide structured follow-up to participants is an essential component of an effective EBP implementation program.

F 10 - "What Did That Mean?" An Examination of Personal Disposition in Nursing Education and Practice

Personal Disposition and With-It-Ness in the Nursing Classroom: Implications for the Science of Nursing Education

Andrew Bobal, MEd, BS, USA

Laura C. Dzurec, PhD, RN, PMHCNS-BC, ANEF, FAAN, RN, PMHCNS-BC, ANEF, FAAN, USA

Barbara J. Patterson, PhD, RN, ANEF, USA

Abstract

Purpose: The goal of the investigators in conducting this study was to examine evidence of the importance of two notions--personal disposition and with-it-ness, a term coined in the early 80s--to improved understanding of the science undergirding nursing education. The metasyntheses conducted for this study lay the groundwork for understanding how nursing education is effectively carried out in the classroom. The act of educating is the primary intervention for the science of nursing education. Because the terms personal disposition and with-it-ness address nursing education's essential, interpersonal nature, they serve to characterize nursing education in action. As individuals work in a classroom environment together, disposition acts across individuals, as emerging group dynamics generate a *gestalt* that characterizes the group as a whole, interweaving people and their values in relationship. With-it-ness moves that established relationship forward. The investigators' systematic review of literature and identification of emergent concepts and themes suggests that because they necessarily commingle in every classroom setting, disposition and with-it-ness serve as core concepts for the science undergirding nursing education.

Methods: Using metasynthesis, the investigators identified concepts and themes from published literature to ascertain the relevance of the notions of personal disposition and with-it-ness in nursing classrooms, to identify whether those terms are found in descriptions and examples within the science of nursing education. Disposition can be defined as the sum of one's personal values, commitments, beliefs, and professional ethics. Disposition acts across individuals, as emerging group dynamics act collectively to meld individual students and faculty into a collective whole, a single entity. With-it-ness is defined as deep understanding of what's going on in a classroom environment. With-it-ness incorporates a faculty member's understanding of the feelings, apprehensions, and expectations of students, as well as awareness of students' prior knowledge and preparation for class. It involves a grasping of the classroom *gestalt*, recognizing what is transpiring in the classroom from moment to moment, predicting where discussion will go in the future, and dealing with the emotions of the students working there. Because in nursing education, learning stakes are high, requiring students' enhancement of skills in ethical decision-making, their personal refinement of professional values, and their development of identity through a focus on knowledge rather than tasks (Andrew, et al., 2009), nurse educators are particularly challenged to recognize and understand their own dispositions and to be with-it. The notions emerging from this perspective on classroom dynamics hold particular significance for advancing the science of nursing education: simply delivering content, in the tradition of the 'sage on the stage,' is inadequate to successful teaching, especially in fields such as nursing where not only information, but an array of skills and professional values, is on the line.

Results: Analyses demonstrated that as both concepts--personal disposition and with-it-ness--address 'ways of seeing' in the classroom, they shape the character of the work faculty and students will do together. Study findings highlight the relevance of both notions to the activities and scholarship inherent in teaching and learning in nursing. Snow noted that student learning is inextricably linked to faculty learning. Without strong foundations in the science undergirding nursing education, as those foundations guide faculty learning, the quality of student learning will certainly diminish. Findings demonstrate that the most with-it teachers are aware not only of student dispositions, but of their own dispositions, as well. From that highly-informed perspective, and recognizing how meaning emerges between themselves and the classroom ecology, the best nursing faculty are able to maximize student outcomes, class by class,

and course by course, responding with comprehensive awareness to student needs and to the needs of the classroom as a whole. Truly with-it nurse educators will effectively contribute to maximizing student outcomes, and ultimately to graduates' performance in professional practice, enhancing not only the skills and expertise of graduates, but contributing understanding of educational interventions that will support graduates' success.

Conclusion: For several decades, nursing's professional focus has been dedicated to the evidence-base undergirding clinical practice; nursing education, as a focus in its own right, has been broadly overlooked. This presentation provides evidence, derived from published literature, supporting the significance of personal disposition and with-it-ness to advancing the science of nursing education, serving to illustrate the relevance of both notions to the activities and scholarship inherent in teaching and learning in nursing. Nurse educators are particularly challenged to be with-it. They are required to recognize and predict how students' understanding and personal dispositions will shape personal and professional responses to the challenges of successful nursing practice. Understanding how disposition and with-it-ness shape education interventions, nurse educators can use their underlying science to good effect.

Shattered Assumptions: Examining Discrepant Perceptions of "Reasonable" Accommodations Among Faculty and Student Nurses with Disabilities

Rose Schwartz, PhD, RN, BC-CNS, USA
Geraldine Bloemker, PsyD, MA, MS, MA, BA, USA

Abstract

Purpose: The purpose of this study, which combined case study and content analysis methods, was to examine and begin to highlight features characterizing the interface between the assumptions of faculty members and student nurses with disabilities (SNWDs), as those assumptions regard implementation of academic accommodations.

Methods: The investigators used explanatory case study method and content analysis to examine how the Theory of Shattered Assumptions (Janoff-Bulman, 1992) helped to explain the responses of both faculty and SNWDs endeavoring to address teaching and learning from their respective viewpoints. Used to categorize data emerging from a systematic review of the literature, the steps in the process included investigator identification of ; the assumptions of both faculty and SNWDs; the character of the 'traumatic events' precipitating clashes of assumptions; the process of disillusionment and change often seen to demarcate the experiences of both faculty and SNWDs; the ways both faculty and SNWDs might process newly recognized data about the accommodation process; and routes to rebuilding relatively more congruency between and among faculty and SNWD assumptions.

Results: Systematic literature review suggested that both nursing faculty and SNWDs processed their academic accommodation experiences through the steps outlined in the Theory of Shattered Assumptions (Janoff-Bulman, 1992). The 'traumatic event,' that is, the process of implementing formally-defined accommodations, challenged the fundamental assumptions of both groups. Both faculty and SNWDs described disillusionment with the changes to their personal perceptions of what constituted the *status quo* in the nursing classroom. For both faculty and students, lack of knowledge about the Americans with Disabilities Act and conjoint interpretation of the term 'reasonable accommodation' interfered with abilities to modify fundamental assumptions. Moreover, as staff in disabilities services sought to support both faculty and students, they found themselves in the tenuous position of identifying and understanding the sometimes disparate needs of each group, while adhering to the law. Analysis demonstrated that although assumptions are not immediately changeable, nursing faculty and SNWDs are able to address concerns that will support them in negotiating reasonable accommodations. Review of literature suggests that faculty and SNWDs work through the steps outlined in the Theory of Shattered Assumptions as they address implementation of academic accommodations.

Conclusion: Although the original premise of the Theory of Shattered Assumptions addressed recovery from traumatic events, it has broad applicability in characterizing the struggle engaging nursing faculty and SNWDs as they try to engage with recommended academic accommodations. Through this presentation, the applicability of the theory of shattered assumptions will be highlighted, demonstrating how historical, hard-wired beliefs can be rebuilt through education, communication, interpretation, and resource support.

"I Won't Dance, Don't Ask Me": Concerning Why Workplace Bullying Bystanders Simply Stand By

Laura C. Dzurec, PhD, RN, PMHCNS-BC, ANEF, FAAN, RN, PMHCNS-BC, ANEF, FAAN, USA
Monica Kennison, EdD, MSN, RN, USA

Abstract

Purpose: Extending Cross's (1981) model addressing deterrents to adults' participation in continuing education, the investigators' purpose was to use hermeneutic analysis to identify situational, institutional, and dispositional factors that serve to immediately dissuade interventions on the parts of workplace bullying bystanders. Bystanders are those individuals who observe bullying but are not directly targeted by bully perpetrators. Bystanders' reticence to act subtly but effectively perpetuates bullying actions.

Methods: Through a review of published first person narratives and descriptions of bystanders' experiences in bullying situations, the investigators selected relevant, textual quotes and accounts (hermeneutic description), identified themes portraying the character and essence of those quotes and accounts (hermeneutic reduction), and then considered the meanings that emerged from the selected text and the emergent themes, collectively (hermeneutic interpretation). Meanings inferred through this three

step, credible and auditable hermeneutic process were considered, then, in light of Cross's (1981) categories of situational, institutional, and dispositional factors. Findings of the study contribute to clarifying the complexity inherent in bystander response to situations of workplace bullying, and speak to the significance of disposition and context to furthering the intervention reticence of the bystanders who observe bullying in the workplace.

Results: Findings of the study address bystanders' concerns about responding to situations of workplace bullying, and speak to the significance of disposition and context to furthering bystanders' tendencies for bystander reticence. This reticence takes place frequently; still, bystanders frequently experience physical and psychological impact as a result of their distant involvement in workplace bullying. Analysis suggests that bystander intervention can influence the outcomes of bullying. Bullying bystanders' active intervention, though, tends to be discouraged by virtue of the way workplace context interfaces with personal disposition. Moreover, when the workplace context fails to provide objective permission to recognize and actively address bullying behaviors, as it often does, bystanders tend to exhibit the group conformity that constrains their active involvement in actions that will thwart bullying actions. Surrounded by others who deny bullying's expression, bullying bystanders tend to overlook bullying behaviors, to doubt that they've actually seen them, and to question what right they have to report them.

Conclusion: Numerous researchers have addressed the significance of workplace bullying bystanders' actions to ultimately abetting or deterring workplace bullying acts. Findings of this study demonstrate that bystanders' tendency to avoid intervening in bullying situations results from a confluence of dispositional, situational, and organizational factors. Consequently, efforts to stem workplace bullying may well be improved by incorporating education and training to empower bystanders to become 'upstanders,' skillful in responding to workplace bullying situations in the context of a safe, supportive organizational climate.

F 11 - Self-Care and Nursing Image: Impact and Opportunities

The Impact of the Image of Nursing on Nurses' Perception of Self and the Profession

Nancy Laplante, PhD, RN, AHN-BC, USA
Wendy Ostendorf, EdD, RN, CNE, USA

Abstract

Purpose: The purpose of this research study was to explore the impact of a professional presentation offered at a national nursing conference, on participants' perceptions of the cinematic images of nursing. Image has been a focus of interest to nursing for over a decade; influenced by sentinel work by Kalisch and Kalisch (1986) that examined the portrayal of nurses compared to those of physicians in different media forms and nursing stereotypes.

A concept analysis of image by researchers in Iran provided validation that image is a multidimensional concept (Rezaei-Adaryani, Salsali, & Mohammadi, 2012), concepts that were explored in the current study. Rezaei-Adaryani et al. found that image encompasses four dimensions: public's perception of nursing, nurses' self-image/ professional identity, nurses' perception of the public's image, and image of nursing in the media.

For the current study, image was examined through the lens of cinematic images and in relation to several Core Values of Holistic Nursing. In particular, the American Holistic Nurses Association's (AHNA, 2013) Core Value #5, which highlights the focus on nurses being self-reflective and instrumental in creating self-care programs. This study provided the opportunity for self-reflection which must come before self-care practices can be identified and created.

Methods: The researchers obtained approval from their Institutional Review Boards and from the Research Committee of the conference prior to the start of the study. At the presentation, all attendees were given a packet of information that included an informational letter with all study details, a response form, and plain white envelope. If an attendee chose to participate responses were written on the form during the presentation.

Positive and negative cinematic images were shown as part of the presentation. Four open ended questions informed by the presentation were individually embedded at various points in slides in the power point presentation. The first question was: Before attending this presentation, what was your perception of the image of nursing? (Slide 2 after introductory slide.) The next two questions were presented on slides 12 and 28 respectively: How does the public's view of the image of nursing impact the way nurses view themselves? and How does nursing's image impact recruitment and retention into the nursing profession? The fourth question was: After attending this presentation how did your attitudes or beliefs about the image of nursing change? (The last slide of the presentation.)

During the presentation the researchers paused at each question to allow time for participants to write their response. At the end of the presentation, participants placed their response forms in the envelope, and placed these in a designated container at the exit of the room. Attendees had the option to not participate and remain as a viewer only of the presentation. They also could write responses, and not submit their forms at the end of the presentation. Once forms were placed in the bag, participants could not withdraw from the study as all forms were anonymous. Content analysis was used for this study. The researchers first individually read through all responses for each question, coming together in person after this to discuss commonalities they found. An audit trail was kept, documenting four additional sessions of discussion, with the researchers further collapsing the data of each question, ultimately to four themes. An expert in qualitative research was contacted to provide validation to the researchers for the process.

Results: Participants ranged in age from 24 to 84 years of age, and practice years of experience ranged from one to 63 years. Four themes were discovered: An Evolving Identity; In Defense of the Profession; Reality to Retain; and The Greater Voice.

Views of image were mixed prior to viewing the presentation. Participants felt they were caring, trusted and well-liked by the public, but at the same time had to defend that they were not “less” than a doctor. Public perception and recruitment/retention issues impact nurses worldwide, and there were many in the study who felt students needed a better understanding of the profession they chose early on to avoid a distorted sense of reality when they began practice.

Participants felt they possessed a positive image of nursing, but that there was a need for a stronger collective voice. Many felt they could do more to promote image; they expressed gratitude for the presentation as it encouraged them to dialogue and realized there is still work to be done to improve the image of the profession.

Conclusion: Nurse educators play an important role in the socialization of undergraduate students from their first year through graduation. They can assist students to develop a positive professional image and support students’ development throughout their education.

When nurses are viewed from a negative perspective, roles can become ineffective when collaborating with persons receiving care or partners in the health care community. These negative stereotypes have caused stress in practicing nurses, therefore the need for self-care is heightened. This study provided practicing nurses an opportunity to self-reflect on their perceptions of image, and participant responses support continuing this dialogue with students and practicing nurses alike to provide context and correct inaccurate stereotypes.

A Mindfulness-Based Approach to Student Self-Care

Brenda Kucirka, PhD, BS, RN, PMH, CNS, CNE, USA

Abstract

Purpose: The purpose of this study was to determine if an 8 week mindfulness based stress reduction (MBSR) and cognitive behavioral intervention would decrease stress, improve sleep and positively impact wellbeing among first semester junior nursing students. The first clinical semester has been identified as inducing the highest levels of stress during the nursing curriculum. Students are confronted with the reality of the profession and are often flooded with fears and anxieties that negatively affect their wellbeing. The National College Health Association’s 2015 National College Health Assessment identified stress as the top ranked impediment to academic performance and wellbeing. Unmanaged stress has been connected to increased student attrition (Kukkonen, Suhonen, & Salminen, 2016), negative physical and psychological consequences, and interpersonal and relationship problems (Hensel & Laux, 2014). Studies employing MBSR and cognitive behavioral interventions among university students support the efficacy of these approaches in increasing student wellbeing and decreasing anxiety and stress (van der Riet, Rossiter, Kirby, Dluzewska, & Harmon, 2015; Regehr, Glancy & Pitts, 2013). Pender’s Health Promotion Model guided this research study. In Pender’s model, perceived barriers, sense of self-efficacy, and situation factors can contribute to action or inaction in the performance of health promoting

behaviors. The Student Nurse Stress Inoculation Study (SNSIS) protocol was designed to increase student self-care behaviors and sense of self efficacy through the use of mindfulness based stress reduction and cognitive behavioral strategies.

Methods: Approval from the university Institutional Review Board was obtained prior to conducting this pilot experimental research study. Students were randomly assigned to an 8 week mindfulness based protocol which included a 12 minute body scan meditation and a 5 minute “brain dump” journal. Both control and experimental groups completed pretest/posttest measures including the Student Nurse Stress Index (SNSI), WHO-5 Wellbeing Index and a questionnaire on coping strategies, sleep, and lifestyle. An Independent t-Test was performed to compare experimental and control groups and paired t-Test for comparing pre and post test scores of each group to measure the effect of the protocol on nursing student wellbeing and stress. Data were analyzed using SPSS 20.

Results: Fifteen junior level nursing students were recruited for the study. Nine students completed the study. The post-test experimental group scores for the WHO-5 (M = 16.75) were 3.75 points higher than the pre-test scores (M = 13.00). Control group post-test WHO-5 scores (M=11.20) were 3.40 points lower than pre-test scores (M = 14.60). Comparison of both groups for WHO-5 post- test scores was significant ($p=.046$). SNSI scores for both groups were higher than pre test scores indicating a higher level of stress at the completion of the study. SNSI scores for the experimental group increased by 6.5 points while students in the control group SNSI scores increased by 1.40 points.

Qualitative findings included themes of academic stress overload, relationship strain, feeling overwhelmed with “no life”, anxiety and sadness, and clinical pressures. Students in the experimental group did not consistently complete the protocol throughout the 8 weeks. The one participant who consistently completed the protocol reported improved sleep and ability to “relax at night”. Several students apologized in their journals for not maintaining the protocol and noted a sense of guilt and feeling overwhelmed with all the academic work that needed to be completed. While the protocol was intended to decrease stress and improve sleep, qualitative data indicated that the protocol induced stress.

Conclusion: This study highlighted the importance of building coping skills and self-care strategies proactively. The study began at the beginning of the semester and ended the week after midterm examinations. The failure to consider the timing of the protocol as it aligned with the academic calendar resulted in unintended added stress at midterm which fell on the week that posttest measures were being collected. The study provided significant evidence that a stress inoculation intervention improved wellbeing. Curriculum design should incorporate MBSR, cognitive behavioral strategies and wellness initiatives throughout the program. Future longitudinal research should explore this type of stress inoculation strategy following students across the curriculum.

Promoting Healthy Behaviors in Nursing Students

Donna M. Callaghan, PhD, RN-BC, GCNS-BC, CNE, USA

Abstract

Purpose: This study investigated the effects of an educational intervention to promote healthy behaviors in nursing students. The development of the intervention was based on the relationships among the variables of health-promoting self-care behaviors, self-care self-efficacy, and self-care agency. The purpose of the study was to identify if the intervention, which focused on spiritual growth as the foundation of health, would lead to an increase in the practice of healthy behaviors in nursing students.

The educational intervention was developed using three models/theories as its framework. Orem's Self-Care Model directed the supportive-educative nursing intervention. Pender's Health Promotion Model defined the healthy behavior topics of the intervention which include spiritual growth, stress management, nutrition, physical activity, interpersonal relations, and health responsibility. Bandura's Theory of Self-Efficacy guided the intervention activities that increase self-efficacy of these healthy behaviors. This educational intervention used spiritual growth as the foundation of healthy behaviors. Bryer, Cherkis, and Raman (2013), who performed a descriptive study that investigated the health-promotion behaviors of undergraduate nursing students, recommended that nursing students should not only learn about health promotion but should also participate in health promotion activities suggesting it could possibly improve the academic success of these students. Hensel and Laux (2014), who performed a longitudinal study that included measures of stress, self-care, and professional identity, suggested that integrating stress management strategies and spiritual growth practices in health promotion activities may be more effective in reducing stress levels in nursing students as well as improving their sense of fit with the profession.

Methods: The intervention was conducted at a school of nursing. It consisted of six one-hour presentations on the healthy behavior topics of spiritual growth, stress management, nutrition, physical activity, interpersonal relations, and health responsibility. Each one-hour presentation included 30 minutes of Power Point information and 30 minutes of selected activities to increase self-efficacy. A pre-test post-test quasi-experimental design was used to investigate the effect of the intervention on students' healthy behaviors. IRB approval was obtained through the university and a letter of support was obtained from the Dean of the School of Nursing. Students completed a consent form and the study instruments, which included the Health-Promoting Lifestyle Profile II Scale (Walker, Sechrist, & Pender, 1987) and a demographic questionnaire, one week before and one week after completion of the program. A paired t-test using SPSS 20 was performed to measure the effect of the educational intervention on the nursing students' healthy behaviors.

