Purpose

Cystic fibrosis (CF) is a chronic, genetically transmitted disease. CF causes thickened secretions that impede mucus clearance in the gastrointestinal, respiratory, and reproductive tracts, thereby requiring daily treatments that last 1.5 hours or more.

With recent advances in early diagnosis and treatment, life expectancy has doubled in the last 20 years placing emphasis on improving quality of life.

Women consistently self-report having an overall lower quality of life across international studies.

The purpose of this study was to examine gender differences in disease-specific health-related quality of life (HRQoL) in adults with CF and then explore gender-specific facilitators and barriers to HRQoL.

Methods

123 adults with CF

- Reported disease-specific HRQoL using 50-item Cystic Fibrosis Questionnaire-Revised (CFQ-R)
- Scores on CFQ-R range from 0 to 100, with higher scores signifying better HRQoL
- Descriptive statistics and gender differences analyzed using SPSS Statistical Software v. 23
- Subsample of 15 men and 15 women took part in a 30-45 minute, semi-structured interview
- Interviews transcribed verbatim and analyzed using Braun and Clarke’s method of thematic analysis and Nvivo 11 Pro software

Results

- Mean age: 31 Years
- 40% College degrees
- 46% Men, 54% Women
- 43% Unemployed, 32% Worked Full-time
- 44% Married, 46% Single

Poorer HRQoL in the Domains of:
- Physical Functioning
- Social Functioning
- Emotional Functioning

Women:
- “Those who need to know”
- Feeling different

Men:
- Open about CF
- Incorporated others into treatment time

Women:
- Labeling

Men:
- Physical strength
- Available resources
- Male roles
- Insurance

Poorer HRQoL in the Domains of:
- Body Image
- Weight
- Digestive Symptoms

Women:
- Insurance
- Male roles
- Available resources

Men:
- Physical strength
- Available resources

* = Statistical significance at p ≤ 0.05

Conclusions

Results demonstrate that women with CF have poorer HRQoL than men in some domains, but better HRQoL in others.

Interview data elaborated on quantitative findings by identifying gender-specific facilitators and barriers to HRQoL using the participants’ rich narratives and thick descriptions of their lived experience.

Study findings will offer insight into priority areas for delivery of comprehensive, individualized care that will improve the quality of life for people with CF.