Results: Thirty-six nursing students started the program, with 23 students completing all six sessions. The mean post-test score (164.4) was 18 points higher than the mean pre-test score (146.2). The paired t-Test result was significant ($t = -5.2, p < .001$). There were significant increases in all six subscale scores (spiritual growth, stress management, nutrition, physical activity, interpersonal relations, and health responsibility).

Conclusion: The models/theory that were used as the framework for this intervention were supported by the statistical results of this study as well as the educational intervention did have a significant effect on the practice of healthy behaviors in the nursing students. This intervention also introduced the nursing students to the importance of spirituality in holistic health promotion including the importance of self-care in their personal lives and professional practices. The study gives direction for nurse educators in the area of teaching students how to promote healthy behaviors in others through promoting their own healthy behaviors. It also provides a strategy for nurse educators to integrate stress management and spiritual growth health promotion practices into the curriculum that could lead to an improvement in nursing students' academic success as well as an enhancement of their professional identities.

F 12 - Vitamin D and Its Impact Across the Lifespan

Can Vitamin D Supplementation Improve Poor Cognition in People with Type 2 Diabetes?

Mary Byrn, PhD, BSN, RN, USA

Abstract

Purpose: One in nine people aged 65 and older has Alzheimer's disease which is a chronic debilitating disease with no known cure (Alzheimer's Association, 2014). Vitamin D deficiency has been found to be related to increased risk of dementia, Alzheimer's and executive dysfunction (cognitive processes including working memory, reasoning, task flexibility, and problem solving). A meta-analysis of 14 observational studies, three prospective cohort studies, and three intervention studies has demonstrated that lower concentrations of vitamin D was associated with executive dysfunction (especially processing speed, mental shifting, and information updating) and that repletion was associated with improved executive functioning (Annweiler et al., 2013). More recently, participants from the United States Cardiovascular Health Study (n=1658 adults) who were followed prospectively for six years and were found to have a doubled the risk for dementia and Alzheimer's if they were vitamin D deficient at baseline (Littlejohns et al., 2014). Persons with diabetes have been reported to have a higher incidence of vitamin D deficiency (Penckofer, Kouba, Wallis, & Emanuele, 2008).

Diabetes is the seventh leading cause of death in the United States. In 2012, there were 1.7 million new cases of diabetes diagnosed and the total costs of diagnosed diabetes in 2012 was \$245 billion (American Diabetes Association, nd). Of concern is that diabetes is associated with cognitive impairment (Tuligenga et al., 2014; Wennberg et al., 2014). A large cohort study reported that for people with known diabetes there was a 45% faster decline in memory, a 29% faster decline in reasoning, and a 24% faster decline in cognition compared to those with no diabetes (Tuligenga et al., 2014). Also, self-reported diabetes was associated with immediate and delayed word recall and poorer memory (Wennberg et al., 2014). Cognitive impairment makes glycemic control challenging because self-management activities are cognitively demanding. Executive function comprises cognitive skills needed for the execution of complex activities which can include self-monitoring and daily management of diabetes. Also, executive dysfunction has been found to be associated with poor glycemic control.

A randomized control trial study of vitamin D supplementation for treatment of cognitive impairment in persons with diabetes has not been done to our knowledge, and the reason this current study is being conducted. The primary aim of the ongoing study is to determine the effect of vitamin D₃ supplementation on cognitive function for persons with type 2 diabetes. The secondary aim is to determine the effect of vitamin D₃ supplementation on diabetes self-management.

Methods: Participants are being randomly assigned to either weekly 50,000 IU of vitamin D₃ (n=31) or 5,000 IUs of vitamin D₃ (n=31). The dose of vitamin D₃ (cholecalciferol) (50,000 IUs) has been safely used in other studies (Nazarian, St. Peter, Boston, Jones, & Mariash, 2011). The control group dose of 5,000 IU approximates The Institute of Medicine recommendation 600 IUs of Vitamin D per day for individuals up to age 70 (600 IUs x 7 days= 4200 IUs).

The sample includes women and men aged 55 years or greater who have type 2 diabetes, a subjective complaint of a cognitive dysfunction or scoring at least one standard deviation below normal on a cognitive functioning screening test, vitamin D deficiency (25-OH D) < 32 ng/mL, and are currently under the care of a healthcare provider.

Study measurements are being completed at a baseline visit and after participants have received the vitamin D₃ for three months. Study measures include: cognitive function using administered standardized tests (Controlled Oral Word Association Test, Animal Naming Test, Letter Number Sequencing, Stroop Interference Test, Digit Symbol Modalities Test, Trail Making Test Part B, Hopkins Verbal Learning Test), serum measurements (HBA1c, blood glucose, vitamin D levels, and cardiometabolic profile) and surveys

to assess cognitive function (Social Adjustment Scale-Self Report and the Endicott Work Productivity Scale), as well as diabetes self-management behaviors (Self-Care Inventory, Diabetes Related Distress (PAIDS)

Results: So far, 35 participants have consented and 17 have been randomized to study treatment. Among these 17 individuals, the median WRAT-IV reading subtest z-score at baseline was below average at -1.07 (IQR -1.20 to -0.40). Further, participants' trail making test part A and part B standardized z-scores at baseline were average at $z = 0.42$ (IQR: -0.33 to 0.74) for part A and $z = 0.14$ (IQR -0.55 to 0.44) for part B, respectively. Participants ability to process a cognitive interference as measured by the Stroop Intereference subtest was below average at baseline ($Mdn z = -0.50$, IQR = -1.00 to 0.14) as was their verbal fluency ($Mdn z = -0.41$, IQR = -1.26 to 0.17). Among the 17 participants randomized to study therapy, their median CES-D score at baseline was 7.00 (IQR = 5.00 – 12.00). Of the 17 randomized, 13 have completed the trial. Further results of the trial will be presented at the meeting.

Conclusion: The importance of this study is several fold. Vitamin D supplementation is a low cost intervention, it has minimal side effects, and it could have high impact for persons with type 2 diabetes who suffer from cognitive impairment which can significantly affect their diabetes self-management.

Depression and Vitamin D3 Supplementation in Women with Type 2 Diabetes

Sue M. Penckofer, PhD, MS, BSN, RN, FAAN, USA

Abstract

Purpose: Depression affects over 25% of women with type 2 diabetes (T2DM) and makes self-management challenging (Penckofer, Doyle, Byrn, Lustman, 2014). Having both T2DM and depression significantly increases mortality for women (Pan et al., 2011). Although antidepressants can effectively relieve depression and its related symptoms in persons with T2DM, side effects include weight gain and for some, difficulty with glycemic control.

Evidence indicates that low levels of vitamin D are associated with depressive symptoms and depression itself. A meta-analysis of cross-sectional and cohort studies examining levels of serum vitamin D measured as 25-hydroxyvitamin D [25 (OH) D], reported a significantly reduced risk for depression with a

10 ng/ml increase in 25 (OH) D levels (Ju, Lee, Jeong, 2013). Another meta-analysis reported that there was an increased risk for depression for the lowest as compared to the highest vitamin D categories for cohort studies when following nondepressed individuals until their first diagnosis of depression (Anglin, Samaan, Walter, McDonald, 2013). Studies examining the benefit of vitamin D supplementation on depression are currently in progress. One systematic review and meta-analysis using Cochran guidelines examined seven RCTs and found no effect on depressive symptoms following vitamin D supplementation; however, for persons who had significant depressive symptoms or depressive disorder, there was a moderate significant effect (Shaffer et al., 2014).

Persons with T2DM have lower levels of 25 (OH) D which may be due to obesity or diabetes itself. Cross sectional studies have examined whether vitamin D was associated with insulin action and secretion, but results were inconclusive. One systematic review and meta-analysis of 15 RCTS examined vitamin D supplementation on insulin resistance in patients with diabetes, impaired glucose tolerance and normal glucose tolerance. Small improvements in fasting glucose and insulin resistance, but no effect on HbA1c were found for those with T2DM (George, Pearson, Witham, 2012).

Currently, there are no studies examining vitamin D supplementation for persons with T2DM who have significant depressive symptoms. Thus, the purpose of this study is to determine the impact of vitamin D supplementation on depressive symptoms and diabetes outcomes.

Methods: These investigators are conducting a randomized clinical trial to determine whether vitamin D₃ supplementation impacts depressive symptoms (Center for Epidemiologic Studies, CES-D) and whether this improves diabetes self-management (Self-Care Inventory). In addition, the role of vitamin D on blood pressure control is being explored. Women must have T2DM, significant depressive symptoms (CESD > 16), and levels of 25 OH D < 32 ng/ml to enroll. Using a stratified block randomization (strata based on depression symptom severity) women are being assigned to either weekly vitamin D₃ supplementation (50,000 IUs) or a matching weekly placebo (5000 IU) for a period of six months. We hypothesize that women receiving 50,000 IU vitamin D₃ supplementation will report fewer depressive symptoms, increased diabetes self-management mediated by depression improvement, and have a lower systolic BP compared to those taking placebo. Measurements of 25 (OH) D, glycemic control (HbA1c), and self-care are being collected at baseline, 3 and 6 months following supplementation.

Results: Thus far, we have phone screened over 1300 women, consented 227, and enrolled 111 participants. Among these participants, 108 have been randomized to treatment. The characteristics of those enrolled are consistent with those who have not enrolled due to exclusion criteria. The 111 women who have met inclusion criteria have the following mean characteristics: age of 51.12 (SD = 10.91), 9.23 years (SD = 6.93) with T2DM, HbA1c of 7.83% (SD = 1.87%), BMI of 38.37 (SD=8.12), and systolic and diastolic blood pressures of 132.73 (SD = 15.34) and 72.53 (SD = 9.22), respectively. The average CES-D is 29.32 (SD = 8.68), and there are 48 (43.2%) in low depression group (CESD < 26) and 63 (56.8%) in high depression group (CESD > 26) for treatment. At baseline, there was no difference in vitamin D levels for those in the low depression group ($M = 20.71$, $SD = 7.13$) and high depression group ($M = 21.05$, $SD = 5.86$; $p = .78$). Thus far, of the women who have started the study drug ($n=108$), we have 96% retention at 3 months and 92% retention at 6 months.

Conclusion: Since women with T2DM have low levels of vitamin D and high levels of depressive symptomology, vitamin D supplementation as a treatment option could have significant implications with minimal side effects. This trial is anticipated to conclude in October 2017, and report its findings shortly thereafter. Given that 1 in 10 Americans now take antidepressants which can have negative effects on weight and metabolic control, positive findings may have implications as a cost-effective therapy for preventing depressive symptoms and/or as an adjunctive treatment for depression in others.

What is the Relationship Between Pregnancy Symptoms, Vitamin D Status, and Quality of Life?

Jennifer G. Woo, MSN, BSN, RN, CNM, WHNP, USA

Abstract

Purpose: There is much evidence in the literature about vitamin D deficiency and associated symptoms such as depression, musculoskeletal pain, sleep disorders, pelvic floor disorders and fatigue, all of which can be present in pregnancy (Spedding, 2014; Aydogmus et al., 2014; McCarty et al., 2013; Bergstrom et al., 2014). However, these observational studies have mainly examined this correlation in the non pregnant population, aside from a handful of studies that have shown this correlation in pregnant women. Since pregnant women are so at risk for vitamin D deficiency, the study of this group is warranted (Hosseini-Nezhad & Holick, 2013; Wagner et al., 2012; Ginde et al., 2010)

However, whether low levels of vitamin D are associated with these and other symptoms during pregnancy is unknown. What is known is that vitamin D deficiency disproportionately affects pregnant minority women, therefore, this study will help nurses, providers, etc. to understand the impact that vitamin D deficiency has on pregnancy symptoms and potential impact on quality of life (Ginde et al., 2010).

Therefore, the purpose of this study is to describe the pregnancy symptoms of a vulnerable patient population at risk for vitamin D deficiency and other poor maternal outcomes. In addition to describing the pregnancy symptoms that most frequently occur in this patient population, their impact on quality of life is also addressed.

Methods: This study utilized a correlational, cross-sectional design and recruited women from an urban, underserved, low income health center. The participants (n=125) were 50 % African American, 42% Hispanic, and 8% other. Women were 24 to 32 weeks gestation and were attending the center for routine healthcare at the time of consent and data collection. They completed demographic, pregnancy symptom questionnaire (Pregnancy symptom Inventory), and quality of life (SF-12) questionnaires, which were available in English and Spanish. At the same visit, they had a blood draw to measure vitamin D levels [25 hydroxy vitamin D= 25 (OH) D]. Women were classified using Institute of Medicine guidelines of < 20 ng/ml as deficient and ≥ 20 ng/ml being sufficient.

Results: The sample composed of 125 pregnant women with a mean age of 26.7 years of age and 60% of sample being multiparous women (n=75) and 40% primiparous (n=50). The pregnancy symptoms reported by at least 70% of all women included: tiredness, urinary frequency, food cravings, back pain, headache, and poor sleep. However, the participants had to rate the limitation in their activities of daily living for each of the pregnancy symptoms they reported on the questionnaire (42 total symptoms on the PSI). The pregnancy symptoms that caused the most limitation varied slightly from those that were most frequently reported. The symptoms that had the most impact on activities of daily living were: tiredness, poor sleep, back pain, and hip/pelvic pain. There was a discrepancy noted from the symptoms that were most frequently occurring and those that impacted their daily living. For example, urinary

frequency was listed as the second most commonly reported symptom, but it only caused limitation to daily living 35% of the time. On the other hand, hip/pelvic pain was reported as the ninth most frequently reported symptom by 66% of women, yet it was the fourth highest symptom causing limitations in daily living. A Mann Whitney U analysis was used to compare group differences of limitation of the top 60% of symptoms reporting limitation to activities of daily living between women who had vitamin D levels < 20 ng/ml (deficient based on IOM standards) and ≥ 20 ng/ml (sufficient based on IOM standards) in their pregnancy symptoms. Significant differences were found for tiredness, poor sleep, back pain, and hip/pelvic pain based on their rating of the effect on their limitation on activities of daily living with p values < .05 with a Bonferroni correction due to risk of inflated type I error.

In addition, women who had higher total pregnancy symptoms scores (sum score of all their pregnancy symptoms) had poorer quality of life as measured by SF-12. There was a significant negative correlation between physical component score and total pregnancy symptom total score ($r = -0.31, p < .001$). Thus, women who had higher pregnancy symptom scores had worse physical functioning. Similarly, there was a significant negative correlation between mental component score and pregnancy symptom total score ($r = -0.32, p < .001$) indicating that women who had higher pregnancy symptom scores had worse mental health.

Conclusion: Based on the results of the study, vitamin D status may potentially impact pregnancy symptoms such as back pain and poor sleep. These symptoms can significantly affect health and quality of life. These findings also suggest that exploration of the association between vitamin D levels and pregnancy symptoms is warranted in a larger sample which could then be followed by a supplementation study to determine its effectiveness in treating these symptoms during pregnancy.

F 14 - Nurse-Managed Technology to Enhance Cancer Care Outcomes for Survivors With Breast Cancer or Head/Neck Cancer

Mobile Platform for Assessment, Early Detection, and Management of Breast Cancer-Related Lymphedema

Jane Armer, PhD, RN, CLT, FAAN, USA

Nathan C. Armer, MEd, USA

Guilherme N. DeSouza, PhD, USA

Abstract

Purpose: Early detection and management of secondary lymphedema (LE) can significantly reduce the potential for symptoms and complications. Unfortunately, many patients fail to seek medical assistance at first signs of the disease. It is estimated that approximately 500,000 people in the U.S. suffer from lymphedema, and 2.4 million breast cancer survivors are at-risk for developing this chronic condition. Objectives were to: (1) Test the two completely automated measuring systems we developed (using an IR depth camera and a smart phone) for individuals to use at home or in the clinic for early detection and self-monitoring of LE; (2) Integrate and evaluate the automated smart phone application in the clinical setting.

Methods: Over 280 data points (upper limbs) were sampled from healthy people and LE patients to exam the correlation between the mobile platform systems and the “gold standards” (water displacement and perometry); and to determine the reliability of both proposed methods. In comparison with water-displacement, 14 measurements of upper limbs from many repetitions for 7 healthy test subjects were done. Regarding the comparison with the Perometer, 34 upper limbs from 17 human subjects, including LE patients, were measured. IRB approval was received for integration of the 3D smart phone images with circumferences and symptom assessment in a prospective surveillance model with breast cancer survivors at risk of lymphedema.

Results: Pearson correlations of 0.97-0.98 with the kinect and smartphone 3D mobile platform systems and clinical limb volume measures of water displacement and perometry are reported. The two completely automated and robust systems for 3D image of human arms outperformed existing methods in many aspects, including cost, maintenance, and ease of use, while they maintained high correlations with the “gold standards.” Patients and staff are open to, and, indeed, eager to, participate in the application of the mobile device in the clinical setting.

Conclusion: The systems will accurately assist patients in managing LE through early detection and monitoring in the clinic and at home. Algorithms will be further refined to facilitate even more efficient and accurate data capture in the clinical and home setting. We will be doing further testing as we work to assess the ease of use by patients and clinicians with variable levels of comfort with technology.

Health Information Technology (IT) to Promote Patient-Centered Care

Mei R. Fu, PhD, RN, FAAN, USA

Abstract

Purpose: A growing body of evidence indicates the use of health information (IT) solutions are effective in implementing patient-centered care and can be instrumental to improving the safety, quality, and efficiency of patient-centered health care delivery. Many breast cancer survivors suffer from daily distressing symptoms related to lymphedema, a chronic illness induced by cancer treatment and currently no medical and surgical intervention can provide a cure. Lymphedema is an abnormal accumulation of lymph fluid in the ipsilateral body area or upper limb with more than 20 distressful symptoms. In spite of the growing body of evidence linking the experience of lymphedema symptoms to risk of lymphedema and poor quality of life, the experience of lymphedema symptoms is not often valued and not considered essential for assessment or inclusion in clinical practice, leading to an overall health disparity manifested as a lack of patient-centered care in clinical practice. The purpose of this presentation is to share our experience of using health IT to promote patient-centered care in lymphedema symptom assessment among breast cancer survivors, focusing on building institutional infrastructure, feasibility, and sustainability of using health IT in clinical practice.

Methods: The Evaluation Planning Incorporating Context (EPIC) model was used to guide this project. Methods used included: i) a literature review on the use of a tablet computer in the assessment of cancer symptoms; ii) a literature review related to detection and referral of lymphedema; iii) a literature review regarding satisfaction related to the use of a tablet computer; iv) observation of the state of the current process at an outpatient breast cancer practice; v) implementation of the evidence-based lymphedema symptom TouchScreen at the outpatient breast cancer practice; vi) survey assessment of patient and clinician satisfaction with the use of the TouchScreen.

Results: By building a sustainable infrastructure we have successfully incorporated this patient-centered care into daily clinical practice. Using the TouchScreen to report lymphedema symptoms is safe, easy-to-use, and no risk of harm to patients. The use of the TouchScreen increased the number of timely referrals for lymphedema treatment and patients' self-recognition of lymphedema symptoms. Overall, clinicians and patients reported being very satisfied with the use of the TouchScreen that improved clinicians' assessment of lymphedema symptoms and improved communication among health care providers and patients and patients' learning about lymphedema symptoms.

Conclusion: Using TouchScreen for patients to report lymphedema symptoms show benefit to patients in terms of earlier self-recognition of lymphedema symptoms, increased communication among clinicians and patients and increased timely referral to lymphedema specialist, all potentially leading to a reduction of lymphedema complications.

Cancer Registry and Electronic Medical Record Data In Head and Neck Cancer Research

Janet Van Cleave, PhD, MSN, RN, USA

Abstract

Purpose: Medically underserved head and neck cancer populations are underrepresented in clinical trials and national datasets in the United States (US). Therefore, limited evidence is available to guide the care of patients receiving cancer treatments in safety-net health systems for low-income, uninsured, or vulnerable populations. Using combined hospital cancer registry and electronic medical record (EMR) data from a northeastern United States integrated safety-net system, we analyzed factors associated with receipt of cancer treatment among medically underserved persons with head and neck cancer. The research objectives of the study were to: 1) Identify demographic and clinical features of the population receiving care for head and neck cancer in an integrated, safety-net health system, and 2) determine factors associated with receipt of cancer treatment.

Methods: A retrospective, multi-institution review was conducted using combined hospital cancer registry and EMR data from 343 patients diagnosed with squamous cell carcinoma of the head and neck between January 1, 2007 and December 31, 2010. All patients received care in an integrated, safety-net health system located in the northeastern US. After receiving human subjects approval from a regional biomedical internal review board, the participating hospital cancer registrars identified the study population and obtained demographic data from their automated registry. After identification of the study population, investigators abstracted cancer treatment data from the electronic medical records and entered this data into an encrypted, password protected Microsoft Excel file. All data were uploaded and analyzed with STATA 13. Descriptive statistics, and multivariable analyses using logistic regression were conducted to determine the association between the dependent variable (receipt of cancer treatment) and independent variables of age, gender, race/ethnicity, cancer stage, and cancer site. Tobacco use was also included as an independent variable because of the association of tobacco use with increased mortality risk.

Results: Among the 343 patients with head and neck cancer, the mean age was 59 years (SD = 13, Range 20 to 100). The population was racially and ethnically diverse (white 19%, black 43%, Hispanic 17%, Asian or other race/ethnicity 20%), and predominantly male (male 78%, female 22%). Most patients presented with advanced stage head and neck cancer (Stage I – III 31%, Stage IV or Metastatic 57%, Unknown 11%). The majority of the study population received chemotherapy, radiation therapy, surgery, or combination of these therapies (85%). While controlling for age, gender, race/ethnicity, cancer stage and site, and tobacco use, the regression model demonstrated that cancer stage, age, and race/ethnicity were associated with receipt of cancer treatment. Specifically, persons with an unknown stage of head and neck cancer were significantly less likely to receive cancer treatment than those with Stage I disease (Odds Ratio [OR] = .07, [95% Confidence Interval (CI): .02 - .22]). Further, those who were ages 60 and over were less likely to receive cancer treatment than those ages 59 and under (OR =.53, [95% CI: .30 - .94]). However, those who identified as Asian or other race/ethnicity were more likely to receive cancer treatment than those who identified as white (OR=2.18, [95% CI: 1.01 – 4.69]).

Conclusion: Using hospital cancer registry and EMR data, our study findings indicate that those who receive care for head and neck cancer in a safety-net health system in the US comprise a racially/ethnically diverse population. Further, a person's cancer stage, age, and race/ethnicity may influence receipt of cancer treatment. Possible explanations for study findings include the impact of physiological status and social support on provider-patient decisions in cancer treatment. Limitations of using a combined hospital cancer registry and EMR data set include the lack of information about episodes of care that occur outside the integrated safety-net system. To address this limitation, more research and policy initiatives are needed to accelerate data sharing across both US and international health care systems.

Assessment of Head and Neck Lymphedema with Ultrasonography

Jie Deng, PhD, RN, OCN, FAAN, USA

Abstract

Purpose: Patients with locally advanced head and neck cancer are at high risk for the development of secondary lymphedema. Lymphedema is associated with damage to the lymphatic system and its

surrounding soft tissues, from tumor infiltration, surgery, and radiation. We have found that head and neck cancer survivors frequently suffer from lymphedema. Lymphedema occurs both externally and internally. External lymphedema results in functional deficits (e.g., impaired swallowing and speaking) and restricted activities of daily living (driving and work-related tasks). Internal swelling causes functional impacts (e.g., difficulty chewing and respiratory distress). Aggressive identification and treatment of lymphedema is critical to ensure optimal function and quality of life. The purpose of this report is to present information regarding the use of ultrasonography for the assessment of head and neck lymphedema.

Methods: A longitudinal design is used in the study. The study will enroll up to 30 head and neck cancer patients. Ultrasonography measures are obtained at baseline and at 3 months post head and neck cancer treatment, then compared to clinical assessment of lymphedema based upon physical examination. Ultrasonography measures are performed by an experienced sonographer, using an EPIC scanner (Phillips Healthcare Bothell, WA) and a standoff gel pad, in 5 preselected anatomical sites on each side of the face and neck. The sites measured include maxillary prominence, mid-mandible, superior and middle sternocleidomastoid muscles, and submental regions. Measurement variables for each site include distance of soft tissues and stiffness of soft tissues. For the purpose of data analysis, anatomical sites are grouped into four regions: peri-orbital, cheek, neck, and submental. SPSS 24.0 is being used to conduct statistical analysis. Area under the curve (AUC) values are derived from the ultrasound values (soft tissue distances at the anatomical sites) for each region. Detectable differences in the ultrasound values among the types of lymphedema will be tested using Kruskal-Wallis tests.

Results: Data collection is ongoing. Preliminary analysis (12 patients has completed all the baseline and 3-month measures) indicates that the strength of the correlation between physical examination and ultrasonography varies based upon each region, however there are statistically significant differences in ultrasound measurement areas (AUC values) in the cheek, submental, and neck regions ($p < 0.05$). Sites without lymphedema demonstrate median elasticity velocities of 2.85m/s; sites with lymphedema show increased elasticity velocities (median value= 3.54m/s).

Conclusion: These preliminary findings indicate that ultrasonography could be an important supplemental tool for quantifying the severity of lymphedema-related soft tissue changes.

F 15 - Improving Quality of Nursing Worklife: A Global Perspective

Quality of Nursing Worklife: A Review of the Science

Beth A. Brooks, PhD, RN, FACHE, USA

Abstract

Purpose: As the largest single employee group within hospitals, nurses are critical to the optimal functioning of the organization, and improving employee productivity continues to be a common theme in the health care literature. However, any increased productivity will be transitory if achieved at the expense of the quality of nurses' work life (QNWL), since improvement in the QNWL is prerequisite to improved productivity. The purpose of this symposium is to review the theoretical and conceptual underpinnings of QNWL, list the various countries that have used the Brooks QNWL Survey to measure nursing worklife, and to describe two strategies to improve nursing worklife. These two strategies align with the assumptions of Socio-technical Systems theory (STS) which underlies the concept of quality of nursing worklife.

Method: Socio-technical systems theory is based on two underlying assumptions: (a) organizational performance can be improved by allowing lower level employees to assume more responsibility for their efforts, and (b) employees will become more responsible and self-directed as their positions offer opportunities to fulfill important psychological needs, such as learning, growth, self-esteem and significance in their working lives. An organization's internal environment has social and technical subsystems, as well as physical design and work settings, which act together to influence and produce the intended outcome (product or service). The social subsystem is comprised of the people who work in the organization and the relationships among them, whereas the technical subsystem of an organization consists of the tools, techniques, procedures, skills, knowledge, and devices used by members of the social subsystem to accomplish tasks of the organization. The major objective of the STS theory approach to organizational change is to optimize jointly the organizational goals and the needs of the employees—an approach significantly different from job satisfaction, which is based on employees' likes and dislikes, a function of personality which employers can do little to change.

The network of relationships defined by STS theory and prior conceptualizations of QNWL implicitly define and identify characteristics of a quality work environment as defined **by nurses for nurses** (Attridge & Callahan, 1990). Leading to quality of nursing work life begins by being defined as the degree to which registered nurses are able to satisfy important personal needs through their experiences in their work organization while achieving the organization's goals (Brooks, 2001). The four dimensions that underlie QNWL are: 1) work life-homelife; 2) work design; 3) work context; and 4) work world (Baumann & O'Brien-Pallas, 1993; O'Brien-Pallas, Baumann, & Villeneuve, 1994).

Methods: These dimensions along with a synthesis of empirical referents gleaned from prior work resulted in the development of Brooks' Quality of Nursing Worklife Survey. The survey has now been used in 30 countries and translated into five languages.

Results: This session will review the origins of the survey.

Conclusion: A number of Human Resources strategies can be used to improve the quality of nursing worklife in select countries.

Including Human Resources Professionals and Practices to Improve Nursing Worklife

Paul T. Skiem, MBA, LCS, USA

Abstract

Purpose: Human resources (HR) professionals can play a major role in improving nursing worklife. The social subsystem, comprised of the people who work in the organization and the relationships among them, must be able to successfully meet a number of interrelated challenges: attain the goals set for the organization, adapt to the organization's environment, integrate the activities of the organization's stakeholders, and fill essential, occupational roles through recruitment, socialization, and retention initiatives.

Methods: More broadly, the social subsystem includes the reasons that employees choose to work for an organization, their attitudes toward it, their expectations of it, patterns of supervisory-subordinate relationships, skill levels of employees, and the nature of the subgroups within the organization. The STS theorists contend that the surest way to direct the efforts of organizational members toward organizational goals is to identify the needs that people bring with them to the workplace, and incorporate the means to meet those needs through technological design and the work itself. In short, the social subsystem encompasses all of the human qualities that each member of an organization brings with them to the workplace.

Results: If provided with an appropriate set of tools, Human Resources can leverage the greatest impact on the social subsystem of an organization. Using data from the quality of nursing worklife survey, Human Resources is able to identify the needs that employees bring with them to the workplace, and can then design means to meet those needs through various compensation and employee benefits, learning and development, and other human resources programs.

Conclusion: Nurse leaders can then partner and collaborate with HR to select those evidence-based practices that can help deliver greater levels of individual performance, organizational performance, productivity, which all help provide the larger organization with a superior financial performance. From labor and employee relations training, to creating effective on-boarding programs, to individual and team coaching initiatives, working in collaboration with Human Resources can influence the social subsystem. In this session, a senior human resources executive will review selected, high impact HR practices that can be used to improve the quality of nursing worklife.

Staffing Optimization: Improving Staffing to Improve Nursing Worklife

Therese A. Fitzpatrick, PhD, RN, FAAN, USA

Abstract

Purpose: The technical subsystem of an organization consists of the tools, techniques, procedures, skills, knowledge, and devices used by members of the social subsystem to accomplish tasks of the organization. The most direct impact of technology is upon organizational productivity, not surprising since organizations acquire technology to increase speed and efficiency.

Methods: Inevitably any survey of nursing worklife reveals issues around staffing and scheduling. Yet many traditional approaches still in use for planning and deploying human capital are not effective in meeting current organizational objectives. Internally, staffing offices are chaotic, budgets are exceeded, staffing is frequently misaligned, and dissatisfaction with work schedules abounds. Externally, a growing number of state legislatures are mandating nurse staffing levels. The growing misalignment between supply and demand suggests that the current methods used to project labor demand, and to budget, staff, and schedule nurses have become both increasingly more complex and less effective.

Results: The multifaceted staffing problems we now face cannot be solved using historic averages or simple algebraic formulas. Because there are multiple dimensions to each staffing subprocess that interacts with or is somehow impacted by other subprocesses, mathematical models are needed along with the power of computer science to simulate solutions for complex staffing problems. A growing body of evidence in a wide variety of diverse industries suggests that systematic and scientifically based process improvement that leverages mathematical optimization can produce a myriad of innovative solutions to intractable business problems. Logistics science offers new insight into planning and deploying clinical human capital.

Conclusion: Optimal outcomes are possible if there is recognition of the complexity and interconnectedness of the systems and processes involved in workforce planning and deployment. The process of optimizing human capital in a complex environment involves 3 distinct steps: (1) analysis or demand planning, (2) optimizing resources, and (3) executing the optimized model. This final session will outline how optimization modeling works for nurse staffing in order to improve the quality of nursing worklife.

F 16 - Direct Oral Anticoagulant Management in Patients Undergoing Cardiac Implantable Electronic Device Procedures

Trends in Direct Oral Anticoagulant Management in Patients Undergoing Cardiac Implantable Electronic Device Procedures

Christen R. Waddell, DNP, RN, CMC, NP-C, USA

Abstract

Purpose: Guidelines on how to manage DOACs in the periprocedural setting are necessary for patient safety; yet, in the United States and many areas of the world, there are currently no consensus guidelines that address this topic. This represents an opportunity for nursing science and leadership to standardize care and improve patient outcomes.

Methods: To evaluate DOAC management strategies in the periprocedural setting, we performed a retrospective chart review of all adult patients taking DOACs at the time of CIED procedures at our three hospital facilities from January 2012-June 2016. We analyzed frequency data regarding the number of days that the DOAC was held before and after the procedure, and if bridging with heparin was utilized. Data trends were assessed for any changes over the years as we have gained more experience with DOACs. We also analyzed for any trends associated with age, gender, location, patient comorbidities, concurrent medications, and calculated bleeding and thrombotic risk scores (HASBLED, CHA2DS2-VASc).

Results: Our study had a total of 309 qualifying cases. We found that the average number of days that the DOAC was held before the procedure was 2.2 days and the average number of days that the DOAC was held after the procedure was 1.5 days. This number did not vary widely by age, gender, location, patient comorbidities, concurrent medications, calculated bleeding and thrombotic risk scores (HASBLED, CHA2DS2-VASc), or across the different years of the study. Bridging with heparin occurred in 8.3% of cases.

Conclusion: Overall, our results show that providers manage DOACs in a fairly consistent manner without consensus guidelines. Given that DOACs are expected to eventually become the most commonly used oral anticoagulants and the majority of institutions do not have standardized protocols in place to address their perioperative management, we would recommend that professional societies develop consensus guidelines on how best to manage DOACs in the periprocedural setting to standardize care and improve patient outcomes (Flake et al., 2015; Oktay, 2015).

Factors Influencing Management of Direct Oral Anticoagulants in Patients Undergoing Cardiac Implantable Electronic Device Procedures

Marci Farquhar-Snow, MN, RN, CCRN, CMC, CNS, ACNP-BC, USA

Abstract

Purpose: Existing literature on anticoagulation management in the periprocedural setting suggests that decisions should be individualized to patient and procedure specific risks, yet there are limited studies on this subject (Baron, Kamath, & McBane, 2013; Daniels, 2015). This represents an opportunity for nursing science and leadership to standardize care and improve patient outcomes.

Methods: To gain more knowledge on how we have been choosing to manage DOACs in the periprocedural setting, we performed a retrospective chart review of all adult patients prescribed DOACs at the time of CIED procedures at our three facilities from January 2012-June 2016. We analyzed frequency data regarding how many days the DOAC was held before and after the procedure, and if they were bridged with heparin. We also collected data on contributing factors such as comorbidities, concurrent medications, calculated CHA2DS2-VASc and HASBLED scores, age, procedure type, facility location, and year to determine if there were any correlations between these factors and DOAC management decisions.

Results: Our study had a total of 309 qualifying cases. When analyzing for any contributing factors that were correlated with DOAC management utilizing Type 3 GEE analysis, we found the following statistically significant relationships: Subjects on dual antiplatelet therapy had their DOAC held for significantly less days after the procedure; subjects receiving a defibrillator implant had their DOAC held for significantly more days after the procedure; subjects receiving a pacemaker generator change had their DOAC held for significantly less days after the procedure; subjects receiving a defibrillator generator change had their DOAC held for significantly less days after the procedure.

Conclusion: Our results found that the type of procedure and the use of dual antiplatelet therapy were significantly related to DOAC management decisions in the perioperative period surrounding CIED procedures. Although research has shown that the bleeding risk of the procedure and the patient's renal function should be taken in to consideration, we did not find a statistically significant correlation with these factors and DOAC management (Heidbuchel et al., 2013). To ensure patient safety in the future, we

would recommend that professional societies develop consensus guidelines on how best to manage DOACs in the periprocedural setting to assess for risk factors and to standardize care.

Complication Rates Associated with Direct Oral Anticoagulants in Patients Undergoing Cardiac Implantable Electronic Device Procedures

Michelle L. Alland, MSN, RN, FNP-C, USA

Abstract

Purpose: There is limited outcome data on bleeding and thrombotic complications in patients taking DOACs at the time of procedures (Beyer-Westendorf et al., 2013). This represents an opportunity for nursing science to study DOAC management in this setting to reduce complications and optimize patient outcomes.

Methods: To gain more knowledge on bleeding and thrombotic complication rates, we performed a retrospective chart review of all adult patients prescribed DOACs at the time of CIED procedures at our three facilities from January 2012-June 2016. We reviewed frequency data regarding bleeding and

thrombotic complication rates and analyzed for any statistically significant correlation with DOAC management in the periprocedural period to include how many days the DOAC was held before and after the procedure, and if they were bridged with heparin. We also analyzed the data for any statistically significant correlation between complication rates and patient comorbidities, concurrent medications, procedure type, facility, and year.

Results: Our study had a total of 309 qualifying cases. The complication rates in our study were low, with three bleeding complications and no thrombotic complications. The three bleeding complications were hematomas in advanced age individuals taking rivaroxaban, however these patient specific factors were not statistically significant as the low numbers of complications prohibited us from running statistical analysis of the complication rates in relation to DOAC management and contributing patient specific factors.

Conclusion: Decisions on how to manage anticoagulation in the periprocedural period consider the patient and procedure specific bleeding and thrombotic risks (Daniels, 2015). Overall, our results show us that performing CIED procedures on patients taking DOACs is safe from a bleeding and thrombosis standpoint regardless of the procedure-specific bleeding and thrombotic risks. They were also safe regardless of the length of time DOACs were held before, after, or bridged in the periprocedural setting. To ensure patient safety in the future, we would recommend that professional societies develop consensus guidelines on how to best manage DOACs in the periprocedural setting to standardize care and reduce potential complications.

F 17 - Enhancing Health/Wellness of Students, Faculty and Staff in Academic Settings: Evidence-Based Strategies for Success

Enhancing Health/Wellness of Students, Faculty and Staff in Academic Settings: Evidence-Based Strategies for Success

Bernadette Mazurek Melnyk, PhD, RN, CPNP/PMHNP, FAANP, FNAP, FAAN, USA

Abstract

Purpose: Academia is a fertile setting to improve population health of 33 million people who live in work in institutions of higher learning. A key strategy to promote healthy lifestyle behaviors includes targeting students, faculty and staff at multiple levels of health promotion, including individual activities, the use of the social environment to promote health, addressing the larger institutional culture, and implementing health policy. Utilizing key national intervention initiatives in the field of health promotion can be fundamental to improving the health of a university. The purpose of this symposium is to discuss the importance of creating a culture of wellness in academic settings that supports implementing wellness programs, activities and resources at multiple levels of health promotion.

Methods: Various methods will be presented in this symposium, including: 1) an evidence review of the current state of population health, including the health of the nursing profession; 2) the incorporation of innovative strategies into educational pedagogy to improve the health of nursing students and promote wellness throughout the nursing profession. Various methods of integrating wellness into curricula include: a faculty wellness toolkit; the concept of "lecturcizing;" using national disease prevention initiatives, such as Healthy People 2020 and Million Hearts, as teaching tools and a means of improving student wellness; and incorporating a variety of assignments and projects related to wellness into nursing courses; 3) description of baseline data from a student wellness on-boarding study; and 4) the methods utilized in the Million Hearts Building Healthy Academic Communities (BHAC) and Ohio State challenge programs.

Results: According to the latest statistics, there over 3 million practicing Registered Nurses (including Advanced Practice Registered Nurses) in the U.S., which represents the largest sector of the health professions. Too often nurses fail to adequately care for themselves. As a result of not engaging in healthy lifestyle behaviors, nurses have higher rates of diabetes, hypertension, obesity and depression than physicians. Not being in optimal health contributes to high rates of burnout, early retirement, and a plethora of chronic conditions, including cardiovascular disease, depression, obesity, and musculoskeletal conditions. For the students enrolled in a RN-BSN course where wellness and self-care and discussed and promoted, participation rates were high with 61% completing all wellness activities and only 4% choosing not to engage in any wellness activities. Eighty percent of students who participated in the wellness activities reported either achieving their wellness goal or were close to achieving their wellness goal. Ninety-five percent of students wished to continue wellness activities in the course. Results from the Million Hearts program challenge saw high level of stress significantly correlated with race ($p=.02$), a diagnoses of at least one chronic condition ($p<.0001$), a BMI of 25-29.9 ($p=.04$), and those who ate 0-1 servings of fruit/vegetables per day ($p=.0002$). High level of stress was significantly correlated with being a smoker ($p=.05$), participants diagnosed with at least one chronic condition ($p<.001$), and a BMI of over 30 ($p=.05$).

Lastly, in regards to the health sciences graduate student wellness on-boarding study, overall, the lower healthy lifestyle beliefs were significantly associated with higher depression ($r = -0.37$, $P < 0.001$), higher anxiety ($r = -0.36$, $P < 0.001$), and higher stress ($r = -0.36$, $P < 0.001$). Significant negative correlations also existed between healthy lifestyle behaviors and depression ($r = -0.36$, $P < 0.001$), healthy lifestyle behaviors and anxiety ($r = -0.30$, $P < 0.001$), and healthy lifestyle behaviors and stress

($r = -0.22$, $P = 0.02$). Positive and significant correlations existed between healthy lifestyle behaviors and healthy lifestyle beliefs ($r=0.52$, $P < 0.001$). Additionally, depression, anxiety, and stress are highly correlated with each other (pair-wise correlation coefficients of 0.60-0.81).

Conclusion: Addressing the health and wellness of students, faculty and staff in academic institutions, as well as the broader culture and environment, is a critical step in improving population health outcomes. As it relates to the field of nursing, emphasizing the health of the provider, not just the patient, needs to start during entry into the profession with nursing education. In addition, national health initiatives, outlined in this presentation, such as Million Hearts, and local programs, such as a student wellness on-boarding intervention, can be successful methods for educating and encouraging populations to adopt healthy lifestyle behaviors.

Incorporating Wellness into Nursing Education

Kate E. Gawlik, DNP, RN, CNP, ANP-BC, FNP-BC, USA

Abstract

Purpose: Despite the central role of nursing in patient health promotion and education, current nursing pedagogy lacks integration of student wellness and self-care. The purpose of this presentation is to discuss the rising need to integrate wellness and self-care into nursing education and place nursing at the forefront of national health promotion initiatives.

Methods: Faculty are incorporating innovative strategies into their educational pedagogy to improve the health of nursing students and promote wellness throughout the nursing profession. Various methods of integrating wellness into curricula include: a faculty wellness toolkit; the concept of "lecturcizing;" using national disease prevention initiatives, such as Healthy People 2020 and Million Hearts, as teaching tools and a means of improving student wellness; and incorporating a variety of assignments and projects related to wellness into nursing courses. An exemplar of an optional, multi-dimensional wellness program that was integrated into a large online RN-BSN course will be discussed. Students were asked to identify a wellness goal at the beginning of the semester. Each week, students were given a short wellness activity to complete. Examples of wellness activities were such things as guided imagery, dancing videos, and trying a new healthy recipe. At the end of each week, students were asked to submit a document stating they completed the wellness activity and how they were progressing with their wellness goal. Student participation rates were tracked and a follow-up survey was administered.

Results: Participation rates were high with 61% completing all wellness activities and only 4% choosing not to engage in any wellness activities. Eighty percent of students who participated in the wellness activities reported either achieving their wellness goal or were close to achieving their wellness goal. Ninety-five percent of students wished to continue wellness activities in the course.

Conclusion: Emphasizing the health of the provider, not just the patient, needs to start during entry into the profession with nursing education. Nurses need to demonstrate leadership by practicing and advocating for health promotion, disease prevention and population health.

Findings from the Building Healthy Academic Communities Million Hearts® Challenge Program

Megan E. Amaya, PhD, CHES, AFAA, USA

Abstract

Purpose: Cardiovascular disease (CV) is the leading cause of death for both men and women in the United States. The Million Hearts initiative emphasizes consistent, evidence-based interventions and education to increase public awareness of preventive lifestyle modifications to reduce CV morbidity and mortality by focusing on the “ABCS” of care. “A” is for aspirin therapy, “B” is for blood pressure control, “C” is for cholesterol management and “S” is for smoking cessation. Targeting management via the ABCS has been shown to prevent more deaths than other clinical preventive services.

Methods: A prospective study design was used to examine trends and correlations among the data. Institutional and individual members of the National Consortium for Building Healthy Academic Communities (BHAC) were asked to participate in the program. Participants from those academic institutions were able to access the free, online program via the e-learning website of a college of nursing housed within a large public land grant University in the mid-west region of the United States. Participants who opted to enroll in the BHAC Million Hearts program joined an online educational program that consisted of the following: 1) an overview of the national Million Hearts initiative; 2) understanding their biometric numbers; 3) improving CV health through healthy lifestyle behavioral changes and 4) managing stress through stress reduction techniques. An anonymous 12-item survey was developed and administered to all participants after they completed the education content.

Results: Analysis was completed for the BHAC Consortium as a whole, and for results at the host institution for BHAC, a majority of the participants were female (81%), between the ages of 20-29 (60%), white (65%), and a spouse/same-sex domestic partner of a faculty/staff member (61%). A majority were non-smoking (85%), ate 2-3 servings of fruits/vegetables per day (47%) and exercised less than 75 minutes per week (32%). 72% responded with no diagnosis of a chronic condition, had a normal body mass index (50%) and scored a 5-8 on the perceived stress scale (40%). High level of stress was significantly correlated with race ($p=.02$), participants diagnosed with at least one chronic condition ($p<.0001$), a BMI of 25-29.9 ($p=.04$), and those that ate 0-1 servings of fruit/vegetables per day ($p=.0002$). For the sub-category of the host institution, a majority of the participants were female (74%), between the ages of 30-39 (30%), white (83%), and a staff member (62%). A majority were non-smoking (90%), ate 3-4 servings of fruits/vegetables per day (43%) and exercised less than 75 minutes per week (32%). 68% responded with no diagnosis of a chronic condition, had a normal body mass index (38%) and scored a 0-4 on the perceived stress scale (39%). High level of stress was significantly correlated with being a smoker ($p=.05$), participants diagnosed with at least one chronic condition ($p<.001$), and a BMI of over 30 ($p=.05$).

Conclusion: The Million Hearts national initiative, as outlined by the intervention components “ABCS” can be a successful method for educating and encouraging populations to adopt healthy lifestyle behaviors. Elevated perceived levels of stress are often observed with the diagnosis of a chronic

condition. Reducing stress and managing chronic condition(s) through behavior change is an ideal way to improve population health.

Mental Health and Healthy Lifestyle Behaviors in First-Year Health Sciences Graduate Students

Jacqueline Hoying, PhD, RN, NEA-BC, USA

Abstract

Purpose: Mental health disorders account for nearly one half of the disease burden for young adults in the United States and the prevalence of depression among college students has increased from 10% in 2000 to a current rate of 15%. The college years are frequently a transition period when students are gaining independence from their parents and developing healthy lifestyle behaviors. However, during this critical phase in development, college students tend to have poor dietary habits and low physical activity levels that may contribute to obesity and related health conditions in later life. The American College Health Association National College Health Assessment-II identified the leading impediments to academic success reported by college students as being stress (30%), anxiety (21%), sleep problems (20%), and depression (14%.) With poor healthy lifestyle habits and a high degree of burden from mental health disorders, there is an urgent need to develop and test interventions to improve the healthy lifestyle behaviors, mental health and academic outcomes in college youth.

Methods: This is a descriptive study of the baseline variables and correlates of healthy lifestyle behaviors of first year graduate students participating in a wellness onboarding study. First year graduate students from 7 health sciences colleges (Dentistry, Health and Rehabilitation Medicine, Nursing, Optometry, Pharmacy, and Veterinary Medicine) were invited to participate in the study. Consent was obtained online. The study consisted of the completion of a personalized wellness assessment, biometric screen, completion of a personalized wellness plan, and then random assignment to either wellness coaching by a Family Nurse Practitioner (FNP) student trained in COPE (Creating Opportunities for Personal Empowerment), a cognitive behavioral skill building program and wellness coaching or counseling about healthy lifestyle resources available and encouragement follow their individual wellness plan. **Analysis:** Descriptive statistics were used to summarize sample characteristics and baseline measures. Pearson correlation coefficients were used to test the pair-wise correlations between healthy lifestyle beliefs, healthy lifestyle behaviors, depression, anxiety, and stress. Chi-square statistics were used to compare the healthy lifestyle behavior risks factors across groups.

Results: 107 students participated in this study. Fifty-nine percent of participants were < 25 years of age, 31% participants were between the ages of 25 and 34, and 10% of the participants were > 35 years of age. The majority of the sample was White, not of Hispanic origin (70%), followed by Asian/Pacific Islander at 10%, Hispanic (7.5%), and Black, not of Hispanic origin (5.6%). The majority of the students were never married (80%) and did not have children (92%). Participants were from Nursing (39%), Veterinary Medicine (23%), Medicine (22%), Pharmacy (6%), Health and Rehabilitation (4%) and

Dentistry and Optometry (2% each). Nineteen percent of the sample described their health as excellent, followed by very good 18%, good 49%, fair 12% and poor 1%. More than half of the participants saw a consistent healthcare provider (60%). Overall, 44% of the total students had elevated symptoms of depression and 43% had elevated symptoms of anxiety. In addition, 88% of the total first year graduate students had elevated stress levels. In addition, lower healthy lifestyle beliefs were significantly associated with higher depression ($r = -0.37, P < 0.001$), higher anxiety ($r = -0.36, P < 0.001$), and higher stress ($r = -0.36, P < 0.001$). A significant negative correlations also existed between healthy lifestyle behaviors and depression ($r = -0.36, P < 0.001$), healthy lifestyle behaviors and anxiety ($r = -0.30, P < 0.001$), and healthy lifestyle behaviors and stress ($r = -0.22, P = 0.02$). Positive and significant correlations existed between healthy lifestyle behaviors and healthy lifestyle beliefs ($r = 0.52, P < 0.001$). Additionally, depression, anxiety, and stress were highly correlated with each other (pair-wise correlation coefficients of 0.60-0.81).

Conclusion: Understanding similarities in baseline correlations among mental health and healthy lifestyle behaviors among first year graduate students can guide interventions to improve mental health and healthy lifestyle behaviors in this at-risk population.

J 07 - Psychological Stress and Multi-Omics Interactions on Health Disparities Among African Americans

Genetic and Perceived Racism-Discrimination on Blood Pressure Among African-Americans in the Jackson Heart Study

Jacquelyn Taylor, PhD, PNP-BC, RN, FAHA, FAAN, USA

Abstract

Purpose: Hypertension is a common disease, affecting over 78 million adults in the US every year (Go et al., 2014). African Americans are disproportionately affected by this disease, with an earlier age of onset as well as higher rates of complications than adults of other racial/ethnic backgrounds (Nwankwo, Yoon, Burt, & Gu, 2013). The etiology of hypertension is complex and multifactorial. Studies have identified social, biological, environmental, and genetic risk factors for hypertension, but few studies have considered the ways in which these risk factors interact or work together in elevating risk among African Americans. Social factors such as experiences of discrimination related to skin color have been associated with high blood pressure in diverse populations, especially in low-income groups (Gravlee & Dressler, 2005; Sweet, McDade, Kiefe, & Liu, 2007). Further, although self-reported race has been associated with poor mental and physical health outcomes in African Americans (Monk, 2015), little is known about the gene-environment interaction that may exacerbate poor outcomes.

Methods: Both GWAS and candidate gene analyses were utilized to study the relationship between everyday (ED) and major life discrimination (MLD) with increases in systolic (SBP) and diastolic (DBP) blood pressure among African Americans in the Jackson Heart Study. Known predictors of blood pressure, such as age, sex, BMI, antihypertensive use and smoking status, were assessed in a multiple regression model including all predictors. Using multiple linear regression models, we assessed the associations between each predictor discrimination variable including and outcome variables (i.e., SBP and DBP) adjusted for age, sex, BMI, antihypertensive use and current smoking status. We used multiple linear regression models to test for association between each SNP and the blood pressure phenotypes (i.e., SBP and DBP). Each SNP was tested for additive effects in association with the outcome of interest in a test with one degree of freedom. We also tested the SNP × perceived discrimination interaction effects of SBP and DBP using multivariable linear mixed models with age, sex, BMI, antihypertensive medication use and top 10 Principal Components of the GWAS data as covariates.

Results: A total of 2,937 participants had both phenotypic and genetic data and were included in analyses for this study. This sample had a mean age of 55 years old, and the majority of the sample were female, obese, non-smokers, had hypertension, and were on antihypertension medication. Mean SBP and DBP were 126.8 and 79.1 mmHg, respectively. Overall, discrimination reported among participants in our sample was low. Multiple linear regression indicates no association between discrimination and blood pressure after adjusting for age, gender, BMI, antihypertensive medication use and current smoking status. Subsequent candidate gene analysis identified five SNPs (rs7602215, rs3771724, rs1006502, rs1791926, and rs2258119) that interacted with discrimination and SBP, and three SNPs (rs2034454, rs7602215, and rs3771724) that interacted with discrimination and DBP. Most notably, there was a significant SNP × discrimination interaction for two SNPs on the SLC4A5 gene: rs3771724 (MLD: SBP $p=.034$, DBP $p=.031$; ED: DBP: $p=.016$) and rs1006502 (MLD: SBP $p=.034$, DBP $p=.030$; ED: DBP $p=.015$).

Conclusion: Our data add to the evidence supporting an association between SNPs in the SLC4A5 gene and increases in blood pressure in one of a number of sample populations of AA reporting similar results, thus showing the replicability of the SLC4A5 gene across various samples (Barkley et al., 2004; Taylor et al., 2012; Taylor, Sampson, Taylor, Caldwell, & Sun, 2013). Replication with similar epidemiological samples is required to determine the role of genes and psychological stressors in the development and expression of hypertension among this understudied population.

Effects of Perceived Racial Discrimination and DNA Methylation on Blood Pressure Among African-American Women

Veronica Barcelona de Mendoza, PhD, MSN, RN, APHN-BC, USA

Abstract

Purpose: Hypertension (high blood pressure) is the most frequently seen condition in primary care settings in the United States (James et al., 2014), affecting approximately 78 million adults (Go et al., 2014). African American females have the highest rate of hypertension (49%) compared to African American males (44%), White males (37%) and White females (32%) (Go et al., 2014). The etiology of hypertension is complex and though several biological, environmental and genetic risk factors have been established, few studies have examined the interactive effects that are unique to African American women. Independently, both discrimination and genetics have been associated with high blood pressure (Gravlee, 2009; Taylor, Sun, Hunt, & Kardia, 2010). Few studies, however, have examined how gene-environment interactions that may result in poorer health outcomes for African American women. Our hypothesis was that women with higher levels of racial discrimination will have elevated blood pressures, more deleterious methylation sites on proposed candidate genes, and women with more DNA methylation and higher levels of racial discrimination will have higher blood pressures.

Methods: Baseline data collected between April 2015 and January 2016 from the Intergenerational Impact of Genetic and Psychological Factors on Blood Pressure Study (InterGEN) were utilized for the present study (N = 81). InterGEN is an ongoing prospective cohort study in Connecticut that aims to examine the independent and combined effects of genetic and psychological factors on blood pressure among African American women and their three to five year old children over time. Full study procedures have been described elsewhere (Crusto, Barcelona de Mendoza, Connell, Sun, & Taylor, 2016; Taylor, Wright, Crusto, & Sun, 2016). To be eligible, women were: (a) ≥ 21 years old; (b) self-identified as African American or Black; (c) English speakers; (d) did not have a psychiatric or cognitive disorder; and (e) had a biological child three to five years old. Racial discrimination was measured using three scales: the Race-Related Events Scale (RES), Experiences of Discrimination (EOD) scale and the Major Discrimination (MD) scale. Blood pressure, height, weight, and saliva for DNA analyses were collected at

the initial study visit together with the measures of discrimination. Candidate gene analyses was utilized to study the relationship between discrimination and increases in systolic (SBP) and diastolic (DBP) blood pressure. Linear regression models were used to examine main effects of discrimination on blood pressure, controlling for age, education, and antihypertensive medication use. Multivariable linear regression models were also used to test for association between each SNP and the blood pressure phenotypes (i.e., SBP and DBP). Mixed linear models were used to test SNP × perceived discrimination interaction effects of SBP and DBP

Results: A total of 81 women contributed data for the present study. A total of 81 women contributed demographic, clinical and genomic data for analyses. Demographic data indicate (Table 1) that most women were between the ages of 30-39, had a normal BMI, and an annual household income of less than \$15,000. Women were most commonly insured by Medicaid (64%), followed by government/ACA insurance (19%) and private insurers (9%). Approximately 15% of women reported ever having received a diagnosis of high blood pressure (n=12) and fewer reported current hypertension medication use (7%, n=6). Most women had higher achieved some college or graduated college (60%). Mean systolic blood pressure was 113.1 mm Hg, and diastolic was 72.3 mm Hg. Overall, women reported relatively few experiences with discrimination based on the three measures (RES, EOD, and MD). A series of linear regression models were then run to examine main effects of experiences of discrimination on systolic and diastolic blood pressure. Models were adjusted for age, education and taking blood pressure medications. Race related events, experiences of discrimination (situational and frequency measures) and major life discrimination were not associated with systolic or diastolic blood pressure in unadjusted or adjusted models. Major life discrimination related to race was associated with a statistically significant increase in systolic blood pressure only ($\beta=4.00$, SE 1.8, $p=0.030$), but this effect was not sustained after adjustment ($\beta=1.73$, SE 1.4, $p=0.235$). Gene and gene-environment analyses will also be presented.

Conclusion: Preliminary analyses suggest that discrimination may be associated with blood pressure in our sample. Ongoing gene and gene-environment analyses will demonstrate whether an interactive effect is present.

Parenting Stress and DNA Methylation Among African-Americans in the Intergen Study

Michelle Wright, PhD, RN, USA

Abstract

Purpose: The experiences of parenting can cause stress related to work, life events, environment, marital relationship, daily hassles, and child rearing responsibilities. African American (AA) mothers have higher levels of parenting stress than mothers of European Ancestry (EA), which can contribute to adverse health outcomes in both child and mother. Parenting stress among AA populations has been correlated with risk factors associated with health disparities in AA populations. This suggests parenting stress may contribute to overall maternal stress, influencing health outcomes of the mother and child similar to other forms of psychological stress. For example, in a previous study we observed higher diastolic blood pressure in AA caregivers reporting higher levels of parenting stress (Jacquelyn Y Taylor, Washington, Artinian, & Lichtenberg, 2007). Chemical modifications to the genome that do not alter the nucleotide sequence may alter gene expression are referred to as epigenetic changes, and recent evidence has implicated epigenetic alterations, such as changes in DNA methylation (DNAm), in the pathogenesis of complex disease states (Wright, Ralph, Ohm, & Anderson, 2013). General life stress and financial stress, have been associated with altered DNAm in AA populations (Chen, Miller, Yu, & Brody, 2016), although the relationship between parenting stress and DNAm have not yet been described. The purpose of this study was to examine the relationship between maternal parenting stress and DNAm among African American mothers and their children.

Methods: This study evaluated epigenome-wide DNAm in 74 mother-child dyads involved in our current prospective study examining the intergenerational impact of genetic and psychological factors on blood pressure. Extensive details on recruitment and statistical methods have been described elsewhere (Crusto, Barcelona de Mendoza, Connell, Sun, & Taylor, 2016; J. Y. Taylor, Wright, Crusto, & Sun, 2016). Briefly, AA mothers were recruited from the community who had a child between the ages of 3-5 years of age. Baseline demographic data and the Parenting Stress Index – Short Form (PSI) (Abidin, 1995) was obtained via audio self-assisted interviewing software. Saliva samples were collected from mothers and children for DNAm analyses with the Illumina Infinium Methylation EPIC (850K) BeadChip. PSI scores were calculated per instructions in the protocol manual (Abidin, 1995). DNAm data were assessed for quality and preprocessing using an established analytic pipeline for DNAm array data (J. Y. Taylor et al., 2016). Descriptive statistics were completed to describe the sample and linear mixed models were used to evaluate DNAm (dependent variable) in mothers and children related to maternal parenting stress levels (primary independent variable) controlling for age and maternal smoking status. Models evaluating DNAm in children also controlled for sex of the child. All analyses were conducted in the R statistical computing environment controlling for cellular proportions significance was determined using a false discovery rate (FDR) of 0.05.

Results: Our maternal participants had a mean age of 32.35 years old and 24 percent indicated that they smoke cigarettes. The mean age of our children was 3.73 years old and 35 percent male. Significant variation in maternal DNA methylation in 95 CpG sites was associated with levels of parenting stress. Notably, the relationship between parenting stress and DNAm was inversely proportional at most sites (87%) had decreased DNAm with higher levels of parenting stress. Notably, we identified a change in DNAm associated with poly(ADP-ribose) polymerase-1 (*PARP-1*), which plays a key role in stress signaling. We did not identify any significant association with child DNAm related to maternal parenting stress. However, the observed DNAm patterns in the children mirrored DNAm patterns observed in their mothers.

Conclusion: Our study results suggest that parenting stress is associated with differential DNAm in mothers experiencing higher levels of parenting stress. Since the study did not collect multiple samples for DNAm over time, it is unclear if the DNAm differences observed were a direct result of parenting stress or were pre-existing differences that contribute to the mother's response or perceived level of parenting stress. Altered DNAm in *PARP-1* warrants further follow-up as the gene is known to play a key role in cellular function and response to stress. Alterations in the *PARP-1* gene have been associated with genome instability, shorter lifespans, and spontaneous tumors in animal models (Luo & Kraus, 2012). Further studies are needed to determine if differences in DNAm at *PARP-1* are associated with altered protein production or other measurable health effects.

J 08 - Improving Nursing Care and Outcomes for Patients Living With End-Stage Renal Disease

Sodium-Restricted Diets and Symptoms in End-Stage Renal Disease: A Randomized Controlled Trial

Maya Nicole Clark-Cutaia, PhD, ACNP-BC, RN, USA

Abstract

Purpose: The purpose of this presentation is to explore the effect of dietary sodium restriction on patient quality of life and hemodialysis related symptom profiles. Dietary sodium intake independently increases the risk of mortality in end stage renal disease (ESRD)^{1,2}. It plays a significant role in hypertension, hypervolemia, and left ventricular hypertrophy (LVH), and blunts the effectiveness of hypertensive agents³. In addition, the hypervolemia associated with excessive dietary sodium intake results in the need for more intense fluid removal during hemodialysis (ultrafiltration), resulting in symptoms such as pain, cramps, hypotension, nausea, and vomiting during hemodialysis (HD) treatment sessions^{4,5}. Although sodium restriction is a universal recommendation for ESRD management, the National Kidney Foundation (NKF) recommendation of 2400 mg per day is consensus-based per the Dietary Approaches to Stop Hypertension (DASH) studies, not an evidence-based recommendation from data derived from a hemodialysis population. In addition, The Dietary Guidelines for Americans 2010 and American Heart Association (AHA), recommend further restriction of dietary sodium intake to 1500 mg per day for persons with hypertension and/or kidney disease, middle-aged and older adults, and African Americans, though there is also little empiric evidence to support this recommendation in the general population and none in the hemodialysis population⁶. Therefore, it remains to be demonstrated that a diet with such sodium restrictions is attainable, sustainable, safe or beneficial.

Methods: We conducted a double-blinded randomized controlled trial of 42 ESRD patients undergoing hemodialysis therapy. Patients were randomized into one of three dietary sodium intake groups. Primary outcomes were quality of life and symptom scores as operationalized by the Kidney Quality of Life and Palliative Outcome Scale-Renal Assessments.

Results: There was no statistically significant difference in symptom scores, though participants reported clinical improvement in symptoms.

Conclusion: The findings from this study provides the first data from a randomized controlled trial on the effectiveness of reduced dietary sodium intake in hemodialysis patients to inform evidenced based practice, patient education, and nursing care quality.

Nurse-Sensitive Indicators and Patient Transition Safety in Outpatient Hemodialysis Units

Charlotte Thomas-Hawking, PhD, RN, USA

Abstract

Purpose: Outpatient hemodialysis centers are the most common site of long-term hemodialysis therapy for persons with ESRD in the United States (U.S.). Although hemodialysis in an outpatient setting is a routine mode of treatment, it is a complex and potentially hazardous procedure⁷. Patient shift changes in outpatient hemodialysis units occur several times a day and are high-volume, error-prone patient transition periods that can threaten patient safety⁸⁻¹⁰. These transition periods in hemodialysis units are associated with adverse events that have been independently linked with hospitalization and mortality in hemodialysis patients¹¹. Despite the patient safety challenges in outpatient hemodialysis units, little attention has been allocated to assessing the patient safety cultures of these health care settings. Consequently, there is little evidence on which to guide strategies to ensure patient safety during peak transition times. A concern expressed by nephrology nurse leaders, nurse managers, and staff nurses is the need for more attention on the impact of the contributions of nephrology nursing on quality of care, patient safety, and outcomes in settings where nephrology nurses provide care^{12, 13}. Thus, the impact of nurse-sensitive indicators (RN staffing, workload, hemodialysis practice environment support, adequacy of nursing care processes) on the safe transition of patients during these periods in outpatient hemodialysis units, merit attention. The purpose of this study was to 1) describe nurses' ratings of patient transition safety during patient shift changes and 2) examine the impact of nurse sensitive indicators on patient transition safety in outpatient hemodialysis units.

Methods: A secondary analysis of data collected in a sample of 422 registered nurses who worked in outpatient hemodialysis facilities in the United States was conducted. Multiple linear regression and ordinary least squares path analysis with bootstrap samples was conducted to examine direct and indirect effects of nurse-sensitive indicators on patient transition safety.

Results: High RN workloads, unsupportive dialysis practice environments, and missed nursing care were independent predictors of unsafe patient transitions. These variables explained 33% of variance in patient transition safety. Additionally, missed nursing care is an important operant mechanism (i.e., mediator) in the relationships between nursing structures (RN staffing, RN workload, practice environment support) and patient transition safety in outpatient dialysis units.

Conclusion: The findings from this study can inform the design and evaluation of innovative care models that target modifiable nursing structures and care processes to improve the safe transition of patients during patient shift changes in outpatient hemodialysis settings.

Stakeholder Perspectives on Care Transition Needs of Patients on Hemodialysis Therapy

Olga F. Jarrín, PhD, RN, USA

Abstract

Purpose: Rehospitalization rates among ESRD patients are twice that of the entire Medicare population and a third of those cases occur among young patients between 20 and 44 years of age.¹⁴ The purpose of this study is to understand the factors associated with frequent and potentially avoidable hospitalizations within the hemodialysis patient population from the perspectives of patients and their family caregivers, as well as interdisciplinary healthcare providers from both outpatient and inpatient settings.

Methods: We used an exploratory study design with mixed qualitative methods that included structured interviews with patients and caregivers, focus groups with health care providers, and research collaborations to maximize our understanding of factors associated with potentially avoidable hospitalizations among patients on hemodialysis. Patient demographic and clinical information was collected through chart review and a pre-interview oral survey including the Kidney Quality of Life and Palliative Outcome Scale-Renal Assessment^{15, 16} for patients, and Coleman's Family Caregiver Tools¹⁷ to assess self-efficacy, caregiver burden, and engagement in care. Interviews were conducted with 20 patients and 10 family caregivers in a large, outpatient hemodialysis clinic. Multiple focus groups were held with four renal physicians, five registered nurses, a patient care technician and five health care professionals including social workers, nutritionists, and a nurse practitioner working in the hemodialysis outpatient setting. Descriptive and thematic analyses were conducted and preliminary findings were presented in a second round of focus groups with health care providers to clarify meaning and interpretation of multiple, and at times conflicting, participant perspectives.

Results: Caregivers reported high self-efficacy and involvement in caregiving. Health care providers identified socio-economic and community factors that contribute to poor patient outcomes, and identified organizational policies, procedures, and systems factors that may contribute to poor patient outcomes. Personal relationships between groups of patients, and between patients and staff, promote better patient outcomes, potential to enhance and leverage social aspect of hemodialysis care to improve outcomes. In addition, there may be potential for expansion of palliative and hospice care and expansion of integrated nutrition and sleep hygiene.

Conclusion: The findings from this study and recommendations for expanded nursing care models can inform the development of a nurse-led transitional care and home visiting program^{18, 19} to support care transitions in the hemodialysis patient population.

J 09 - Translational Research: Dissemination and Implementation of Interventions From Research to Practice

Implementation of Project Students are Sun Safe (SASS) in Rural and Underserved High Schools

Lois J. Loescher, PhD, RN, FAAN, USA

Abstract

Background: Skin cancer is a major public health issue in the US and Arizona with overexposure to ultraviolet radiation (UVR) a known cause. Most people living near the rural Arizona-Mexico border are Hispanic; skin cancer incidence is rising within that population. Youth are prone to UVR overexposure and increased skin cancer risk, yet few skin cancer prevention programs target rural and underserved youth. Schools are ideal intervention settings, but teachers have limited time and resources to provide skin cancer prevention education. For 5 years, health educators and researchers at the University of Arizona (UA) have successfully implemented Project Students are Sun Safe (SASS) in urban schools. In the current model, UA health sciences students (peer leaders) take a one-semester skin cancer prevention academic course, consisting of online modules on skin cancer epidemiology, types, prevention and communication, followed by in-person skills training and evaluation. Trained peer leaders implement, in community classrooms, a brief PowerPoint™ SASS lesson (basic epidemiology, skin structure, skin cancer types, UVR and protection strategies, and tanning consequences), reinforced by three interactive activities. Adapting this model for high school students will allow further dissemination of SASS.

Purpose: To: a) adapt the SASS hybrid training for high school student peer leaders (accounting for culture, age, developmental stage, and literacy); b) engage the trainees to implement SASS in rural, border-area classrooms; c) evaluate feasibility and effectiveness of the peer training and the peer-to-peer education; and d) sustain SASS within the community.

Methods: Using a CBPR framework, our UA research team and community stakeholders adapted the SASS training modules and classroom lesson. Eighteen students from three border-area high schools completed the online training and online pretest and posttest measuring skin cancer prevention knowledge, attitudes, beliefs and behaviors.

Results: The majority of trainees were female, Hispanic, and had skin cancer risk factors: 83.3% lived in Arizona for 14+ years, and over 70% reported fair skin and propensity to sunburn, with 35.3% having two or more sunburns in the past 12 months. Following training, sun-safety knowledge improved ($p = .002$), perceived seriousness ($p = .000$) and risk ($p = .02$) were more favorable, and self-reported sun safety behaviors improved, including wearing a wide-brimmed hat ($p = .005$), applying SPF 30+ sunscreen, and wearing sunglasses (both $p = .000$). From December 2016 to April 2017, the trainees will implement SASS to about 500 peer students in border-area classrooms; we anticipate that 250 will complete pretest and the posttest evaluations by May 2017.

Conclusions: We successfully adapted SASS sun-safety training to Hispanic youth who had stronger skin cancer risk factors than we anticipated. We will report findings of SASS implementation in classrooms. Our community partner ultimately will integrate the SASS training into its menu of student training activities to sustain dissemination into rural and underserved communities.

Implementation of a Diabetes Self-Management Intervention for Mexican-American Families in the Arizona-Mexico Border Region

Marylyn M. McEwen, PhD, RN, FAAN, USA

Abstract

Background: The 50 million Hispanics who represent 16% of the U.S. population are disproportionately affected by diabetes (12.8%) when compared to non-Hispanic Caucasians (7.6%). The chronic and complex trajectory of type 2 diabetes (T2DM) requires daily engagement in self-management activities and occurs in a family environment. Diabetes self-management education and support (DSME/SS) builds knowledge, skills and abilities for successful T2DM self-management, decreases A1C and weight, reduces A1C by 1%, has a positive effect on other clinical indicators and health care costs. But, there is a paucity of evidenced-based lifestyle modification programs tailored to Hispanic culture and integrate family members into the intervention. We report on the refinement and testing of a 3-month culturally tailored family-based T2DM DSME/SS intervention on behavioral and biological outcomes.

Purpose: The purpose of this study was to refine, expand (Phase I), test and evaluate the effectiveness of a culturally tailored family-based intervention to improve behavioral and biological outcomes for Hispanic adults with T2DM and their family members (Phase II).

Methods: In Phase I we used a CBPR approach to engage a Family Action Board (FAB) (n=24) to refine and expand a culturally tailored individual-based T2DM DSME/SS intervention to a family-based intervention. In Phase II we used a randomized, two group experimental design, participants with T2DM and a family member (n=87 dyads) completed questionnaires, biological measurements, immediately following intervention, and at 6 months post intervention.

Results: The FAB participated in intervention revision, improving the reach of the family level intervention. Participants with T2DM ranged in age from 38 to 73 (M=54, SD=9); family members from 18 to 88 (mean=48, SD=16), most had less than a high school education (73% participant; 53% family member), family income was \$20,000 or less (69% participant; 58% family member). Participants had significant intervention effects for total self-management activities (p=.001), total self-efficacy (p=.003), and total diabetes distress (p<.001) with self-management and self-efficacy being sustained for 6 months. Family members had significant intervention effects for total family self-efficacy (p=.016), pedometer steps (p=.016), and pedometer miles (p=.008) with family self-efficacy being sustained for 6 months.

Conclusions: We are in the second translational research phase. We used CBPR to improve the reach of the study and promotoras and a diabetes educator to improve intervention effectiveness. Further research is required to strengthen the impact of the intervention on targeted outcomes before dissemination and adoption of the intervention can occur.

Dissemination and Implementation of Colon Cancer Screening Program for Latinos Living Near the U.S.-Mexico Border

Laura Szalacha, EdD, RN, USA

Abstract

Background: The recent trends in increased colorectal cancer (CRC) screening test utilization are not mirrored in poor and minority populations. CRC screening rates are particularly low for those who do not identify a primary care provider or clinic and who also have lower levels of education, income, and insurance. We will detail this process of conducting a dissemination and implementation study in the context of our present funded D & I program: Navigation from Community to Clinic to promote CRC Screening in Underserved Populations (*Navegantes por Salud*).

Purpose: Combing two successful programs of research, we developed and tested a community to clinic tailored navigation intervention using a dissemination (randomized phase) and implementation (non-randomized phase). The final outcome measured was a) clinic attendance and, b) CRC screening. We also examined the roles and responsibilities of the statistician and/or methodologist in a D&I study and how those procedures and practices differ from those in a randomized control trial. This includes the design of a study, appropriate models or theoretical frameworks, frameworks for evaluation (i.e., RE-AIM), measurement issues, concerns of fidelity and re-invention or adaptation of successful interventions and the diffusion of innovation principles.

Methods: We randomized 232 sites to General Education +Tailored Navigation and 116 General Education only. In phase one, all participants received group education on cancer screening and risk. Those in the general education group received up to 5 reminder calls, and those in the navigation group received up to 10 calls from navigators who assisted them with barriers using a tailored message bank. In phase two, all those who attended a clinic received tailored navigation from a trained study navigator, through a combination of in-person meetings and phone calls.

Results: Of the 389 people enrolled, 25% made clinic appointments and of those, 61% complete colon cancer screening. We will frame our discussion with the 5 core values for D & I proposed by the NIH: rigor and relevance, efficiency, collaboration, improved capacity, and cumulative knowledge with specific examples from the present D & I study.

Conclusions: As such we have demonstrated that community-engaged cancer screening programs in Arizona are feasibility and acceptability (*Reach*), are *Effective*, and that *Adaptation* is necessary for success.

Dissemination and Implementation of a Cervical Cancer Screen and Treatment Program in Ethiopia

Usha Menon, PhD, RN, FAAN, USA

Abstract

Background: Cervical cancer incidence and mortality are rising in Ethiopia. With low resources for cancer treatment and no population-based screening program in the country, prevention of cervical cancer is a key strategy to decreasing incidence. Approximately 95% of women have never been screened for cervical cancer. Visual inspection with acetic acid followed by cryotherapy or Loop Electrosurgical

Excision Procedure (LEEP) treatment is an efficacious and accepted method for cervical cancer control in low and middle income countries.

Purpose: The purpose of this presentation is to describe dissemination and implementation research in the context of a cervical cancer screen and treat program in Gondar, Ethiopia.

Methods: A non-profit US organization called GO DOC GO trained 17 nurses and physicians to perform visual inspection with acetic acid (VIA), cryotherapy, and LEEP. The program was implemented at the University of Gondar, Ethiopia, GYN clinic in October, 2014. Providers were trained over 3 days with half a day of pathophysiology and clinical presentation followed by two and half days of observation and supervised procedures.

Results: All women offered the program accepted and 402 women were screened. The incidence of pre-cancer and invasive cancer was 36% (n=142) and 15% (n=6), respectively. In logistic regression models predicting cervical lesions, controlling for age and education, each pregnancy was associated with 11 times the odds of presenting with lesions (CI=113-121, $p<0.01$). Controlling for age, education and parity, those with an HIV diagnosis had 3.24 times the odds of presenting with lesions (CI=190-550, $p<0.0001$) than those with out a diagnosis of HIV; 2 people were referred for additional testing and diagnoses.

Conclusions: The SVA program was safe, acceptable, and feasible in Gondar city, Ethiopia. Challenges were garnering the trust of women; establishing partnership with providers; IRB approvals across multiple institutions; Translation to ensure content equivalence; Shortage of materials such as acetic acid, purified CO2 gas, and LEEP wires, and inadequate space and occasional power interruption.

J 10 - Advancing Science in Community-Engaged Research: Increasing Capacity to Reach Diverse Populations and Address Health Disparities

Community-Engaged Strategies for Recruitment and Retention of Asian Immigrant Women in a Church-Based Randomized Trial

Hae-Ra Han, PhD, RN, FAAN, USA

Abstract

Background: Ensuring adequate representation of underrepresented populations in clinical research is an essential part of the recruitment and retention process. To achieve this goal, it is vital that researchers engage stakeholders that serve or represent these communities in the development, implementation, and evaluation of recruitment and retention strategies. Cumulative evidence suggests that effective community engagement can overcome social and structural barriers to clinical research participation such as mistrust, stigma, or lack of adequate health knowledge that are common among ethnic minority communities (Centers for Disease Control and Prevention, 2011). Community engagement occurs via an iterative process by actively soliciting the knowledge, experience, and values of selected individuals to represent a broad range of interests including recruitment and retention (George, Duran, & Norris, 2014). Community health workers (CHWs) have been noted as an effective recruitment and retention agent when targeting culturally and linguistically isolated ethnic minority women for cancer screening intervention programs. Yet, there is little published documentation about recruitment and retention strategies used by CHWs as a key group of interest in research.

Purpose: The purpose of this study was to explore effective recruitment and retention strategies used by CHWs in a church-based randomized clinical trial designed to promote breast and cervical cancer screening among Korean immigrant women in the United States.

Methods: We conducted 4 focus groups with 23 CHWs who enrolled Korean immigrant women in a church-based randomized trial to promote mammogram and Papanicolaou tests and retained them for 6 months (Han et al., 2016). Trained bilingual research assistants conducted interviews in Korean. Using an inductive content analytic approach, focus group data were analyzed. Two trained research assistants worked independently to identify common themes across focus groups.

Results: Four themes emerged in relation to effective strategies for recruitment: personal networks, formal networks at churches, building on trust and respect, and facilitating a nonthreatening environment. These main themes characterized CHWs' experiences related to recruitment through seven relevant subthemes: approaching people that I know, building on existing church groups, expanding personal network through referrals, public announcement in church bulletin/newsletter or by pastor, use of church directory, dovetailing an existing meeting or random encounters (often with food), and kind explanation/making them comfortable. The themes related to effective retention included: trust and realizing benefits. These themes were supported by five subthemes: good existing relationship, CHW competency, genuine attention and care, contributions to the church, and fulfilling additional needs of the participants using community resources.

Conclusions: The findings suggest that qualified, well-trained CHWs can recruit and retain hard-to-reach immigrant women in a randomized trial by using multiple culturally sensitive strategies. Most themes identified in the study pertained to varying types of quality and characteristics of the CHWs; hence, for successful recruitment and retention, CHWs in a randomized intervention trial should be active, trustworthy, and culturally sensitive in their community. Addressing benefits of the participants and responding sensitively about their needs was also confirmed as useful retention strategies in this study. Sufficient training and ongoing support for CHWs would be important for CHWs to expand their social networks beyond immediate personal networks, maintain trust relationships, and help participants realize the benefits of study participation.

Training and Consultation are Effective Strategies to Build Capacity for Community Engaged Research

Cheryl Dennison Himmelfarb, PhD, RN, ANP, USA

Abstract

Purpose: There is increasing recognition and acceptance that traditional research approaches have, for the most part, failed to solve rising health disparities. To address the complexity of factors contributing to health disparities, we must conduct research that better reflects the context of individuals' experience and lives through meaningful engagement of individuals and communities in the research process. Community engaged research (CER) requires that communities have the capacity to participate as full partners; communities are consulted for their research priorities; all stakeholders are respected, valued and rewarded for their time and expertise, effective implementation and dissemination strategies, and public support for research (NIH 2016; Ahmed & Palermo 2010; Michener 2012). A CER approach can enable researchers to conduct research and produce results which may be more directly translated to improve health and eliminate disparities thus positively impacting the health and well-being of communities. The body of science supporting CER is growing and there is a need at most institutions to build capacity for use of CER methods. The purpose of this paper is to describe institutional efforts to build capacity for CER among researchers, students and our local community through education and training, establishment of translational research communities for investigators, and the development of Community Research Advisory Councils (C-RACs) and report iterative evaluation data and implications for future capacity building efforts..

Methods: We have applied a multi-prong strategy to build capacity for CER. Through the Johns Hopkins Institute for Clinical and Translational Research (ICTR), we have implemented the following strategies: 1) Offer expert consultations, trainings and resources to better equip faculty, staff and students to collaborate with community on research activities, and 2) Support activities that promote the meaningful involvement of patients and community members throughout the research process—from topic selection through design and conduct of research to dissemination of results. CER consultations provide researchers the opportunity to meet with a panel of community members to obtain feedback and guidance at any stage of the research process. The CER consultations are conducted by the C-RAC's Research Review Committee, a panel of community member stakeholders - with key insights and knowledge of patient/community experience, interests and research design. The panel includes health professionals, community leaders, communication specialist, patient advocates, students, and local residents.

The two C-RACs are fully supported by the ICTR: Johns Hopkins East Baltimore and Johns Hopkins Bayview. In the past year, we have conducted the following three training workshops. 1) In the "Dissemination Workshop: How to Communicate and Share Research Findings with the Public", we described the role of dissemination in the research process and effective dissemination plans. Attending

were 80 participants representing 16 advisory boards and 12 community based organizations. 2) In the “Nuts & Bolts of Community and Patient-Engaged Research” training, we provided an introduction to community-based participatory research principles, patient engagement, role of community members in research, and strategies to improve dissemination. There were 150 attendees (53% JHU researchers/students, 47% members of the community). 3) In the “Community-Engaged Recruitment” workshop, we provided introduction to community-based participatory research principles, patient engagement, and role of community members in research, with specific guidance on effective approaches to enhance research participant recruitment and retention efforts. Attendees included 180 research staff and investigators engaged in research participant activities.

Results: The two C-RACs were formed in 2009 and are fully supported by the ICTR: 1) Johns Hopkins East Baltimore (25 members) and Johns Hopkins Bayview (18 members). C-CRAC membership has evolved and we see a need enhance the diversity of membership in terms of ethnic and racial identity as well as representation of additional stakeholder groups. C-RAC members have identified the need for additional training in the community advisory board member role, with more intense training for those interested in serving as co-investigators (e.g., on PCORI projects) as well as the need for the ICTR to establish a directory of community research advisory councils at JHU to facilitate communication and coordination of CER activities. Investigators initiating CER consults reported that the service provided an efficient and effective approach to engaging communities in research. Several have sought ongoing feedback on their study design, implementation and evaluation through the consult service. We also identified the need to better prepare investigators to respectfully communicate with C-RAC members.

Participants in the various trainings stated that the description of CBPR principles, hearing the ‘how I did it’ part, learning about the social problems community partners face, and learning how to identify community assets through a case study example were the most useful approaches. In addition, respondents identified hearing from community members during panel discussions, breakout sessions through which they were given a chance to work on CBPR projects, and learning how research positively impacts the community as the features that they most valued. However, some noted researcher resistance to the suggestions offered by community participants during the breakout sessions. C-RAC members rated the topics discussed as very useful for their work (93%) with the most useful information identified to be the list of questions used to assess the risks and benefits of research. They reported an opportunity to apply what they learned to research projects (64%) and reported increased capacity to evaluate risks and benefits of health research (72%). Respondents recommended that future workshops describe the full continuum of research process from planning (development of a research question) to community dissemination of research results, protection of study participants as well as additional time to network.

Conclusions: The C-RAC provides a valuable platform to support CER. However, both C-RAC members and researchers require training to maximize benefit. Practical training targeting audiences with didactic and hands-on activities can be a useful tool to enhance capacity of academic and community partners for CER. Furthermore, our evaluation suggests that the training contributed to an increase in capacity and confidence of CAB members. Evaluation of long-term impact of CER trainings that involve academic and community partners together—such as ours—on the development of sustainable community-based research efforts is warranted. Evaluating the longer term impact of educational workshops is needed to prioritize and provide rationale for continuing to offer trainings and guide the trainers in selection of topics and skill building exercises for future trainings.

Church-Based Recruitment of African Immigrants: Evidence and Lessons Learned from the Afro-Cardiac Study

Yvonne Commodore-Mensah, PhD, RN, USA
Joycelyn Cudjoe, BSN, RN, USA
Cheryl Dennison Himmelfarb, PhD, RN, ANP, USA

Abstract

Purpose: The United States (US) is experiencing its highest immigration rate since the 1930s. African immigrants (AIs) are a growing yet understudied immigration population in the US. The Migration Policy Institute estimates a 40-fold increase in the size of this population between 1960 and 2007, from 35,555 to 1.4 million.¹The existence of hundreds of African-initiated churches signifies the growing demographic importance of AIs in the US. AIs have created their own social, cultural and religious institutions to meet their needs as they face the challenges of integration into the US society. Churches go beyond the fulfillment of spiritual needs and serve as an important avenue to foster their social and cultural identity in AIs. Because a large proportion of AIs attend churches on a regular basis, churches may be a promising venue for understanding the cardiovascular health and health needs of AIs.

Historically, AIs and African Americans have been studied as a homogenous racial group, although health outcomes may differ due to differences in socioeconomic status, culture and genetic admixture.²Given the growing size of AIs, a paradigm shift in approach to research, gathering health information and program planning is required to reflect the diversity of Blacks in the US. Like other immigrant groups, AIs experience many challenges to maintaining ideal cardiovascular health upon migrating to the US. They face challenges with obtaining adequate health care coverage, access to needed healthcare services and navigating the complex US healthcare system.

Methods: In this presentation, we will discuss the evidence and lessons learned from the Afro-Cardiac Study³, a cross-sectional epidemiological study of Ghanaian and Nigerian-born AIs residing in the Baltimore-Washington, D.C metropolitan area. We recruited participants from seven churches that serve the AI population in the US to accomplish the study goal of examining the cardiovascular disease risk of AIs and the association with acculturation. The evidence and lessons learned from this study are outlined below.

Results: Churches are feasible settings for engaging AIs in community-based research: Churches and other religious institutions are increasingly popular settings in which to conduct community-based research because they are relatively stable institutions with frequent attendees over many years. Churches provide timely and cost-effective access to a rapidly changing population of new AIs. Several of the churches that participated in our study included health as part of their mission and had existing and robust health ministries which assisted with coordinating the recruitment of participants for the study. Since churches attendees are from diverse socioeconomic backgrounds, in the Afro-Cardiac Study, we were able to recruit a sample that spanned the socioeconomic ladder including homemakers, taxi drivers, lawyers, educators, nurses, technicians and physicians.

Religious leaders play an integral role in recruitment of AIs: Engaging religious leaders in the AI community is an essential step in community engagement. In our experience, leaders of churches that serve the AIs were eager to meet a variety of social and health needs of their congregation and surrounding community. They served as gate-keepers to ensure that the research procedures did not unduly burden the congregation and provided tangible benefits. They believed that assisting with the medical needs of their members was an important aspect of their mission. The leaders were aware of, and described several health needs of their congregations including hypertension management and control as well as healthy weight maintenance. The leaders understood the importance of the

dissemination of research findings, and also requested that we give presentations to the congregation on topics related to cardiovascular health.

Partnership development and building trust is critical: Recruitment of participants into community-based research is particularly challenging when working with AIs who traditionally have not been well served by health programs or research. A critical step in recruiting participants from the AI community is establish trust and credibility within the community. The endorsement of the research by the community leaders afforded credibility to our research. Since a number of AIs may not have legal status, it is important to communicate that maintaining confidentiality is an important component of the proposed study and that data will be published and reported on the aggregate level. Methods to ensure confidentiality must be clearly communicated and enforced through-out the research study.

Research procedures should be time- and resource-efficient: It is important that research procedures are efficient and require minimal time commitment by the church and congregation. The principal investigator should ensure that the size of the research team is adequate to ensure that the research procedures are completed within the allotted time for the study. Creating a standardized protocol and providing training opportunities for all the research team members is critical to ensure data integrity and efficiency of procedures. The research team should make every effort to minimize disruptions of the church service unless permission is granted by the church leadership.

Limitations: There are limitations and challenges to consider in using churches as recruitment sites for research. Participants recruited from churches may not be representative of the larger AI population. Participants in our study may have underreported smoking behavior due to social and religious desirability, and health behaviors of church attendees may differ from non-attendees; these aspects may limit the generalizability of our results. Smaller churches may not have adequate space for research procedures. Hence, the research team should meet in advance with the church leadership to determine space needs and strategies for overcoming this challenge.

Conclusion: In summary, churches or religious institutions provide a familiar and reassuring environment for targeting high risk or “hard to-reach” groups such as AIs. Our experience in the Afro-Cardiac Study suggests that churches have a high potential to play an important role in the health of AIs. Hence, health-care providers, researchers and community-based organizations should consider this setting as a viable avenue for engaging AIs in research and delivering and testing culturally-sensitive interventions to improve cardiovascular health and other health conditions.

Contribution of Community-Research Advisory Councils to Research Institutions: An Effective Strategy to Inform Community-Engaged Research

Sabianca Delva, BSN, RN, USA

Abstract

Purpose: To describe strategies on how to partner with community-research advisory councils to inform community-engaged research.

Methods: The Johns Hopkins Center for Clinical and Translational Research organized the Community Research Advisory Council (C-RAC) to serve a representative group of key stakeholders of the East Baltimore city and Bayview community. The C-RAC was designed to ensure that research proposals are relevant and responsive to the priorities of target populations in the Baltimore community by seeking input from patients, families, healthcare professionals, advocates, and stakeholders who live, work, or serve a specific target population. The council chapters meet four times a year with researchers and conducts community related events and programs throughout the year (i.e. disaster preparedness education, blood pressure screenings and flu vaccine inoculation) throughout the year in partnership with academicians. The mission of the C-RAC is to safeguard the health of Baltimore City residents while supporting the advancement of patient centered research within the Johns Hopkins institution. The C-RAC carries out its mission by 1) evaluating and reviewing health research, 2) informing researchers about community interests and preferences, 3) sharing health and research information and 4) supporting community and faith-based projects. To facilitate attendance, meetings are held in the evening to ensure optimal representation of all interest groups.

Results: Since their establishment in 2009, the Johns Hopkins East Baltimore and Bayview community research advisory councils have informed Hopkins researchers on multiple research projects in the recruitment, cultural sensitivity, research design and dissemination phases of their proposed projects. They have contributed to repairing the strained tie between the Hopkins institution and its surrounding community. They have been a part of the movement to improve the health of Baltimore city residents by conducting health fairs and by providing education to vulnerable populations within the community.

Conclusions: Research institutions should aim for synergistic collaboration with community research advisory councils for developing and maintaining partnerships within their respective communities and to eliminate health disparities, especially when employing a CER approach.

J 11 - Nursing Research on Sexual Assault: Utilizing Data to Increase Knowledge and Improve Practice

Descriptive Study of 2,300 Sexual Assault Victims: Identifying Vulnerabilities to Promote Healthy Communities

Leslie W. Miles, DNP, APRN, PMHNP-BC, USA

Abstract

Purpose: According to a United States survey, nearly 1 in 5 women and 1 in 71 men reported being raped at some time in their lives (Black et al., 2011). Population surveys from different countries indicate sexual violence rates vary from 15% to 71% (World Health Organization [WHO], 2016). The negative consequences of sexual assault have been well documented worldwide. The WHO (2016) reported increased poor physical health effects including abdominal pain, back pain, fibromyalgia, gastrointestinal disorders, headaches, limited mobility and poor overall health. Adverse mental health outcomes (posttraumatic stress disorder [PTSD], depression, substance abuse and use) associated with sexual assault are also well documented (Zinzow et al., 2011; Zinzow et al., 2012). To combat sexual violence, studies are needed to increase our understanding of this crime and its victims through aggregated descriptive data.

There are very few studies exploring descriptive data on sexual assault victims and crime factors obtained from forensic medical examination charts. One large-scale study of 1,172 patients seen for forensic examination following sexual assault found that victims were more likely to be female, young (less than 25 years of age), and acquainted with the perpetrator (Avegno, Mills, & Mills, 2004). A similar study of 2,541 female victims seen for a forensic examination in Denmark were found to be primarily young (15-24 years) and to have known the perpetrator (Larsen, Hilden, & Lidegaard, 2014).

Exploring descriptive data regarding victims of sexual assault helps to identify vulnerable populations, an initial first step in developing prevention strategies. In this study, the following descriptive data of victims was collected: age, gender, race, alcohol and/or drug consumption, prior history of mental and physical illness, and prior history of sexual assault.

Data on rape crime factors provides information on variables related to the crime and suspect. The following descriptive data on rape crime factors was collected: relationship between victim and suspect, degree of lethality (strangulation, physical force, and use of a weapon), physical injuries, anogenital injuries, multiple suspects, and suspected drug-facilitated assault.

In many countries, specially educated health care providers care for victims of sexual assault. In the United States, sexual assault nurse examiners (SANE) are usually the first medical contact for victims, post assault. However, victims have contact with a variety of professional care providers, including nurses, prior to becoming a victim. All health care providers have a professional responsibility to understand the phenomena of sexual assault by using available data. With an increased understanding of the specific vulnerabilities for being a victim of sexual assault, nurses are positioned to identify populations at risk, educate individuals and communities, and implement evidence based practice prevention strategies.

Methods: Setting: Four sites in the western United States with established SANE programs providing 24/7 care for victims of sexual violence. All sites have a 4-year university with campus police.

Sample: Retrospective, exploratory study design with data obtained from hard copy charts of Sexual Assault Examination Forms (2010-2014) completed by SANEs when providing care to sexual assault victims ($N = 2,350$). Inclusion criteria: a) adolescent or adult sexual assault victims, ages 14 and older; b) completion of full forensic examination including written history of assault and sexual assault kit collection by SANE c) assault occurred in the State, d) assault was reported to law enforcement.

Methods: De-identified data was coded into SPSS software for statistical analysis by the research team of four investigators. Ten percent of the examination forms were recoded to ensure reliability of at least $\kappa > .80$, with a final κ across all variables of .955, indicating high reliability of the data. Chi square analysis explored the associations between the variables.

Self-reported mental illnesses were categorized according to groupings as listed in the *Diagnostic and Statistical Manual of Mental Disorders, IV- TR (DSM-IV)*. Data about preexisting mental health conditions was also derived from self-disclosure about current medications. Psychotropic medications were then coded into common classification and uses categories.

Results: The age of victims ranged from 14-93 years, with 45% of the victims from 17 to 24 years old. Minorities with higher amounts of victimization included black victims (3.4% compared to census finding of 1.3% in Utah population) and American Indian victims (2.9% compared to census findings of 1.2% in Utah population). Less than half of the victims reported alcohol consumption (47%) and drug use (12%). Almost one-third of the victims reported prior history of sexual assault.

A significant number of sexual assault victims (35%) reported a current history of mental health illness. Over 40 % of victims were currently taking psychotropic medications (antipsychotics, anti-anxiety, antidepressants, mood stabilizers, stimulants, and sleep aids). When compared to a United States mental illness prevalence rate of 18% (SAMSHA, 2012), the study finding of a 45% rate of mental illness in one western state is extremely high. The most frequently identified mental illnesses included: depression 19.6%; anxiety 14.3 %; bipolar 8.1%; posttraumatic stress disorder 4.8%; and psychotic disorders 2.2%.

Overall, psychotropic medication use in the study population was higher (40 % versus 15%) compared to the only available national medication data source (Medco, 2010). Common medication classes were: antidepressants (34.5%), anti-anxiety (19.5%), atypical antipsychotics (12.8%); bipolar (11.4%); sleep aid (11%), and stimulants (6.3%). Each of these medication category findings were higher than reported data (Medco, 2010). Results are indicative that having a current mental or physical illness increases a victim's vulnerability to being sexually assaulted.

Stranger assaults accounted for 18% of the sexual assaults with the majority of the assaults perpetrated by known suspects: acquaintance (60%), spouse/partner (7%), other known relationships (5%, such as family member, boss or teacher), and ex-boyfriend (5%). The variables assessing increased lethality in sexual assault cases were weapon involved (10% of cases) and strangulation (12% of cases). Multiple suspect rapes occurred in 10% of the cases, while suspected drug-facilitated assaults occurred in 17% of rapes. Physical injuries were documented in 74% in cases and anogenital injuries noted in 60% of cases.

Conclusion: Unfortunately, sexual violence is widespread in our global society. The findings from this study aid in our understanding of sexual assault victims and crime factors. It was found that a high percentage of victims were between the ages of 17-24 years, indicating higher degree of vulnerability for this younger age group. Races with increased victimization included Black Americans and American Indians. A key finding in this study was the increased percentage of victims who self-disclosed mental illness and use of psychotropic medications. These research findings suggest that persons who suffer with any mental illness (mild to severe) are at higher risk for being a victim of sexual assault. These findings have important future clinical and research implications to develop evidence based nursing care practices and in implementing community prevention strategies for identified vulnerable groups in our population. The findings on rape crime factors confirm that most sexual assault victims know the suspect. Community education programs on healthy relationships may be instrumental in decreasing sexual violence.

Understanding Peri-Traumatic Symptoms of Sexual Assault: Transforming Nursing Care of Victims World-Wide

Linda Mabey, DNP, RN, PMHCNS-BC, USA

Abstract

Purpose: Sexual assault is a world-wide mental and physical health epidemic (Dartnall & Jewkes, 2013) and often results in peri-traumatic symptoms, such as loss of memory, or changes in consciousness or awareness (van der Kalk, 2014). Nurses across the globe treat victims of sexual assault and need to be knowledgeable about peri-traumatic symptoms of sexual assault in order to provide evidenced-based care. The purpose of this presentation is discuss how the care of sexual assault victims can be transformed through improved understanding of the prevalence of peri-traumatic symptoms, and the alterations in brain function that underlie these symptoms (Valentine, Mabey, & Miles, 2016, Wheeler, 2014). The presentation is based on the results and implications of a large retrospective chart review ($n=2350$) of sexual assault nurse examiner records, exploring the prevalence of peri-traumatic symptoms of sexual assault, and factors associated with vulnerability to them. Background information on the neurobiological mechanisms which produce peri-traumatic symptoms will be discussed, and nursing implications will be explored utilizing a case study. Next steps in improving the care of sexually assaulted will be proposed.

Methods: A retrospective chart review of 722 sexual assault victims was completed to identify peri-traumatic symptoms from written statements by sexual assault nurse examiners on a chart section inquiring about victims' reports of loss of consciousness or awareness. Themes related to victims' disclosures of peri-traumatic symptoms were identified from both male and female victims using Nvivo10 software. The emerging themes included loss of consciousness, alteration of awareness, memory loss, tonic immobility, and dissociation from self and/or environment. These themes were then coded as variables in SPSS for analysis of study sample of charts from 2,350 sexual assault victims. Frequencies were calculated for variables measuring peri-traumatic symptoms. These themes were then transferred as variables into SPSS to calculate frequencies. Chi-square tests of association were completed to identify factors associated with loss of memory or change in consciousness or awareness. Logistic regression was conducted on the predictor variables with statistical significance from the Chi-square tests of association. The logistic regression model was especially important to explore if the predictor variables explain all of the occurrence of changes in or loss of consciousness, awareness or memory, or if there

might be other factors such as the neurobiological effects of sexual assault trauma that influence changes in or loss of consciousness, awareness or memory.

Results: The majority of sexual assault victims (54%) who had a forensic examination reported loss of memory, or changes in consciousness or awareness. Themes identified from victims' statements about loss or change in consciousness or awareness included loss of consciousness, changes in feelings of awareness, memory loss, symptoms of dissociation, and symptoms of tonic immobility. Factors associated with peri-traumatic symptoms of memory impairment and loss of consciousness or awareness identified through Chi-square tests of association were: use of drugs prior to the assault ($X^2 = 9.645$, $df=1$, $p=.002$); use of alcohol prior to the assault ($X^2= 126.011$, $df = 1$, $p= .000$); suspected drug facilitated assault ($X^2= 178.246$, $df = 1$, $p = .000$); strangulation ($X^2= 208.610$, $df = 2$, $p= .000$); and history of sexual assault prior to age 14 ($X^2= 7.100$, $df = 2$, $p = 0.029$). The logistic regression model predicted 71.5% of the cases in which victims reported a loss in consciousness or awareness, but failed to classify 28.5% of the cases. These results indicate variables not measured in this study impact victims' peri-traumatic loss of consciousness or awareness during a sexual assault.

Conclusion: The findings from this study indicate that a significant portion of victims, 28.5%, reporting peri-traumatic symptoms following sexual assault of loss of consciousness and memory loss have these symptoms without the statistically significant predicting variables of use of alcohol or drugs, suspected drug-facilitated assault, and strangulation. We postulate that the victims experience loss of or changes in consciousness and memory loss due to the brain's response to the traumatic event of the rape. Peri-traumatic symptoms have significant consequences for sexual assault victims, including rendering them unable to defend themselves at the time of the attack and difficulties describing the attack to health care providers and law enforcement personnel. Nurses should conduct sexual assault victim interviews and examinations with the knowledge of how peri-traumatic symptoms present, and provide nursing care utilizing trauma-informed approaches that do not further traumatize victims (Substance Abuse and Mental Health Services Administration, 2015). They can act as advocates for victims of sexual assault by improving the process of sexual assault examinations, and educating healthcare providers and community justice system partners about peri-traumatic symptoms of sexual assault. Finally, because sexual assault is a global health issue affecting individuals, families, communities, and nations, nurses must be in the forefront of a world-wide effort to improve the care of victims of sexual assault.

Sexual Assault Evidence Kits: Interprofessional Research on Submission Rates and Implications on Practice

Julie Valentine, PhD, RN, CNE, SANE-A, USA

Abstract

Purpose: The purpose of this presentation is to share findings from an interprofessional, retrospective study evaluating the submission rates of 1,874 sexual assault kits from multiple sites in a Western state in the United States, explore the predicting variables associated with sexual assault kit submissions, and discuss the implications of these findings on the community and state. Over the past few years, numerous

reports have been published in the United States regarding large amounts of unsubmitted sexual assault kits found in LE custody indicating that many SAKs were not submitted to crime laboratories for analysis (Telsavaara & Arrigo, 2006; Strom & Hickman, 2010; Sacco & James, 2015). Yet, the discovery of unsubmitted sexual assault kits does not provide information on the actual submission rates of sexual assault kits and their predicting variables. This study focused on sexual assault kit submissions in Utah, a Western state in the United States, in locations with established SANE programs. As in most areas of the United States, the submission of sexual assault kits to the state crime laboratory for analysis has been up to the discretion of law enforcement.

Few studies have been completed on exploring the submission rates of sexual assault kits. The National Institute of Justice reported that the number of untested sexual assault kits throughout the United States is unknown, as most jurisdictions do not track submission rates of collected sexual assault kits or the amount of sexual assault kits in evidence storage facilities (Ritter, 2011). The studies that have been completed indicate that sexual assault kit submission rates are highly variable and based upon the jurisdiction in which the rape occurred (Fallik & Wells, 2015). In one study examining the submission rates of sexual assault kits collected at a sexual assault nurse examiner program in a large Midwestern county, it was found that 58.6% of SAKs were submitted to the crime laboratory for analysis (Patterson & Campbell, 2012). In another study focused on the submission rates of sexual assault kits collected at a sexual assault nurse examiner program from adolescent victims in two Midwestern communities, 59.3% were submitted to the crime laboratory (Shaw & Campbell, 2013).

In the limited studies exploring the predicting variables related to sexual assault kit submissions, a consensus of predicting variables has not been determined. In one study it was found that sexual assault kits were more likely to be submitted if the victim had physical injuries and the law enforcement agencies had high levels of engagement with the forensic nursing program (Patterson & Campbell, 2012). Another study on adolescent victims found that sexual assault kits from younger teens (13-15 years old), non-white victims, and victims of highly assaultive rapes were more likely to be submitted (Shaw & Campbell, 2013). This study adds valuable knowledge to understanding decision-making practices related to sexual assault kit submissions, a topic area with minimal research.

Methods: Data was entered by from 1,874 sexual assault examination forms completed by forensic medical/nurse examiners into SPSS 20 statistical database. Approximately 200 variables were coded for each sexual assault case. As this was an interprofessional research study, data was linked from the sexual assault examination forms with data from the state crime laboratory. Forensic scientists from the crime laboratory received information on all fully collected SAKs including victims' names, date of assault, date of SAK collection, and law enforcement agency and case number to track SAKs and determine if submitted to crime laboratory. Reliability of the data entry was evaluated by recoding 10% of the examination forms, resulting in a final kappa across all variables of .955. Descriptive data analysis was completed on all variables. Generalized estimating equation logistic regression analysis was completed to evaluate legal and extralegal variables associated with SAK submission.

Results: It was found that within a year of the assault only 22.8% of sexual assault kits were submitted by law enforcement to the state crime laboratory for analysis. An additional 15.4% were submitted in late 2014 through 2015 following community and media pressure for law enforcement to submit SAKs in storage. Sixty-two percent of SAKs were found not submitted; therefore, they remain in law enforcement custody, have recently been submitted, or have been destroyed. The site or jurisdiction of the sexual assault was found to be the primary factor affecting submission of sexual assault kits.

Statistical analysis of generalized estimating equation logistic regression controlling for site variability examined legal and extralegal characteristics statistically significant in predicting if SAKs submitted or not. Variables that increased odds of SAK submissions: male victims (46% more likely) and suspected drug-facilitated assaults (25% more likely). Variables that decreased odds of SAK submissions: victim used drugs prior to assault (22% less likely), victim bathed or showered following rape (17% less likely), victim with physical or mental impairment (17% less likely), and victim knew the suspect (16% less likely).

The results from this interprofessional study on the community and state include media attention, community discussions on improving response to sexual assault, increased submission rates of sexual assault kits by law enforcement, and increased reporting by victims for sexual assault forensic medical examinations. The study findings also lead to significant policy and statewide legislative changes, including legislation mandating submission and testing of all sexual assault kits.

Conclusion: SAKs not submitted by law enforcement to the state crime laboratory for analysis indicates justice denied for victims of rape. The findings represent an inequity of justice, as there is great variability between SAK submission rates within the study sites. For example, in adjacent counties (Site B and C) the SAK submission rate within a year of assault for Site B was 4.1%, while Site C was 37.5%; submission rate from Site C is almost ten times the submission rate from Site B. This extreme variability of SAK submission rates suggests that subjectivity and bias within law enforcement agencies largely determines if SAKs are submitted or not.

Most jurisdictions do not track their SAKs from evidence collection through DNA analysis. Studies in other areas of the United States of similar methodology to this study have found SAK submission rates of approximately 60%. This study found SAK submission rate of only 22.8% within a year of the assault, almost 1/3 the submission rates in other studies.

The only legal characteristic found to predict SAK submissions was if the rape was a suspected drug-facilitated assault. The finding that SAKs collected from male victims were 46% more likely to be submitted indicates gender bias within law enforcement. The other variables predicting SAK submissions relate to characteristics of the victim or relationship between victim and suspect, not crime factors.

The findings from this interprofessional study linking forensic nurses and scientists generated widespread attention to issues related to sexual assault and sexual assault kits resulting in statewide policy changes. The multiple community forums and media stories triggered a community outcry to make statewide improvements in the response to victims of sexual assault. The overarching goal is that as the state improves in its response to sexual assault, communities will become safer and healthier with decreased incidences of sexual assault.

J 12 - Addressing the Global Burden of Alcohol Use in Nursing Curricula

Integrating Alcohol-Use-Related Content in Nursing Curricula

Deborah S. Finnell, DNS, RN, FAAN, USA

Abstract

Purpose: There is a strong evidence base for alcohol screening, brief intervention, and referral to treatment (SBIRT). Screening is an essential first step for nurses in detecting persons who are at-risk because of alcohol consumption. Based on the risk level, evidence-based interventions can be feasibly delivered by nurses and such interventions are acceptable to patients (Broyles, et al, 2012). Findings across studies including various providers on alcohol-related outcomes following interventions reveal that interventions delivered by nurses had the most effect in reducing quantity of alcohol consumption (Platt et al., 2016). For those persons who could benefit from alcohol specialty treatment, nurses are in key roles as the most trusted healthcare providers who have the most sustained contact with patients to refer them to treatment and facilitate their access to, and linkage with treatment.

The purpose of this presentation is to illustrate how faculty in a nursing school have integrated alcohol-related content in prelicensure and master's curricula. The curricular map will be used to demonstrate how specific teaching/learning modules have been integrated across the nursing curricula.

Methods: Curricular mapping has been completed to guide the placement and timing of teaching/learning modules related to alcohol and other substance use. Learning objectives were developed for multiple educational modules, including screening, motivational interviewing, brief intervention, referral to treatment, neurobiology, and FDA-approved medications for alcohol use disorder. In turn, each module and respective objectives were mapped to the particular course where it is delivered. Faculty subject matter experts developed each module and in turn were filmed in delivery of the content. The videos ensure that all students receive the same information and that the education and delivery are sustainable. Faculty subject matter experts also worked with actors to develop videos of nurse-delivered screening, brief intervention, and referral to treatment. These videos serve as exemplars for students prior to their delivery of these strategies in the clinical setting.

Results: Compared with the current amount of content in nursing curricula in the US, integrating content in courses has resulted in a 3-fold increase in exposure.

Conclusion: The proposed implementation model can be utilized by nurse educators wishing to provide an optimal integrative program of alcohol education.

Alcohol Screening, Brief Intervention, and Referral to Treatment: Evidence for Use in Older Adults

Bryan R. Hansen, PhD, RN, APRN-CNS, ACNS-BC, USA

Abstract

Purpose: Alcohol use among older adults has been identified as a significant and potentially growing public health problem with the growing entry of the baby boomer cohort in older adulthood (Le Roux, Tang, & Drexler, 2016). As adults age, they become more sensitive to the effects of alcohol, are more likely to have one or more health conditions requiring medication, and more likely to encounter interactions between alcohol and health conditions or medications. There is also an increased risk of malnutrition with alcohol use (Barry & Blow, 2016). Heavy alcohol use and alcohol withdrawal have been implicated as risk factors for cognitive impairment and the development of delirium (Bommersbach, Lapid, Rummans, & Morse, 2015). Therefore, the purpose of this presentation is to examine the evidence for alcohol screening, brief intervention, and referral to treatment for older adults.

Methods: The application of Screening, Brief Intervention, and Referral to Treatment (SBIRT) to the care of older adults is well supported by the literature. Screening is recommended for all older adults and several alcohol screening instruments have been developed and validated for use with older adults, including the Short Michigan Alcoholism Screening Test – Geriatric Version (SMAST-G) and the Alcohol Use Disorders Identification Test short form (AUDIT) (Bommersbach et al., 2015). Brief intervention has been well-established in the literature as a highly effective tool for adults under age 60 and the few studies validating its use among older adults have found similar results (Barry & Blow, 2016). Referral to treatment is especially important among older adults who are at-risk or currently engaging in heavy alcohol use. Older adults' reduction in alcohol use must be carefully monitored and managed to avoid complications such as delirium, seizures, and other adverse health outcomes for which they are at substantial risk (Bommersbach et al., 2015).

Results: This content is included in a teaching and learning module, which is integrated in the nursing curriculum for pre-licensure nursing program.

Conclusion: SBIRT is a recommended for use with older adults, but special care must be used for those at highest risk or those currently with heavy alcohol use to minimize the risk of harm. Incorporation of this content into nursing curricula is suggested to enhance the nursing care of older adults and promote positive health outcomes.

Alcohol Screening, Brief Intervention, and Referral to Treatment for Nurses Working with Persons with HIV/AIDS

Michael Sanchez, DNP, CRNP, FNP-BC, USA

Abstract

Purpose: Alcohol use among people living with HIV (PLWH) can have deleterious effects on health outcomes. Some of the consequences associated with alcohol use are include unsustained viral suppression, poor adherence to antiretroviral treatment (ART), increased risk taking leading to a higher likelihood of HIV transmission, increased risk for neurocognitive decline and depression, and increased mortality rates. Thus, addressing alcohol use is important for promoting the health of PLWH.

The purpose of this presentation is to illustrate a guided step-by-step intervention for nurses working with PLHW to screen, provide brief intervention and referral to treatment.

Methods: A guide published by the Center for Disease Control and Prevention served as the framework for educating nurses working with PLHW on alcohol screening and brief intervention. Educational content was developed to provide the rationale for alcohol screening and introduce the learner to established measures for screening. An algorithm was developed to guide the nurse from assessment of alcohol consumption to assessment of harm and possible alcohol use disorder and corresponding interventions. Sample scripts were written to illustrate how the nurse-patient conversation flows through the process. These conversations will focus on identifying and addressing alcohol-toxicity beliefs, and discussing the impact of alcohol use and skipping doses of ART.

Results: This content is included in a teaching and learning module for nursing students. The module is integrated in the nursing curriculum for our pre-licensure program.

Conclusion: By using the guided step-by-step intervention offered in this presentation, nurses working with PLHW can screen, provide brief intervention and referral to treatment. This evidence-based set of clinical strategies will also facilitate nurses' engaging in a patient conversation based on the level of alcohol-related risk. These conversations will focus on identifying and addressing alcohol-toxicity beliefs, and discussing the impact of alcohol use and skipping doses of ART. The overall goal of these nurse-led interventions is to promote positive health outcomes in this population.

L 05 - Transforming Nursing Knowledge, Education, and Practice Through Pre-Briefing and Debriefing

Simulation Pre-Briefing: Supporting Competency and Judgment Development in Nursing Learning

Karin Page-Cutrara, PhD, RN, Canada

Abstract

Purpose: The purpose of this experimental study was to describe a newly developed model-based, structured prebriefing intervention and its effect on nursing students' competency performance, clinical judgment, and their perceived prebriefing experience, and to describe its application to teaching practice. Prebriefing begins the simulation process and introduces the participants to the simulation, learning experience (Chamberlain, 2015; Rudolph, Raemer, & Simon, 2014). However, little nursing education research is available on this activity, and how it relates to the development of nursing knowledge and practice. Reflection theory and concept mapping underpinned the development of a model on which this intervention was based, to prepare students for meaningful simulation learning (Decker et al., 2010; author, 2014).

Methods: An experimental group-randomized design was used to compare the intervention group, which received structured prebriefing and the control group, which received customary orientation activities. This study was conducted at a university school of nursing in Canada. Baccalaureate nursing students (N = 76) in a traditional four-year program, who were enrolled in a fourth-year medical-surgical course, participated. Competency performance, clinical judgment, and the perceptions of the prebriefing experiences in each group were examined, in addition to the relationship between simulation performance and students' self-rated prebriefing experience. Scores from the *Creighton Competency Evaluation Instrument* and the *Prebriefing Experience Scale* were analyzed using parametric and non-parametric statistics.

Results: A statistically significant difference was demonstrated between groups for competency performance ($p < 0.001$), clinical judgment ($p < 0.001$) and prebriefing experience ($p < 0.001$). No relationship was found between students' self-perceptions of prebriefing experience and the researcher-rated simulation performance.

Conclusion: Theory-based, structured prebriefing can impact nursing student competency performance, clinical judgment and perceptions of prebriefing, and may enhance meaningful simulation learning. A detailed description of the model-based prebriefing intervention worksheet will be provided, and an interactive discussion of possibilities for its use in varied academic and clinical settings, with global applications, will be facilitated. Prebriefing, as the first phase of simulation, has implications for transforming nursing knowledge, education and practice throughout the entire simulation process, and beyond.

Using Debriefing for Meaningful Learning to Foster Clinical Reasoning and Transform Nursing Practice

Kristina Thomas Dreifuerst, PhD, RN, CNE, ANEF, USA

Abstract

Purpose: The purpose of this exploratory, quasi-experimental, pre-test-post-test study was to discover the effect of the use of the Debriefing for Meaningful Learning (DML) method of debriefing on the development of clinical reasoning in traditional prelicensure nursing students in a BSN program in the United States. Debriefing has been found to be the most significant part of a simulation experience on student learning (Shinnick, 2011). DML is one evidence based method of debriefing that can be used in simulation and other clinical and educational settings to uncover and foster thinking and acting like a nurse. DML is a systematic process for debriefing in which different aspects of the relationship between thinking and actions practice are uncovered, reflected upon and explicated to generate new meanings and understandings which foster clinical reasoning (Author, 2015).

Methods: Clinical reasoning was measured in 238 participant students from a traditional baccalaureate program in a School of Nursing located in the United States (US) who took an adult health course that incorporated simulation experiences into the curriculum. Participants were assigned to either the experimental or control group where DML was compared to customary debriefing using the Health Sciences Reasoning Test (HSRT) and the Debriefing Assessment for Simulation in Healthcare®–Student Version (DASH®–SV) with four supplemental questions about the DML (DMLSQ) process, during the post-debriefing assessment.

Results: The data revealed that there was a statistically significant difference in the change in scores between pre-test and post-test for those who used the DML as compared to the control when the relative difference between mean scores was calculated and a Mann-Whitney-Wilcoxon test was performed, $U = 3973.5$, $W = 10759.5$, $Z = -6.059$, $p = 0.000$.

Conclusion: The findings from this study are important because they represent the incremental impact of learning by students from one DML debriefing intervention. DML did not teach students the content on the HSRT test, or how to take the test, but rather how to think about clinical information and decision-making within the context of simulated patient care. By actively modeling reflection-in-action, reflection-on-action, and reflection-beyond-action, the student not only debriefs the clinical experience but also anticipates how to use this knowledge and information in other clinical contexts and builds clinical reasoning skills. The literature on learning offers two possible explanations. The DML strategy may have been either so innovative that it stimulated learning and adoption, or so credible that it affirmed how students were already reasoning and supported their ability to be confident in how they reason through clinical situations. Since this research has been replicated with similar findings to this original research (Forneris et al., 2015), the former explanation is further supported.

These study findings have led to the adoption of DML in schools of nursing and clinical practice settings across the United States, Canada, China, the United Kingdom and Australia. DML was also chosen as the debriefing method for the National Council of State Boards of Nursing National Simulation Study (Hayden et. al., 2014) and regulatory bodies in the US and Canada have begun adopting language advocating the use of evidence-based debriefing practices by schools of nursing. This session will include a detailed description of DML and an interactive discussion of the implications from these findings for transforming nursing knowledge, education and practice globally including regulation changes that are beginning to be seen in the United States that are correlated to use of DML.

Transforming Debriefing by Exploring Faculty Preparation and Use with the Debriefing for Meaningful Learning Inventory

Cynthia Sherraden Bradley, PhD, RN, CNE, CHSE, USA

Abstract

Purpose: The purpose of this study was to look at the relationship between training received in debriefing using an evidence based debriefing method and the application of that training into educational practice. Debriefing is the most significant component of simulation, and faculty report varied ways of receiving training (Wazonis, 2015) yet the impact of debriefer training on how a debriefing method is applied has not been reported. Although training of debriefers in the use of a structured debriefing method is recommended by regulating bodies and international nursing organizations following the methods used in the NCSBN National Simulation Study (Alexander et al., 2015; Jeffries, Dreifuerst, Kardong-Edgren & Hayden, 2015), a description of its impact on the understanding and application of debriefing is unknown.

An evidence-based debriefing method adopted widely across nursing curricula is Debriefing for Meaningful Learning©(DML). DML promotes the development of clinical reasoning among nursing students, yet little is known regarding how debriefers trained in this method use it, or the resulting impact on nursing knowledge and practice (Dreifuerst, 2015).

Methods: To measure the understanding and application of the central concepts of DML, the DML Inventory (DMLI) was developed using the Debriefing for Meaningful Learning Evaluation Scale (Author & Dreifuerst, 2016) and psychometrically tested for validity. The DMLI was then used to quantify the debriefing behaviors of 234 debriefers during simulation debriefing with baccalaureate nursing students.

Results: Statistically significant differences were found between debriefers in their understanding and application of DML, based on the training sources received. The DMLI data revealed that DML trained debriefers consistently apply DML behaviors after receiving training, and application increased in consistency with multiple training sources. Statistically significant interactions were found between groups in the application of DML and understanding of the central concepts of the method.

Conclusion: This study contributes to the growing body of knowledge of debriefing and provides a tested instrument to be used for assessing debriefers using DML. The findings demonstrate the impact of the type of training on how structured debriefing methods are implemented, which could improve future debriefing training for simulation and clinical experiences. This session will include a description of the development, testing, and use of the DMLI and an interactive discussion of implications from these findings for transforming nursing knowledge, education and practice globally.

L 15 - Educating for Person-Centredness: Leading Collaborative Research

Leading Collaborative Research with a Person-Centred Academic Culture Project

Brendan G. McCormack, PhD, DPhil (Oxon), BSc (Hons) (Nurs), PGCEA, RGN, RMN, United Kingdom

Abstract

Purpose: This presentation will share the results of our 18-month collaborative research project that has focused on generating a person-centred academic environment in nursing. Person-centredness and person-centred practice is now a common discourse in nursing and health care generally. Significant developments have occurred in Scotland, across the UK and internationally in the development of person-centred nursing and healthcare services. However, a similar pace of development has not been evident in nursing education programmes. It remains the case that there are few person-centred nursing curricula and at best most have 'the person-centred course' as a part of the curriculum. This is an issue that we at xx University have been addressing over the past 24 months. A key part of this work has been creating an academic environment that 'lives' person-centred values in all aspects of our work.

Methods: We have used case study methodology to evaluate the existing programme of culture change in the Division of Nursing and develop transferrable principles for other academic departments. The case study methodology of Simons (2009) has been used, where the primary purpose for undertaking a case study was to explore the particularity and the uniqueness of the single case. The single case being 'The Division of Nursing'. Simons' methodology has been developed for education contexts and so is particularly suitable for this case study research.

Results:

1. *Understanding a person-centred culture in action and stories of stakeholders*
We have identified the key characteristics of the person-centred culture in the Division of Nursing. We have collated self-assessment data (routinely collected data; reflective accounts; stakeholder evaluation data) collected in 2014 (baseline data) and compared with rounds of key-stakeholder data (claims, concerns, issues) collected in 2015 and 2016
2. *Developing a shared interpretation and meaning making*
Themed data from the key characteristics of a person-centred culture will be presented for critique.
3. *Agreeing transferable principles*
We will propose person-centred culture principles that are transferable across the university system. The findings from the previous stages will be presented for participants to discuss and critique. A set of transferable principles will be proposed and implementation issues surfaced. A position statement on 'person-centred Environments for HEIs' will be presented.

Conclusion: Further investigation is required to explore the culture of academia and the lessons to be learned from implementing a person-centred culture within an academic environment.

Leadership within an International Community of Practice for PhD Students: Person-Centred Practice Research

Janet Dewing, PhD, United Kingdom

Abstract

Purpose: To tell the story of the evolution of the international CoP, share outcomes and outputs from the CoP Background. Communities of Practice (CoPs) are formed by people who engage in social or collective learning in a shared area of interest; in this case, all the members were connected through PhDs at one university in Scotland and underpinned by values and research approaches consistent with person-centredness. The learning culture is an important factor affecting the quality of doctoral education (Lahenius 2012; Shacham and Cohen 2009) yet PhD students often report a dissonance between the expectations of being engaged with practising researchers and a community of peers and other experts and their experiences. We will show how the CoP has developed through a collaboration between student learners and professoriate learners. Given the social learning underpinnings, particular attention is given to process review and to evaluation in the CoP among the growing international membership with members at different stages in their research and lifelong learning.

Methods: A participatory approach was used along with evaluation questions. Data was collated retrospectively over the last 2 years from the CoP facebook page and concurrent data was collected from critically creative reflections across a number of the CoP members.

Results: The CoP members are committed to learning how to do their own research more authentically and to advancing our knowledge on person-centred practice and theory. Members help and support each other, and challenge each other in various ways. They build relationships that enable them to learn from each other and they care about each other and their relationships. The QMU CoP for PhD students appears to be evolving into a hybrid between a social learning community and a distributed virtual network crossing multiple countries and organisational boundaries (Fischer et al 2007).

Conclusion: A model of joint professional and academic learning is emerging that has relevance for professional development and research capacity building in the topic of person-centredness and in the university. Although Wenger (2001) makes it clear that the technology itself is secondary to social and cultural aspects, as we evolve into a more geographically distributed CoP, we have a greater need to understand how technology affects social learning within the CoP and how we can use it more creatively.

The MSc Person-Centred Practice Framework Curriculum: Underpinning Philosophy and Model

Savina Tropea, PhD, RN, United Kingdom

Abstract

Purpose: This presentation will focus on the philosophy underpinning the new MSc Person-centred Practice Framework curriculum in the Division of Nursing at Queen Margaret University, Scotland, and on the curriculum model that was co-created by the team; it will also discuss issues around the role of curriculum in changing and transforming the present (Pinar 2012).

Methods: The curriculum underpinning philosophy builds around a blend of humanistic and constructivist theories (McCormack and McCance 2010, Schunk 2004). Three of the main strands of this philosophy are: the centrality of the concepts of 'personhood' (of the person/learner) and of 'person-centredness'; the inter-relationship between person-centred teaching and learning (facilitation) and the development of person-centred practitioners (at Master Level); the development of practice (praxis). The continuum between 'product' and 'process' in designing the MSc Person-centred Practice curriculum will be also discussed. Emphasis will be placed on the process of identification of shared values and beliefs, in particular on the use of critical dialogues to develop a shared understanding of commonly used terms, locally and globally, in current policy documents (such as person and people centred care, child and family centred care) with a view at reaching shared definitions. The use of creative visual representations to capture and synthesise, first of all, the key concepts and principles in the form of a 'ripple' and then to embed these in a new curriculum model will be also presented.

Results: The implementation process culminated in the co-creation of the innovative Hourglass Curriculum which highlights the collaborative nature of learning and of practice, and the dynamic and evolving nature of a curriculum grounded in practice and aimed at developing and improving practice, in collaboration with different stakeholders.

Conclusion: Tentative conclusions will be put forward for consideration. The achievement of a consensus on the values and beliefs about the learning process is of paramount importance in curriculum development (Keating 2010). This initiative has provided impetus to engage in a dialogue within the division, to revise our undergraduate BSc Hons curriculum and other post-graduate pathways within the MSc Person-centred Framework.

R 07 - Building Evidence-Based Practice in a Complex System: The Visionary Approach in the U.S. Air Force

Building a Program to Bring Evidence-Based Practice to the U.S. Air Force Nursing Enterprise

Lynn Gallagher-Ford, PhD, RN, DFPNAP, NE-BC, USA

Abstract

Purpose: To describe the need for an evidence-based approach to healthcare decision making and practice to deliver best care and outcomes and discuss how this goal was met through education and collaboration.

Methods: In a new era of healthcare, success will be achieved through collaborative relationships and development of teams that can deliver evidence-based, patient-centered care to improve healthcare safety, patient and clinician outcomes, and demonstrable returns on investments. The development of evidence-based practice (EBP) knowledge, skills, and attitudes along with creation of organizational cultures and infrastructures that support EBP is a comprehensive strategy that can effectively propel organizations toward achieving and sustaining these goals and meeting required healthcare mandates. Many healthcare organizations have identified that their staff are not competent in EBP as demonstrated by clinicians' and leaders' lack of EBP knowledge, skills and attitude. These organizations are seeking opportunities build such competence and capacity in their settings. The Center for Transdisciplinary Evidence-based Practice has worked with a wide range of both clinical and academic organizations to build and sustain EBP with significant results achieved.

A unique opportunity emerged when a CTEP leader and a USAF Nursing leader participated in a Magnet site visit as community partners of an Ohio Children's Hospital. The relationship that grew out of that chance meeting led to the development of a rich and robust EBP program at Wright Patterson Medical Center, and ultimately across the USAF nursing enterprise.

Results: This session will highlight the innovative work of The Center for Transdisciplinary Evidence-based Practice (CTEP) in advancing EBP through a collaborative relationship with the nursing enterprise of the United States Air Force (USAF) to create a successful EBP education and follow-up program that is delivering improved care and significant outcomes. The details related to forging an effective relationship between these enterprises to develop and deliver an EBP education program to meet the unique needs of this complex, global enterprise will be highlighted. The characteristics of the original education program designed and implemented including: the evidence-based educational pedagogies and interventions utilized to assure the successful sharing of EBP knowledge and skills; the multiple tracks offered with specific content for different practitioners (front-line clinicians, EBP mentors, educators, organizational leaders) and; the structured follow-up sessions utilized to reinforce knowledge acquisition and promote implementation of EBP initiatives. The impact of planned and ongoing discussions between the collaborating entities, that led to further customization of the education program as the EBP capacity at the USAF is forming and growing, and performing, will also be presented.

Conclusion: Collaboration and innovation can forge relationships to transform traditional organizations into evidence-based organizations that deliver best practice and improved outcomes.

Implementation of Programs and Infrastructures to Sustain Evidence-Based Decision Making and Practice

Penelope F. Gorsuch, DNP, RN, ACNP-BC, CCNS, CCRN-K, NEA-BC, USA

Abstract

Purpose: To describe the collaborative, innovative work of two organizations that transformed a highly complex, global healthcare enterprise from a tradition-based approach to care to an evidence-based approach to decision-making and care to achieve improved outcomes.

Methods: The collaboration and synergy between The Center for Transdisciplinary Evidence-based Practice (CTEP) and the United States Air Force nursing enterprise facilitated the development of strategies set forth from the Institute of Medicine (IOM) (2001) *Crossing the Quality Chasm*. We will present three successful academic and nursing enterprise collaborative programs: 1) educational process for EBP, 2) developing specific teams of EBP Mentors, 3) creating EBP councils.

Results: The first program was an effort in collaboration with CTEP to develop the skill set needed for problem-solving that integrates the best evidence from well-designed studies as well as internal evidence with clinical expertise and patient preferences and values to inform practice decisions. As this was a new skill set for our clinicians and leaders, it required structured education in a systematic approach because in order for an EBP culture and environment to be actualized ... "a standardized process must be used for teaching, implementing and sustaining evidence-based decision making" (Melnyk & Fineout-Overholt, 2015). The second initiative was forged from lessons learned from the initial structured education programs, when we recognized the critical importance of leadership participation and support in building effective and sustainable EBP programs. A grant was applied for and awarded to determine if providing an intensive EBP education program combined with a structured follow up Military Nursing Teams composed of representatives from three levels of practice: An Executive Leader, a Clinical Leader, and a Direct Care Clinician was an effective strategy to develop evidence-based competence, practice and culture. The teams that participated in the grant program were from military healthcare organizations from around the globe and represented both inpatient and ambulatory environments. The unique opportunity and the expected outcomes of this project is to demonstrate how these evidence-based Tri-Level teams are effective in changing practice as well as building and sustaining an evidence-based practice culture in their respective organizations. The third initiative focused on the development of an organized EBP structure and process configuration, that included both a centralized EBP core and a facility-based component, would provide the needed support to assure ongoing development and sustainability of an evidence-based approach to care and decision making across the global USAF nursing enterprise.

Conclusion: A strategic, planned approach to: building EBP knowledge, skills and attitude; creating EBP infrastructure and support, and; leading an EBP culture can effectively transform highly complex, global healthcare enterprises.

Outcomes of an Evidence-Based Practice Transformation Across the USAF Nursing Enterprise

Dorothy A. Hogg, MSN, MPA, WHNP-BC, USA

Abstract

Purpose: To describe the plan set in motion by leaders in the US Air Force nursing enterprise to achieve a healthcare delivery paradigm where research, evidence-based practice (EBP), and quality improvement experts come together to create, translate, and implement best practices that generate high- quality, cost-effective patient outcomes (Melnyk, 2015).

Methods: A new paradigm is required that teams up research, evidence-based practice (EBP), and quality improvement experts to create, translate, and implement best practices that generate high- quality, cost-effective patient outcomes (Melnyk, 2015). In order to support this paradigm, infrastructure and support are essential for success. The USAF nursing enterprise has set a plan in motion to achieve this goal by establishing A Clinical Inquiry Cell concept. This concept is being pilot tested at the 711 Human Performance Wing (HPW), at the United States Air Force School of Aerospace Medicine (USAFSAM). The Clinical Inquiry Cell includes Nurse Scientists, Nursing EBP experts, and other Allied Health research specialists. Research and EBP specialists will be utilized to capitalize on their expertise, allowing for facilitated translation of evidence to nursing practice and patient care. The Cell is targeting variances in current practices at Air Force medical facilities and is connecting the clinical staff with current, relevant literature to implement evidence-based decision making and practice changes. Additionally, the EBP expert/Clinical Nurse Specialist is able to connect front-line practitioners and leaders at the medical facilities to the Nurse Scientists when evidence is found to be insufficient and research initiatives are indicated. The EBP expert/Clinical Nurse Specialist then continues to serve as a liaison as the practitioners and researchers work together to conduct research that is needed to address current clinical challenges.

Results: Lessons learned from this pilot project will be discussed along with how the results will be utilized to inform and improve the Clinical Inquiry Cell concept before expanding to other Clinical Inquiry Cells across disciplines.

The proposed Clinical Inquiry Cell structure is expected to optimize and standardize evidence-based care, and ultimately inform policies, procedures, and practices across the continuum of care for our patients and families, in all settings in the USAF. As we continue to learn from our pilot Clinical Inquiry Cell in collaboration with our CTEP partners, we will further define how to establish and disseminate best practices.

Conclusion: Strategically planned processes and structures for implementing an evidence-based practice/research/QI approach to decision making and practice can be successfully implemented across a highly complex, global healthcare enterprise to drive best practice and deliver improved outcomes.
